Under the ''Policy Statement on Adequacy and Compatibility of Agreement State Programs'' approved by the Commission on June 30, 1997, and published in the **Federal Register** on September 3, 1997 (62 FR 46517), this final rule is classified as Compatibility Category ''NRC.'' Compatibility is not required for Category ''NRC'' regulations. The NRC program elements in this category are those that relate directly to areas of regulation reserved to the NRC by the Atomic Energy Act of 1954, as amended, or the provisions of 10 CFR. Although an Agreement State may not adopt program elements reserved to the NRC, it may wish to inform its licensees of certain requirements via a mechanism that is consistent with the particular State's administrative procedure laws, but does not confer regulatory authority on the State.

VI. Plain Writing

The Plain Writing Act of 2010 (Pub. L. 111–274), requires Federal agencies to write documents in a clear, concise, and well-organized manner. The NRC has written this document to be consistent with the Plain Writing Act as well as the Presidential Memorandum ''Plain Language in Government Writing,'' published June 10, 1998 (63 FR 31883).

VII. Environmental Assessment and Finding of No Significant Environmental Impact

A. The Action

The action is to amend 10 CFR 72.214 to add the Holtec International HI–STORM UMAX Canister Storage System to the listing within the ''List of approved spent fuel storage casks'' as CoC No. 1040. Under the National Environmental Policy Act of 1969, as amended, and the NRC's regulations in subpart A of 10 CFR part 51, ''Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions,'' the NRC has determined that this rule, if adopted, would not be a major Federal action significantly affecting the quality of the human environment and, therefore, an environmental impact statement is not required. The NRC has made a finding of no significant impact on the basis of this environmental assessment.

B. The Need for the Action

This final rule adds CoC No. 1040 for the Holtec International HI–STORM UMAX Canister Storage System design within the list of approved spent fuel storage casks that power reactor licensees can use to store spent fuel at reactor sites under a general license. Specifically, Holtec International's intent with this design is to provide an underground storage option compatible with the Holtec International HI–STORM FW System.

C. Environmental Impacts of the Action

On July 18, 1990 (55 FR 29181), the NRC issued an amendment to 10 CFR part 72 to provide for the storage of spent fuel under a general license in cask designs approved by the NRC. The potential environmental impact of using NRC-approved storage casks was initially analyzed in the environmental assessment for the 1990 final rule. The environmental assessment for this CoC addition tiers off of the environmental assessment for the July 18, 1990, final rule. Tiering on past environmental assessments is a standard process under the National Environmental Policy Act.

Holtec International HI–STORM UMAX Canister Storage Systems are designed to mitigate the effects of design basis accidents that could occur during storage. Design basis accidents account for human-induced events and the most severe natural phenomena reported for the site and surrounding area. Postulated accidents analyzed for an ISFSI, the type of facility at which a holder of a power reactor operating license would store spent fuel in casks in accordance with 10 CFR part 72, include tornado winds and tornado-generated missiles, a design basis earthquake, a design basis flood, an accidental cask drop, lightning effects, fire, explosions, and other incidents.

Considering the specific design requirements for each accident condition, the design of the HI–STORM UMAX Canister Storage System would prevent loss of containment, shielding, and criticality control. If there is no loss of containment, shielding, or criticality control, the environmental impacts would be insignificant. In addition, any resulting occupational exposure or offsite dose rates from the use of the HI–STORM UMAX Canister Storage System would remain well within the 10 CFR part 20 limits. Therefore, the proposed addition of CoC No. 1040 will not result in radiological or non-radiological environmental impacts that significantly differ from the environmental impacts evaluated in the environmental assessment supporting the July 18, 1990, final rule. There will be no significant change in the types or significant revisions in the amounts of effluent released, no significant increase in the individual or cumulative radiation exposure, and no significant increase in the potential for or consequences from radiological accidents. The staff documented its safety findings for this review in the SER.

D. Alternative to the Action

The alternative to this action is to withhold approval of this new design and issue a site-specific license to each utility that proposes to use the casks. This alternative would cost both the NRC and utilities more time and money for each site-specific license. Conducting site-specific reviews would ignore the procedures and criteria currently in place for the addition of new cask designs that can be used under a general license, and would be in conflict with NWPA direction to the Commission to approve technologies for the use of spent fuel storage at the sites of civilian nuclear power reactors without, to the maximum extent practicable, the need for additional site reviews. This alternative also would

tend to exclude new vendors from the business market without cause and would arbitrarily limit the choice of cask designs available to power reactor licensees. This final rule will eliminate the above problems and is consistent with previous Commission actions. Further, the rule will have no adverse effect on public health and safety. Therefore, the environmental impacts would be the same or less than the action.

E. Alternative Use of Resources

Approval of the addition of CoC No. 1040 would result in no irreversible commitments of resources.

F. Agencies and Persons Contacted

No agencies or persons outside the NRC were contacted in connection with the preparation of this environmental assessment.

G. Finding of No Significant Impact

The environmental impacts of the action have been reviewed under the requirements in 10 CFR part 51. Based on the foregoing environmental assessment, the NRC concludes that this final rule entitled, ''List of Approved Spent Fuel Storage Casks: Holtec International HI–STORM UMAX Canister Storage System, Certificate of Compliance No. 1040,'' will not have a significant effect on the human environment. Therefore, the NRC has determined that an environmental impact statement is not necessary for this final rule.

VIII. Paperwork Reduction Act Statement

This rule does not contain any information collection requirements and, therefore, is not subject to the requirements of the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 *et seq.*).

Public Protection Notification

The NRC may not conduct or sponsor, and a person is not required to respond to, a request for information or an information collection requirement unless the requesting document displays a current valid OMB control number.

IX. Regulatory Analysis

On July 18, 1990 (55 FR 29181), the NRC issued an amendment to 10 CFR part 72 to provide for the storage of spent nuclear fuel under a general license in cask designs approved by the NRC. Any nuclear power reactor licensee can use NRC-approved cask designs to store spent nuclear fuel if it notifies the NRC in advance, the spent fuel is stored under the conditions specified in the cask's CoC, and the conditions of the general license are met. A list of NRC-approved cask designs is contained in 10 CFR 72.214.

By letter dated June 29, 2012, and as supplemented on July 16 and November 20, 2012; January 30, April 2, April 19, June 21, August 28, December 6, and December 31, 2013; and January 13, and January 28, 2014, Holtec International submitted an application to add the HI-STORM UMAX Canister Storage System.

The alternative to this action is to withhold approval of this new design and issue a site-specific license to each utility that proposes to use the casks. This alternative would cost both the NRC and utilities more time and money for each site-specific license. Conducting site-specific reviews would ignore the procedures and criteria currently in place for the addition of new cask designs that can be used under a general license, and would be in conflict with NWPA direction to the Commission to approve technologies for the use of spent fuel storage at the sites of civilian nuclear power reactors without, to the maximum extent practicable, the need for additional site reviews. This alternative also would tend to exclude new vendors from the business market without cause and would arbitrarily limit the choice of cask designs available to power reactor licensees. This final rule will eliminate the above problems and is consistent with previous Commission actions. Further, the rule will have no adverse effect on public health and safety.

Approval of this final rule is consistent with previous NRC actions. Further, as documented in the SER and the environmental assessment, the final rule will have no adverse effect on public health and safety or the environment. This final rule has no significant identifiable impact or benefit on other Government agencies. Based on this regulatory analysis, the NRC concludes that the requirements of the final rule are commensurate with the NRC's responsibilities for public health and safety and the common defense and security. No other available alternative is believed to be as satisfactory, and therefore, this action is recommended.

X. Regulatory Flexibility Certification

Under the Regulatory Flexibility Act of 1980 (5 U.S.C. 605(b)), the NRC certifies that this rule will not, if issued, have a significant economic impact on a substantial number of small entities. This final rule affects only nuclear power plant licensees and Holtec International. These entities do not fall within the scope of the definition of small entities set forth in the Regulatory Flexibility Act or the size standards established by the NRC (10 CFR 2.810).

XI. Backfitting and Issue Finality

The NRC has determined that the backfit rule (10 CFR 72.62) does not apply to this final rule. Therefore, a backfit analysis is not required. This final rule adds CoC No. 1040 for the Holtec International HI–STORM UMAX Canister Storage System to the ''List of approved spent fuel storage casks.''

The addition of CoC No. 1040 for the Holtec International HI–STORM UMAX Canister Storage System was initiated by Holtec International and was not submitted in response to new NRC requirements, or in response to an NRC request. The addition of CoC No. 1040 does not constitute backfitting under 10 CFR 72.62, 10 CFR 50.109(a)(1), or otherwise represent an inconsistency with the issue finality provisions applicable to combined licenses in 10 CFR part 52. Accordingly, no backfit analysis or additional documentation addressing the issue finality criteria in 10 CFR part 52 has been prepared by the staff.

XII. Congressional Review Act

In accordance with the Congressional Review Act of 1996 (5 U.S.C. 801–808), the NRC has determined that this action is not a rule as defined in the Congressional Review Act.

XIII. Availability of Documents

The documents identified in the following table are available to interested persons through one or more of the following methods, as indicated.

The NRC may post materials related to this document, including public comments, on the Federal rulemaking Web site at *http://www.regulations.gov* under Docket ID NRC–2014–0120. The Federal rulemaking Web site allows you to receive alerts when changes or additions occur in a docket folder. To subscribe: (1) Navigate to the docket folder (NRC–2014–0120); (2) click the ''Sign up for Email Alerts'' link; and (3) enter your email address and select how frequently you would like to receive emails (daily, weekly, or monthly).

List of Subjects in 10 CFR Part 72

Administrative practice and procedure, Criminal penalties, Manpower training programs, Nuclear materials, Occupational safety and health, Penalties, Radiation protection, Reporting and recordkeeping requirements, Security measures, Spent fuel, Whistleblowing.

For the reasons set out in the preamble and under the authority of the Atomic Energy Act of 1954, as amended; the Energy Reorganization Act of 1974, as amended; and 5 U.S.C. 552 and 553, the NRC is adopting the following amendments to 10 CFR part 72.

PART 72—LICENSING REQUIREMENTS FOR THE INDEPENDENT STORAGE OF SPENT NUCLEAR FUEL, HIGH-LEVEL RADIOACTIVE WASTE AND REACTOR-RELATED GREATER THAN CLASS C WASTE

■ 1. The authority citation for part 72 continues to read as follows:

Authority: Atomic Energy Act secs. 51, 53, 57, 62, 63, 65, 69, 81, 161, 182, 183, 184, 186, 187, 189, 223, 234, 274 (42 U.S.C. 2071, 2073, 2077, 2092, 2093, 2095, 2099, 2111, 2201, 2232, 2233, 2234, 2236, 2237, 2239, 2273, 2282, 2021); Energy Reorganization Act secs. 201, 202, 206, 211 (42 U.S.C. 5841, 5842, 5846, 5851); National Environmental Policy Act sec. 102 (42 U.S.C. 4332); Nuclear Waste Policy Act secs. 131, 132, 133, 135, 137, 141, 148 (42 U.S.C. 10151, 10152, 10153, 10155, 10157, 10161, 10168); Government Paperwork Elimination Act sec. 1704, (44 U.S.C. 3504 note); Energy Policy Act of 2005, Pub. L. 109–58, 119 Stat. 788 (2005).

Section 72.44(g) also issued under Nuclear Waste Policy Act secs. 142(b) and 148(c), (d) (42 U.S.C. 10162(b), 10168(c), (d)).

Section 72.46 also issued under Atomic Energy Act sec. 189 (42 U.S.C. 2239); Nuclear Waste Policy Act sec. 134 (42 U.S.C. 10154).

Section 72.96(d) also issued under Nuclear Waste Policy Act sec. 145(g) (42 U.S.C. 10165(g)).

Subpart J also issued under Nuclear Waste Policy Act secs. 117(a), 141(h) (42 U.S.C. 10137(a), 10161(h)).

Subpart K also issued under Nuclear Waste Policy Act sec. 218(a) (42 U.S.C. 10198).

■ 2. Section 72.214 is amended by adding Certificate of Compliance 1040 to read as follows:

§ 72.214 List of approved spent fuel storage casks.

* * * * *

Certificate Number: 1040.

Initial Certificate Effective Date: April 6, 2015.

SAR Submitted by: Holtec International, Inc.

SAR Title: Final Safety Analysis Report for the Holtec International HI–STORM UMAX Canister Storage System.

Docket Number: 72–1040.

Certificate Expiration Date: March 6, 2035.

Model Number: MPC–37, MPC–89.

Dated at Rockville, Maryland, this 24th day of February 2015.

For the Nuclear Regulatory Commission.

Energy Conservation Program: Energy Conservation Standards for Walk-In Coolers and Freezers; Correction

AGENCY: Office of Energy Efficiency and Renewable Energy, Department of Energy.

ACTION: Final rule; correction.

SUMMARY: On June 3, 2014, the U.S. Department of Energy (DOE) issued a final rule adopting conservation standards for some classes of walk-in cooler and walk-in freezer components. The final rule was published with typographical errors to some of the reported values. DOE is providing corrections to address these errors. Neither the errors nor the corrections in this document affect the substance of the rulemaking or any of the conclusions reached in support of the final rule.

DATES: This correction is effective March 6, 2015.

FOR FURTHER INFORMATION CONTACT: Mr. John Cymbalsky, U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Building Technologies Program, EE–5B, 1000 Independence Avenue SW., Washington, DC 20585–0121. Telephone: (202) 287–1692. Email: *walk-in_coolers_and_walk-in_freezers@EE.Doe.Gov.*

Mr. Michael Kido, U.S. Department of Energy, Office of the General Counsel, GC–33, 1000 Independence Avenue SW., Washington, DC 20585–0121. Telephone: (202) 586–8145. Email: *Michael.Kido@hq.doe.gov.*

SUPPLEMENTARY INFORMATION: The Department of Energy (''DOE'') is

U.S. NUCLEAR REGULATORY COMMISSION

NRC FORM 651
(10-2004)
10 CFR 72

CERTIFICATE OF COMPLIANCE FOR SPENT FUEL STORAGE CASKS

The U.S. Nuclear Regulatory Commission is issuing this Certificate of Compliance pursuant to Title 10 of the *Code of Federal Regulations*, Part 72, "Licensing Requirements for Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste" (10 CFR Part 72). This certificate is issued in accordance with 10 CFR 72.238, certifying that the storage design and contents described below meet the applicable safety standards set forth in 10 CFR Part 72, Subpart L, and on the basis of the Final Safety Analysis Report (FSAR) of the cask design. This certificate is conditional upon fulfilling the requirements of 10 CFR Part 72, as applicable, and the conditions specified below.

Certificate No.	Effective Date	Expiration Date	Docket No.	Amendment No.	Amendment Effective Date	Package Identification No.

Safety Analysis Report Title

Holtec International
Final Safety Analysis Report for the
HI-STORM FW MPC Storage System

Holtec International
Final Safety Analysis Report for the
HI-STORM UMAX Canister Storage System

This certificate is conditioned upon fulfilling the requirements of 10 CFR Part 72, as applicable, the attached Appendix A (Technical Specifications) and Appendix B (Approved Contents and Design Features), and the conditions specified below:

APPROVED SPENT FUEL STORAGE CASK

Model No.: HI-STORM UMAX Canister Storage System

DESCRIPTION:

The HI-STORM UMAX Canister Storage System consists of the following components: (1) interchangeable multi-purpose canisters (MPCs), which contain the fuel; (2) underground Vertical Ventilated Modules (VVMs), which contains the MPCs during storage; and (3) a transfer cask (HI-TRAC VW), which contains the MPC during loading, unloading and transfer operations. The MPC stores up to 37 pressurized water reactor fuel assemblies or up to 89 boiling water reactor fuel assemblies.

The HI-STORM UMAX Canister Storage System is certified as described in the" UMAX" Final Safety Analysis Report (FSAR) supplemented by the information on the MPCs and transfer cask in the HI-STORM FW FSAR, and in the U. S. Nuclear Regulatory Commission's (NRC) Safety Evaluation Report (SER) accompanying the Certificate of Compliance (CoC).

The MPC is the confinement system for the stored fuel. It is a welded, cylindrical canister with a honeycombed fuel basket, a baseplate, a lid, a closure ring, and the canister shell. All MPC components that may come into contact with spent fuel pool water or the ambient environment are made entirely of stainless steel or passivated aluminum/aluminum alloys. The canister shell, baseplate, lid, vent and drain port cover plates, and closure ring are the main confinement boundary components. All confinement boundary components are made entirely of stainless steel. The honeycombed basket provides criticality control.

DESCRIPTION (continued)

There are two types of MPCs permitted for storage in HI-STORM UMAX VVM: the MPC-37 and MPC-89. The number suffix indicates the maximum number of fuel assemblies permitted to be loaded in the MPC. Both MPC models have the same external diameter.

The HI-TRAC VW transfer cask provides shielding and structural protection of the MPC during loading, unloading, and movement of the MPC from the cask loading area to the VVM. The transfer cask is a multi-walled (carbon steel/lead/carbon steel) cylindrical vessel with a neutron shield jacket attached to the exterior and a retractable bottom lid used during transfer operations.

The HI-STORM UMAX VVM utilizes a storage design identified as an air-cooled vault or caisson. The HI-STORM UMAX VVM relies on vertical ventilation instead of conduction through the fill material around the VVM, as it is essentially a below-grade storage cavity. Air inlets and an air outlet allow air to circulate naturally through the cavity to cool the MPC inside. The subterranean steel structure is seal welded to prevent ingress of any groundwater in the MPC storage cavity from the surrounding subgrade, and it is mounted on a stiff foundation. The surrounding subgrade and a top surface pad provide significant radiation shielding. A loaded MPC is stored within the HI-STORM UMAX VVM in a vertical orientation.

HI-STORM UMAX Version MSE is a structurally strengthened embodiment of the VVM engineered for deployment at sites with its Design Basis Earthquake with ZPA in excess of 2.12Gs (resultant horizontal) and up to 1.0G (vertical).

CONDITIONS

1. OPERATING PROCEDURES

   Written operating procedures shall be prepared for handling, loading, movement, surveillance, and maintenance. The user's site-specific written operating procedures shall be consistent with the technical basis described in Chapter 9 of the FSAR.

2. ACCEPTANCE TESTS AND MAINTENANCE PROGRAM

   Written acceptance tests and a maintenance program shall be prepared consistent with the technical basis described in Chapter 10 of the FSAR. At completion of welding the MPC shell to baseplate, an MPC confinement weld helium leak test shall be performed using a helium mass spectrometer. This test shall include the base metals of the MPC shell and baseplate. A helium leakage test shall also be performed on the base metal of the fabricated MPC lid. The confinement boundary welds leakage rate test shall be performed in accordance with ANSI N14.5 to "leaktight" criterion. If a leakage rate exceeding the acceptance criteria is detected, then the area of leakage shall be determined and the area repaired per ASME Code Section III, Subsection NB, Article NB-4450 requirements. Re-testing shall be performed until the leakage rate acceptance criterion is met.

3. QUALITY ASSURANCE

   Activities in the areas of design, purchase, fabrication, assembly, inspection, testing, operation, maintenance, repair, modification of structures, systems and components, and decommissioning that are important-to-safety shall be conducted in accordance with a Commission-approved quality assurance program which satisfies the applicable requirements of 10 CFR Part 72, Subpart G, and which is established, maintained, and executed with regard to the storage system

4. HEAVY LOADS REQUIREMENTS

Each lift of an MPC or a HI-TRAC VW transfer cask must be made in accordance to the existing heavy loads requirements and procedures of the licensed facility at which the lift is made. A plant-specific review of the heavy load handling procedures (under 10 CFR 50.59 or 10 CFR 72.48, as applicable) is required to show operational compliance with existing plant specific heavy loads requirements. Lifting operations outside of structures governed by 10 CFR Part 50 must be in accordance with Section 5.2 of Appendix A.

5. APPROVED CONTENTS

Contents of the HI-STORM UMAX Canister Storage System must meet the fuel specifications given in Appendix B to this certificate.

6. DESIGN FEATURES

Features or characteristics for the site or system must be in accordance with Appendix B to this certificate.

7. CHANGES TO THE CERTIFICATE OF COMPLIANCE

The holder of this certificate who desires to make changes to the certificate, which includes Appendix A (Technical Specifications) and Appendix B (Approved Contents and Design Features), shall submit an application for amendment of the certificate.

8. PRE-OPERATIONAL TESTING AND TRAINING EXERCISE

A dry run training exercise of the loading, closure, handling, unloading, and transfer of the HI-STORM UMAX Canister Storage System shall be conducted by the licensee prior to the first use of the system to load spent fuel assemblies. The training exercise shall not be conducted with spent fuel in the MPC. The dry run may be performed in an alternate step sequence from the actual procedures, but all steps must be performed. The dry run shall include, but is not limited to the following:

a. Moving the MPC and the transfer cask into the spent fuel pool or cask loading pool.

b. Preparation of the HI-STORM UMAX Canister Storage System for fuel loading.

c. Selection and verification of specific fuel assemblies to ensure type conformance.

d. Loading specific assemblies and placing assemblies into the MPC (using a dummy fuel assembly), including appropriate independent verification.

e. Remote installation of the MPC lid and removal of the MPC and transfer cask from the spent fuel pool or cask loading pool.

f. MPC welding, NDE inspections, pressure testing, draining, moisture removal (by vacuum drying or forced helium dehydration, as applicable), and helium backfilling. (A mockup may be used for this dry-run exercise.)

g. Transfer of the MPC from the transfer cask to the VVM.

h. HI-STORM UMAX Canister Storage System unloading, including flooding MPC cavity and removing MPC lid welds. (A mockup may be used for this dry-run exercise.)

Any of the above steps can be omitted if the site has already successfully loaded a Holtec MPC System.

9. AUTHORIZATION

The HI-STORM UMAX Canister Storage System, which is authorized by this certificate, is hereby approved for general use by holders of 10 CFR Part 50 licenses for nuclear reactors at reactor sites under the general license issued pursuant to 10 CFR 72.210, subject to the conditions specified by 10 CFR 72.212, this certificate, and the attached Appendices A and B. The HI-STORM UMAX Canister Storage System may be fabricated and used in accordance with any approved amendment to CoC No. 1040 listed in 10 CFR 72.214. Each of the licensed HI-STORM UMAX Canister Storage System components (i.e., the MPC, overpack, and transfer cask), if fabricated in accordance with any of the approved CoC Amendments, may be used with one another provided an assessment is performed by the CoC holder that demonstrates design compatibility. .

UNITED STATES
NUCLEAR REGULATORY COMMISSION
REGION IV
1600 EAST LAMAR BOULEVARD
ARLINGTON, TEXAS 76011-4511

July 9, 2019

EA-18-155

Mr. Doug Bauder
Vice President and Chief Nuclear Officer
Southern California Edison Company
San Onofre Nuclear Generating Station
P.O. Box 128
San Clemente, CA 92674-0128

SUBJECT: NRC SUPPLEMENTAL INSPECTION REPORT 050-00206/2018-006, 050-00361/2018-006, 050-00362/2018-006, 072-00041/2018-002

Dear Mr. Bauder:

This letter refers to a supplemental inspection using the U.S. Nuclear Regulatory Commission's (NRC's) Inspection Procedure 92702, "Follow-up on Traditional Enforcement Actions," conducted on January 28 through February 1, February 11-15, March 19, March 21-23, and April 10-13, 2019, at your facility in San Clemente, California. The inspection continued with in-office reviews of information provided by your staff from November 2018 through May 17, 2019.

The NRC performed this inspection to review corrective actions taken by the Southern California Edison Company in response to the misalignment of a loaded spent fuel storage canister as it was being downloaded into a storage vault at San Onofre Nuclear Generating Station (SONGS). Our initial review of the incident was documented in NRC Special Inspection Report 050-00206/2018-005, 050-00361/2018-005, 050-00362/2018-005, 072-00041/2018-001 and Notice of Violation (NRC's Agencywide Documents Access and Management System (ADAMS) Accession ML18341A172) and finalized in NRC letter "Notice of Violation and Proposed Imposition of Civil Penalty - $116,000 and NRC Inspection Report 050-00206/2018-005, 050-00361/2018-005, 050-00362/2018-005, 072-00041/2018 001," (ADAMS Accession ML19080A208).

The enclosed report documents the results of the supplemental inspection. The inspectors discussed the preliminary inspection findings with you and members of your staff on February 15, 2019, at the conclusion of a portion of the onsite inspection. A final exit briefing was conducted telephonically with Mr. Al Bates, Regulatory and Oversight Manager, and members of your staff on June 13, 2019.

The NRC performed this supplemental inspection to determine if: (1) the root and contributing causes of the significant performance issues were understood, (2) the extent of condition and extent of cause for the significant performance issues were identified, (3) the corrective actions taken to address and preclude repetition of significant performance issues were prompt and effective, and (4) the corrective action plans direct prompt actions to effectively address and

preclude repetition of significant performance issues. Additionally, the inspection team reviewed and determined if follow-up items from the NRC Special Inspection had been completed.

The NRC determined that your staff's causal evaluations to address the previously issued violations were adequately performed to the depth and breadth required. The NRC noted that your staff's evaluations identified that the primary root cause of the Severity Level II violation for failure to provide redundant lift protection features during downloading operations was that management failed to recognize the complexity and risks associated with a long duration fuel transfer campaign using a relatively new system design. Your staff determined that the primary cause for the Severity Level III violation for failure to make a report to the NRC was that management failed to recognize the required integration and application of 10 CFR Part 72 reporting requirements.

The NRC determined that your staff identified and implemented appropriate corrective actions to revise loading procedures, revise the reportability program, utilize equipment enhancements, require adequate training, enhance oversight of operations, and enhance the corrective action program at SONGS. The NRC also determined that your staff's extent of condition and extent of cause evaluations adequately reviewed whether other operations were susceptible to similar performance deficiencies. However, even though your causal evaluations and corrective actions were comprehensive, the NRC staff identified four observations associated with the evaluations and corrective actions.

Based on the results of the supplemental inspection, the NRC identified five findings that were identified as violations of NRC requirements and were determined to be Severity Level IV violations of low safety significance under the traditional enforcement process. The NRC is treating these violations as non-cited violations (NCVs) consistent with Section 2.3.2.a of the NRC Enforcement Policy.

If you contest the violations or significance of the NCVs, you should provide a response within 30 days of the date of this inspection report, with the basis for your denial, to the U.S. Nuclear Regulatory Commission, ATTN: Document Control Desk, Washington, DC 20555-0001, with copies to: (1) the Regional Administrator, Region IV, and (2) the Director, Office of Enforcement, U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001.

In accordance with 10 CFR 2.390 of the NRC's "Agency Rules of Practice and Procedure," a copy of this letter, its enclosure, and your response if you choose to provide one, will be made available electronically for public inspection in the NRC Public Document Room or from ADAMS. ADAMS is accessible from the NRC's Website at http://www.nrc.gov/reading-rm/adams.html. To the extent possible, your response should not include any personal privacy or proprietary information so that it can be made available to the Public without redaction.

If you have any questions regarding this inspection report, please contact Lee Brookhart at 817-200-1549, or the undersigned at 817-200-1223.

Sincerely,

Greg Warnick, Chief
Reactor Inspection Branch
Division of Nuclear Materials Safety

EXECUTIVE SUMMARY

NRC Supplemental Inspection Report 050-00206/2018006; 050-00361/2018006; 050-00362/2018006; and 072-00041/2018-002

On January 28 through February 1; February 11-15; March 19; March 21-23; and April 10-13, 2019, the U.S. Nuclear Regulatory Commission performed an announced on-site Supplemental Inspection of the Independent Spent Fuel Storage Installation at the decommissioning San Onofre Nuclear Generating Station in San Clemente, California. The inspection continued with an in-office review of the licensee's analyses, procedures, and other materials gathered and provided prior to and after the on-site portion of the inspection through May 17, 2019.

The scope of the inspection was to evaluate and review the licensee's follow-up investigation, causal evaluations, implemented corrective actions, and planned corrective actions associated with violations described in the NRC's Special Inspection Report 050-00206/2018-005, 050-00361/2018-005, 050-00362/2018-005, and 072-00041/2018-001 and Notice of Violation (NRC's Agencywide Documents Access and Management System (ADAMS) Accession ML18341A172) and Notice of Violation and Proposed Imposition of Civil Penalty - $116,000 and NRC Inspection Report (ADAMS Accession ML19080A208).

The NRC determined that the licensee's causal evaluations were conducted to a level of detail commensurate with the significance of the problems and reached reasonable conclusions as to the root and contributing causes of the event. The NRC determined that completed or planned corrective actions were comprehensive and sufficient to address the performance issues that led to the previously identified violations.

Additionally, the inspectors identified five Severity Level IV, non-cited violations that involved failures to: (1) ensure appropriate quality standards on new equipment for downloading/withdrawal operations; (2) ensure purchased material conformed to the procurement documents for load sensing shackles; (3) ensure the loaded transfer cask and its conveyance was evaluated under the site-specific design basis earthquake; (4) provide adequate written basis for the initial 10 CFR 72.48 scratch evaluation; and (5) request the certificate holder to obtain a Certificate of Compliance amendment for use of the intermediate shelf in the spent fuel pool.

Follow-up on Traditional Enforcement Actions, Inspection Procedure 92702

- The inspectors independently reviewed the licensee's causal evaluations for the performance issues and significant findings that led to the August 3, 2018, misalignment incident. The NRC concluded that the evaluations were conducted to a level of detail commensurate with the significance of the problems and the root causes combined with the contributing causes adequately addressed the findings presented in the NRC Special Inspection Report. The inspectors also concluded that the root and contributing causes of the significant performance issues were understood by the licensee. One observation was identified by the NRC which related to the licensee's contributing causes. Subsequently, the licensee addressed and resolved the NRC observation by implementing additional corrective actions. (Section 1.2.1)

- The inspectors determined that the licensee evaluated the performance issues using systematic methodologies to identify root and contributing causes. The inspectors concluded that the licensee's causal evaluations addressed the extent of condition and extent of cause of the issues and appropriately considered safety culture traits. One observation was identified by the NRC regarding the licensee's extent of condition evaluation. Subsequently, the licensee addressed and resolved the issue by implementing additional corrective actions. (Section 1.2.2)

- The NRC concluded that the licensee's evaluations and corrective actions taken in the areas of licensee oversight, procedures, training, equipment, corrective action program, and reportability were appropriate to prevent recurrence of prior inspection findings and violations and were adequately prioritized with consideration to risk significance and regulatory compliance. The inspectors concluded that the licensee's completed corrective actions in the areas of training, corrective action program, and procedures were adequate to restore compliance and prevent recurrence for the relevant violations issued in the NRC Special Inspection Report, dated December 19, 2018. (Section 1.2.3.b (1)-(6))

- During the NRC's review, the inspectors identified two additional observations and two violations of NRC requirements relating to the licensee's corrective actions. The two violations were related to the licensee's failure to establish measures to ensure appropriate quality standards were specified in design documentation in accordance with 10 CFR 72.146 and the licensee's failure to establish measures to ensure that purchased equipment conformed to the procurement documents in accordance with 10 CFR 72.154 for the recent enhancements to fuel canister transfer equipment. The licensee entered the findings into the corrective action program as action requests 1218-20333 and 1219-52380. The violations were determined to have a low safety significance and the Severity Level IV violations were treated as non-cited violations. Subsequently, the licensee addressed and resolved the NRC observations and violations by implementing additional corrective actions. (Section 1.2.3.c)

- The inspectors evaluated and concluded that the licensee's corrective actions were prompt and effective, and the licensee had adequately established appropriate quantitative or qualitative measures of success for the actions implemented to monitor the effectiveness of the corrective actions to prevent recurrence. (Section 1.2.4)

<u>Follow-up of Events and Notices of Enforcement Discretion, Inspection Procedure 71153</u>

- The NRC reviewed Licensee Event Report 2018-001-1 (ADAMS Accession ML18317A060), dated November 8, 2018, for the licensee's actions which led to the inadvertent disablement of redundant important-to-safety slings during downloading operations on August 3, 2018. The NRC inspectors reviewed all the implemented and planned corrective actions and found them to be adequate to restore compliance and prevent recurrence. This licensee event report is closed. (Section 2.2.1)

- The NRC reviewed Licensee Event Report 2018-002-0 (ADAMS Accession ML19050A170), dated February 14, 2019. The licensee notified the

NRC that previous operations utilizing the low-profile-transporter were performed outside the clearance limits calculated in the station's site-specific seismic analysis. The NRC inspectors reviewed all the implemented corrective actions and found them to be adequate to restore compliance and prevent recurrence. The licensee event report described that an analysis was still in progress to determine if past operations were acceptable. This licensee event report remains open, pending NRC review of the additional information. (Section 2.2.2)

- The NRC reviewed Licensee Event Notification 53858, dated February 2, 2019. The licensee notified the NRC that previous operations utilizing the vertical cask transporter had been performed, for short periods of time, outside conditions described in the station's site-specific seismic analysis. Specifically, the licensee prematurely removed the seismic restraint band prior to stack-up operations. The NRC inspectors reviewed all the implemented and planned corrective actions and found them to be adequate to restore compliance and prevent recurrence. This licensee event notification is closed. (Section 2.2.3)

- The inspectors documented a violation of Certification of Compliance 72-1040, Appendix B, Technical Specification 3.4.15, for the licensee's failure to conduct transportation operations in accordance with the station's site-specific seismic analysis. Specifically, the NRC identified, the licensee prematurely removed the seismic restraint band prior to stack-up operations during vertical cask transporter operations. The licensee entered the finding into the corrective action program as action requests 0219-88442, 0219-22465, and 0319-95843. The NRC determined that the finding was of low safety significance since the licensee had re-performed the seismic evaluations restoring compliance and demonstrated the canister and its conveyance would not have tipped-over or slid off the haul route during those transportation operations. This Severity Level IV violation was treated as a non-cited violation. (Section 2.2.4)

- As a follow-up to the Special Inspection Charter, the NRC reviewed the licensee's evaluation to analyze the potential effects of dropping a canister approximately 18 feet onto the base of the UMAX vault. The NRC agreed with the evaluation conclusion that the canister would not have breached had the canister fell to the bottom of the UMAX vault. Additionally, the NRC concluded that the canister would have continued to perform all safety functions, including structural, thermal, criticality control, and shielding. (Section 2.2.5.a)

- The licensee performed a change under the 10 CFR 72.48 process to evaluate and accept scratches from incidental contact during insertion and withdrawal operations on previously loaded and future canisters placed in the UMAX independent spent fuel storage installation. The licensee's subsequent written evaluation, based on in-situ visual assessments and statistical analyses of eight loaded canisters, was adequate to demonstrate that the proposed change would not affect the canisters' ability to meet the confinement design function and structural functions as specified in the Holtec Final Safety Analysis Report.

  The licensee's evaluation also demonstrated that American Society of Mechanical Engineers Section III code tolerances for wear were met and did not require a change to the storage system's technical specifications. The NRC utilized the data

obtained through the visual assessments to perform independent statistical assessments using several models that were appropriate for the sample size. The NRC concluded that the conclusion presented by the Southern California Edison Company was conservative and reasonably bounded the maximum anticipated scratch or wear depth resulting from routine operational activities. The NRC concluded the licensee's 10 CFR 72.48 change did not require prior NRC review and approval through an amendment request. (Section 2.2.5.b)

- The inspection results documented one violation of NRC requirements for the licensee's failure to include an adequate evaluation to support a design change in accordance with 10 CFR 72.48. The NRC identified that the licensee's original evaluations to allow scratching and gouging on canisters contained multiple errors and inadequacies, and the NRC determined that the calculation could not adequately bound the maximum possible scratch depth on a canister.

  The licensee entered the finding into the corrective action program as action requests 1218-11302 and 0219-96601. The NRC determined that the finding was of low safety significance since the licensee re-performed the written evaluation utilizing in-situ visual assessment and statistical analyses that calculated a maximum probable scratch depth, which provided an adequate basis for the determination that the change did not require NRC review through an amendment request. This Severity Level IV violation was treated as a non-cited violation. (Section 2.2.6)

- The NRC closed an Unresolved Item from NRC Inspection Report 07200041/2017-001 dated, August 24, 2018 (ADAMS Accession ML18200A400). The Unresolved Item was related to a 10 CFR 72.48 evaluation for the scenario of a hypothetical accident of the loaded HI-TRAC VW transfer cask contacting the sides and bottom of the spent fuel pool during the short period of time that a loaded multi-purpose canister was in an unconstrained condition on an intermediate shelf in the spent fuel pool.

  The inspectors determined one violation of NRC requirements occurred, for the licensee's failure to request the certificate holder to obtain an amendment prior to implementing a change in accordance with 10 CFR 72.48. The licensee's design change created the possibility of an accident of a different type than any previously evaluated in the Holtec Final Safety Analysis Report. The licensee entered the issue into the corrective action program as action requests 0718-10512 and 0617-86918. The NRC determined that the finding was of low safety significance since the accident condition had been analyzed and NRC approved in NUREG-0712 "Safety Evaluation Report related to the operation of SONGS Units 2 and 3, dated February 1981," and described in the San Onofre Nuclear Generating Station Decommissioning Safety Analysis Report. The licensee restored compliance by revising the loading procedures to no longer utilize the intermediate shelf in the spent fuel pool. This Severity Level IV violation was treated as a non-cited violation. (Section 2.2.7)

- The inspection team observed the licensee perform several dry run exercises utilizing a simulated canister. On January 28, 2019, the licensee successfully demonstrated operations utilizing the low-profile transporter to transport the simulated canister within the transfer cask to the independent spent fuel storage

installation pad while maintaining compliance with the station's site-specific seismic analysis. On February 14, 2019, the licensee successfully demonstrated removal of the transfer cask from the bottom of the spent fuel pool directly to the cask washdown pit without utilizing the intermediate shelf in the spent fuel pool.

On January 28-30, 2019, the inspection team observed the licensee implementing all the corrective action enhancements to download and retrieve a simulated canister at the independent spent fuel storage installation pad. These exercises contained: (1) all vendor personnel trained and qualified under the new training program, (2) use of more personnel, located in strategic positions to observe canister downloading, (3) utilization of the enhanced procedures, (4) implementation of the new canister transfer monitoring equipment, and (5) enhanced oversight by licensee personnel qualified under a new oversight training program. The station was fully successful in downloading and retrieving the canister during the exercises and the corrective actions taken were determined by the inspectors to be adequate to restore compliance and prevent recurrence of the performance issues that led to the misalignment event. (Section 2.2.8)

- The NRC inspectors closed the violation for the licensee failure to ensure that redundant drop protection features were available during the August 3, 2018, misalignment event. The NRC thoroughly reviewed the licensee's completed and proposed corrective actions related to the misalignment event and concluded the corrective actions were adequate to restore compliance, address extent of condition, and prevent recurrence. (Section 2.2.9)

- The NRC inspectors performed independent measurements and verifications of the radiological conditions at the licensee's independent spent fuel storage installation. The inspectors measured various locations including background areas, public access areas, owner-controlled areas, and representative locations on both generally licensed independent spent fuel storage installation pads. Based on the number and age of canisters in service, the NRC did not identify any radiological concerns during the survey. Additionally, the NRC did not identify any measurements at the owner-controlled area boundary or in the public access areas to be above normal background measurements. (Section 2.2.10)

REPORT DETAILS

Summary of Plant Activities

The San Onofre Nuclear Generating Station (SONGS) independent spent fuel storage installation (ISFSI) consists of two ISFSI designs located adjacent to each other. The Transnuclear, Inc. (TN) nuclear horizontal modular storage (NUHOMS) ISFSI contains 51 loaded concrete advanced horizontal storage modules (AHSMs), which hold stainless steel dry shielded canisters (DSCs). Spent fuel from all three reactors are stored at the NUHOMS ISFSI in 50 of the storage modules.

Greater-than-Class-C (GTCC) waste from the Unit 1 reactor decommissioning project is stored in one module. There is a total of 63 AHSMs on the NUHOMS ISFSI pad. The 12 empty AHSMs will be available for storage of additional GTCC waste from Units 2 and 3. The 63 AHSMs currently on the pad are designed for the 24PT1-DSC (Unit 1 fuel) and 24PT4-DSC (Unit 2/3 fuel) canisters, which hold a maximum of 24 spent fuel assemblies. The 24PT1-DSCs are loaded and maintained under Amendment 0 of Certificate of Compliance (CoC) No. 72-1029 and the 24PT4-DSCs are loaded and maintained under Amendment 1 of CoC No. 72-1029. Both systems were being maintained under Final Safety Analysis Report (FSAR), Revision 5.

The Holtec UMAX ISFSI portion was designed to hold 75 multi-purpose canisters (MPCs). The MPC-37s contain 37 pressurized water reactor fuel assemblies in accordance with UMAX CoC No. 72-1040, Amendment 2, the HI-STORM UMAX FSAR, Revision 4, and the HI-STORM FW FSAR, Revision 5. The licensee has 29 loaded canisters in service at the UMAX ISFSI. A 30th canister had been loaded, welded, dried, and helium backfilled, but remained inside the Unit 3 spent fuel building. The licensee ceased all loading operations to address the investigation and implementation of corrective actions associated with the August 3, 2018, misalignment incident.

1 Followup on Traditional Enforcement Actions (Inspection Procedure 92702)

1.1 <u>Inspection Scope</u>

The NRC performed this supplemental inspection in accordance with Inspection Procedure 92702, "Follow-up of Traditional Enforcement Actions Including Violations, Deviations, Confirmatory Action Letters, Confirmatory Orders, and Alternative Dispute Resolution Confirmatory Orders," to assess the licensee's response to the issues identified during the inspection documented in NRC Special Inspection Report dated, December 19, 2018, "Special Inspection Report 050-00206/2018-005, 050-00361/2018-005, 050-00362/2018-005, and 072-00041/2018-001 and Notice of Violation," (NRC Special Inspection) (ADAMS Accession ML18341A172), using the following inspection objectives:

- Objective 1: To assure that the root and contributing causes of significant performance issues were understood;
- Objective 2: To independently assess and assure that the extent of condition and extent of cause of significant performance issues were identified;

- Objective 3: To assure that corrective actions taken to address and preclude repetition of significant performance issues were prompt and effective;
- Objective 4: To assure that corrective action plans directed prompt actions to effectively address and preclude repetition of significant performance issues.

The NRC Special Inspection Report documented the NRC's review of an August 3, 2018, misalignment incident that occurred when a loaded spent fuel canister came to rest on the shield ring near the top of the UMAX ISFSI vault, which prevented it from being fully lowered into the storage vault. At that time, the important-to-safety (ITS) rigging and lifting slings were slack and were no longer capable of performing their safety function of supporting and controlling the loaded canister. This failure to maintain redundant drop protection placed the canister (No. 29) in an unanalyzed condition because the ISFSI FSAR assumed a postulated drop was a non-credible event. The estimated time the canister was in an unsupported position was approximately 45 minutes.

Following the misalignment incident, the licensee failed to notify the NRC that ITS equipment was disabled and would fail to function as designed when required by the Certificate of Compliance to provide redundant drop protection features to prevent and mitigate the consequences of a drop accident and no redundant equipment was available and operable to perform the required safety function. The licensee's failure to make the required report to the NRC existed for 39 days until the report was submitted and compliance restored.

On March 25, 2019, the NRC issued letter, "Notice of Violation and Proposed Imposition of Civil Penalty - $116,000 and NRC Inspection Report 050-00206/2018-005, 050-00361/2018-005, 050-00362/2018-005, 072-00041/2018-001," (ADAMS Accession ML19080A208), to document the final significance determination for the identified escalated violations. The licensee's failure to ensure ITS equipment was available to provide redundant drop protection during downloading operations was characterized as a finding having significant safety consequence and was identified as a Severity Level II violation of NRC requirements. The licensee's failure to make a timely notification to the NRC Headquarters Operations Center for the August 3, 2018, disabling of ITS equipment impacted the ability of the NRC to perform its regulatory oversight function and was identified as a Severity Level III violation of NRC requirements.

The inspectors reviewed the licensee's causal evaluations and supplemental information during the inspection period. The inspectors held discussions with licensee personnel to determine if the root causes, contributing causes, and the contribution of safety culture components related to the issues were understood, and that corrective actions taken or planned were appropriate to address the causes and preclude repetition.

1.2 Observations and Findings

1.2.1 Problem Identification and Cause Evaluations (Objective 1)

a. Overview

The inspectors verified that the licensee's evaluations adequately documented identification of the issues. The violation involving failure to provide redundant drop protection features during downloading operations was self-revealed and the violation for

failure to make a report to the NRC was NRC identified. The inspectors determined that the evaluations documented how long the issues existed and prior opportunities for identification. The inspectors also determined that the evaluation documented significant plant-specific consequences and compliance concerns associated with the issues.

The inspectors evaluated whether the licensee's causal evaluations were conducted to a level of detail commensurate with the significance of the problem, and whether the licensee's evaluations included consideration of prior occurrences of the problem and knowledge of prior operating experience.

b. Assessment

The licensee performed four causal evaluations to address the issues resulting from the August 3, 2018, misalignment incident. The four causal evaluations were tracked in the licensee's Corrective Action Program (CAP) and addressed the following areas:

- Root Cause Evaluation (RCE) Quality Investigation (QI)-2529 was initiated to identify the root causes and corrective actions necessary to address the misalignment event and enhance Holtec's processes and procedures to prevent recurrence.

- Apparent Cause Evaluation (ACE) (Action Report (AR) 0818-20356) was initiated to determine why the Southern California Edison Company (SCE) oversight was ineffective in preventing the misalignment event.

- Common Cause Evaluation (CCE) (AR 0618-77146) was initiated to identify common issues that challenged construction of ISFSI facilities and fuel transfer operations.

- Reportability Root-Cause Evaluation (RRCE) (AR 1218-33805) was initiated to determine why a report was not submitted to the NRC within the required time-frame.

The RCE QI-2529 identified one root cause and five contributing causes. Specifically, the evaluation determined that the root cause of this event was: "*Holtec Management failed to recognize the complexity and risks associated with fuel transfer operation while using a relatively new system design (UMAX) in conjunction with a long duration campaign, and thus, did not implement necessary program improvements or the necessary level of oversight.*" The licensee determined that the contributing causes were: (1) inadequate content in procedures to recognize special conditions related to a new equipment system (UMAX); (2) the design review process did not ensure that unintended consequences of design features were captured; (3) communication protocols with a chain of command established during canister movements were not well defined; (4) Holtec had not established a continuous learning environment which promoted the use of internal and external operating experience; (5) the Holtec Training Program did not consider the uniqueness of the UMAX system relative to the other HI-STORM systems nor the uniqueness of challenges raised in a long-term project, which led to not fully establishing qualification or proficiency requirements for the task performers.

As a result, Holtec identified and addressed a significant number of weaknesses in the areas of design review, procedures, training, safety culture, operating experience,

corrective action processes, and communications. The SCE reviewed and approved Holtec RCE QI-2529 and the associated corrective actions through the SONGS's Corrective Action Program (CAP) as Action Request (AR) 0818-76588.

The ACE 0818-20356 identified one apparent cause and two contributing causes. Specifically, the evaluation determined that the apparent cause was: *"SCE ISFSI Project Management failed to establish a rigorous process to ensure technically accurate Holtec Procedures, adequate SCE and Holtec training to support procedure implementation, and sufficiently detailed Oversight Specialist guidance."* The licensee determined that the contributing causes were: (1) SCE project management observations were not being routinely performed, and (2) SCE project management had not consistently reinforced initiation of an AR for deviations from what was expected, even if covered by procedure, or that result in additional dose. As a result, the licensee identified and addressed a significant number of weaknesses in the areas of vendor material reviews, training for oversight individuals, oversight processes, safety culture, operating experience, and corrective action processes.

The CCE 0618-77146 identified one common cause and one contributing cause. Specifically, the licensee's evaluation determined that the common cause was: *"Holtec did not staff the project with knowledgeable experienced personnel to effectively manage, and administer, the Holtec Quality Assurance Program or the Holtec Corrective Action Program."* The licensee determined that the contributing cause was: (1) Holtec procedures and processes that feed into the Holtec CAP, were not sufficiently detailed or prescriptive to guide or instruct a person with limited quality and CAP experience to identify and effectively resolve conditions adverse to quality and/or trends in a timely manner. As a result, the licensee identified and addressed weaknesses in the areas of CAP processes and CAP training in both the Holtec and SCE CAP programs.

The RRCE 1218-33805 identified one root cause and two contributing causes. Specifcally, the licensee's evaluation determined that the root cause was: *"SCE Management failed to recognize the transition to fuel transfer operations as requiring the integration, familiarization, and application of 10 CFR 72.75 reporting requirements into plant processes."* The licensee determined that the contributing causes were: (1) There was a lack of guidance to facilitate understanding of the wording in 10 CFR 72.75(d); and (2) SCE management did not encourage, and the organization did not demonstrate, a conservative bias for reporting. As a result, the licensee identified and addressed weaknesses in the areas of reportability training and the reportability process.

c. Observations

An observation was identified by the NRC inspectors during the review of the four causal evaluations, which related to contributing causes. The inspectors identified that the licensee failed to address one potential contributing cause of the spent fuel storage canister downloading event. Specifically, the inspectors noted that the site emphasis on minimizing radiation dose directly led to personnel critical to the oversight of the downloading evolution being relocated to a low dose area where direct observation of the downloading activities was not possible. This led to a partial loss of command and control of the evolution and was likely a contributing cause of the event.

The inspectors noted that this potential causal factor was identified in the ACE 0818-20356. However, the causal factor was not identified as a contributing factor

nor tracked as a specific corrective action in the ACE 0818-20356 or RCE QI-2529. The inspectors identified through interviews with the loading personnel that training on this causal factor was conducted for personnel involved in future downloading operations. However, the inspectors were unable to verify the subject was captured in the licensee's training lessons and training presentations. In response, the licensee initiated corrective action AR 0219-25489 to address the NRC identified issue. Corrective actions taken included revising the radiation protection work plan and training lesson plans to include radiation protection lessons learned. Corrective actions taken were adequate to resolve the NRC observation.

d. Conclusions

The inspectors independently reviewed the licensee's causal evaluations for the performance issues and significant findings that existed which led to the misalignment incident. The NRC concluded that the evaluations were conducted to a level of detail commensurate with the significance of the problems and the root causes combined with the contributing causes and adequately addressed the findings presented in the NRC Special Inspection Report. The inspectors also concluded that the root and contributing causes of the significant performance issues were understood by the licensee. One observation was identified by the NRC related to the identified contributing causes, which was subsequently entered into the CAP and addressed by the licensee to resolve the NRC concern. As a result, Inspection Objective 1 was met.

1.2.2 Extent of Condition and Extent of Cause Evaluation (Objective 2)

a. Overview

The inspectors verified that the significant performance issues were evaluated using a systematic methodology. The inspectors evaluated whether the root-cause evaluation was conducted to a level of detail commensurate with the significance of the problems, and that it included a consideration of prior occurrences of the problems and knowledge of prior operating experience. Additionally, the inspectors assessed whether the causal evaluations addressed the extent of condition and extent of cause associated with the significant performance issues and assessed whether the licensee appropriately considered safety culture traits.

b. Assessment

The inspectors determined that the licensee's causal evaluations used systematic methodologies and were conducted to a level of detail commensurate with the significance of the problems. The identified causes, discussed in the previous section, are the results of an aggregate review using multiple analytical techniques. The inspectors also determined that the causal evaluations included a consideration of prior occurrences of the problems and knowledge of prior operating experience.

The licensee used the following systematic methods to complete the four causal evaluations:

- The RCE QI-2529 applied: 1.) Five Whys Approach; 2.) Barrier Analysis; 3.) Organizational and Programmatic Assessment; 4.) Human Factor Analysis; 5.) Comparative Time Line; and 6.) Safety Culture Assessment

- The ACE 0818-20356 applied: 1.) Cause and Effect Charting; and 2.) Lines of Inquiry List
- The CCE 0618-77146 applied: 1.) Pareto Chart; and 2.) Bin Assessment
- The RRCE 1218-33805 applied: 1.) Cause and Effect Charting; 2.) Barrier Analysis; and 3.) Safety Culture Assessment

The inspectors determined whether the licensee's causal evaluations addressed extent of condition and extent of cause of the problems identified in the reviews. Specifically, the RCE QI-2529 assessed the degree that the actual condition may exist in plant equipment, processes, or human performance that could result in the same or similar consequences. The extent of cause-initiated changes within Holtec's processes, which included evaluation of other facility's downloading procedures, verification of crew composition, qualifications, lessons learned, training enhancements, and design reviews.

The licensee's ACE 0818-20356 assessed all other fuel movements and heavy lifts at SONGS. The extent of cause review-initiated changes in all other ISFSI loading procedures and reviews of ISFSI non-loading procedures. Additionally, changes were initiated in licensee oversight of other vendor activities, including decommissioning activities, in the areas of training, document reviews, oversight observation programs, and lessons learned.

The licensee's RRCE 1218-33805 assessed additional areas where reportability may have been required but was not made to the NRC. Through that review the licensee determined one notification to the NRC was required. This notification related to the lateral clearance between the low-profile transporter and other structures (e.g. light posts), and the low-profile transporter's center of gravity was not maintained in accordance with the seismically analyzed limits. The licensee made the required notification to the NRC under 10 CFR 72.75(d)(1) on December 20, 2018 (Event Notification (EN) 53798) (see Section 2.2.2 for further discussion of the licensee event report). The extent of cause review addressed other reporting requirements within 10 CFR 72.75 and other applicable federal regulations. Additional actions were taken to enhance training and procedural processes to ensure reporting requirements would be followed as required in 10 CFR Parts 20, 49, 50, 71, and 72.

c. Observations

An observation was identified by the inspectors during the extent of condition review for the four causal evaluations. The inspectors identified that the licensee failed to perform one of the extent of condition reviews described in ACE 0818-20356. Specifically, Corrective Action (CA) 17 (CA-17), which stated, for Holtec procedures, other than operating procedures, determine which ones have a potential impact on operations and conduct a review using the review guidance in Corrective Action to Prevent Recurrence 2 (CAPR-2). The CAPR-2 task actions were to include additional requirements in procedure S0123-XV-93, "Contractor Oversight," to ensure a more rigorous review was completed by SCE oversight staff before accepting the document for use at the station.

The NRC inspectors identified that this review of Holtec non-loading/maintenance procedures had not been performed as specified in CA-17. In response, the licensee initiated corrective action AR 0818-20356 to perform the required review. The review included approximately 15 Holtec procedures which involved areas of crane maintenance, special lifting device maintenance, vertical cask transporter (VCT) maintenance, foreign material control program, weld examination program, etc. The inspectors reviewed the comments and discrepancies that were identified by the SCE staff from the review. The documentation of the review included a table of all comments identified by SCE staff and the revised procedures that documented that identified issues were changed. The corrective actions taken were adequate to address the NRC observation.

d. Conclusions

The inspectors determined that the licensee evaluated the issues using systematic methodologies to identify root and contributing causes. Additionally, the inspectors concluded that the licensee's causal evaluations addressed the extent of condition and extent of cause of the issues and appropriately considered safety culture traits. One observation was identified by the inspectors which was related to the extent of condition review. The licensee addressed the issue by taking adequate corrective actions. As a result, Objective 2 was met.

1.2.3 Corrective Actions Taken (Objective 3)

a. Overview

The inspectors reviewed the licensee's causal evaluations to assess whether appropriate corrective actions were specified for the root and contributing causes or that the licensee had an adequate evaluation for why no corrective actions were necessary. The inspectors also assessed whether the corrective actions had been prioritized with consideration of the safety significance and regulatory compliance. The inspectors evaluated whether the corrective actions taken to address and preclude repetition of significant performance issues were prompt and effective, and whether the violations, related to the NRC Special Inspection, had been adequately addressed.

b. Assessment

The corrective actions taken by the licensee are described below in the following areas: (1) Licensee Oversight; (2) Procedures; (3) Training; (4) Equipment and Personnel; (5) Corrective Action Program; and (6) Reportability.

(1) Licensee Oversight

The licensee's ACE 0818-20356, contained the majority of the corrective actions for the area of licensee oversight. Corrective actions drove extensive changes to the training and qualification program that an ISFSI oversight specialist is required to complete. The licensee increased the number of oversight specialists that directly observe ISFSI operations from approximately 10 to 14 individuals. All existing and new specialists were required to complete the enhanced qualification program requirements. The licensee assigned a specific training manager to oversee the enhanced training/qualification program. The licensee developed new lesson plans as

part of the qualification process. The new lesson plans included training on new load monitoring equipment, new task specific guides for field observations, new oversight roles and responsibilities, expectations, procedure changes, use of the corrective action program, acceptance review process changes, lessons learned, and other topics.

The licensee developed procedure G-XV93-PTP-01, "Pool to Pad Job Guide Desktop Guide," Revision 0. The inspectors reviewed the procedure and observed that it contained job guides for the ISFSI oversight specialists to use as a tool to assist in preparation and observational direction on the critical tasks during fuel transfer operations. The procedure described key elements of all work activities, detailing how and why tasks were critical. The guide directed the ISFSI oversight specialists to which specific tasks were required to be observed. The inspectors' review concluded that the task guide contained all critical tasks associated with fuel operations.

The licensee's site acceptance process of vendor procedures and training documents were revised. The changes included additional requirements to ensure a rigorous review prior to procedure acceptance and use at SONGS. The inspectors reviewed the procedure changes and the package of reviews conducted by oversight personnel to ensure all new and previously accepted documents received the same level of review. The inspectors concluded that the changes were appropriate, the reviews were thorough, and all identified issues were adequately addressed and corrected.

The licensee's changes included developing an oversight management organization to conduct observations on oversight specialists while they performed their field duties. The program included peer-to-peer observational requirements by decommissioning oversight personnel, as well as management observational requirements of the ISFSI oversight personnel. The program also contained effectiveness review requirements to ensure the required peer and management observations were effective and completed as required. The inspectors reviewed audit packages that were performed on oversight specialists during training exercises. The peer and management observations were well documented, and all identified enhancements and coaching items were captured in the licensee's CAP. The NRC concluded that the licensee had made substantial improvements throughout the ISFSI oversight program. No NRC observations were identified in this area.

(2) Canister Handling Procedures

The licensee's ACE 0818-20356 and RCE QI-2529 evaluations of the misalignment incident identified corrective actions which were intended to address procedural inadequacies that contributed to the incident. To address identified issues, the causal evaluations recommended corrective actions for the procedures that included the following changes: (1) continuous monitoring of weight sensing equipment during downloading operations; (2) establishment of clear underload criteria for when to halt downloading operations; (3) defining crew member roles and responsibilities by title; (4) listing qualification requirements for the specified roles; (5) listing critical steps in procedures; (6) defining responsibilities of cask loading supervisors; and (7) identifying areas where escalated management oversight was required.

Changes (1) and (2) were specifically directed at Holtec Procedure HPP-2464-400, "MPC Transfer at SONGS," Revision 17. The NRC inspectors reviewed the procedure revisions that included the new requirement to continuously monitor the canister

weight. The procedure revisions included establishment of clear underload criteria for when to halt downloading operations. The revised procedure directed the VCT operator and VCT platform rigger to maintain visual contact with the VCT control panel screen, load shackle tablet weight display screen, and downloader slings during canister downloading operations.

Procedure HPP-2464-400, Section 7.6, "Canister Download into Cavity Enclosure Container (CEC)," was revised to include steps to record the canister weight and to establish an underload restriction value. These changes included contingency steps for re-centering the canister if downloading operators noted a restriction in downward travel. The procedure also directed stop work requirements if certain underload conditions were experienced. Those actions included withdrawing the canister back into the transfer cask, making the appropriate notifications to site management, and condition report initiation into the CAP.

Changes (3) through (7) were applied to all operational procedures related to dry cask storage operations at SONGS. Those procedures included HPP-2464-100, "MPC Pre-Operation Inspection;" HPP-2464-200, "MPC Loading at SONGS;" HPP-2464-300, "MPC Sealing;" HPP-2464-400, "MPC Transfer at SONGS;" HPP-2464-500, "MPC Unloading;" and HPP-2464-600, "Responding to Abnormal Conditions." The NRC inspectors verified that each of those procedures were updated with the new requirements.

<u>(Closed) Notice of Violation VIO 07200041/2018-001-04, Failure to provide adequate instructions in procedures, 10 CFR 72.150, EA-18-155</u>

The NRC Special Inspection Report documented a violation of NRC requirements related to the licensee's failure to prescribe activities affecting quality by documented instructions or procedures of a type appropriate to the circumstances and include appropriate quantitative or qualitative acceptance criteria for determining that important activities had been satisfactorily accomplished.

The licensee responded to the Notice of Violation and described the corrective steps taken to ensure full compliance in SCE submittal to the NRC, dated December 26, 2018 (ADAMS Accession ML18362A148). The inspectors reviewed the licensee's implemented corrective actions related to procedural direction during follow-up inspection activities. The inspectors concluded, based on the changes described above, that the licensee had performed adequate corrective actions to restore compliance, address extent of condition, and prevent recurrence.

However, the inspectors made observations related to the corrective actions to improve Holtec Procedure HPP-2464-400 (see Section 1.2.3.c.(2)). The licensee subsequently addressed the NRC observations. No additional deficiencies were identified during NRC's review of this violation.

This closes VIO 07200041/2018-001-04, "Failure to provide adequate instructions in procedures" (10 CFR 72.150), EA-18-155.

(3) <u>Training</u>

Inadequate training was identified by the licensee as a contributing cause that led to the canister misalignment event. Specifically, RCE QI-2529 Contributing Cause 5

stated, in part, that the "Holtec training program did not consider uniqueness of UMAX system relative to HI-STORM or uniqueness of challenges raised in a long-term project which led to not fully establishing qualification or proficiency requirements for the Task Performers when transferring a canister into a UMAX system."

The licensee had several corrective actions associated with training, for both fuel handling personnel and oversight personnel, which broadly included: updated initial training, on-the-job demonstrations, updated qualifications, ongoing proficiency requirements, updated training lesson plans, scripted pre-job briefs, and the incorporation of site-specific operating experience into the training program. The specific corrective actions associated with training included:

- CA-19 and CA-20: Developed a SONGS site-specific training program and procedures which augmented the existing Holtec corporate training program and procedures. The corrective actions required that the site training program to include a site-specific task list and a task to training matrix which described all the applicable positions of a fuel handling crew to be utilized at SONGS. The corrective actions required all positions to be described and minimum training and qualifications for each position listed. The training program was required to include the appropriate elements of a systematic approach to training (SAT).

- CA-22: Included a 10 CFR 72.48 evaluation to incorporate additional text into Chapter 9 of the FSAR to add criteria for load limits, training, procedure compliance, and use of engineering features.

- CA-23: Required the addition of a training consultant to perform an evaluation of the current site-specific training program, including effectiveness, and to provide recommendations for improvements to the Holtec standard training program. Areas of evaluation included, but were not limited to, review and enhancement of task analysis matrices, the development of training programs, implementation plans, proficiency requirements, and requalification requirements.

- CA-24: Required training and qualification for all loading personnel currently assigned to the project in accordance with new SONGS site-specific training program requirements (CA-20).

The licensee concluded that procedure HSP-34, "Training of Subcontracted Field Service Personnel," which was previously used to train and qualify the pool-to-pad personnel, was not based on a SAT. A site-specific training program, HPP-2464-1134, "Training of site services personnel," Revision 1, was developed by the licensee and reviewed by the inspectors. This SAT based program was developed to be used in conjunction with procedure HSP-34.

A SAT program is defined in 10 CFR 55.4, and includes the following attributes: (1) systematic analysis of job performance requirements and training needs; (2) the derivation of learning objectives, based upon the preceding analysis, which describe desired performance after training; (3) the training program design and implementation based on the learning objectives; (4) the evaluation of trainee mastery of learning objectives during training; and (5) the training program evaluation and revision based upon the performance of trained personnel in the job setting.

The new site-specific training procedure HPP-2464-1164 required:

- All positions to be described and minimum training and qualifications for each position listed in a training matrix.
- To contain the minimum qualification requirements to ensure that personnel were appropriately trained prior to performing fuel transfer activities.
- To include the appropriate elements of a SAT program.

The training corrective actions required the licensee to update all lesson plans, which included an additional 13 new lesson plans and development of seven new on-the-job training requirements using the SAT process. The corrective action program and Operating Experience (OE) programs were included as a feedback loop into the training program as required by procedure HPP-2464-1164. In addition, the licensee staffed a site program training manager to oversee the training program and ensure the SAT program elements were maintained. Finally, the inspectors reviewed the changes in UMAX FSAR, Chapter 9, to verify the change included revised language from CA-22.

(Closed) Notice of Violation VIO 07200041/2018-001-03, Failure to assure that operations of important-to-safety equipment were limited to trained and certified personnel, 10 CFR 72.190, EA-18-155

The NRC Special Inspection documented a violation of NRC requirements related to the licensee's failure to assure that operation of equipment and controls, that had been identified as ITS in the Safety Analysis Report, were limited to trained and certified personnel or were under the direct supervision of an individual with training and certification in the operation.

The licensee submitted a response to the NRC on December 26, 2018 (ADAMS Accession ML18362A148), which contained the corrective steps taken to ensure full compliance was achieved. The inspectors reviewed the licensee's implemented corrective actions related to the training of personnel during follow-up inspection activities. The inspectors concluded, based on the changes described above, that the licensee had performed adequate corrective actions to restore compliance, address the extent of condition, and prevent recurrence. No additional deficiencies were identified during the inspectors' review of this violation.

This closes VIO 072-00041/2018-001-03, "Failure to assure that operations of important-to-safety equipment were limited to trained and certified personnel" (10 CFR 72.190), EA-18-155.

(4) Equipment and Personnel

The licensee's causal evaluation contained corrective actions to implement a new load monitoring system, increased the number personnel present during downloading operations, and added remote monitoring capabilities to limit canister misalignments and prevent a condition in which the lifting devices no longer controlled the weight of the canister.

The new load monitoring equipment included two load sensing shackles, which were placed in-line with each respective downloading sling. These dual and redundant load sensing shackles were calibrated by an approved vendor to an accuracy of ±1% of the actual weight. The load sensing shackles wirelessly transmitted the weight of the canister to two digital readout tablets. Each tablet was equipped with an audible and visual alarm that would activate when the weight decreased below the established set points. One tablet was positioned next to the Holtec cask loading supervisor and SCE oversight specialist. The second tablet was positioned above the VCT control box and could be observed by both the VCT operator and an additional spotter, who was required to be on the VCT platform during downloading operations.

As part of the equipment enhancements, the licensee installed a camera on the side of one of the VCT towers. The camera was positioned to provide an overhead view of the top of the canister as it passed through the transfer cask into the ISFSI vault. The camera wirelessly displayed the video feed to a monitor that was located next to the Holtec cask loading supervisor and the SCE oversight specialist.

Other enhancements included increased number of personnel on the ISFSI pad during downloading operations from the two personnel (VCT operator and rigger in the man-basket) during the August 3rd incident to nine individuals on the ISFSI pad. This included an additional rigger in a separate elevated lift-basket to visually observe the canister as it was lowered through the transfer cask into the ISFSI vault.

During the downloading demonstrations performed by the licensee January 28 through February 1, 2019, the NRC inspectors observed the licensee successfully utilize the new equipment to safely lower a canister into the ISFSI vault. However, the inspectors identified two violations of NRC requirements regarding the licensee's equipment implementation and procurement of the new load monitoring equipment (see Section 1.2.3.c.(3) and (4)).

(5) Corrective Action Program

The licensee's ACE 0818-20356, RCE QI-2529, and CCE 0618-77146 identified corrective actions to address deficiencies in the CAP. The ACE 0818-20356 identified that ISFSI project management had not encouraged initiation of condition reports for deviations experienced in dry cask storage operations as a contributing cause. The RCE QI-2529 identified that Holtec had not fostered an environment that promoted sharing of internal and external operating experiences among the dry cask storage workers. The CCE 0618-77146 identified Holtec procedures and processes that input to the Holtec Field Condition Report (FCR) process and the Holtec CAP, were not sufficiently detailed or prescriptive to guide or instruct a person with limited quality assurance (QA) and CAP experience to identify, and effectively resolve, conditions adverse to quality and/or trends in a timely manner.

To address these issues, all three of these causal evaluations recommended corrective actions in the area of the CAP which included the following actions: (1) conducting a lessons learned case study based on recent events to clarify condition report initiation; (2) developing oversight specialist condition report training; (3) revising procedure HSP-42, "Project Manager's Desktop guide for Site Services Pool to Pad Projects," to include a section on operational experience; (4) revising procedure HSP-35, "Procedure for Field Condition Reports and Procedure Field

Change Notices for All Site Work," to provide clarification on the threshold for condition report initiation; (5) establishing a process to ensure operational experiences were communicated across and within project areas; (6) assigning a qualified and experienced full time Holtec QA Manger to the ISFSI Project to oversee the CAP; (7) developing a SCE CAP training plan; and (8) requiring Holtec to adopt and adhere to SCE's CAP for SONGS related work activities.

Action (1) required SCE to develop a personnel training module that included specific events identified during active fuel transfer operations that provided lessons learned applicable to improving SCE's implementation of its CAP. The training developed by SCE included examples of deviations experienced during the loading campaign and at other sites as well as the August 3, 2018, downloading operations. The inspectors reviewed the training documentation and verified that applicable dry cask storage staff had completed the required training.

Action (2) involved training the SCE oversight specialists in documenting issues into the oversight specialist database. The training emphasized the documentation of relevant issues or comments into the database with sufficient detail such that the observed deficiencies could be understood. The inspectors reviewed the training documentation and verified the roster of ISFSI oversight specialists had completed the required training.

Action (3) revised procedure HSP-42 to include steps which required operating experience, lessons learned, and best practices encountered during the execution phases of fuel loading operations to be captured by the Holtec project manager. Six sources of operating experience were identified: (1) standard shift turnover sheets; (2) FCRs; (3) management observation program comments; (4) site services weekly project updates/conference calls; (5) the Holtec Users Group database; and (6) the Holtec Lessons Learned database. The operating experience collected from these sources was required to be shared with dry cask storage workers during pre-job briefings and two-minute drills, as applicable, by the Holtec site project manager.

Action (4) revised procedure HSP-35 to provide procedural clarification on the threshold for initiating an FCR. The definitions section of procedure HSP-35 was expanded to include "Short-term Operations." A procedure step was included that explained that "any observed event during Short-term Operations that indicated an abnormal or unexpected condition shall be entered into the FCR tool for further evaluation."

Action (5) revised procedure HSP-42 to require the project manager to collect and disseminate pertinent operating experience to the appropriate dry cask storage personnel on a routine basis. This corrective action also relied on changes made to procedure HSP-35, which lowered the threshold for FCR reporting; SCE CAP training, which redefined the lower thresholds for problem identification; and procedure HSP-1101, "Procedure for Project Risk Management," which was revised to include lessons learned and operating experience documentation that must be reviewed for potential risk impacts.

Action (6) appointed a QA manager for Holtec to the SONGS facility. The appointee had experience with 10 CFR Part 50, Appendix B, and 10 CFR Part 72, Subpart G, requirements. The quality manager tasks included actions to improve quality in work

performed at SONGS, interface with Holtec personnel, maintaining high standards for Holtec work activities, performing corrective action evaluations, performing trending on FCRs, and addressing quality related issues as they are identified on site. The NRC inspectors reviewed the new quality assurance manager's resume and confirmed the individual had the knowledge and experience to perform the required responsibilities.

Action (7) required CAP training to be provided to site personnel. The NRC reviewed lesson plans and attendance records. The training lesson plans contained all the required information described in the causal evaluation and included additional enhancements to strengthen the CAP.

Action (8) required all workers, including contractors, to use the SCE CAP for activities on site. The NRC reviewed the revised process, which included an organization chart to identify which onsite personnel would have access to SCE's Action Request system and documentation that showed Holtec managers and workers had been provided credentials to access the Action Request system.

(Closed) Notice of Violation VIO 07200041/2018-001-01, Failure to identify and correct conditions adverse to quality (10 CFR 72.172), EA-18-155

The NRC Special Inspection documented a violation of NRC requirements related to the licensee's failure to establish measures to ensure that conditions adverse to quality, such as failures, malfunctions, deficiencies, and deviations were promptly identified and corrected.

The licensee submitted a response to the NRC on December 26, 2018 (ADAMS Accession ML18362A148) which contained the corrective actions taken to ensure full compliance was achieved. The inspectors reviewed the corrective actions implemented related to the use of the licensee's corrective action program during follow-up inspection activities. The inspectors concluded, based on the changes described above, that the licensee had performed adequate corrective actions to restore compliance, address the extent of condition, and prevent recurrence. No additional deficiencies were identified during the inspectors' review of this violation.

This closes VIO 07200041/2018-00101, "Failure to identify and correct conditions adverse to quality" (10 CFR 72.172), EA-18-155.

(6) Reportability

The licensee performed a reportability root cause evaluation (RRCE 1218-33805) to evaluate their failure to make an event notification to the NRC Operations Center for the August 3, 2018, misalignment incident. The corrective actions to address the identified causes included the following actions: (1) developing 10 CFR 72.75 training that identified ITS components, potential accidents, and failures that influence reportability; (2) establishing requirements for biennial refresher training; (3) conducting reviews to determine potential reportability requirements related to other site activities; (4) conducting reviews to determine the target audience for training the reportability changes; (5) revising site notification procedures to have a more conservative reporting bias and the identification of the Shift Manager as the individual responsible for the final decision on reportability for the site; (6) developing and conducting a case study with licensee managers and regulatory assurance

personnel on the communications and reportability aspects of the August 3, 2018, incident; and (7) conducting all-hands briefings regarding the reportability violation and future expectations for reporting.

For actions (1) through (4), SCE developed 10 CFR 72.75 training and required biennial refresher training. This training was delivered to SCE managers and Regulatory Assurance personnel. The training included discussions of accidents and design basis events for both the UMAX and NUHOMS ISFSI designs. The training included the descriptions and function of ITS structures, systems, and components and potential failures that would require reporting under 10 CFR 72.75. The training and biennial refresher requirements were included under the Shift Manager/Certified Fuel Handler Training Program. The initial target audience was SCE managers and Regulatory Assurance staff.

Action (5) required that SCE revise procedure SO-123-0-A7, "Notification and Reporting of Significant Events," to have a conservative bias toward reporting requirements. The procedure was revised to include guidance that if the condition being considered did not literally meet the reporting criteria, but was close, then the staff was directed to make a voluntary report using the closest reporting requirement that matched the condition under consideration. This was required to be completed within the time-frame stipulated by the reporting requirement. Procedure SO-123-0-A7 was also revised to encourage the voluntary reporting of any event or condition that could have safety significance or represent a generic concern.

The reporting procedure was further revised to identify the Shift Manager as the site individual responsible for making the final decision on reportability. Lastly, the SCE notification procedure was revised to include Attachment 11, "Reportability Determination," for a decision-making flow-chart. The flow-chart required the Shift Manager to chair a Reportability Management meeting/conference call to discuss potential reporting conditions. The call decision was required to be documented with the date and time of the decision, the start-time of the reportability clock, when the report was due, and the date/time the event notification was made.

Action (6) required the licensee to develop a case study training module that covered the specifics of the August 3, 2018, misalignment incident and the contributing factors that led to the licensee's failure to properly assess the event and to report the incident to the NRC Operations Center, as required by 10 CFR 72.75(d)(1). The case study discussed the specific details of the incident, acknowledged missed opportunities, and provided examples of how the notification procedure was revised to prevent recurrence of the notification failure. The case study required attendees to fill out a work-sheet that asked specific questions related to the event.

Action (7) required that the Chief Nuclear Officer provide an all-hands briefing to SCE staff and a separate briefing to SCE managers to discuss the violation. The briefings were to discuss the licensee's failure to make the 24-hour NRC notification, the causes of the failure, and management expectations for a conservative bias when making reportability decisions moving forward.

(Closed) Notice of Violation VIO 072-00041/2018-001-05, "Failure to make 24-hour notification" (10 CFR 72.75), EA-18-155

The NRC Special Inspection documented a violation of NRC requirements related to the licensee's failure to make a required 24-hour notification to the NRC within the required timeframe.

On November 8, 2018, the licensee issued Licensee Event Report (LER) 2018-001-0 (ADAMS Accession ML18317A060) in accordance with 10 CFR 72.75(d)(1) for the event and restored compliance. The licensee submitted its response to the Notice of Violation, on April 23, 2019 ADAMS Accession ML19116A056), which contained the corrective actions taken to ensure full compliance was achieved.

The NRC concluded that SCE's completed and proposed corrective actions, as described above, restored compliance, addressed extent of condition, and were adequate to prevent recurrence. No additional deficiencies were identified during the inspectors' review of this violation.

This closes VIO 072-00041/2018-001-05, "Failure to make 24-hour notification," (10 CFR 72.75), EA-18-155.

c. Observations and Findings

(1) Executive Oversight Board

The inspectors observed that CAPR-1 associated with the RCE QI-2529 appeared to be administrative in nature and did not meet the level of rigor associated with a CAPR, which should serve to preclude repetition of significant performance issues. The CAPR assigned changes to the Executive Oversight Board agenda to provide an increased focus on early identification of challenges to the project to ensure issues were properly resolved before undesired events occurred.

In response to the inspectors' observation, the licensee placed the identified observation into the corrective action program as AR-0818-7655. The licensee bolstered the required changes to the Executive Oversight Board agenda to incorporate additional techniques to review Management Review Meeting data, participation to evaluate current performance against risk registers, evaluate industrial safety trends, review quality metrics, and review SCE oversight effectiveness. The changes provided rigor to the agenda which served to consistently evaluate project performance against pre-determined standards. The NRC inspectors reviewed the new meeting agenda to verify the topics reviewed would ensure early identification of challenges to the project. Based on the licensee's changes and level of detail that would be reviewed during the meetings, the NRC concluded that the changes were appropriate to support early identification of significant performance deficiencies.

(2) Downloading Procedure

The inspectors determined that SCE had made substantial improvements to fuel handling procedures to ensure safe operations. However, the NRC identified that notable procedural weaknesses remained in downloading procedure HPP-2464-400 "MPC Transfer at SONGS," Revision 17. Procedure weakness included: (1) missing contingency steps for potential new equipment failures; (2) while there were some

criteria specified for when to suspend downloading operations, not all scenarios were addressed; and (3) the procedure lacked some steps necessary to maintain seismic qualifications during cask transport from the fuel building to the spent fuel storage pad.

In response, the licensee initiated AR 0119-81239-10 and AR 0119-81239-9 to capture the inspectors' observations. The licensee took corrective actions and addressed the identified omissions in the next procedural revision.

(3) Equipment Designation

Corrective action CA-1, associated with ACE 0818-20356, implemented guidance for a load monitoring device to ensure load indication was available to assist with suspending operations if the load was lost. SCE implemented the design change to incorporate the new load monitoring equipment using Nuclear Engineering Change Package (NECP) 0918-64884, "VCT Live Load Monitoring System," Revision 1. The load monitoring equipment included intermediate slings, a master link, and load sensing shackles which would be placed in-line with each of the ITS downloading slings. The inspectors identified that the NECP inappropriately designated the new load monitoring equipment as not-important-to-safety (NITS). Inspectors determined that since the new equipment was to be placed in-line with existing ITS downloading equipment, the new equipment, which failure could result in the drop of a loaded canister, should be controlled and designated under SCE Quality Assurance Program as ITS equipment.

10 CFR 72.146(a) states, in part, the licensee shall establish measures to ensure that the design bases are correctly translated into specifications, drawings, procedures, and instructions. These measures must include provisions to ensure that appropriate quality standards are specified and included in design documents.

Contrary to the above, on December 7, 2018, the licensee failed to establish measures to ensure that the appropriate quality standards were specified and included in design documents. Specifically, the licensee inappropriately designated the new load monitoring equipment at the wrong quality standard in NECP 0918-64884-1, Revision 1.

This violation was dispositioned per the traditional enforcement process using Section 2.3 of the NRC's Enforcement Policy. The NRC determined that the finding was of low safety significance since the equipment had not been used with any loaded canisters and the load monitoring equipment had been purchased by the vendor at the appropriate quality assurance designation of ITS. This finding was determined to be of more than minor safety significance since if left uncorrected, the deficiency could lead to a more significant safety concern.

Consistent with the guidance in Section 1.2.6.D of the NRC Enforcement Manual, if a violation does not fit an example in the Enforcement Policy Violation Examples, it should be assigned a severity level: (1) commensurate with its safety significance; and (2) informed by similar violations addressed in the Violation Examples. The violation was evaluated to be similar to Enforcement Policy Section 6.5.d.2.

The licensee entered the issue into the CAP as AR 1218-20333. The licensee restored compliance by verifying that the load monitoring equipment met all applicable

industry standards of NUREG 0612 and American National Standards Institute (ANSI) N14.6 requirements to meet the ITS qualification and revised the design change package to include the correct designation. Additional corrective actions taken by the licensee to preclude repetition included: performing an event investigation, conducting training for the SCE engineering team, conducting reviews of implementing procedures, and updating the site's Quality Equipment List. Because the licensee entered the finding into the CAP, the safety significance of the issue was low, and the issue was not repetitive or willful, this Severity Level IV violation was treated as a non-cited violation (NCV), consistent with Section 2.3.2.a of the Enforcement Policy (NCV 07200044/2018-002-01, Failure to ensure appropriate quality standards (10 CFR 72.146)).

(4) Equipment Procurement

The NRC inspectors reviewed all the procurement documents associated with the new load monitoring equipment that was described in NECP 0918-64884-1. This included reviewing the Holtec purchase specifications and equipment's certificate of conformance for each of the new components (load sensing shackles, master links, and intermediate slings).

The weight of the loaded canister, rigging equipment, and an additional 15% dynamic factor was calculated to be 118,640 lbs (59.34 tons) per HI-2156458 "Cask Handling Weights at SONGS," Revision 1. Each side of the rigging was required to be able to handle the load in the event that one side fails. This would require all rigging on each side to have a minimum rating of 59.34 tons.

The inspectors identified an issue with the certificate of conformance for the StraightPoint load sensing shackles. The load sensing shackles were rated to the capacity of 185,000 (92.5) tons, which was well above the required rating. However, the Holtec Purchase Specification PS-223 "Procurement Specification for Significant Rigging," Revision 0, Step 7.0, "Special Tests," required a proof test load of twice the rated vertical capacity to all rigging components. This is also required by common industry rigging standards contained in American Society of Mechanical Engineers (AMSE) B30.26 "Rigging Hardware," Section 1.4.2. The inspectors identified that the load sensing shackles were only load tested to 1.5 times the rated capacity instead of the required twice the rated capacity per purchase specification PS-223.

Additionally, Holtec's Approved Vendor List, contained the following restriction, "lifting equipment load testing must be performed at Aston I&I Sling factory." The inspectors observed that the proof load testing for the new load sensing shackles was performed at the manufacturer's facility (StraightPoint) and not by Aston I&I Slings factory per Holtec's Approved Vendor List's restrictions.

10 CFR 72.154(a) states, in part, the licensee shall establish measures to ensure that purchased material, equipment, and services, whether purchased directly or through contractors and subcontractors, conform to the procurement documents.

Contrary to the above, on December 7, 2018, the licensee failed to establish measures to ensure that purchased equipment conformed to the procurement documents. Specifically, the licensee accepted the StraightPoint load sensing shackles, which had not been proof load tested to twice the rated capacity as specified in Holtec Purchase

Specification PS-223, Step 7.0. Additionally, the licensee failed to ensure the proof load testing was performed by an approved vendor.

This violation was dispositioned per the traditional enforcement process using Section 2.3 of the NRC's Enforcement Policy. The NRC determined that the finding was of low safety significance since the equipment had not been used with any loaded canisters. This finding was determined by inspectors to be of more than minor safety significance because, if left uncorrected, the deficiency could lead to a more significant safety concern.

Consistent with the guidance in Section 1.2.6.D of the NRC Enforcement Manual, if a violation does not fit an example in the Enforcement Policy Violation Examples, it should be assigned a severity level: (1) commensurate with its safety significance; and (2) informed by similar violations addressed in the Violation Examples. The violation was evaluated to be similar to Enforcement Policy Section 6.5.d.2.

The licensee entered the issue into the CAP as AR 1219-52380. The licensee restored compliance by having the load sensing shackles proof tested to twice the rated capacity in accordance with purchase specification PS-223, by the Aston I&I Slings factory per Holtec's Approved Vendor List's restrictions. Additional corrective actions taken by the licensee to preclude repetition included: performing an apparent cause evaluation, reviewing other procured equipment documentation from Aston I&I Slings to ensure testing requirements were met, developing a revised SONGS rigging program to require an independent review and approval of vendor ITS rigging documentation, creating a project specific purchase specification for downloading shackles to provide clear details on load testing requirements, and conducting training for SCE site service project managers. Because the licensee entered the finding into the CAP, the safety significance of the issue was low, and the issue was not repetitive or willful, this Severity Level IV violation was treated as a NCV, consistent with Section 2.3.2.a of the Enforcement Policy (NCV 07200044/2018-002-02, Failure to ensure purchased material conformed to the procurement documents (10 CFR 72.154)).

d. Conclusions

Based on the licensee's evaluations and actions taken in the areas of licensee oversight, procedures, training, equipment, corrective action program, and reportability, the inspectors concluded that the corrective actions implemented were appropriate to prevent recurrence of the issues and were adequately prioritized with consideration of the risk significance and regulatory compliance. The inspectors concluded that SCE's completed corrective actions in the areas of training, corrective action program, and procedures restored compliance for the violations document in the NRC Notice of Violation issued in the NRC Special Inspection Report.

Additionally, the licensee's corrective actions taken to address the violation for failure to make a report to the NRC, documented in NRC letter of Notice of Violation and Civil Penalty, were adequate to restore compliance and prevent recurrence. However, during the NRC's review of the corrective actions taken, the inspectors identified two observations and two violations of NRC requirements related to the licensee's corrective actions. The licensee took adequate corrective action to restore compliance on the issues identified through the CAP. The violations were determined to have low safety

significance and the Severity Level IV violations were treated as NCVs. As a result, Inspection Objective 3 was met.

1.2.4. Corrective Actions Planned (Objective 4)

a. Overview

The inspectors evaluated whether the corrective actions planned to address and preclude repetition of significant performance issues were prompt and effective, and that appropriate quantitative or qualitative measures of success had been developed for determining the effectiveness of planned corrective actions.

b. Assessment

The licensee's causal evaluations contained effectiveness assessments to validate that the corrective actions were successful. In the area of training, the licensee's corrective action plan included acquiring a training consultant to perform an evaluation of the new site-specific training program, including effectiveness, and develop recommendations for improvement. The recommendations would support training enhancements for the SONGS training program and the vendor's standard training program. The area to be evaluated included task analysis matrices, training program, implementation plans, proficiency requirements, and requalification requirements.

In the area of operations, an effectiveness review schedule was established to assess the effectiveness of all corrective actions during both dry run demonstrations/training evolutions and during actual fuel movement activities. The review included an assessment of trends in lifting activities, verification of trained personnel, and detailed observational surveillance of lifting activities by independent auditors. The surveillance tasks included a review of training verification, procedure proficiency, adequate use of the CAP, and verification of management observations.

The licensee's oversight effectiveness review included corrective actions to conduct additional procedure reviews to identify new technical deficiencies, review of oversight task guides to verify sufficient guidance and enhancements, and various peer observations of oversight individuals to verify proficiency in procedures, task guide knowledge, initiation of corrective actions, and ensure desired behaviors. The effectiveness review actions contained detailed criteria that an independent assessor was required to verify during the dry-run exercises and during continued fuel loading activities.

In the area of reportability, the licensee's corrective actions included a new real time reporting exercise to be conducted monthly. All applicable individuals would be required to participate in the exercise. The exercises would take place for three consecutive months and success would be based on no incorrect reportability determinations. In addition, the new reportability process required the assignment of a "meeting skeptic" to monitor the reportability meetings to ensure the desired behavior changes continued and adequate determinations were made.

c. Observations and Findings

No findings were identified with the licensee's corrective actions planned.

d. Conclusion

Based on the licensee's evaluations and documented actions planned, the inspectors concluded that the licensee had adequately established measures to validate the effectiveness of the corrective actions to prevent recurrence. As a result, Inspection Objective 4 was met.

2 Follow-up of Events and Notices of Enforcement Discretion (IP 71153)

2.1 Inspection Scope

The inspectors evaluated licensee events to verify the licensee's corrective actions were adequate to restore compliance. The inspectors reviewed LERs to ensure the reports were timely, accurate, and the required corrective actions had been completed. Additionally, inspectors documented review of follow-up items from the NRC Special Inspection Report.

2.2 Assessment

2.2.1 (Closed) Licensee Event Report 2018-001-0, Spent Nuclear Fuel Canister Temporarily Wedged in Dry Cask Storage Container

On November 8, 2018, the licensee issued LER 2018-001-0 (ADAMS Accession ML18317A060) in accordance with 10 CFR 72.75(d)(1) and (g) for inadvertently disabling redundant ITS slings while lowering a spent fuel canister into the ISFSI on August 3, 2018.

The NRC Special Inspection Report, dated December 19, 2018, documented three cited violations and two apparent violations associated with this event that were handled through the NRC's escalated enforcement process.

During this supplemental inspection, the NRC inspectors reviewed the planned and implemented corrective actions taken by the licensee for the identified violations and determined the actions to be adequate to restore compliance and prevent recurrence.

This LER is closed.

2.2.2 (Discussed) Licensee Event Report 2018-002-0, Spent Nuclear Fuel Transport Conveyance Vehicle Operated Outside Obstacle Clearance Limits

On February 14, 2019, the licensee issued LER 2018-002-0 (ADAMS Accession ML19050A170) in accordance with 10 CFR 72.75(d)(1) and (g) for past operations of the low-profile-transporter. The licensee identified that transporter's center of gravity was not maintained within limitations specified in the site's specific analysis and operations had been conducted too close to adjacent structures (light posts) and was outside the calculated clearance limits specified in the site's seismic analysis. The licensee identified that the site procedures did not provide sufficient detail to comply with the seismic stability calculation. No actual incidents with structures or collisions with obstacles occurred during past fuel transfer operations and there was no impact to plant personnel or public health and safety.

As part of the licensee's extent of condition review associated with licensee causal evaluation RRCE 1218-33805, the licensee notified the NRC Operations Center within 24 hours of discovery of the issue (Event Notification 53798) and submitted an LER to the NRC within the 60-day time limit in accordance with 10 CFR 72.75(d)(1) requirements.

As part of the review of the August 3, 2018, event, the inspectors reviewed the licensee's corrective actions to restore compliance and prevent recurrence. This included reviewing the licensee's updated seismic analysis which determined that the variance in the height of the conveyance, during the past operations was acceptable and the licensee's changes made to the transportation procedures. Additionally, the inspectors observed licensee perform dry run exercises that demonstrated the procedural changes were adequate to ensure the conveyance would remained within the bounds and limitations of the analysis (see Section 2.2.8). However, as reported in the LER, the licensee was still in progress of developing an analysis to determine if the operation of the conveyance with the reduced obstacle clearance was acceptable. Thus, this LER will remain open, pending NRC review of this additional information.

2.2.3 (Closed) NRC Event Notification #53858, Inadequate Analysis for VCT Operations

During the on-site portion of this inspection, the NRC inspectors observed demonstrations of the licensee's corrective actions associated with downloading operations. As the VCT approached the mating device, the procedural steps directed the removal of the restraint band from around the HI-TRAC VW transfer cask. As operations continued, the transfer cask was raised and continued to travel approximately 15-20 feet before being lowered onto the mating device to allow downloading operations to begin. While traveling without the restraint band, the transfer cask was visibly rocking as the VCT approached the mating device. The inspectors questioned the licensee during the site observations to determine if the site's seismic analysis addressed and evaluated travel of the loaded HI-TRAC VW without the restraint band.

On February 2, 2019, in accordance with 10 CFR 72.75(d)(1) the licensee notified the NRC Operations Center within 24 hours of the discovery of issues regarding the past use of the VCT to transport spent fuel storage canisters to the ISFSI pad. The licensee reported that over short periods of time, the canister transport process utilizing the VCT could have been operated without a supporting seismic analysis while transporting loaded canisters for storage. The licensee subsequently retracted Event Notification #53858 on April 2, 2019, citing a revised seismic calculation which confirmed the transport process and VCT operations met the seismic requirements of the Holtec Certificate of Compliance.

The licensee's failure to follow the initial site specific seismic analysis was determined by inspectors to be a violation of NRC requirements. This event notification is closed (see Section 2.2.4 below).

2.2.4 Finding related to the Licensee's Event Notification

The licensee's event notification EN #53858 documented that past VCT operations had not been conducted within the requirements of seismic evaluation HI-2156626, "VCT Stability Analysis on Route to ISFSI Pad and on ISFSI Pad for SONGS," Revision 3. For short periods of time, the VCT seismic restraint band was prematurely removed from the

transfer cask prior to stack-up evolutions. Evaluation HI-2156626, Section 4.0, "Assumptions," stated that, "the transfer cask and the VCT were considered to behave as a rigid body." The evaluation conservatively assumed the seismic restraint band, which braced the transfer cask to the VCT, was in position at all times during transportation operations.

10 CFR 72.212(b)(3), requires, in part, that the general licensee shall ensure that each cask used conforms to the terms, conditions, and specifications of a Certificate of Compliance as listed in 10 CFR 72.214.

10 CFR 72.214 states, in part, that Certificate Number 1040 [Docket Number 072-01040] Amendment Number 2, effective date January 9, 2017, is an approved cask for storage of spent fuel under the conditions specified in the Certificate of Compliance for the Holtec HI-STORM UMAX Storage System.

Certificate of Compliance 072-01040, Appendix B Technical Specification 3.4.15 requires, in part, the loaded transfer cask and its conveyance shall be evaluated to ensure, under the site-specific Design Basis Earthquake (DBE), that the cask and its conveyance does not tip-over or slide off the haul route.

Contrary to the above, from January 30, 2018, to August 3, 2018, the licensee failed to ensure the cask and its conveyance was evaluated under the site-specific DBE. Specifically, the NRC identified that past VCT transportation operations were not evaluated under the site-specific DBE, since operations were conducted outside the requirements in seismic evaluation HI-2156626.

This violation was dispositioned per the traditional enforcement process using Section 2.3 of the NRC's Enforcement Policy. The NRC determined that the finding was of low safety significance since the licensee had re-performed the evaluation, addressed the deviation that occurred, and demonstrated the canister and its conveyance would not have tipped over or slipped off the haul route during those transportation operations due to prematurely removing the seismic restraint band. This finding was determined by inspectors to be of more than minor safety significance, since if left uncorrected, the deficiency could lead to a more significant safety concern.

Consistent with the guidance in Section 1.2.6.D of the NRC Enforcement Manual, if a violation does not fit an example in the Enforcement Policy Violation Examples, it should be assigned a severity level: (1) commensurate with its safety significance; and (2) informed by similar violations addressed in the Violation Examples. The violation was evaluated to be similar to Enforcement Policy Section 6.1.d.1.

The licensee entered the finding into the CAP as AR 0219-88442, 0219-22465, and 0319-95843. The licensee restored compliance by revising the site-specific seismic analyses to bound transportation operations conducted at the site. Additional corrective actions taken by the licensee to preclude repetition included: performance of an apparent cause evaluation, submittal of formal reports to the NRC in accordance with 10 CFR 72.75(d)(1), conducted training on the lessons learned, briefed the Holtec Users Group, and revised the process used to transmit vendor information to the NRC to require a documented review by the appropriate SONGS organization prior to transmittal. Because the licensee entered the issue into the CAP, the safety significance of the issue was low, and the issue was not repetitive or willful, this Severity Level IV

violation was treated as a NCV, consistent with Section 2.3.2.a of the Enforcement Policy (NCV 07200044/2018-002-03, Failure to ensure the loaded transfer cask and its conveyance was evaluated under the site-specific DBE (10 CFR 72.212)).

2.2.5 Follow-up of Special Inspection Charter Items from the NRC Special Inspection

a. Drop Evaluation

The inspectors independently reviewed licensee's evaluation to analyze the potential effects of a canister drop. The licensee evaluation was documented in evaluation HI-2188261 "Structural Evaluation of the MPC Handling Event at SONGS," Revision 3. Evaluation HI-2188261 conservatively assumed the canister fell, uninterrupted, 25 feet to the base of the UMAX vault. The actual height the canister potentially could have dropped was 18 feet. The evaluation defined a canister breach as the point at which the strain measured at any location exceeded the specified strain limit for the material.

Following the guidance from NUREG-1864 "A Pilot Probabilistic Risk Assessment of a Dry Cask Storage System at a Nuclear Power Plant," dated March 2007, the evaluation considered the effects of strain rate and temperature, using a strain in the weld material to be estimated at 0.73 in/in (extension length/original length). Conservatively, the evaluation used one standard deviation below the allowable strain to establish a limit of 0.55 in/in for the weld material. The 316 stainless steel base material had an even higher acceptable strain limit. Conservatively, the evaluation limited the strain of the base material to 0.55 in/in as well.

The drop analysis was performed using the finite element code LS-DYNA, which has been validated under Holtec's Quality Assurance Program, and was a method of evaluation that had been used in the UMAX FSAR for other canister analyses. The results of the analysis resulted in a maximum computed effective strain of 0.468 in/in, which was below the conservative limit of 0.55 in/in for both the base metal and weld material. NRC inspectors independently reviewed the analysis and concluded that the canister would not have breached had the canister fallen 18 feet to the bottom of the UMAX vault.

The condition of the fuel after the postulated drop and the canister's ability to continue to perform its safety function in the regards of pressure, thermal, criticality control, and shielding was analyzed in evaluation HI-2188261, and Storage Position Paper DS-470, "Expected Fuel Damage after MPC Drop," dated November 6, 2018. The analysis concluded that the damage would be mostly limited to deformation and buckling of lowest section of the fuel rods of the spent fuel assemblies. The inspectors independently reviewed each safety function analysis for accident conditions with regard to criticality, thermal performance, shielding, and pressure.

The inspectors concluded that expected temperature and pressure limits would have remained under the accident limits described in FSAR, criticality safety would have been maintained since the confinement boundary was not breached and the system remained dry, and external radiological dose rates of the canister, located in the vault, would have minimal increases. However, the condition of fuel after the postulated drop would not meet the licensing requirements for storage or transportation. The licensee would be required to perform either significant evaluations or supplemental operations to ensure

the safe retrieval, unloading, and re-packaging of the fuel while minimizing the dose to personnel.

b. Scratch Evaluation

As part of the corrective actions from the ACE 0818-20356 and RCE QI-2529, actions were taken to address the discrepancies within the UMAX FSAR, specifically the incidental contact that occurs when a canister was downloaded into the UMAX vault. The UMAX FSAR, Revision 4, Sections 1.2.4 and 9.5 vii, contained design statements that stated:

- Section 1.2.4, "Operational Characteristics of HI-STORM UMAX," *The vertical insertion (or withdrawal) of the MPC eliminates the risk of gouging or binding of the MPC with the CEC parts*

- Section 9.5 vii, "Regulatory Compliance," *Because the MPC insertion (and withdrawal) occurs in the vertical configuration with ample lateral clearances, there is no risk of scratching or gouging of the MPC's external surface (Confinement Boundary). Thus, the ASME Section III Class 1 prohibition against damage to the pressure retaining boundary is maintained.*

The HI-STORM UMAX MPC-37 used at SONGS is made of a type 316 stainless steel. It is approximately 76 inches in diameter and 17 feet tall. The 5/8" thick shell is made by seam welding together two cylinders of stainless steel rolled plate. The base plate of the MPC is approximately 3 inches thick and the top lid is 9 inches thick. Additionally, the divider shell inside the CEC of the UMAX vault is painted with a coating developed to assist in limiting scratches to the stainless steel canister during downloading.

The canisters for the Holtec UMAX Storage System are designed and licensed to meet the stress intensity limits per ASME Section III, Subsection NB for Class 1 pressure vessels. Localized scratches are examples of local structural discontinuities per the ASME Code definition in NB-3213.3. As such, the stresses attributed to these local discontinuities are categorized as peak stresses per NB 3213.11, which are "objectionable only as a possible source of a fatigue crack or brittle facture."

Chapter 3 of the HI-STORM FSAR states that the MPC is not vulnerable to fatigue failure or brittle fracture because of the passive nature of the HI-STORM UMAX system and its highly ductile material of construction (Type 316 austenitic stainless). Namely the amplitude of cyclic stresses and pressure pulsation is limited in the pressure vessel and remains orders of magnitude below the canister's material endurance limits. Moreover, peak stresses are not subject to a prescribed stress limit as summarized in FSAR Table 2.2.10 for primary and secondary stress categories.

Therefore, FSAR Section 3.1.2.5 states failure from fatigue is not a credible concern for the HI-STORM UMAX system components. Peak stresses are specifically addressed in Table 3.1.10 of the UMAX FSAR which states: "*Increment added to primary or secondary stress by a concentration (notch), or, certain thermal stresses that may cause fatigue but not distortion. Because fatigue is not a credible source of failure in a passive system with gradual temperature changes, the cumulative damage factor from fatigue is not computed for HI-STORM UMAX components.*" The NRC inspectors concluded that

the localized scratches (peak stresses) on the canister are not a safety concern from the standpoint of ASME Section III, Subsection NB stress intensity limits.

The SONGS canisters were designed and fabricated to contain a shell thickness of 1/8" (0.125 inch) thicker than the standard canister (0.50" nominal wall thickness) associated with the Holtec UMAX Storage System. Additionally, the canisters at SONGS have been laser peened which was developed, applied, and confirmed for SONGS to add a protective layer against high tensile stress over the heat affected zones of the canister seam welds to assist in possible elimination of future stress corrosion cracking concerns. Confirmed by laboratory tests performed by the vendor and licensee, the protective layer over the welds and heat affected zones resulted in an approximately 0.080" inch (80 mil) thick layer of additional protection.

The NRC determined that scratches that occur on the surface of the MPC during insertion and withdrawal due to incidental contact with the internal features of the CEC internals are not of any safety concern from a stress limit. However, allowing the MPC to scratch, or suffer mechanical wear, presented a potential impact to the MPC design basis requirements as specified in the technical specifications. The confinement design function is required by the Holtec Certificate of Compliance 072-01040, Appendix B Technical Specifications, Section 3.3 to meet ASME Section III acceptance limits.

The ASME Section III code acceptance limits for scratches is 10 percent of the nominal wall thickness per ASME Section III, NB-3324.1 Cylindrical Shells and NB-3213.10 Local Primary Membrane Stress, which specifies a local primary membrane stress limit of 1.1Sm (or 10 percent higher than the general primary membrane stress limit). The 10 percent allowance is consistent with NUREG 2214 "Managing Aging Processes in Storage Report," Table 6-2, that states flaws must be assessed in accordance with the acceptance standards identified in ASME Section XI IWB-3514 which provides allowable flaw depths that are below 10% of nominal wall thickness.

For the 0.625-inch thick MPC shell in use at SONGS the maximum allowable scratch depth would be 0.0625 inches per ASME Section III code and required by Technical Specification 3.3, Appendix B.

The licensee performed a change under the 10 CFR 72.48 process to evaluate and accept the scratches on canisters 1 thru 29 placed in the site's UMAX ISFSI. Through the 10 CFR 72.48 process the licensee revised the FSAR Section 1.2.4 and Section 9.5 vii. design statements to allow scratches to previous and future canisters during installation and retrieval. The 10 CFR 72.48 regulation permits a licensee to make changes to the spent fuel storage cask design as described in the FSAR without obtaining prior NRC approval as long as the change does not require a change to the technical specifications or the change does not conflict with the eight criteria of 10 CFR 72.48 (c)(2).

The calculation to demonstrate the maximum depth of any possible scratch from downloading operations was documented in Holtec Dry Storage Position Paper DS-469, "Incidence and Consequence of Canister Shell Scratching from Misaligned Insertion of a Loaded MPC at SONGS," dated November 7, 2018. The DS-469 calculation was used as the basis to support a 10 CFR 72.48 evaluation performed by the licensee. Position paper DS-469 calculated the maximum force on the canister shell during downloading based on dimensional tolerances of components and the maximum angle the canister

could be misaligned. The maximum force was calculated to be approximately 2400 pound-force (lbf).

The licensee's analysis utilized Archard's wear equation to calculate the maximum depth of a possible scratch from the carbon steel shield ring to be 0.010 inches (10 mils) based on the force of 2400 lbf. The NRC inspectors reviewed the calculation and identified several inadequacies with position paper DS-469. The inadequacies included: (1) the calculation did not address contact with the harder stainless steel seismic restraints and was only based on the contact with the softer carbon steel shield ring; (2) the evaluation lacked adequate review of corrosion deposits on the stainless steel canister; and (3) the written evaluation did not address scratches and gouges in the canister's seam weld areas.

The licensee addressed the inspectors' concerns in a subsequent evaluation, HI-2188437, "Incidence and Consequence of Canister Shell Wear Scars from Misaligned Insertion of a Loaded MPC at SONGS," dated March 1, 2019. The licensee's revised 10 CFR 72.48 evaluation contained more details and analysis, which was used as a basis for concluding the change did not require prior NRC approval. The inspectors observed that evaluation HI-2188437 utilized the same methodology as the DS-469 calculation which determined the maximum depth of a possible scratch would be less than 0.0091 inches or (9.1 mils).

However, the inspectors identified additional inadequacies associated with evaluation HI-2188437 which included: (1) the licensee utilized the wrong hardness values in the calculation; (2) the hardness values did not account for the temperature of the canister; (3) the calculations utilized the wrong sling lengths for determining initial point of contact for where contact on the MPC shell could occur; and (4) the inspectors did not agree that the calculation alone could provide adequate basis without empirical evidence (i.e. testing or inspection) to support the calculation's basis.

The licensee addressed the inspectors' concerns in a revision to evaluation HI-2188437, dated March 13, 2019. Additionally, the licensee's third written evaluation included test report HI-2188450, "Simulation of High Force Contact Between MPC and UMAX CEC Storage System Components," dated March 12, 2019. In the test report, simulations were performed using representative samples for the MPC shell and UMAX CEC components most likely to damage the MPC surface. The test simulations were conducted at Holtec's Orrvilon fabrication facility. The test simulations utilized a range of test loads to demonstrate what the maximum wear on a canister would be from contact with the UMAX CEC components. Scratch depths were measured after the completion of the test runs.

The evaluation HI-2188437 calculation was revised using Archard's wear equation to contain the correct hardness values and to account for temperature of the canister. The maximum possible scratch depth utilizing the same force had decreased to 0.0024 inches (2.4 mils). However, the test data reported in test report HI-2188450 found maximum depth of scratches on the samples, using a similar test load of 2,000 lbs, to have a maximum depth of 0.007 inches (7 mils). The NRC staff concluded that the licensee test data invalidated the licensee's calculation that utilized Archard's wear equation to define the maximum possible depth of a scratch on the canister.

Subsequently, the licensee determined that the Archard's wear equation only provided an estimate of abrasive wear (removal of material from a surface by harder material) but the calculation could not account for adhesive wear (localized bonding between contacting solid surfaces leading to material transfer between two surfaces or loss from either surface). The inspectors determined that the licensee's initial written evaluations which contained numerous errors and deficiencies were inadequate and represented a violation of NRC requirements (see Section 2.2.6).

Evaluation HI-2188437 had been revised to address corrosion, pitting, and corrosion induced stress corrosion cracking (CISCC). The evaluation stated, for CISCC to occur, three conditions were necessary; a susceptible material, a strong tensile stress, and a corrosive environment. Type 316 stainless steel is a resistant austenitic material, but CISCC is possible under sufficiently severe conditions. However, for CISCC to occur, a through-wall high tensile stress is needed. The primary tensile stresses for the storage system is due to internal pressure of the helium gas which is low (approximately 45 psi). Also, the residual stresses due to rolling operations on stainless steel plates introduced a compressive stress on the outside surface of the canister shell. Seam welds of the canister were the only areas where local tensile stresses from weld shrinkage could potentially result in a through wall high tensile stress.

However, as previously explained, the canisters purchased at SONGS have been laser peened over all the seam welds and heat affected zones to provide a layer of compressive stress relief of 0.080" depth. Additionally, water is necessary for CISCC. The UMAX vault canisters are sheltered from weather intrusion. The canisters are hotter than the ambient air, so wetting from condensation is not possible during the current licensing period. Specifically, the canisters' temperature would remain above ambient temperatures well beyond the current licensing expiration date of 20 years. As such, any additional required monitoring for corrosion, pitting, and CISCC would be addressed in license renewal and through the licensee's ageing management program. The inspectors concluded that the issues related to possible corrosion, pitting, and CISCC on the canister did not pose an immediate safety concern nor immediately affect any of the system's design basis functions and could be adequately monitored and addressed as part of the licensee's ageing management program.

The licensee's subsequent written evaluation to support the site-specific 10 CFR 72.48 change to allow and bound incidental contact used in-situ visual assessment of surfaces of the canister shell and baseplate from eight loaded canisters in the UMAX ISFSI at SONGS. The sample set of eight canisters was consistent with using the guidance of ANSI ASQ Z1.4, "Sampling Procedures and Tables for Inspection by Attributes." The visual assessment was documented in "SONGS Downloading Effects on HI-STORM MPC Visual Assessment Report," dated April 15, 2019.

The eight canisters selected for inspection included: 1.) MPC serial number (SN) 067, which was involved in the August 3, 2018, misalignment incident; 2.) MPC SN 064, which was documented as having made contact with the internals of the CEC on July 22, 2018; and 3.) six additional MPCs located on different rows than the previous two MPCs. The different rows were selected to account for the drainage slope on the ISFSI pad and its potential effect on canister vertical alignment during downloading operations.

The visual assessment was performed by a robotic crawler equipped with navigational cameras and a borescope. The borescope was a flexible camera with interchangeable tips (general area tip and measurement tip). Two stages were utilized to perform the visual assessment. During the first stage, the robotic crawler and borescope with the general area tip was used to identify general locations of surface irregularities. During the section stage, the robotic crawler with the borescope using the measurement tip characterized the surface irregularities (width and depth measurements as applicable). The equipment selected by the licensee to perform the visual assessment was the General Electric borescope (VideoProbe™), along with the Robotic Technologies of Tennessee robot.

This same equipment had been used by Electric Power Research Institute for their Extended Storage Collaboration Program Non-destructive examination subcommittee, which is researching and developing technology to support inspection of dry storage canisters. This equipment had been used at multiple U.S. nuclear sites for Part 72 license renewal applications. The GE inspection Technologies' VideoProbe with Real3D™ point cloud surface scanning and analysis had been used in aviation, military, and oil & gas applications. Additionally, an NRC inspector was on-site during seven of the eight canister inspections to observe the visual assessment activities.

All surface irregularities were recorded and compared to post-fabrication photos to determine whether the surface irregularities were a result of downloading operations. All irregularities that were identified to have occurred during downloading operations were recorded and characterized. A few identified areas of interest crossed over or resided within the canisters' seam welds or weld heat affected zones. However, the protective layer of 0.080 inches provided by laser peening operations was never exceeded. The majority of wear marks identified were correlated to contact with the divider shell shield ring and had maximum wear depths of up to 0.012 inches (12 mils) deep. Additional wear marks identified were correlated to contact with seismic restraints and a maximum wear depth was 0.026 inches (26 mils) deep. Many wear marks had negligible depths.

Wear profiles for divider shell shield ring and inner seismic restraints were different. The divider shell ring wear marks were broader and shallower in comparison. The maximum depth caused by the stainless inner seismic restraint occurred over relatively short lengths in a localized narrow area and did not apply over the entire length nor width of the wear mark. In summary, the wear marks from incidental contact were not uniform, the maximum depths observed were very small in width and area and a majority of the scratch lengths contained negligible depths.

With the gathered information from the visual assessment report, the licensee performed two statistical analyses to bound the potential wear mark depths on the remaining canisters. Licensee report MPR 0299-0057-MEMO-001, "Canister Inspection Plan," dated April 15, 2019, concluded that the eight canister measurements were sufficient to support a conclusion that there is a 95 percent probability with 95 percent confidence that each of the remaining and future canisters would not have a scratch deeper than 0.035 inches (35 mils) due to downloading operations.

The second statistical analysis was documented in licensee report MPR 0299-0042-MEMO-024, "Canister Installation and Removal Effects on Wall Thickness," dated May 5, 2019. This statistical analysis determined the deepest scratch resulting from insertion and then withdrawal and assumed the two scratches occurred in

the same location. The licensee utilized the same methodology and determined that the deepest scratch at one location resulting from insertion followed by withdrawal with a 95 percent probability and 95 percent confidence to be 0.0584 inches (58 mils), which was still below the ASME code limit of 10 percent (0.0625 inches).

The NRC inspectors utilized the data obtained through the visual assessments to perform independent statistical assessments using several models that were appropriate for the sample size. The inspectors concluded, through the independent assessments, that the conclusion presented by SCE was conservative and reasonably bounded the maximum anticipated scratch or wear resulting from operational activities.

As such, the licensee's written evaluation using the visual assessments and statistical evaluations was adequate to demonstrate that the proposed change to allow the incidental contact on previous and future canisters will continue to meet the confinement design functions as specified in the FSAR and ASME Section III code tolerances and does not require a change to the storage system's technical specifications. The inspectors found that the licensee's site-specific 10 CFR 72.48 change to be acceptable and met all applicable criteria to not require NRC review and approval through a Certification of Compliance amendment.

2.2.6 Finding Related to 10 CFR 72.48 Evaluations

10 CFR 72.48(d)(1) requires, in part, that the licensee and certificate holder shall maintain records of changes in the facility or spent fuel storage cask design, of changes in procedures, and tests and experiments made pursuant to paragraph (c) of the section. These records must include a written evaluation, which provides the bases for the determination that the change does not require a Certificate of Compliance (CoC) amendment pursuant to paragraph (c)(2) of this section.

Contrary to the above, from November 7, 2018, to April 15, 2019, on two occasions the licensee did not maintain records of changes that included a written evaluation that provided the bases for the determination that the change does not require a CoC amendment pursuant to paragraph (c)(2) of 10 CFR 72.48. Specifically, the first two revisions of the 10 CFR 72.48 written evaluations to allow scratching on canisters failed to provide an adequate basis for determination that the change did not require a CoC amendment. As noted in Section 2.2.5.b of this report, the inspectors identified numerous technical errors with the calculations used as the bases for the 10 CFR 72.48 written evaluations. In addition, the first two revisions of the licensee's written evaluation did not demonstrate that the maximum possible scratch depth would not exceed ASME Section III code limits, a technical specification requirement.

The inspectors determined that the finding was of low safety significance because the inspectors assessed that the in-situ visual assessment and statistical analysis provided an adequate basis for the determination that the canister will continue to meet structural and confinement design functions as specified in the FSAR and continue to meet ASME Section III code tolerances.

The inspectors determined that the violation was similar to the violation examples in Section 2.1.3.D.5 of the NRC Enforcement Manual, which states that violations of 10 CFR 50.59 will be considered more than minor and categorized at Severity Level IV if

the licensee failed to perform an adequate 10 CFR 72.48 evaluation, similar to a 10 CFR 50.59 evaluation, that resulted in a condition having low safety significance.

Consistent with the guidance in Section 1.2.6.D of the NRC Enforcement Manual, if a violation does not fit an example in the enforcement policy violation examples, it should be assigned a severity level: (1) commensurate with its safety significance, and (2) informed by similar violations addressed in the violation examples. The violation was evaluated to be similar to Enforcement Policy Section 6.1.d.2.

The licensee entered the finding into the CAP as AR 1218-11302 and AR 0219-96601. The licensee restored compliance by revising the written evaluation to provide an adequate basis to conclude the change did not require NRC approval. Specifically, the revised written evaluation provided a basis that incidental contact of the canister with the internal components of the CEC during insertion and withdrawal operations would not remove greater than 10% nominal wall thickness of the canister in accordance with ASME Section III which was required by Appendix B Technical Specification 3.3 requirements. Because the licensee entered the issue into the CAP, the safety significance of the issue was low, and the issue was not repetitive or willful, this Severity Level IV violation was treated as a NCV, consistent with Section 2.3.2.a of the NRC Enforcement Policy (NCV 07200044/2018-002-04, Failure to provide adequate written basis for 72.48 change (10 CFR 72.48)).

2.2.7 <u>(Closed) Unresolved Item 07200041/2017-001-02, 10 CFR 72.48 Methodology</u>

NRC Inspection Report 05000206/2017-003, 05000361/2017-003, 05000362/2017-003, and 07200041/2017-001 dated, August 24, 2018 (ADAMS Accession ML18200A400), documented an Unresolved Item (URI) 07200041/2017-001-02, "10 CFR 72.48 Methodology." The issue related to a 10 CFR 72.48 evaluation for the scenario of a hypothetical accident of the loaded HI-TRAC VW transfer cask contacting the sides and bottom of the spent fuel pool, which was analyzed in report HI-2177713 "HI-TRAC VW Drop in Cask Storage Pool at SONGS," Revision 1.

For a short period of time, the HI-TRAC VW and loaded MPC was in an unconstrained condition on an intermediate shelf in the spent fuel pool. If a DBE seismic event was to occur during that time frame, the HI-TRAC VW with a loaded MPC could hypothetically fall to the lower level of the spent fuel pool and experience a higher lateral force than previously analyzed by the HI-STORM FW and UMAX FSARs. In report HI-2177713, the licensee demonstrated acceptability of the peak impact deceleration for the HI-TRAC VW scenario at SONGS by comparing those lateral forces to the peak impact deceleration values used to support the 10 CFR Part 71 HI-STAR 190 transport package safety analyses which utilized the same canister.

The licensee's evaluation concluded that the maximum peak lateral deceleration value of the HI-TRAC VW in the pool at SONGS to be 74g's, which was below the HI-STAR 190 side drop evaluation of 85.9g's. Additionally, the MPC and fuel basket evaluated stresses were identified by the licensee to be less than the design basis criteria described in the limiting values from HI-STORM FW FSAR, Section 2.2.8. The licensee stated that the same computer software (LS-DYNA) was utilized in all three evaluations (SONGS site-specific drop evaluation, HI-STORM FW/UMAX FSAR non-mechanistic tip-over evaluation, and HI-STAR FSAR transportation cask drop evaluation).

At the time of the initial inspection, the NRC needed more information to determine if the utilization of evaluations conducted for the 10 CFR Part 71 HI-STAR 190 transportation license to bound conditions for storage operations under 10 CFR Part 72 UMAX license through SONGS's 10 CFR 72.48 process was appropriate and in compliance with NRC regulations. The NRC subsequently determined that licensee's change was in violation of 10 CFR 72.48 requirements.

The UMAX FSAR references the FW FSAR for the use of the HI-TRAC VW, also both FSARs discuss various tip-over/drop events or requirements that must be followed such that a tip-over/drop event is not credible.

The FW FSAR, Table 1.2.10, "Criteria for Site-Specific Safety Qualification of HI-TRAC VW," item #10 states, in part, *the transfer cask's kinematic stability is established under all loading evolutions where the cask is freestanding to ensure kinematic compliance (no tip-over or collision with a proximate structure).*

Additionally, a tip-over/drop event as well as kinematic stability of a canister in a HI-TRAC VW was described as either a non-credible accident or must be demonstrated per analysis to have kinematic stability for tornado missiles (FW Section 2.2.3 e.), cask handling (FW Section 2.2.3 f.), and transportation operations (UMAX Appendix B, Technical Specification 3.4.15).

Nuclear Energy Institute Guidance Document 96-07, Appendix B, "Guidelines for 10 CFR 72.48 Implementation," Section 4.3.5, states that, "a change or activity, which increases the frequency of an accident previously thought to be incredible to the point where it becomes as likely as the accidents in the FSAR, could create the possibility of an accident of a different type."

10 CFR 72.48 (c)(1)(ii)(C) states in part, a licensee may make a change in the facility or spent fuel storage cask design as described in the FSAR without obtaining a CoC amendment if the change does not meet any of the criteria in paragraph (c)(2).

10 CFR 72.48 (c)(2)(v) states in part, a general licensee shall request that the certificate holder obtain a CoC amendment pursuant to 10 CFR 72.244, prior to implementing a proposed change if the change would: Create a possibility for an accident of a different type than any previously evaluated in the FSAR.

Contrary to the above, from January 30, 2018, to August 3, 2018, the licensee made a change in the spent fuel storage cask design as described in the FSAR and failed to request the certificate holder to obtain a CoC amendment prior to implementing the proposed change which created a possibility of an accident of a different type than any previously evaluated in the FSAR. Specifically, the licensee created the possibility of a new accident not previously analyzed in the FSAR through a 10 CFR 72.48 change (10 CFR 72.48 Assignment 0718-10512-3) to allow placement of a loaded HI-TRAC VW cask on an intermediate shelf in the spent fuel pool which was evaluated, by the licensee, to not be kinematically stable and had the potential to collide with proximate structures during a seismic event.

This violation was dispositioned per the traditional enforcement process using Section 2.3 of the NRC's Enforcement Policy. The inspectors determined that the finding was of low safety significance since the accident condition of a spent fuel cask

drop (due to a seismic event) from the intermediate shelf in the cask pool to the lower portion of the cask pool was an accident condition that had been analyzed and NRC approved in NUREG-0712, "Safety Evaluation Report related to the operation of SONGS Units 2 and 3, dated February 1981," and described in the SONGS Decommissioning Safety Analysis Report Section 15.1.1.5. Additionally, the licensee's calculations demonstrated that maximum lateral deflection in the fuel basket's active fuel region would not have exceeded requirements in the Holtec FW FSAR.

The inspectors determined that the violation was similar to the violation examples in Section 2.1.3.D.5 of the NRC Enforcement Manual, which states that violations of 10 CFR 50.59 will be considered more than minor and categorized at Severity Level IV if the licensee failed to request a license amendment, the NRC would likely approve the amendment, and the change resulted in a condition having low safety significance.

Consistent with the guidance in Section 1.2.6.D of the NRC Enforcement Manual, if a violation does not fit an example in the Enforcement Policy Violation Examples, it should be assigned a severity level: (1) commensurate with its safety significance; and (2) informed by similar violations addressed in the Violation Examples. The violation was evaluated to be similar to Enforcement Policy Section 6.1.d.2

The licensee entered the issue into the CAP as AR 0718-10512 and AR 0617-86918. The licensee restored compliance by revising the loading procedures to no longer utilize the intermediate shelf in the pool. The revised procedures required the transfer cask to be moved, after spent fuel assembly loading, from the bottom of the spent fuel pool directly to the cask wash-down pit for further processing (see Section 2.2.8). Because the licensee entered the issue into the CAP, the safety significance of the issue was low, and the issue was not repetitive or willful, this Severity Level IV violation was treated as a NCV, consistent with Section 2.3.2.a of the Enforcement Policy (NCV 07200044/2018-002-05, Failure to request the certificate holder to obtain a CoC amendment (10 CFR 72.48)).

No additional deficiencies were identified during the review of the Unresolved Item. This Unresolved Item 07200041/2017-001-02, "10 CFR 72.48 Methodology," is closed.

2.2.8 Dry Runs (Transportation, Downloading, Uploading)

Week of January 28, 2019

During the week of January 28, 2019, inspectors observed SCE perform demonstrations of sections of revised procedures HPP-2464-400, "MPC Transfer at SONGS," Revision 19 and HPP-2464-500, "MPC Unloading at SONGS," Revision 6. The demonstrations for this week of NRC on-site inspection activity involved movement of the HI-TRAC VW transfer cask with a canister simulator from the Unit 2 fuel building along the haul path to the ISFSI pad and included downloading operations.

During the first day of field demonstrations, SCE demonstrated spent fuel travel along a revised travel path for the low-profile transporter while carrying the canister simulator and HI-TRAC VW transfer cask from the Unit 2 fuel building. The haul path was revised based on seismic analyses and the revisions were intended to keep the low-profile transporter and transfer cask the required height and distance from structures along the path that could possibly be impacted if a seismic event were to occur during travel. The

revised path included white and yellow painted lines on the pavement to serve as guides for the operator to travel within. There were also restricted zone markings on the haul path near adjacent structures that were required to be avoided. The transfer cask was transported by the operator from the fuel building to the outside of the plant protected area, and into the SONGS ISFSI protected area, where it met up with the VCT. The VCT continued the movement of the canister simulator onto the ISFSI pad and into stack-up configuration for downloading.

The transfer cask was transported by use of the VCT until it was secured to the UMAX ISFSI mating device. A nighttime downloading demonstration of the canister simulator was performed after the ISFSI haul path travel demonstration. No adverse conditions were identified during the downloading demonstration operations. The new load monitoring equipment, cameras, and personnel present on the ISFSI pad ensured that loss-of-load indications was promptly responded to during downloading operations. The new equipment worked as intended and provided a positive load indication for the canister simulator. The cask loading crew used procedure adherence and the equipment enhances at their disposal to successfully perform the nighttime downloading demonstration.

The following day, the cask loading crew used the most recent revision of procedure HPP-2464-500 to demonstrate removal of the simulator from the UMAX ISFSI vault. Uploading operations proceeded without any issues. In the same manner as the previous evening, the cask loading crew used procedure adherence and the equipment enhancements at their disposal to successfully retrieve the canister simulator from the ISFSI vault.

Finally, a daytime downloading operation was demonstrated in accordance with procedure HPP-2464-400. The daytime downloading proceeded with the same requirements as the nighttime demonstration. The inspectors observed rigorous procedure adherence and oversight supervision during the cask loading operations.

Week of February 11, 2019

During the week of February 11, 2019, NRC observed SCE perform demonstrations of sections of its revised procedures HPP-2464-400, "MPC Transfer at SONGS," Revision 19, and HPP-2464-500, "MPC Unloading at SONGS," Revision 6, inside the fuel building. The second-week demonstrations were performed to support procedure revisions that removed usage of the spent fuel pool intermediate shelf location during fuel loading operations. To remove usage of the intermediate shelf required that the crane hook be fully immersed into the pool when placing the transfer cask and empty canister into the cask loading pit. The previous procedure revision avoided immersing the crane hook, block, and wire rope into the potentially contaminated spent fuel pool water.

To facilitate the procedure revisions, SCE performed modifications to the Unit 2 cask handling crane hook that would allow it to be immersed into the spent fuel pool water. At the time of the inspection, the Unit 3 cask handling crane hook had not yet been modified. However, the inspectors noted that the work orders were in place for the modification.

The inspectors observed SCE successfully demonstrate placement of an empty transfer cask and canister into the spent fuel cask loading pit. Next, the licensee successfully demonstrated placement of the MPC lid and drain tube into the transfer cask while at the bottom of the cask loading pit and removal of the transfer cask from the cask loading pit to the cask washdown area. The inspectors observed rigorous procedure adherence and oversight supervision during the fuel loading operations.

2.2.9 (Closed) Notice of Violation SLII 072-00041/2018-001-02, "Failure to ensure redundant drop protection features were available" (10 CFR 72.212), EA-18-155

As a result of the NRC Special Inspection a violation was identified for the licensee's failure to provide redundant drop protection features during downloading operations.

The licensee submitted its response to the NRC letter within the required 30-day time frame, on April 23, 2019 (ADAMS Accession ML19116A056), which contained the corrective steps taken to ensure full compliance was achieved.

During supplemental inspection activities conducted from November 2018 to May 2019, the NRC inspectors concluded that SCE's proposed and completed corrective actions, as described in this report, restored compliance, addressed extent of condition, and were adequate to prevent recurrence. No additional deficiencies were identified during NRC's review of this violation.

This closes VIO 072-00041/2018-001-02, "Failure to ensure redundant drop protection features are available," (10 CFR 72.212), EA-18-155.

2.2.10 ISFSI Pad Surveys

On October 22, 2018, during a routine decommissioning inspection (ADAMS Accession ML18323A024) the NRC inspectors performed independent measurements and verifications of the radiological conditions at the SONGS ISFSI. The inspectors measured various locations including the background areas, public access areas, owner-controlled areas, protected areas, and representative locations on both generally licensed ISFSI Pads: Transnuclear, (TN) Inc. Nuclear Horizontal Modular Storage (NUHOMS) and Holtec HI-STORM UMAX dry fuel storage systems.

The inspectors used a Ludlum Model 19, NRC Tag Number 033906, serial number 84259 with a calibration due date of July 23, 2019, to perform the survey measurements. The data in Attachment 2 shows the ranges of the measurements of each UMAX location by the VVM number at the inlet air vents, closure lid, and outlet air vent. Attachment 2, also shows the measurements taken on the NUHOMS locations, on contact with the inlet vent and 1 foot away from the inlet vent.

The VVM with the highest gamma measurement was VVM 33 with the inlet air vents ranging from 310-330 μR/hr. The NUHOMS location with the highest gamma measurement was TN 21, on contact with the inlet vent was 1,600 μR/hr. Background measurements from around the site ranged from 3-10 μR/hr. The NRC inspectors did not identify any measurements at the owner-controlled area boundary or in the public access areas to be above normal background measurements. A more detailed discussion of the surveys taken can be found at "NRC Surveys of SONGS ISFSI Pad,"

dated October 22, 2018 (ADAMS Accession ML19011A457) and on the provided table in Attachment 2 of this report.

2.3 Conclusions

The inspectors reviewed two LERs and one licensee event notification which had been reported to the NRC since the last inspection. The review of the event notification resulted in one Severity Level IV violation of NRC requirements that was treated as a NCV. The inspectors reviewed inspection follow-up items from the NRC Special Inspection Report which included the NRC's evaluation of the licensee's drop analysis, scratch analysis, and observations of dry run demonstrations. The review of the scratch analysis resulted in one Severity Level IV violation of NRC requirements that was treated as a NCV. The inspectors closed one violation which resulted from the NRC Special Inspection for the licensee's failure to ensure redundant drop protection features during downloading operations on August 3, 2018. The inspectors documented the results of the independent measurements and verifications of the radiological conditions at the SONGS ISFSI.

3 Exit Meeting Summary

On February 15, 2019, following an onsite portion of the inspection, the inspectors provided a debrief of the preliminary results to Mr. Doug Bauder, Vice President and Chief Nuclear Officer, and other members of the licensee staff. The licensee acknowledged the issues presented by the NRC inspection team.

On March 25, 2019, the NRC performed a public webinar meeting to discuss the inspection team's preliminary results. On March 28, 2019, the NRC participated in a San Onofre Community Engagement Panel Meeting to discuss the inspection team's preliminary results. On June 3, 2019, the NRC performed a public webinar meeting to discuss the NRC's decision on resumption of fuel loading activities at SONGS. On June 5, 2019, the NRC participated in a San Onofre Community Engagement Panel Meeting and discussed the NRC's decision on resumption of fuel loading activities at SONGS.

On June 13, 2019, the inspectors presented the final inspection results to Mr. Al Bates, Regulatory and Oversight Manager and other members of the licensee staff. The licensee acknowledged the issues presented.

UNITED STATES
NUCLEAR REGULATORY COMMISSION
REGION IV
1600 E. LAMAR BLVD
ARLINGTON TX 76011-4511

August 24, 2018

Mr. Thomas J. Palmisano
Vice President and Chief Nuclear Officer
Southern California Edison Company
San Onofre Nuclear Generating Station (SONGS)
P.O. Box 128
San Clemente, CA 92674-012

SUBJECT: SAN ONOFRE NUCLEAR GENERATING STATION – NRC INSPECTION REPORT 05000206/2017-003, 05000361/2017-003, 05000362/2017-003, AND 07200041/2017-001

Dear Mr. Palmisano:

This letter refers to routine U.S. Nuclear Regulatory Commission (NRC) team inspections conducted from June 2017 through June 2018. The purpose of the inspection was to observe your dry fuel storage preoperational testing activities, to independently assess your readiness to load spent fuel into the newly constructed UMAX Independent Spent Fuel Storage Installation (ISFSI), and to inspect initial fuel loading operations. The initial loading of the spent fuel into the first dry fuel storage cask of your UMAX ISFSI occurred between January 22-31, 2018. After continued in-office review of information following the loading of the first canister into the UMAX ISFSI, a final telephonic exit meeting was conducted on August 8, 2018, with Mr. Lou Bosch, Plant Manager, and other members of your staff.

The NRC inspection team examined activities conducted under your license as they relate to public health and safety, and to confirm compliance with the Commission's rules and regulations, and with the conditions of your license. The inspection reviewed compliance with the requirements specified in the Holtec HI-STORM UMAX storage system's Certificate of Compliance 72-1040, the associated Technical Specifications, the FW and UMAX Final Safety Analysis Reports, and the regulations in Title 10 of the *Code of Federal Regulations* (CFR) Parts 20, 50, and 72. Within these areas, the inspection consisted of selected examination of procedures and representative records, observations of activities, and interviews with personnel. The inspection determined that you had completed all required activities identified in the Holtec Certificate of Compliance 72-1040 for use of the Holtec HI-STORM UMAX storage system at your site.

Based on the results of these inspections, the NRC has determined that one Severity Level IV violation of NRC requirements occurred. The violation was related to the design control of field changes made to important to safety equipment associated with your loading activities. Because the violation was of low safety significance and the licensee initiated a condition report with appropriate resolutions to address and correct the issue, this violation is being treated as a Noncited Violation (NCV), consistent with Section 2.3.2 of the NRC Enforcement Policy. The NCV is described in the subject inspection report.

Additionally, the NRC opened an Unresolved Item (URI) related to the methodology utilized in the licensee's 10 CFR 72.48 evaluation regarding a hypothetical transfer cask drop within the spent fuel pool during a seismic event. Additional information is needed to determine if the change could be performed through the 10 CFR 72.48 process. The URI is described in the subject inspection report.

If you contest the violation or significance of the NCV, you should provide a response within 30 days of the date of this inspection report, with the basis for your denial, to the Nuclear Regulatory Commission, ATTN: Document Control Desk, Washington DC 20555-0001, with copies to: (1) the Regional Administrator, Region IV and (2) the Director, Office of Enforcement, United States Nuclear Regulatory Commission, Washington, DC 20555-0001.

In accordance with 10 CFR 2.390 of the NRC's "Agency Rules of Practice and Procedure," a copy of this letter, its enclosure, and your response, if you choose to provide one, will be made available electronically for public inspection in the NRC Public Document Room or from the NRC's Agencywide Documents Access and Management System, accessible from the NRC Web site at http://www.nrc.gov/reading-rm/adams.html. To the extent possible, your response should not include any personal, privacy, or proprietary information so that it can be made available to the public without redaction.

Should you have any questions concerning this inspection, please contact the undersigned at (817) 200-1151 or Mr. Lee Brookhart at (817) 200-1549.

Sincerely,

/RA/

Janine F. Katanic, PhD, CHP, Chief
Fuel Cycle and Decommissioning Branch
Division of Nuclear Materials Safety

EXECUTIVE SUMMARY

San Onofre Nuclear Generating Station, Units 1, 2, 3, and ISFSI
NRC Inspection Report 05000206/2017003; 05000361/2017003; 05000362/2017003; 07200041/2017001

Between June 2017 and January 2018, the NRC conducted six separate on-site inspections related to the San Onofre Nuclear Generating Station's (SONGS) program for the safe handling and storage of spent fuel at their UMAX Independent Spent Fuel Storage Installation (ISFSI). The inspection teams observed five dry run pre-operational training demonstrations and the loading of the first spent fuel canister for the Holtec UMAX cask system. The licensee selected the Holtec Certificate of Compliance No. 72-1040, HI-STORM UMAX cask storage system to house the remaining fuel from Units 2 and 3 after the decision was made to cease power operations. The ISFSI was licensed by the NRC under the general license provisions of Title 10 *Code of Federal Regulations* (CFR) Part 72, Subpart K.

Topical areas reviewed during the inspections included overhead crane requirements, loading operations, fuel verification, radiation protection, quality assurance, nondestructive testing, training, welding, and fire protection. Between the site dry run inspections and continuing after the first loading inspection, an in-office review was performed by the NRC inspectors relating to additional documentation provided by the SONGS staff. This effort involved the review of licensee reports, procedures, calculations, training documentation, test results, personnel qualification records, safety evaluations, and condition reports. During the dry run inspections, the licensee completed the pre-operational demonstrations of equipment and the implementation of the procedures to verify all operations required by the conditions of the license and the technical specifications could be performed safely. The first cask was placed within the SONGS UMAX ISFSI on January 31, 2018.

<u>Preoperational Testing of an ISFSI (60854)</u>

- Forced helium dehydration dryness limits, helium purity, and helium backfill requirements had been incorporated into the licensee's procedures. Operation of the forced helium dehydration system and backfill to the required dryness limits was demonstrated during the pre-operational dry run exercises and first loading activities. (Section 1.2.a)

- The cask loading cranes used in the spent fuel handling buildings to lift the spent fuel canisters had been previously accepted by the NRC as single failure proof cranes. The cranes were designed to retain control of and hold loads during design basis seismic events at the SONGS site. Calculations were reviewed by NRC's Division of Spent Fuel Management that demonstrated that the forces from a seismic event in the upward and horizontal directions would not exceed the strength of the crane's seismic restraints. Additional seismic evaluations were reviewed to ensure seismic stability during transfer operations. This review included the transfer cask (loaded with a canister) in the spent fuel building during decontamination and closure operations, on the low profile transporter, on the vertical cask transporter, and during transfer of the canister into the UMAX ISFSI. Based on the review of the design documents and calculations, the Division of Spent Fuel Management's staff concluded that there was reasonable

assurance that the cranes and other handling/restraining equipment were structurally adequate to withstand design basis earthquake loads during fuel loading operations. (Section 1.2.b)

- The 125-ton spent fuel building cranes were subjected to daily prior-to-use inspections that satisfied the requirements of American Society of Mechanical Engineers (ASME) B30.2, "Overhead and Gantry Cranes". On an annual basis the cranes were subjected to a more rigorous inspection that met the requirements of ASME B30.2 and the Ederer Generic Licensing Topical Report EDR-I(P) "Ederer's Nuclear Safety Related Extra Safety and Monitoring Cranes," Revision 3. (Section 1.2.c)

- The 125-ton spent fuel building cranes were properly load tested, as required by ASME B30.2, in the fall of 2017. The tests included a full performance test with 100 percent of the maximum critical load and a 125 percent static load test. The cranes' hooks were subjected to a 200 percent hook load test in 2003 by Ederer Inc. (Section 1.2.d)

- The NRC inspectors observed the licensee successfully complete all the required pre-operational tests specified in the Certificate of Compliance. This included fuel assembly selection, welding, nondestructive testing, drying, helium backfilling, and the unloading of a sealed canister. A weighted canister was used to demonstrate heavy load activities inside the fuel handling building, transport between the fuel handling building and the ISFSI, and movement back into the fuel handling building for unloading purposes. (Section 1.2.e)

- The licensee's fuel loading characterization plan met the Certificate of Compliance limits for length, width, weight, irradiation cooling time, average burn-up, cladding, decay heat, and fuel enrichment. The licensee had established provisions for independent verification of the correct loading of spent fuel assemblies into the canister. (Section 1.2.f)

- The licensee had incorporated the requirements related to heavy loads for lift height limits, travel paths, and temperature restrictions during movement of the transfer cask into its procedures. The site's vertical cask transporters were load tested and maintained in accordance with NUREG-0612 criteria. (Section 1.2.g)

- The requirements for nondestructive testing of a spent fuel canister were incorporated into the licensee's procedures. The helium leak testing equipment used during the dry run demonstration and first loading was verified to meet the requirements listed in the technical specifications. The visual and liquid dye penetrant examination procedures implemented all the applicable requirements from ASME Boiler and Pressure Vessel Code Section III, Section IV, and the Final Safety Analysis Report regarding nondestructive examination of welds. (Section 1.2.h)

- The requirements for canister hydrostatic testing had been incorporated into the licensee's procedures and were consistent with the requirements of ASME Boiler and Pressure Vessel Code Section III Subsection NB, Article NB-6000. The hydrostatic testing sequence and criteria described in the Final Safety Analysis Report had been incorporated into the licensee's procedures. (Section 1.2.i)

- The licensee's special lifting device program complied with American National Standard Institute (ANSI) N14.6, "Special Lifting Devices for Shipping Containers Weighing 10,000 Pounds or More," (1993) criteria for stress design, annual inspections, and 300 percent proof loadings for the MPC lift cleats, HI-TRAC lift lugs, HI-TRAC lift links, lift yokes, and the lift yoke extensions. (Section 1.2.j)

- The licensee had established procedures and work orders to perform the required daily monitoring surveillances required by the technical specifications, monthly vent inspections for damage, and monthly/annual/five year inspections of the ISFSI and Vertical Ventilated Module per Final Safety Analysis Report requirements. (Section 1.2.k)

- All welding procedures contained the required variables specified in ASME Boiler and Pressure Vessel Code Section IX for gas tungsten arc welding. Requirements for hydrogen monitoring during welding of the inner cask lid had been incorporated into the procedures. The welders had met the qualification testing requirements for manual and machine welding of the canister lid. (Section 1.2.l)

Operations of an ISFSI (60855)

- The first loading inspection conducted in January 2018 included 24-hour observation of loading operations for the critical tasks associated with the licensee's first UMAX loading. Inspectors observed operations which included fuel loading, heavy lifts associated with the fuel building crane, welding and nondestructive testing of the canister lid-to-shell weld, hydrostatic pressure testing, forced helium dehydration, helium backfill, vent/drain port cover welding and nondestructive testing, helium leak testing, radiological surveying, and transport of the loaded transfer cask to the UMAX ISFSI pad. (Section 2.2.a)

- During the first loading operations, the NRC inspectors identified one violation of 10 CFR 72.146 (c), "Design Control," requirements. The licensee had made modifications to Important to Safety components associated with the transfer cask seismic restraint system through the vendor's (Holtec) corrective action program and did not follow the SONGS Engineering Design Change Process. The licensee failed to ensure that design changes or field changes to Important to Safety components were subjected to design control measures commensurate with those applied to the original design. The original documentation for the changes did not contain a rigorous engineering analysis that demonstrated the changes were acceptable and those changes were not properly accepted for implementation through the Licensee's 10 CFR 50.59/72.48 program. This violation was determined to have a low safety significance since all the deviations or modifications from the original design were subsequently found to be acceptable and the changes did not affect the specific components' safety design function or bases. Because the licensee entered the issue into their corrective action program, the safety significance of the issue was low, the licensee restored compliance, and the issue was not found to be repetitive or willful, this Severity Level IV violation was treated as a Noncited Violation, consistent with the NRC Enforcement Policy. (Section 2.2.b)

Review of 10 CFR 72.212(b) Evaluations (60856)

- Emergency planning provisions for the UMAX ISFSI had been incorporated into the site's emergency plan. This included adding a specific emergency action level for an event involving damage to a loaded UMAX casks. (Section 3.2.a)

- A fire and explosion hazards analysis had been performed specific to the SONGS UMAX ISFSI. Administrative controls were established to limit the quantity of combustible and flammable liquids around the ISFSI and near the transport path during movement of the canister. The licensee provided calculations demonstrating that the worst case postulated fire event during transportation would not result in a significant increase in the temperature of the spent fuel inside a loaded canister. (Section 3.2.b)

- The licensee evaluated the bounding environmental conditions specified in the Holtec Final Safety Analysis Report and Certificate of Compliance 72-1040 Technical Specifications against actual site conditions. These included: tornados/high winds, flood, seismic events, tsunamis, hurricanes, lightning, burial of the ISFSI under debris, normal and abnormal temperatures, collapse of nearby facilities, and fires/explosions. The site environmental conditions at SONGS were bounded by the Holtec storage system's design parameters. (Section 3.2.c)

- The licensee had implemented its approved reactor facility 10 CFR Part 50 quality assurance program and corrective action program for the activities associated with the UMAX ISFSI. Selected quality assurance activities were reviewed related to calibrations, audits, surveillances, and receipt inspections. (Section 3.2.d)

- The licensee had incorporated keeping radiation exposures As Low as Reasonably Achievable into planning for the cask loading program. Requirements for radiation surveys described in the Final Safety Analysis Report and technical specifications had been incorporated into the licensee's procedures for cask loading operations. Projected radiation levels at the ISFSI were calculated for an assumed individual located at the owner controlled area boundary. The analysis demonstrated the dose to this individual would meet the requirements of 10 CFR 72.104. (Section 3.2.e)

- The licensee was maintaining 10 CFR Part 72 records in their quality related records system. (Section 3.2.f)

Review of 10 CFR 72.48 Evaluations (60857)

- Safety screenings had been performed in accordance with the licensee's procedures and 10 CFR 72.48 requirements. All screenings reviewed were determined to be adequately evaluated. One 10 CFR 72.48 evaluation identified three areas (fire hazards, tornado missiles, and transfer cask drop scenario) where implementation of the UMAX storage system at the SONGS site was identified to be different than the descriptions provided in the HI-STORM FW and UMAX Final Safety Analysis Reports. All three changes were evaluated by the licensee through the site's 10 CFR 72.48 process to demonstrate the evaluations continued to meet the system's original design basis acceptance criteria listed in the HI-STORM FW and UMAX Final Safety Analysis Reports. An Unresolved Item was opened to track the NRC's review of the methodology

utilized in the evaluation for the transfer cask drop within the spent fuel pool and determine if the change could be performed through the 10 CFR 72.48 process. (Section 4.2.a)

Report Details

Summary of Facility Status

The SONGS ISFSI consists of two ISFSI designs located adjacent to each other. The Transnuclear, (TN) Inc. Nuclear Horizontal Modular Storage (NUHOMS) ISFSI contained 51 loaded concrete advanced horizontal storage modules (AHSMs) which housed stainless steel dry shielded canisters (DSCs). Spent fuel from all three reactors were stored at the NUHOMS ISFSI in 50 of the canisters. Greater-than-Class-C (GTCC) waste from the Unit 1 reactor decommissioning project was stored in one canister. There were a total of 63 AHSMs on the NUHOMS ISFSI pad. The twelve empty AHSMs will be available for storage of additional GTCC waste. The NUHOMS ISFSI pad consisted of two adjacent pad areas designed to hold the AHSMs. The pads were both 293 feet in length. The first pad area was 43 feet 6 inches wide and held 31 canisters. The second pad area was 60 feet 6 inches wide and was designed to hold 62 AHSM in a double row, positioned back to back. The 63 AHSMs currently on the TN ISFSI pads were designed for the 24PT1-DSC (Unit 1 fuel) and 24PT4-DSC (Unit 2/3 fuel) canisters, which hold a maximum of 24 spent fuel assemblies. The 24PT1-DSCs were loaded and maintained under Amendment 0 of Certificate of Compliance (CoC) 72-1029 and the 24PT4-DSCs were loaded and maintained under Amendment 1 of the CoC 72-1029. Both systems were being maintained under Final Safety Analysis Report (FSAR) Revision 5.

The Holtec UMAX ISFSI portion was designed to hold 75 multi-purpose canisters (MPCs). The UMAX ISFSI is 231 feet long and 102 feet wide. However, its dimensions are not rectangular. The ISFSI is wider on its northern end than on its southern end. The support foundation pad was constructed below grade at the 8.5’ Mean Lower Low Water (MLLW) elevation. The top of the ISFSI top pad was located at the 31.5’ MLLW elevation. Approximately half of the UMAX ISFSI was located below grade while the other half had excavated common fill that sloped up to the top of the ISFSI top pad. The licensee has begun loading MPC-37s containing 37 pressurized water reactor fuel assemblies in accordance with UMAX CoC No. 72-1040 and Technical Specifications, Amendment 2, the HI-STORM UMAX FSAR, Revision 4, and the HI-STORM FW FSAR, Revision 5. The licensee plans to remove all the remaining fuel from the Units 2 and 3 spent fuel pools to the UMAX ISFSI.

1 Preoperational Testing of an ISFSI at Operating Plants (60854)

1.1 Inspection Scope

The NRC inspectors reviewed by direct observation and independent evaluation that the licensee has developed, implemented, demonstrated, and evaluated preoperational testing activities to safely load spent fuel into a dry cask storage system and transfer the loaded canister to the ISFSI. The inspections verified the licensee fulfilled all appropriate testing acceptance criteria and implemented all required changes to the appropriate plant programs and procedures to support ISFSI operations.

1.2 Observations and Findings

a. Canister Drying

The licensee utilized forced helium dehydration (FHD) to achieve the dryness levels required by Technical Specification Appendix A, Table 3-1. The operation of the system

was described in procedure HPP-2464-300 “MPC Sealing at SONGS,” Revision 0. The NRC inspectors verified that the licensee met the technical specifications required limits for dryness during the loading of the first canister in the January 2018 inspection. Helium meeting the Technical Specification, Appendix A, Table 3-1 requirement for a purity of 99.995 percent or greater was verified to be utilized during dry run demonstrations and first loading operations associated with MPC blowdown, drying, and backfill operations. Helium backfill pressure requirements were incorporated into licensee procedure HPP-2464-300. The NRC inspectors observed that the required backfill pressure was met during the loading of the first canister.

b. Crane Design and Loading Operations Seismic Analysis

The licensee utilized 125-ton Ederer’s Extra Safety and Monitoring (X-SAM) single-failure-proof cranes in each of their Unit 2 and Unit 3 spent fuel buildings to transfer the MPC and transfer cask (HI-TRAC VW) out of the spent fuel pool to the cask washdown area and then onto the low-profile transporter (HI-PORT). The NRC had reviewed the safety features of the X-SAM crane and issued a Safety Evaluation Report on January 2, 1980, related to Ederer’s Generic Licensing Topical Report EDR-I(P), “Ederer’s Nuclear Safety Related Extra Safety and Monitoring (X-SAM) Cranes,” Revision 1 and on August 26, 1983, related to Revision 3. In the 1980 letter, the NRC stated that the design features presented in the topical report for the Ederer X-SAM crane were acceptable for assuring that a single failure would not result in the loss of capability to safely retain a critical load. In the 1983 letter, the NRC Safety Evaluation Report discussed the features of the wire rope used for the X-SAM crane and noted the safety criteria for the wire rope was met and was found acceptable to the NRC.

The fuel building overhead crane used a dual rope reeving system with individual attaching points and a load balancing system to hold and transfer the critical load without excessive shock in case of failure of one of the rope systems. The X-SAM crane is equipped with an energy absorbing torque limiter (EATL) which allows the hoist to safely withstand two blocking, overloading, or load hang-up, and still retain the load even if the drive motor is de-energized. Not only are the loads controlled following a two-blocking, load hang-up, etc., but the hoist’s components are also protected, throughout their life, from being overstressed by these incidents. To provide this protection, the EATL directly converts the hoists high speed kinetic energy to heat during an overloading incident. The crane also utilized a system of upper travel limit switches that were designed to shut the crane down before a two-blocking event could occur.

The hoist drum was provided with the structural and mechanical safety devices to limit its drop during a shaft or bearing failure. The devices would also prevent disengaging from the holding brake. Ederer Topical Report EDR-I (P)-A, Section III.B.1.b, stated “The emergency drum brake system provides an independent means for reliably and safely stopping and holding the load following a failure in the hoist machinery.” Hoist machinery failures included shaft or bearing failures. The crane was designed to retain control of and hold loads during seismic events. The bridge and trolley were designed to remain in place on their respective runways with their wheels prevented from leaving the tracks during a seismic event.

All of the Licensee’s 10 CFR Part 72 seismic evaluations, for use of the UMAX system, were reviewed by NRC Division of Spent Fuel Management (DSFM) during the

inspection period. This review included seismic loading analysis for cranes, as well as the seismic stability analysis of the transfer operations of the MPC to the ISFSI pad. The seismic stability during transfer operations included the HI-TRAC VW transfer cask (loaded with an MPC) in the spent fuel building during decontamination and closure operations, on the HI-PORT, on the vertical cask transporter (VCT), and during transfer of the MPC to the UMAX storage system ISFSI.

The rated load and seismic analysis was conducted using GT-STRUDL to analyze a three-dimensional model to create the mass and stiffness properties of the crane components using line elements and lumped masses. The response spectrum method from American Society of Mechanical Engineers (ASME) NOG-1, “Rules for Construction of Overhead and Gantry Cranes,” was used in the analysis of the seismic loads. The load combinations applied to the model were consistent with those of Crane Manufacturers Association of America, Inc. (CMAA)-70 “Specification for Top Running Bridge and Gantry Type Multiple Girder Electric Overhead Traveling Cranes,” (2000) which included Operational Basis Earthquake (OBE) and Design Basis Earthquake (DBE) loads as well as the 125-ton live load, which is the rated capacity of the crane. The three orthogonal components of the earthquake motion were combined using the square root sum of squares of the structural response and combined with the static load cases. A two percent critical damping was used for OBE case and a four percent critical damping was used for the DBE case. Hand calculations and the finite element software ANSYS were used to analyze the forces on the individual components to determine their acceptability. The codes, standards and regulations used for the analysis and acceptance criteria included ASME B30.2 (1996); CMAA-70; ASME NOG-1 (2000); American Society of Civil Engineers 4-86, “Seismic Analysis of Safety-Related Nuclear Structures” (1986); NUGREG-0554, “Single Failure Proof Cranes for Nuclear Power Plants,” (1976); American Institute of Steel Construction (AISC) Manual of Steel Construction, 9th edition; American Welding Society (AWS) D1.1, “Structural Welding – Steel;” AWS D14.1, “Specification for Welding of Industrial and Mill Cranes and other Material Handling Equipment;” and American National Standards Institute (ANSI) N14.6, “Special Lifting Devices for Shipping Containers Weighing 10,000 Pounds or More,” (1993).

As part of the analyses, members classified as non-compact according to the AISC, were checked for local buckling. Several upgrades were completed to satisfy the seismic qualification of the 125-ton crane, including a 12-wheel trolley option in lieu of the 4-wheel trolley. Other specific upgrades included: replacing bolts in connection between the girder and the truck, adding fillet welds between the lower connection plate and the bottom of the bridge truck, adding a shim plate to the inside face of the box girder top flange (the shim provided a contact surface for the X-SAM trolley uplift seismic restraints), adding longitudinal stiffeners below the top flange, and adding vertical/transverse stiffeners to limit the web panel size to 48-inches to satisfy CMAA-70 and ASME NOG-1 web buckling requirements.

Based on the review of the design documents and calculations, the DSFM staff concluded that there was reasonable assurance that the cranes were structurally adequate to withstand the earthquake loads during fuel loading operations.

The HI-TRAC VW loaded with the MPC containing spent nuclear fuel was analyzed using a 1.20g zero period acceleration at the floor level of the cask wash down area. The HI-TRAC VW was prevented from tipping over by restraints at two levels that connect to the wall of the cask wash down area. The restraints consist of two slings that connect to the wall mounted attachments and wrapped around the cask in a crisscross fashion to prevent the cask from tipping over. The analysis included a concrete wall evaluation, a base plate and anchor bolt evaluation, and a transfer cask stop evaluation.

The concrete wall evaluation demonstrated that the wall had sufficient strength to withstand the added bending and shear forces caused by the seismic loads on the cask, to include impact with the wall. In addition, should the concrete cask impact the wall, the wall had sufficient thickness to prevent penetration or perforation, and sufficient strength to resist the punching shear that results from compression on the steel tubes that make up the cask stop.

The analysis of the seismic restraint anchor assembly demonstrated that the base plate, stiffener plates and associated welds, and anchor bolts had sufficient strength to withstand the seismic loads due to restraining the cask.

The transfer cask stop consisted of a steel tubes connected together with welded gusset plates. The analysis of the stop assembly determined that the steel tubes, gusset plates and associated welds were structurally adequate to resist the compressive, bending, and shear forces due to the seismic load. Additionally, the force generated from the seismic load was within the load capacity of the seismic restraints and shackle.

Based on a review of the design documents and calculations, the DSFM staff concluded that there was reasonable assurance that the seismic restraint system as well as the concrete wall to which it was attached, had adequate strength to maintain the HI-TRAC VW transfer cask, loaded with an MPC and spent nuclear fuel, stable in the cask washdown area under the DBE.

The HI-PORT, loaded with the HI-TRAC VW and MPC, during transit on the haul path at SONGS was analyzed for stability (tip-over and sliding) during a design basis seismic event. The HI-PORT was comprised of two trailers with a drop deck between them. The HI-TRAC VW bottom flange was bolted to a seismic restraining ring which was bolted to the drop deck of the HI-PORT.

Five time history sets were used to perform the stability analysis which was simulated with the computer code LS-DYNA. The mean values of peak axial and shear loads on the individual bolts were obtained from the dynamic analysis, as were the mean bending and shear loads in the trailers and drop-deck, and the mean loads at the connections between the trailers and the drop-deck. These loads were compared against the structural capacities of the respective components. All load bearing components were shown to have safety factors greater than 1.0 (structural capacity was greater than structural demand). The maximum rocking angle in the lateral direction was 0.035 degrees and the maximum sliding distance of the HI-PORT was 10.38 inches. Using a factor of safety of three, a minimum clearance of 32 inches to the outer edge of safety related structures was established and implemented in the licensee's transportation procedures. In addition, the HI-PORT was restricted to 3.1 miles per hour.

Based on a review of the design documents and calculations, the DSFM staff concluded that there was reasonable assurance that the HI-PORT, loaded with the HI-TRAC VW transportation cask, would not tip over, and that the HI-TRAC VW would remain attached to the HI-PORT during a DBE. Additionally, with the imposed transport limitations (distance and speed), the HI-PORT would not impact safety related structures while in transit during a potential DBE.

The seismic response of the VCT carrying the HI-TRAC VW was analyzed on the haul path, the transfer slab, the ISFSI ramp, the approach slab, and the ISFSI pad during the bounding DBE. The design basis response spectra and corresponding time histories at grade level were used in the stability evaluation to ensure the VCT did not tip over and remained on the respective path, transfer/approach slab, and ISFSI pad.

The ISFSI ramp was assumed to have a grade of seven percent. Based on Licensee UMAX design drawings, the maximum grade of six percent existed on the ISFSI ramp. Additionally, the VCT was assumed to tip in the lateral direction (shortest footprint dimension), which would require the VCT, loaded with a HI-TRAC VW, to travel across the path instead of up or down the path. The site specific zero period acceleration for SONGS was 0.67g horizontal and 0.45g vertical. The amplification from the HI-STORM UMAX soil structure interaction (SSI) analysis was 1.1, 1.0, and 1.08 in the E-W, N-S, and vertical directions for the top of the ISFSI pad. The zero period acceleration was amplified by 15 percent for the analysis on the ISFSI pad, approach slab, and ramp.

The center of gravity of the VCT loaded with the HI-TRAC VW was based on a maximum lift height of 11 inches on the haul path and 51 inches on the ISFSI pad. These lift height distances were controlled by the licensee’s transfer operation procedures.

Upon review of the sliding analysis, it was determined that the VCT will slide under the bounding DBE. A minimum distance of 47 inches from the edge of the ISFSI ramp, approach slab, and ISFSI pad was recommended to ensure the VCT would not slide off of the structures. This limit was based on a safety factor of greater than 1.0. The licensee’s transportation procedure contained the required standoff distance and a white line was painted around the edge of the ISFSI ramp, approach slab, and ISFSI pad to ensure workers would abide by the limitations from the evaluation.

Based on a review of the design documents and calculations, the DSFM staff concluded that there was reasonable assurance that the VCT, loaded with the HI-TRAC VW transfer cask, would not tip over on the transfer slab, ISFSI ramp, approach slab, or the ISFSI pad as a result of the DBE. Additionally, with the imposed transport limitations, the staff had reasonable assurance that the VCT, loaded with the HI-TRAC VW, would not slide off of the ISFSI ramp, approach slab, or the ISFSI pad as a result of the DBE.

The stack-up evolutions at the UMAX ISFSI pad consisted of the HI-TRAC VW transfer cask bolted to the Mating Device (MD), the MD bolted to the Mating Device Adapter (MDA), and the MDA bolted to the HI-STORM UMAX Cavity Enclosure Container (CEC). An evaluation was performed to determine the structural adequacy of

the HI-TRAC VW-to-MD, MD-to-MDA, and MDA-to-CEC connections as well as the ISFSI pad bearing capacity under the DBE.

A finite element model of the HI-TRAC VW, MD, and MDA on top of the ISFSI pad was built in LS-DYNA to determine the loading on the bolts, welds, and components, as well as the ISFSI pad. Hand calculations were then used to determine the structural adequacy of the connections and components in accordance with ASME Boiler and Pressure Vessel Code (BPVC), Section III, Division I, Subsection NF, and the structural adequacy of the ISFSI pad in accordance with American Concrete Institution (ACI) 318-05. A scale factor of 20 percent was applied to the at-grade DBE basis earthquake time history set in all directions to account for amplification at the top of the pad.

The peak axial and shear loads on the bolts that connected the HI-TRAC VW, MD, MDA and CEC were all less than the maximum allowable load for the bolts. The bolt interaction ratio (used to evaluate the combination of axial and shear forces on the bolts) were less than one, indicating the bolts were adequate under the combined axial and shear forces. Additionally, an analysis of the shear strength of the threads determined that the engagement lengths of the bolts were adequate for the connections.

The plate stresses in the MD were taken directly from the LS-DYNA analysis and compared with the allowable stress for that material. Components and welds that were not explicitly modeled were evaluated using bounding loads obtained from the analysis. All load bearing components and welds were determined to have safety factors greater than 1.0, meaning the calculated stress was less than the allowable stress for that material.

The tensile loads at the MD-to-MDA and MDA-to-CEC bolted connections were used to evaluate the supporting components and welds within the MDA. All bearing components and welds were determined to have safety factors greater than 1.0.

Finally, the ISFSI pad concrete bearing capacity was evaluated using the total load along each side of the MDA that was extracted from the LS-DYNA analysis. The safety factors against bearing on the ISFSI pad concrete due to the loads between the MDA and the CEC cover plate during stack-up were determined to be greater than 1.0.

Based on a review of the design documents and calculations, the DSFM staff concluded that there was reasonable assurance that the stack-up of the HI-TRAC VW, MD, and MDA on the CEC had adequate strength to sustain the DBE on the ISFSI pad. Additionally, the staff concluded that the ISFSI pad concrete strength was sufficient to withstand the DBE during stack-up operations.

c. Crane Inspection and Operation

During the licensee's programs review, NRC inspectors reviewed SONGS crane maintenance program for the 125-ton single-failure-proof X-SAM cranes located in the Unit 2 and 3 spent fuel buildings. Frequent crane inspections were performed daily during use, on the X-SAM cranes as required by the ASME B30.2 code. The inspection criteria from the ASME B30.2 code was captured in the licensee's Procedure HPP-2464-010, "SONGS Cask Handling Crane Checkout and Operation,"

Revision 2. The NRC inspectors observed the licensee perform the daily inspection during dry run demonstrations and first canister loading operations.

The required annual testing of the overhead X-SAM cranes followed HPP-2464-009, “Maintenance and Inspection of Cranes,” Revision 1. The latest annual inspection was completed during the recent load testing of the cranes on November 11, 2017, for Unit 2 and October 2, 2017, for Unit 3. The licensee’s procedure contained all the required inspection criteria outlined in ASME B30.2 and ASME B30.10, “Hooks.” Additionally, all the crane’s safety devices were tested in accordance with the Ederer Topical Report, Revision 3. The safety devices tested included: overload sensing system, hydraulic load equalization system fluid level, EATL, emergency drum brake system, drive train continuity detector, and wire rope spooling monitor.

Crane operation requirements and crane operator qualification requirements from ASME B30.2 were reviewed during dry run demonstrations and the first loading operations by NRC inspectors. The NRC inspectors verified that the crane operators training and qualification program met the requirements of the ASME code. Documentation was provided that demonstrated the crane operators for the first loading operations were trained and qualified in accordance with the licensee’s program. The NRC inspectors observed the operators perform the required ASME code brake test prior lifting a load that approached the rate load. This was accomplished by raising the load a short distance and applying the brakes to ensure the load would not lower unexpectedly. In accordance with the site’s heavy load program and NUREG-0612, “Control of Heavy Loads and Critical Lifts,” lift heights, load paths, special provisions, temperature restrictions, and rigging diagrams were placed in the appropriate procedures for the transfer operations that were occurring.

d. Crane Load Testing

The maximum calculated weight of the HI-TRAC VW with a MPC loaded with spent fuel and water raised out of the spent fuel pool was described in Holtec Report No. HI-2156458, “Cask Handling Weights at SONGS,” Revision 3 as 246,537 pounds (123.3 tons). Both Units’ 125-ton X-SAM cranes had recently completed a static load tested to 125 percent the rated capacity followed by a dynamic performance load test at 100 percent of the rated capacity. The Unit 2 crane’s load testing was completed on November 20, 2017, and the Unit 3 crane’s load testing was completed on October 2, 2017. The dynamic testing included movement in all directions and verifying all limiting and safety control devices. Additionally, the licensee provided documentation that demonstrated that each of the 125-ton hooks had been statically load tested to 200 percent the rated capacity in accordance with ASME B30.10 in 2003 by Ederer Inc.

e. Dry Run Demonstrations

The Holtec CoC 72-1040 Condition #8 required that dry run training exercises of the loading, closure, handling, unloading, and transfer of the HI-STORM UMAX Canister Storage System shall be conducted by the licensee prior to the first use of the system to load spent fuel assemblies. The dry runs shall include, but are not limited to the following: (a) Moving the MPC and the transfer cask into the spent fuel pool or cask loading pool; (b) Preparation of the HI-STORM UMAX Canister Storage System for fuel loading; (c) Selection and verification of specific fuel assemblies to ensure type

conformance; (d) Loading specific assemblies and placing assemblies into the MPC (using a dummy fuel assembly), including appropriate independent verification; (e) Remote installation of the MPC lid and removal of the MPC and transfer cask from the spent fuel pool or cask loading pool; (f) MPC welding, nondestructive examination (NDE) inspections, pressure testing, draining, moisture removal (by vacuum drying or forced helium dehydration, as applicable), and helium backfilling (A mockup may be used for this dry-run exercise); (g) Transfer of the MPC from the transfer cask to the HI-STORM UMAX Vertical Ventilated Module (VVM); and (h) HI-STORM UMAX Canister Storage System unloading, including flooding MPC cavity and removing MPC lid welds (A mockup may be used for these dry-run exercises).

On June 26-30, 2017, NRC inspectors observed SONGS perform dry run demonstrations listed in Condition #8 (f) and (h): MPC welding, NDE inspections, and removing MPC lid welds. The licensee utilized Holtec's welding vendor PCI Energy Services (PCI) to perform the welding on a mock-up canister. The welding demonstration included MPC lid to shell welding, welding of the vent and drain cover plates, welding of the plug on the cover plates, welding of the canister closure ring, and demonstration of the in-line hydrogen monitoring system. The visual NDE examinations and the liquid dye penetrant examinations were performed on all the welds. Additionally, helium leak testing of the vent and drain port covers was performed during the dry run by Leak Test Services (LTS). The licensee successfully demonstrated all required welding and the NDE examinations.

The removal of the canister lid welds was demonstrated by providing the NRC with a videotape of a welded MPC-37 lid being removed. The DSFM has accepted that if the cutting evolution had been successfully completed on the same model of MPC canister at one site, another general licensee can take credit for the demonstration, as long as the same equipment and procedures would be utilized. The demonstration to remove the welds from a MPC-37 canister was performed July 16-18, 2015, at the Holtec Manufacturing Division located in Turtle Creek, PA. Inspectors from NRC's DSFM observed the cutting dry run at the Holtec facility. The cutting activities included boring through the cover plate and the MPC vent/drain port covers. The lid cutting machine was then utilized to cut through the cover plate and the MPC lid-to-shell weld. During the cutting evolution, Holtec personnel purged the area under the lid with argon while monitoring for hydrogen as required by the FSAR. All cutting demonstrations were successful, and the MPC lid was removed from the shell. This inspection was documented in an NRC Inspection Report (ADAMS Accession No. ML15303A348). The procedures and arrangements to use the same cutting system had been adopted into the SONGS ISFSI program.

On August 1-3, 2017, NRC inspectors observed SONGS complete dry run demonstrations of Condition #8 (f) and (h). The specific operations included: pressure testing, draining, moisture removal (by forced helium dehydration), helium backfilling and the unloading portion of flooding the MPC cavity. The fluid operations demonstration included observing the licensee's implementation of their radiation protection and foreign material exclusion programs. All demonstrations were successfully performed on a mock-up canister.

On September 25-28, 2017, NRC inspectors observed SONGS complete dry run demonstrations of Condition #8 (b), (g), and (h). The specific operations included:

preparation of the UMAX for canister loading, transfer of the MPC/transfer cask from the spent fuel pool building to the UMAX ISFSI, downloading the MPC into the VVM, and unloading portions that included removing the MPC from the VVM and returning the MPC/transfer cask to the spent fuel building. The heavy loads demonstration included preparing the UMAX for the canister by installing the mating device, use of the HI-PORT and the VCT to move the canister from the spent fuel pool building to the UMAX ISFSI and back. All demonstrations were completed with a mock-up canister that was filled with concrete to simulate the weight of the MPC loaded with spent fuel. The licensee successfully completed all required movements associated with the required demonstration.

On October 9-13, 2017, during the programs review, the inspectors reviewed the licensee's fuel selection and verification procedure completing dry run demonstration Condition #8 (c). Additional information related to the fuel selection is contained in Section 1.2.f of this report. Additionally, a physical walk-through of the selection and verification process associated with the licensee's program was demonstrated during the final dry run when the licensee performed fuel loading operations of a dummy fuel assembly into several positions in the canister basket on December 4-7, 2017. The licensee successfully implemented an adequate process to select fuel and to verify the assemblies loaded.

On December 4-7, 2017, the NRC inspectors observed SONGS complete dry run demonstrations of Condition #8 (a), (c), (d), and (e). The specific operations included: moving the MPC and the transfer cask into the spent fuel pool, a walk-through of the independent verification process for fuel loading, loading a dummy fuel assembly into a number of positions in the MPC, remote installation of the MPC lid, and removal of the MPC and transfer cask from the spent fuel pool. These operations were completed in the Unit 3 spent fuel building using the licensee's 125-ton overhead cask handling crane and the Unit 3 bridge crane that moves fuel assemblies within the pool. This demonstration completed all the required dry run demonstrations from the CoC. The licensee successfully completed the above listed operations and demonstrated that the procedures, programs, and training related to the dry cask storage operations for the Holtec HI-STORM UMAX system had been successfully integrated into their site operations.

f. Fuel Selection/Verification

Dry cask storage planning for the SONGS UMAX ISFSI included removing all fuel contents from the Unit 2 and 3 spent fuel pools (SFPs) to support decommissioning activities at the formerly operational nuclear plant. The items to be placed into the UMAX ISFSI included 2,668 spent fuel assemblies and associated hardware, Rod Storage Baskets, and other fuel associated debris from the two SFPs. The NRC inspectors reviewed Holtec Report HI-2167416, "Loading Plans for SONGS ISFSI Expansion," Revision 6. All of the SFP contents to be stored in the SONGS ISFSI met the HI-STORM UMAX CoC 72-1040, Appendix B requirements for storage of spent fuel assemblies, damaged fuel assemblies, and other associated fuel related items. The spent fuel planned for storage in the SONGS UMAX ISFSI also met the loading requirements of the proposed Holtec HI-STAR 190 transportable cask.

The licensee performed a full characterization of the spent fuel contents of their Unit 2 and 3 SFPs. The fuel assemblies selected for storage met all of the Holtec CoC 72-1040 requirements, including length, width, weight, cooling time, fuel utilization (burn-up), cladding types, decay heat, and fuel initial enrichment. The majority of the contents to be loaded into the Holtec UMAX ISFSI were intact spent fuel assemblies. There were, however, a number of a fuel assemblies that met the Holtec UMAX CoC Appendix B definition of damaged fuel assemblies. The items identified as damaged fuel or fuel debris can be stored in the UMAX ISFSI but can only be loaded into twelve peripheral locations of the MPC-37 canister in damaged fuel containers. Approximately 28 MPC-37s with damaged fuel containers will be loaded into the SONGS UMAX ISFSI.

In the event of an MPC misloading (violation of CoC 72-1040, Appendix B, Section 2.1), SONGS Procedure SO123-0-A7, "Notification and Reporting of Significant Events," Revision 44, required that SONGS notify the NRC Operations Center within 24 hours after the licensee or other entity discovers the violation.

Procedure HPP-2464-200, "MPC Loading at SONGS," Revision 0 included steps that address the requirements of Holtec CoC 72-1040, Appendix A, including meeting the proper boron concentrations for loading the intact and damaged spent fuel assemblies at SONGS. The procedure included steps for independent post loading verification of fuel assemblies by SONGS Reactor Engineering personnel by video. The post loading verification is required by the HI-STORM FW FSAR, Section 9.2.3.3. Site procedures provided provisions for controlling and tracking the stored spent fuel records in accordance with 10 CFR 72.72 and 10 CFR 72.174. In accordance with the requirements of 10 CFR Part 74, SONGS Procedure SO123-X-1.7, "Special Nuclear Material Accountability," Revision 22 controlled tracking spent fuel and special nuclear material.

g. Heavy Loads

The licensee utilized two VCTs to lift the loaded HI-TRAC VW with MPC from the HI-PORT to the UMAX ISFSI pad for long term storage. The VCT was classified as an Important to Safety (ITS) component since the device provided the function of a crane to download the MPC from the HI-TRAC VW into the CEC. Each VCT was factory tested, statically to 125 percent and dynamically to 100 percent of the rated load. The VCTs were rated to 207.5 tons, in order to accommodate users that utilize the same VCT to carry a loaded HI-STORM FW overpack that weighs considerably more than a loaded HI-TRAC VW (118.5 tons). One VCT was tested on April 9, 2015, the other on April 7, 2016. All the weights utilized were verified to be slightly over the 125 percent and 100 percent weight requirements. During the dynamic load test, each VCT was traveled in all directions while testing the systems' safety devices.

The VCT's MPC downloader system was statically tested to 150 percent and dynamically to 100 percent of the rated load on the same dates as the VCT load testing described above. The MPC downloader system was rated to 128 tons. The weight of an MPC loaded with spent fuel and backfilled with helium weighed approximately 49 tons. After the testing of each downloader system, all accessible load bearing welds for the VCT that were designated as ITS, were subjected to visual and magnetic particle testing.

Technical Specification 5.2.c.2 required the VCTs to be inspected and maintained in accordance with NUREG-0612. Based on Holtec guidance, the licensee inspected the transporter in accordance with applicable sections of ASME B30.2 to meet the requirement. The daily inspection guidance was provided in HPP-2464-400, "MPC Transfer at SONGS," Attachment 8.8, "VCT Frequent Use Inspection Checklist." The annual inspection guidance was provided in HPP-2464-720, "Inspection and Maintenance for Vertical Cask Transporter," Revision 2 and was last completed on December 15, 2017 for each VCT. The inspection procedure met the applicable requirements of the ASME code.

The NRC inspectors verified that the transportation procedures associated with the VCT movements contained lift heights, load paths, special provisions, temperature restrictions, and rigging diagrams for all heavy lifts in accordance with the site's heavy load program and NUREG-0612 requirements.

h. Nondestructive Examination (NDE)

The NDE program adopted by SONGS to perform NDE inspections on the MPC welds was reviewed by the NRC inspectors to ensure the program and implementing procedures met the applicable ASME codes required by the UMAX FSAR. The NDE inspections of welds were performed by PCI's personnel. The helium leak testing was performed by LTS. During the welding dry run inspection on June 26-30, 2017, NRC inspectors reviewed the qualification requirements for the Level II or Level III inspectors for each program, the procedures utilized for each type of inspection, the work process, and the qualification of materials utilized in the inspections to verify the ASME/ANSI code requirements and technical specifications of license were properly incorporated in to licensee's program.

The helium leak testing was performed in accordance with ANSI N14.5, "Leak Tests on Packages for Shipment for Radioactive Materials," Revision 1997, to the established leak tight criteria of a leakage less than $2x10^{-7}$ atmosphere cubic centimeters per second (atm*cc/sec) as required by CoC 72-1040 Technical Specification, Appendix A Surveillance Requirement 3.1.1.3. The leak testing was performed in accordance with Procedure MSLT-MPC-Holtec, "Helium Mass Spectrometer Leak Test Procedure for MPC," Revision 3665-00. The process utilized a helium leak rate detector with a sensitivity level well below the technical specification leak rate criteria. Additionally, a calibration standard traceable to the National Institute of Standards and Technology was utilized to calibrate the helium leak rate detector prior to use. Four LTS Level III inspectors' certificates of qualification were reviewed to verify their certifications met American Society for Nondestructive Testing Inc. (SNT-TC-1A), "Recommended Practices for Qualification and Certification of NDE testing Personnel," Revision 1992 criteria and were current for the dates of the dry run and first loading inspection. During the first loading inspection, the licensee successfully performed the leak testing of the first MPC and results were below the required helium leak rate limit.

The NDE visual testing of the MPC canister welds was performed in accordance with Procedure GQP-9.6, "Visual Examination of Welds," Revision 16. The NRC inspectors verified the procedure contained the required acceptance criteria listed in ASME BPVC, Section III, "Rules for Constructions of Nuclear Facility Components," Article NF-5360,

Revision 1995. The procedure's qualification record demonstrated that the examination process was adequate to identify the required standard reference indications.

The NDE liquid penetrant testing of the MPC canister welds was performed in accordance with Procedure GQP-9.2, "High Temperature Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 9. The NRC inspectors verified the procedure contained the minimum elements from ASME BPVC Section V, "Nondestructive Examination," Article 6, T-621, and the acceptance criteria listed in ASME Section III, NB-5352. The procedure's qualification record was reviewed to verify the process was capable of detecting the required indications. Certified mill test reports with chemical analysis for the materials used in the high temperature liquid penetrant examinations (cleaner solvent, developer, and dye penetrant) met ASME Section V, Article 6, T-641 requirements. All cleaning, developing, and final interpretation time limits, based on the temperature of the component, were specified in the procedure and adhered to by the NDE personnel. The liquid penetrant examination was required by the procedure to be performed on the root pass weld, prior to any intermediate weld exceeding 3/8", and the final weld in accordance with CoC 72-1040 Appendix B Table 3-1 criteria. The NDE personnel complied with ASME code requirements regarding surface preparation and avoiding excess penetrant removal. Two PCI Level II inspectors certifications of qualification were reviewed to verify their training was current and in accordance with the SNT-TC-1A qualification requirements for visual and liquid dye penetrant examinations. During the first loading inspection, the licensee successfully performed the NDE examinations on first MPC with no indications identified.

i. <u>Pressure Testing</u>

The Holtec HI-STORM UMAX FSAR states that the Holtec MPCs placed into the UMAX VVM for storage are pressure tested in accordance with Section III, Subsection NB-6000 of the ASME BPVC to meet structural requirements and to verify the confinement function of the UMAX dry fuel storage system. The UMAX FSAR established the MPC pressure testing requirements by making direct reference to the pressure testing requirements listed in the HI-STORM FW FSAR. Both HI-STORM FW and HI-STORM UMAX dry fuel storage systems utilize the MPC-37. In addition, the Holtec HI-TRAC VW water jacket was required to be hydrostatically pressure tested per the applicable ASME code after being manufactured and the test results documented.

Holtec HI-STORM FW FSAR, Section 10.1.2.2.2, "MPC Confinement Boundary," required that either a hydrostatic test to 125 percent of the design pressure or a pneumatic pressure test to 120 percent of the design pressure take place in accordance with the requirements of the 2007 ASME Code when field welding of the MPC lid-to-shell weld was completed. The design pressure of the MPC-37 canister is 100 psig.

The NRC inspectors reviewed Procedure HPP-2464-300, "MPC Sealing at SONGS," Revision 0, and found that the procedure described the hydrostatic testing of the MPC lid-to-shell weld, including holding the pressure between 125.5 to 129.5 psig for 10 minutes, and specified that the pressure be maintained. During the pressure test, the weld area was to be inspected for water leakage. After the test was completed, the canister was allowed to depressurize and a liquid dye penetrant test of the weld area was required. The steps of the procedure were aligned with the requirements of ASME code.

The NRC inspectors observed SONGS successfully perform the hydrostatic testing requirements of a mock-up MPC-37 canisters during the fluid operations dry run demonstration on August 1-3, 2017, and during the NRC inspection of loading activities for the first MPC-37 processed during the loading campaign on January 25, 2018. The hydrostatic test and the post visual and liquid penetrant examinations were performed satisfactorily on both occasions in accordance with ASME code requirements.

Procedure HPP-2464-300 controlled pressure gauge calibrations in accordance with ASME Code, Section III, Article NB-6413 to not exceed two weeks. The NRC inspectors verified that the pressure gauges used for the hydrostatic testing of the MPC had been calibrated within an acceptable date range during the first loading inspection.

j. Special Lifting Devices and Slings

The special lifting devices utilized for the UMAX loading operations were reviewed by the NRC inspectors to verify compliance with ANSI N14.6 requirements. The list of special lifting devices included: MPC lift cleats, HI-TRAC lift lugs, HI-TRAC lift links, lift yoke, and lift yoke extension. Component purchase specifications or structural evaluations of selected devices were reviewed to verify the material used for fabrication met the six times yield strength and ten times ultimate strength in accordance with ANSI requirements. Dual path components were required to be capable of lifting three times the combined weight of the shipping container plus the weight of the intervening components of the special lifting device, without generating a combined shear stress or maximum tensile stress at any point in the device in excess of the corresponding minimum tensile yield strength of the material of construction. The devices were also required to be capable of lifting five times the weight without exceeding the ultimate tensile strength of the materials.

The required load testing documentation was provided for each special lifting device to verify the devices underwent 300 percent load testing at the manufacturer's facility. The test loads were held for ten minutes and then a visual, dimensional, and NDE inspection were conducted on the components. No NDE indications or issues were identified during the post load testing of the devices reviewed.

Annual inspection of the special lifting devices was established in the licensee's programs. Procedure HSP-355 "Annual Recertification of Special Lifting Devices," Revision 3, covered the annual inspection requirements for the MPC lift cleats, HI-TRAC lift lugs, HI-TRAC lift links, lift yoke, and the Holtec lift yoke extension. Procedure HPP-2464-030 "Testing and Inspection of Trans Nuclear Dry Fuel Storage Special Lifting Devices at SONGS," Revision 1, provided the instructions to perform the annual testing of the TN equipment. In accordance with ANSI requirements, the procedures required either a load test with a visual and dimensional test or a nondestructive test of the critical areas with a visual and dimensional test if the load test was omitted.

k. Storage Operations

The licensee had established procedures and work orders to perform the required daily vent or air temperature monitoring surveillances required by the technical specifications, monthly vent inspections for damage, and monthly/annual/five year inspections of the ISFSI and VVMs per FSAR requirements. The daily vent or temperature monitoring inspections was implemented in licensee Procedure S023-3-2.37 "Advanced Horizontal Storage Modules/Vertical Ventilated Modules System," Revision 9 in accordance with CoC 72-1040, Appendix A, Technical Specification 3.1.2. The monthly vent inspection for damage was implemented in licensee Work Order Task Sheet 0917-77051-3 "HI-STORM UMAX ISFSI VVM Vent Screens," in accordance with UMAX FSAR Table 10.4.1 requirements. The monthly, annual, and five year inspections of UMAX ISFSI and VVMs was implemented in a number of work orders which met the requirements listed in UMAX FSAR Tables 10.4.1 and 10.4.2.

l. Welding

The NRC inspectors reviewed the licensee's MPC closure procedure to ensure that the lid-to-shell weld, closure ring weld, and vent and drain cover welds met the requirements of CoC 72-1040, Appendix B, such that all applicable welds were subjected to liquid dye penetrant examination and helium leak testing, when applicable, and combustible gas monitoring was in place during the lid-to-shell welding. As required by CoC 72-1040 Condition 8.f (see Section 1.2.e, above), the licensee successfully demonstrated that their welding processes during the welding dry run demonstration on June 26-30, 2017. The NRC inspectors also verified that the CoC 72-1040, Appendix B requirements were satisfied during the processing of the first MPC-37 for SONGS' UMAX loading campaign.

During the welding dry run, the NRC inspectors verified that all of the applicable requirements of ASME BPVC Sections -II, -III, and -IX were being followed for welding materials, procedure qualification, and welding performance in the field. In specific, the NRC inspectors verified through procedure and document review that the appropriate weld qualification records were in place and that certain welding processes, such as tack welding, gas tungsten arc welding, and weld repairs, followed the appropriate guidance.

The NRC inspectors verified by records review that weld filler materials and electrodes met the minimum applicable requirements of ASME BPVC, Sections -II and -III, including delta ferrite content. The NRC inspectors also verified by procedure review and field verification that the licensee had procedures in place to direct the specification, control, and storage of purchased weld materials in accordance with 10 CFR 72.154.

The licensee had procedures in place to direct all welding activities, including weld repairs. The training and qualification records for the welders were provided for inspection. The welders performing the MPC closure operations during the dry runs and for the loading of the first MPC-37 met all of the required training and were qualified to perform all of the welds applicable to MPC-37 closure operations.

1.3 Conclusions

The FHD dryness limits, helium purity, and helium backfill requirements established in Technical Specification Appendix A Table 3-1 had been incorporated into the licensee's

procedures. The licensee planned to use the FHD system for drying all canisters loaded at the site. Operation of the FHD system and backfill to the required limits was demonstrated during the pre-operational dry run exercises and first loading activities.

The cask loading cranes used in the spent fuel handling buildings to lift the spent fuel canisters had been accepted by the NRC in 1980 as single failure proof cranes. The cranes were designed to retain control of and hold loads during a DBE at the SONGS site. Calculations were reviewed by NRC's DSFM that demonstrated that the forces from a seismic event in the upward and horizontal directions would not exceed the strength of the crane's seismic restraints. Additional seismic evaluations were reviewed to ensure seismic stability during transfer operations. This review included the transfer cask (loaded with a canister) in the spent fuel building during decontamination and closure operations, on the low profile transporter, on the vertical cask transporter, and during transfer of the MPC into the UMAX ISFSI. Based on the review of the design documents and calculations, the Division of Spent Fuel Management's staff concluded that there was reasonable assurance that the cranes and other handling/restraining equipment were structurally adequate to withstand DBE loads during fuel loading operations.

The 125-ton spent fuel building cranes were subjected to daily prior-to-use inspections that satisfied the requirements of ASME B30.2. On an annual basis the cranes were subjected to a more rigorous inspection that met the requirements of ASME B30.2 and the Ederer Generic Licensing Topical Report

The 125-ton spent fuel building cranes were properly load tested, as required by ASME B30.2, in the fall of 2017. The tests included a full performance test with 100 percent of the maximum critical load and a 125 percent static load test. The cranes' hooks were subjected to a 200 percent hook load test in 2003 by Ederer Inc.

The NRC inspectors observed the licensee successfully complete all the required pre-operational tests specified by License Condition #8 of the CoC. This included fuel assembly selection, welding, nondestructive testing, drying, helium backfilling, and the unloading of a sealed canister. A weighted canister was used to demonstrate heavy load activities inside the fuel handling building, transport between the fuel handling building and the ISFSI, and movement back into the fuel handling building for unloading purposes.

The licensee's fuel loading characterization plan met the HI-STORM UMAX CoC 72-1040, Appendix B limits for length, width, weight, irradiation cooling time, average burn-up, cladding, decay heat, and fuel enrichment. The licensee had established provisions for independent verification of the correct loading of spent fuel assemblies into the canister by use of video.

The licensee had incorporated the requirements related to the ISFSI project into the site heavy loads programs and procedures. Lift height limits, travel paths, and temperature restrictions during movement of the transfer cask had been incorporated into the licensee's procedures consistent with the requirements in the FSAR. The site's VCT were load tested and maintained in accordance with NUREG-0612 criteria.

The requirements for nondestructive testing of a spent fuel canister were incorporated into the licensee's procedures. The helium leak testing equipment used during the dry run demonstration and first loading was verified to meet the requirements listed in the technical specifications. The visual and liquid dye penetrant examination procedures implemented all the applicable requirements from ASME BPVC Section III, Section IV, and the FSAR regarding nondestructive examination of welds. A review of the nondestructive testing personnel's qualifications revealed they were properly qualified as a Level III or Level II examiners.

The requirements for canister hydrostatic testing had been incorporated into the licensee's procedures and were consistent with the requirements of ASME BPVC Section III Subsection NB, Article NB-6000. The hydrostatic testing sequence and criteria described in the FSAR had been incorporated into the licensee's procedures.

The licensee's special lifting device program complied with ANSI N14.6 criteria for stress design, annual inspections, and 300 percent proof loadings for the MPC lift cleats, HI-TRAC lift lugs, HI-TRAC lift links, lift yokes, and the lift yoke extensions.

The licensee had established procedures and work orders to perform the required daily monitoring surveillances required by the technical specifications, monthly vent inspections for damage, and monthly/annual/five year inspections of the ISFSI and VVM per FSAR requirements.

All welding procedures contained the required variables specified in ASME BPVC Section IX for gas tungsten arc welding. Requirements for hydrogen monitoring during welding of the inner cask lid had been incorporated into the procedures. The welder's performance qualification test records were reviewed and documented that the welders had met the qualification testing requirements for manual and machine welding of the canister lid. Weld qualification test coupons satisfactorily passed the required tests.

2 Operations of an ISFSI (60855)

2.1 Inspection Scope

The inspection included 24-hour coverage of the loading operations for the critical tasks associated with the licensee's first UMAX loading. Inspectors from NRC Region IV observed operations which included fuel loading, heavy lifts associated with the fuel building crane, welding and nondestructive testing of the canister lid-to-shell weld, hydrostatic pressure testing, forced helium dehydration, helium backfill, vent/drain port welding and nondestructive testing, helium leak testing, radiological surveys, and transport of the loaded HI-TRAC VW to the UMAX ISFSI pad. The inspectors reviewed selected procedures and records to verify ISFSI operations were in compliance with the Holtec CoC 72-1040 license technical specifications and Holtec FSARs.

2.2 Observations and Findings

a. Loading Operations

On January 22-31, 2018, NRC inspectors were onsite to observe the first canister loading operations. Inspectors observed all fuel assemblies loaded into the canister.

The fuel assemblies were inspected for damage prior to placement in the canister by use of an underwater camera. No damage was observed on any of the fuel assemblies loaded and the assemblies were free of foreign material. The canister's contents were reviewed to verify that the licensee was loading fuel in accordance with the technical specifications for approved contents. Documents reviewed included MPC loading maps and fuel assembly specific information such as identification, decay heat, cooling time, average U-235 enrichment, burn-up values, and other information. All fuel documents reviewed documented that SONGS had met the requirements listed in Appendix B of the CoC.

Observations of heavy lifts included placement of the MPC lid, removal of the HI TRAC VW with a loaded MPC from the spent fuel pool, placement of the HI-TRAC/MPC onto the HI-PORT, and lifting of the HI-TRAC/MPC from the HI-PORT to the VCT. The smooth operation of the 125-ton single failure proof crane and VCT was due, in part, to the licensee's extensive preventative maintenance effort on the lifting equipment. Numerous crane components had been replaced or upgraded to ensure successful completion of the upcoming continuous loading campaign. All lifting operations observed were performed in accordance with the site's heavy loads program.

Welding of the canister lid-to-shell weld began on January 24, 2018. The licensee utilized a calibrated in-line hydrogen monitor throughout the welding operations to ensure hydrogen levels were well below the lower explosive limit. Following the lid-to-shell welding, the required NDE (visual and dye penetrant testing) was performed to meet license requirements. No indications were identified during the NDE tests. Welding on the vent and drain port cover plates was completed after hydrostatic pressure testing, blowdown, FHD drying, and helium backfilling. The welds on the vent and drain port cover plates successfully passed all NDE examinations. After the vent/drain ports were helium leak tested, the closure ring was placed on the canister and properly welded.

The NRC inspectors observed the licensee successfully perform the hydrostatic pressure testing, blowdown, FHD drying, and helium backfill operations. The MPC was hydrostatically tested to the required pressure range, held for the required timeframe, and subsequently passed a second NDE exam. All water was then removed from the canister using the FHD and then successfully dried. The licensee met the time-to-boil time limit and had removed the water from the canister without having to initiate alternate cooling operations. The helium gas temperature exiting the freezer section of the dryer was below the required temperature and held for over 30 minutes in accordance with Technical Specification Appendix A Table 3-1, verifying the canister was adequately dried. The canister was then backfilled with helium of a purity greater than 99.995 percent, to the pressure range required in Technical Specification Appendix A Table 3-2.

Radiological coverage was provided throughout the loading campaign in accordance with the licensee's procedures. The radiation protection (RP) staff implemented adequate ALARA controls to minimize the overall collective dose during cask loading. The RP staff provided a sufficient amount of RP technician coverage during work activities, conducted detailed and comprehensive pre-job briefings on radiological conditions, effectively used portable radiation shielding, and effectively directed personnel to remain in low dosage areas when not actively working on the canister. The NRC inspectors observed the RP perform the required Technical Specification

Appendix A Section 5.3 surveys and verified the results were below the radiation and contamination limits specified.

During transportation operations to the ISFSI pad, NRC inspectors observed the licensee perform the required fire hazard walk-down of the haul path to ensure procedural requirements were met prior to transportation operations. The HI-PORT and VCT successfully transported the canister to the UMAX ISFSI without any malfunctions.

b. Design Control

During the first canister loading inspection on Monday January 22, 2018, the NRC inspector observed that the HI-TRAC VW transfer cask's seismic restraint system had been modified from its original design in order to be installed the Unit 2 spent fuel building. A 16 inch by 2 inch section of the back support plate for the seismic restraint system had been removed to allow the base plate to be installed around the existing sling restraints associated with the overall seismic restraint system. Additionally, the lift yoke extension had been non-structurally modified to be stored in the Unit 2 Spent Fuel Building. These design changes had been performed after the last NRC dry run inspection. The NRC inspector requested from SONGS the design change packages and applicable 10 CFR 50.59/72.48 reviews that were performed to ensure the newly modified ITS equipment would still be able to perform their safety function in accordance with the system's original design basis.

The licensee determined that the modification to both ITS components were processed through Holtec's field condition report (FCR) process under FCR-2464-LOA-065 for the seismic restraint base plate modification and under FCR-2464-LOA-041 for the lift yoke extension. The FCR-2464-LOA-065 for the seismic restraint base plate stated the system would continue to perform as designed, but the document did not contain sufficient technical analysis to justify the modification. The lift yoke extension FCR-2464-LOA-041 did contain the sufficient technical analysis to support that ITS equipment would continue to adequately meet its designed safety function which was documented in Holtec response to request for technical information (RRTI) #2464-034. However, the licensee discovered that neither change had been fully processed in accordance with SONGS engineering design control process or fully accepted under the Licensee's 10 CFR 50.59/72.48 review process.

These NRC identified issues led to SONGS placing the conditions into their corrective action program (CAP) as action request (AR) 0118-14935. An apparent cause evaluation (ACE) was conducted which reviewed the extent of condition related to vendor changes made to ITS components. The ACE was completed on April 26, 2018. The ACE review documented SONGS's engineering review of 391 Holtec documents, which included 255 construction FCRs, 36 RRTIs, 10 supplier manufacturing deviation reports (SMDRs), and 90 loading FCRs. From that review, the NRC discovered four additional examples where ITS components were modified under Holtec's FCR process without fully following SONGS engineering design change process or SONGS's 10 CFR 50.59/72.48 review process. These items included accept-as-is deviations to one ITS divider shell, two deviations related to the ITS self-hardening subgrade of the ISFSI pad, and one deviation related to the ITS ISFSI top pad surface.

As necessary, the licensee's vendor completed additional calculations for all the components which did not contain rigorous analysis in the original FCR. All the revised calculations and justifications were reviewed by the NRC inspector and were found to contain sufficient engineering analysis to demonstrate the modified ITS components would still be capable of performing their design basis safety functions. Additionally, the design changes were subsequently accepted for implementation by SONGS in accordance with their 10 CFR 50.59/72.48 program.

Section 10 CFR 72.146 (c), "Design Control," states, in part, that the licensee shall subject design changes including field changes, to design control measures commensurate with those applied to the original design.

The licensee's Procedure SO123-XXIV-10.1 titled "Engineering Design Control Process – NECP" Attachment 8, Step 5.5.2, stated, "Design changes to the Dry Cask Storage system are required to be supported by calculations prepared in accordance with this procedure and the 72.48 program."

Contrary to the above, SONGS failed to ensure that design changes or field changes to ITS components were subjected to design control measures commensurate with those applied to the original design. Specifically, a number of field changes to ITS components were not processed in accordance with SONGS engineering design change process with rigorous engineering analysis that demonstrated the changes were acceptable and those changes were not properly accepted for implementation through the Licensee's 10 CFR 50.59/72.48 program.

Consistent with guidance in Section 2.2 of the NRC Enforcement Policy, this violation was dispositioned through the traditional enforcement process. The inspectors used the NRC Enforcement Policy to evaluate the significance of the violation. This violation was determined to have a low safety significance since all the deviations or modification from the original design were found to be acceptable and did not affect the specific components' safety design function or bases. This violation was found to be more than minor since if left uncorrected, it could have the potential to lead to a more significant safety concern. Specifically, failure to adequately control changes and modifications to ITS components could lead to a condition where the appropriate calculation and review was not performed to ensure the component would continue to meet its safety function in accordance with their design basis.

Because the licensee entered the issue into its CAP (AR 0118-14935), the safety significance of the issue was low, the licensee restored compliance, and the issue was not found to be repetitive or willful, this Severity Level IV violation was treated as a Noncited Violation (NCV), consistent with Section 2.3.2.a of the NRC Enforcement Policy (07200041/2017001-001).

2.3 Conclusions

The first loading inspection conducted in January 2018 included 24 hour coverage of the loading operations for the critical tasks associated with the licensee's UMAX loading. Inspectors from NRC Region IV observed operations which included fuel loading, heavy lifts associated with the fuel building crane, welding and nondestructive testing of the canister lid-to-shell weld, hydrostatic pressure testing, FHD drying, helium backfill,

vent/drain port cover welding and nondestructive testing, helium leak testing, radiological surveying, and transport of the loaded transfer cask to the UMAX ISFSI pad.

During the first loading operations, the NRC inspectors identified one violation of 10 CFR 72.146 (c), “Design Control” requirements. The licensee had made modifications to ITS components through the vendor’s (Holtec) corrective action program and did not follow SONGS engineering design change process. The licensee failed to ensure that design changes or field changes to ITS components were subjected to design control measures commensurate with those applied to the original design. The original documentation for the changes was identified to not contain a rigorous engineering analysis that demonstrated the changes were subsequently found to be acceptable and those changes were not properly accepted for implementation through the Licensee’s 10 CFR 50.59/72.48 program. This violation was determined to have a low safety significance since all the deviations or modifications from the original design were found to be acceptable and the changes did not affect the specific components’ safety design function or bases. Because the licensee entered the issue into their corrective action program, the safety significance of the issue was low, the licensee restored compliance, and the issue was not found to be repetitive or willful, this Severity Level IV violation was treated as a NCV, consistent with the NRC Enforcement Policy.

3 Review of 10 CFR 72.212(b) Evaluations (60856)

3.1 Inspection Scope

The programs review inspection conducted on October 9-13, 2017, performed an in depth review of the programs, evaluations, and procedures established to demonstrate that the licensee had met the requirements listed in 10 CFR 72.212 before operation of the UMAX ISFSI.

3.2 Observations and Findings

a. Emergency Planning

The NRC inspectors reviewed the licensee’s Permanently Defueled Emergency Plan (PDEP) to verify and assess the following: (1) the licensee’s emergency action levels (EAL) for accidents that affect the ISFSI; (2) the licensee’s offsite emergency support; and (3) the licensee’s training of employees and conducting periodic drills.

The licensee conducted an evaluation in accordance with 10 CFR 50.54(q) to incorporate the operation of the SONGS UMAX ISFSI into the existing SONGS PDEP. The licensee added definitions and EAL E-HU1.2, “Damage to a loaded canister CONFINEMENT BOUNDARY,” to cover the Holtec spent fuel transport and storage system. The additional EAL threshold for the Holtec system is two times the HI-STORM UMAX technical specifications allowable radiation level on the surface of the VVM or the Holtec transfer cask. The revised PDEP and emergency plan implementing procedures described arrangements with offsite emergency organizations including provisions on how the licensee would conduct periodic drills and training of employees.

b. Fire Protection

The licensee provided an analysis that demonstrated that the site-specific potential for fire and explosions was bounded by the conditions analyzed by the Holtec in accordance with license requirement CoC 72-1040 Appendix B Section 3.4.5. The fire and explosion hazards were analyzed along the haul path and at the UMAX ISFSI in Holtec Report HI-2156567 “Evaluation of Plant Hazards at SONGS,” Revision 2. The explosion hazards analyzed systems and structures which included gasoline tanks, acetylene tanks, lube oil hazards, transformer oil hazards, buildings, and off-site explosions. The assumptions used for the explosion hazards in the report appeared reasonable. No credible explosion hazard was identified at SONGS that exceeded the allowable stress levels identified in the UMAX FSAR which included the overpressure needed to tip over the HI-TRAC VW during transport operations or the structural limits of the closure lids for the UMAX ISFSI. The overpressures for acetylene and gasoline hazards did not exceed the acceptable limits for the UMAX ISFSI or the HI-TRAC VW as long as the specified stand-off distances were met that were incorporated into licensee transportation Procedure HPP-2464-400 “MPC Transfer at SONGS,” Revision 1.

The fire hazards which might affect the cask were identified and reviewed by the licensee. If a fire potential was credible, an evaluation was performed for each postulated hazard to determine if the hazard could exceed the allowable heat input to the cask. Site specific fire hazards included the trailer-mounted fire pump, fixed diesel fire pump, cold and dark standby diesel generator, miscellaneous acetylene tanks, a fuel buggy, and miscellaneous diesel tanks. The assumptions used for the fire hazards in the report appeared reasonable. No credible fire hazard was found to exceed the acceptable heat input to either the HI-TRAC VW or UMAX ISFSI as long as administrative actions included in the licensee Procedure HPP-2464-400 were followed.

During the review of the 10 CFR 72.212 report, the NRC inspectors reviewed the licensee’s analyzed worst case fire during transportation operations to determine whether it was bounded by the analyzed fire in the UMAX FSAR of 50 gallons of diesel fuel from the cask transporter. This evaluation was documented in Holtec report HI-2167264 “Thermal Evaluation of HI-TRAC VW Fire,” Revision 3. The HI-PORT was used to transport the HI-TRAC VW from the fuel handling building to the base area of the UMAX ISFSI. The most limiting scenario was identified to be when the HI-PORT and VCT were next to each other to allow the VCT to engage the HI-TRAC VW to continue transportation to the top of the UMAX ISFSI. Two telescoping man-lifts were also utilized during this transfer event. The combined fire hazard included both fuel tanks of the HI-PORT and VCT, hydraulic fluid from all four pieces of equipment, and the tire rubber associated with the HI-PORT. This fire loading exceeded the 50 gallons of diesel fuel described in the UMAX FSAR. The evaluation determined that the fuel temperature, MPC components, and MPC cavity pressure remained well below the limits established in the UMAX FSAR and the credible fire event did not exceed any FSAR fire accident acceptance criteria. The implementation of this change and associated evaluation was document in a SONGS 10 CFR 72.48 evaluation. Since all the predicted temperatures from the thermal analysis were below the specified temperature limits of short-term events reported in Section 4.5 of the UMAX FSAR, the safety conclusions remained unchanged. The 10 CFR 72.48 evaluation concluded the change did not require NRC approval. The inspectors determined that the 10 CFR 72.48 evaluation was performed adequately.

During the programs review inspection, NRC inspectors reviewed the licensee's Pre-Transport Haul Route Walkdown Checklist (Attachment 8.9) in Procedure HPP-2253-400 to ensure adequate controls were in place to limit combustibles along the haul path and that all fire and explosion hazards had been adequately identified in the reports. No issues were identified by the inspectors relating to the controls implemented to ensure the requirements of the licensee's fire and explosion hazards analyses were met.

c. General License Requirements for 10 CFR 72.212

The SONGS 10 CFR 72.212 Report evaluated the terms, conditions, and specifications in Amendment 2 for the HI-STORM UMAX CoC 72-1040 and documented the conditions as set forth had been met at the SONGS site. Each section of the 10 CFR 72.212 report documented the licensee's compliance with a requirements specified in 10 CFR 72.212(a) through (e). The sections covered topics which included conditions of the license, technical specifications, pad design adequacy, direct radiation, reactor site parameters, written evaluations, physical security, document retention, records, procedures, and program effectiveness.

The NRC inspectors performed a comprehensive review of the Licensee's 10 CFR 72.212 report during the programs review inspection conducted on October 9-13, 2017, and continued the inspection throughout the inspection period with in-office review of the licensee's documentation.

Section 11.0 "Reactor Site Parameters," documented the required written evaluations to verify requirements specified in the Holtec UMAX and FW FSAR and the associated NRC safety evaluation reports were met. The NRC inspectors reviewed these evaluations which related to specific analyses for fires and explosions, tornados, floods, tsunamis and hurricanes, earthquakes, lightning, burial of the ISFSI under debris, environmental temperatures, snow, and collapse of nearby facilities.

The licensee performed a review of the reactor emergency plan, quality assurance program, training program, and radiation protection program and documented the review in Section 15.0, "Program Effectiveness," of the report. Since the TN storage system was already in use, the licensee performed the necessary changes to the programs to incorporate the use of the Holtec UMAX storage system. No issues were identified relating to the NRC's review of the topics discussed above.

d. Quality Assurance

SONGS had a preexisting Generally Licensed 10 CFR Part 72, Subpart G Quality Assurance (QA) program in place for its TN CoC 72-1029 ISFSI. To address transitioning the site from power operations to decommissioning, SONGS developed a decommissioning quality assurance program (DQAP) to support decommissioning activities and to ensure continued oversight of the SONGS ISFSI. The DQAP was SONGS' NRC approved QA program that will be the basis for satisfying the QA requirements of the newly established Holtec HI-STORM UMAX ISFSI and the current TN ISFSI. The NRC inspectors reviewed selected QA activities related to calibrations, receipt inspections, surveillances, and audits.

The Holtec HI-STORM UMAX and HI-STORM FW FSARs identified structures, systems, and components that were ITS and categorized each item into one of three levels (A, B, or C) based on safety significance. The NRC inspectors verified through a review of the SONGS Quality Component List, Rev. 11 that the licensee had incorporated the Holtec HI-STORM UMAX and HI-STORM FW safety designations into their classification scheme along with those of the TN Advanced NUHOMS® System.

The licensee also had a preexisting NRC approved CAP that included the TN Advanced NUHOMS® ISFSI. Holtec, their newest dry fuel storage vendor, also had an NRC-approved CAP. Holtec was handling all fuel loading and radiation protection duties for the pool-to-pad dry fuel storage project for the UMAX ISFSI. After the identification by the NRC of items discussed in Section 2.2.b, Design Control, the licensee made a number of additional changes to ensure that proper evaluation of Holtec condition reports would be performed by SONGS personnel.

e. Radiation Protection

In accordance with 10 CFR 72.104, the licensee provided technical evaluations that demonstrated that the radiation dose from the TN and the UMAX ISFSIs would not exceed 25 mrem per year to the whole body or critical organ or 75 mrem per year to the thyroid of any individual located beyond the owner controlled area. The analyses reviewed by the NRC inspectors also included evaluations that demonstrated no individual would receive a dose greater than the limits specified in 10 CFR 72.106 during any design basis accident at the SONGS site. The UMAX ISFSI was assumed to be fully loaded with fuel characteristics that conservatively exceeded the fuel currently stored in the licensee's spent fuel pools. During loading operations personnel from the SONGS security force established control of public access in areas near the site seawall. The NRC inspectors reviewed site controlled area boundary dose projections in Holtec Report Nos.: HI-2177793, "On-Site and Off-Site Dose Calculations for the SONGS ISFSI," Revision 1, and HI-2156895, "Dose Versus Distance Calculations for the SONGS ISFSI for Compliance with 10 CFR 72," Revision 1. The UMAX accident scenarios were discussed in the Holtec HI-STORM UMAX FSAR.

The UMAX FSAR requires that the radiation protection concept of As Low as Reasonably Achievable (ALARA) be applied to all operations related to dry fuel storage at the SONGS ISFSI. The NRC inspectors verified that SONGS had ALARA policies in place in its radiation protection program through a review of site radiation protection policies and dry fuel loading procedures, including the SONGS Units 2 and 3 Spent Fuel Pool to Pad Project ALARA Plan, Revision 1.

The UMAX FSAR Section 10.3 requires that the shielding effectiveness of the UMAX VVM be assessed after the first MPC canister is placed into the ISFSI. The NRC inspector observed SONGS RP technicians make confirmatory neutron and gamma radiation measurements on the lid of the loaded VVM. The radiation levels present on the VVM lid were consistent with the licensee's site specific Technical Specification 5.3.3 requirements.

The licensee's RP group addressed the external gamma and neutron monitoring of personnel onsite by using electronic dosimeters. The electronic dosimeters used conservative neutron correction factors. This ensured that the real-time monitoring

would provide an over-estimate of actual neutron doses so that these exposures would be managed conservatively. Personnel dose of legal record was measured using thermo-luminescent dosimeters which contained elements sensitive to the presence of neutrons.

The CoC 72-1040 Appendix A Technical Specification 5.3, “Radiation Protection Programs,” included numerous radiation measurement requirements, including the survey locations, and radiation limits. The licensee had incorporated all of the requirements of Section 5.3 in its site procedures and forms. In addition to radiation limits, the technical specification included removable contamination limits on the transfer cask and accessible portions of the MPC. The NRC inspectors verified that SONGS had incorporated those requirements into Procedure HPP-2464-031, “Pool to Pad Certificate of Compliance Radiological Surveys at SONGS,” Revision 0.

f. Records

The inspectors reviewed the licensee procedure SO123-VI-29, “Records Management,” to verify that provisions were in place to maintain records for each cask.

The licensee maintained cask records in accordance with its quality “Procedure SO123-VI-29,” “Records Management,” such that the cask package contained the required information to meet 10 CFR Part 72 requirements for record retention. The inspectors also verified that the licensee incorporated the requirement to register with the NRC no later than 30 days after using the cask to store fuel in Section 7.8.14 of HPP-2464-400, “MPC Transfer.”

3.3 Conclusions

Emergency planning provisions for the UMAX ISFSI had been incorporated into the site’s emergency plan. This included adding a specific EAL for an event damaging loaded UMAX casks.

A fire and explosion hazards analysis had been performed specific to the SONGS UMAX ISFSI. Administrative controls were established to limit the quantity of combustible and flammable liquids around the ISFSI and near the transport path during movement of the canister. The licensee provided calculations demonstrating that the worst case postulated fire event during transportation would not result in a significant increase in the temperature of the spent fuel inside a loaded canister.

The licensee evaluated the bounding environmental conditions specified in the Holtec FSAR and CoC 72-1040 technical specifications against actual site conditions. These included: tornados/high winds, flood, seismic events, tsunamis, hurricanes, lightning, burial of the ISFSI under debris, normal and abnormal temperatures, collapse of nearby facilities, and fires/explosions. The site environmental conditions at SONGS were bounded by the Holtec storage system’s design parameters.

The licensee had implemented their approved reactor facility 10 CFR Part 50 DQAP and CAP for the activities associated with the UMAX ISFSI. Selected QA activities were reviewed related to calibrations, audits, surveillances, and receipt inspections.

The licensee had incorporated keeping radiation exposures ALARA into planning for the cask loading program. Requirements for radiation surveys described in the FSAR and technical specifications had been incorporated into the licensee's procedures for cask loading operations. Projected radiation levels at the ISFSI were calculated for an assumed individual located at the owner controlled area boundary. The analysis demonstrated the dose to this individual would meet the requirements of 10 CFR 72.104.

The licensee was maintaining the 10 CFR Part 72 records in their quality related records system. Records required for retention by 10 CFR 72.174, 10 CFR 72.212, 10 CFR 72.234, and the FSAR had been identified in the licensee's program and were required to be maintained for the life of the ISFSI.

4 Review of 10 CFR 72.48 Evaluations (60857)

4.1 Inspection Scope

The Licensee's 10 CFR 72.48 screenings and evaluations performed to incorporate the use of the UMAX ISFSI were reviewed to determine compliance with regulatory requirements.

4.2 Observations and Findings

a. Safety Evaluations

The licensee had combined the 72.48 screening and evaluation process with the 10 CFR 50.59 process used at the site. Changes to the ISFSI and part 50 facility were processed in accordance with Procedure SO123-XV-4410 "CFR 50.59, 50.82, and 72.48 Program," Revision 21. As part of the programs review inspection, the NRC inspectors reviewed a number of 10 CFR 50.59/72.48 applicability determinations, screens, and one 10 CFR 72.48 evaluation that related to SONGS implementation of the UMAX Storage System.

The licensee completed four larger, nuclear engineering change packages (NECP) to encompass the use of the new UMAX ISFSI. A review was performed by the licensee for each NECP in accordance with 10 CFR 50.59 and 10 CFR 72.48 requirements. Construction of the UMAX ISFSI pad, approach slab, approach ramp, transfer pad, sump area berm, and ISFSI thermal monitoring system was performed under NECP 801372566. The new ISFSI security building was implemented under NECP 801372567 and 801372567. The umbrella NECP that supported implementation of the UMAX system operations for loading spent fuel into a MPC, use of HI-TRAC VW, drying and sealing, transfer of a loaded MPC, and placement at the ISFSI pad was implemented by NECP 801372564. Additionally, the NECP packages were reviewed for potential impacts against the existing TN ISFSI in accordance with 10 CFR 72.48. None of the 10 CFR 50.59/72.48 reviews identified a need for a Part 50 license amendment for the facility.

Section F of the 10 CFR 72.212 report contained a list of changes to the canister storage system licensing basis beyond UMAX FSAR Revision 4. The Holtec engineering change orders (ECO) and SMDRs were identified by the licensee as applicable to the storage system at SONGS. Additional changes to the storage system made by the

vendor would be captured in this list and processed in accordance with SONGS 10 CFR 50.59/72.48 program. Some of these changes were incorporated through the 10 CFR 50.59/72.48 under the previously reviewed NECPs conducted by the licensee. Other changes that occurred after the issuance of the NECPs were accepted by the licensee through standalone or combined screenings with exception of the FCRs previously discussed, for which corrective actions were taken.

The licensee performed one 10 CFR 72.48 evaluation for the implementation of the Licensee's 10 CFR 72.212 report. The 10 CFR 72.48 evaluation identified three areas where implementation of the UMAX storage system at the SONGS site was identified to be different than the descriptions provided in the HI-STORM FW and UMAX FSARs. The three areas related to the combined fire hazard loading (see discussion in Section 3.2.a. of this report), the site's tornado-borne missile differences, and the seismic lateral forces experienced during a DBE when a loaded HI-TRAC VW transfer cask contains a loaded canister in the spent fuel pool.

The SONGS design and licensing basis postulated tornado-borne missiles differed from the missiles addressed in the Holtec FSARs. The licensee's design basis values for rotational wind speed, translational speed, maximum wind speeds, and pressure drop were all less than the values listed in the FSARs. However, the SONGS missiles imparted slightly higher kinetic energy to the various targets for moderate and small missile scope than demonstrated in the FSARs. Since the generic tornado-borne missiles as defined by Holtec do not necessarily bound the site-specific missile parameters for several sites (including SONGS), Holtec prepared a generic report which evaluated the effect of a broader range of postulated site-specific tornado missiles based on the parameters from multiple sites. The generic Holtec Report HI-2135869, "Site-Specific Tornado Missile Analysis for the HI-STORM FW System", Revision 6, re-evaluated the structural impact of the tornado driven missiles on the HI-TRAC and the potential for tip-over and penetration. The applicable tornado-borne missiles evaluated in the generic report bounded all of the SONGS design basis tornado-borne missiles and were summarized in Appendix D of HI-2156567, "Evaluation of Plant Hazards at San Onofre Nuclear Generating Station," Revision 3. The additional evaluations demonstrated that the hypothetical deformations of the UMAX closure lid and impacts to the HI-TRAC VW transfer cask did not compromise the containment boundary of the MPC, locally deform the lid or transfer cask such that the irretrievability of the MPC was threatened, or deform the equipment plastically such that the shielding effectiveness was affected. The evaluation concluded the impacted components had sufficient capacity to withstand the slightly higher loads imparted by the SONGS missiles.

During the site's 10 CFR 72.212 review, the licensee identified that when rigging equipment is being exchanged, for a short period of time, the HI-TRAC VW and loaded MPC is in an unconstrained condition on an intermediate shelf in the spent fuel pool. If a seismic event was to occur during that time frame, the HI-TRAC VW with a loaded MPC could hypothetically fall to the lower level of the spent fuel pool and experience a higher lateral force than previously analyzed by the HI-STORM FW and UMAX FSARs.

The Licensee's 10 CFR Part 50 license and Updated Final Safety Analysis Report had analyzed a potential cask drop from the intermediate shelf to the bottom of the pool as a credible accident. In the past, the licensee had utilized the TN NUHOMS storage system, which contained a lateral side drop evaluation of the TN transfer cask in the TN

FSAR that bounded the site's configuration. The Holtec HI-STORM FW and UMAX FSARs does not contain a side drop analysis for the HI-TRAC VW transfer cask. However, the HI-STORM FW FSAR does contain a tip-over analysis for an MPC inside the HI-STORM overpack storage container.

To evaluate the scenario for this hypothetical accident of the loaded HI-TRAC VW contacting the sides and bottom of the spent fuel pool, the licensee's vendor (Holtec) prepared report HI-2177713 "HI-TRAC Drop in Cask Storage Pool at SONGS", Revision 1. In the report, the licensee demonstrated acceptability of the peak impact deceleration for the HI-TRAC VW scenario at SONGS by comparing those lateral forces to the peak impact deceleration values used to support the 10 CFR Part 71 HI-STAR 190 transport package safety analyses which utilizes the same MPC canister. The licensee's evaluation concluded that the maximum peak lateral deceleration value of the HI-TRAC VW in the pool at SONGS to be 74g's, which was below the HI-STAR 190 side drop evaluation of 85.9g's. Additionally, the MPC and fuel basket evaluated stresses were identified by the licensee to be less than the design basis criteria described in the limiting values from HI-STORM FW FSAR Section 2.2.8. The licensee stated that the same computer software (LS-DYNA) was utilized in all three evaluations (SONGS site specific drop evaluation, HI-STORM FW/UMAX FSAR tip-over evaluation, and HI-STAR FSAR transportation cask drop evaluation).

To utilize this evaluation conducted for the Part 71 HI-STAR 190 transportation license to bound conditions for the storage operations under the 10 CFR Part 72 UMAX license, additional information will need to be submitted by the licensee and evaluated by the NRC to determine if the methodology and implementation of the evaluation through the 10 CFR 72.48 process was appropriate. This item will be tracked as an Unresolved Item (URI) (07200041/2018001-02) until the NRC completes its review of the additional information to determine if the issue of concern potentially constitutes a violation of 10 CFR 72.48 requirements.

4.3 Conclusions

Safety screenings had been performed in accordance with the licensee's procedures and 10 CFR 72.48 requirements. All screenings reviewed were determined to be adequately evaluated. One 10 CFR 72.48 evaluation identified three areas (fire hazards, tornado missiles, and transfer cask drop scenario) where implementation of the UMAX storage system at the SONGS site was identified to be different than the descriptions provided in the HI-STORM FW and UMAX FSARs. All three changes were evaluated by the licensee through the site's 10 CFR 72.48 process to demonstrate the evaluations continued to meet the system's original design basis acceptance criteria listed in the HI-STORM FW and UMAX FSARs. An URI was opened to track the NRC's review of the methodology utilized in the evaluation for a transfer cask drop within the spent fuel pool and determine if the change was acceptable to be performed through the Licensee's 10 CFR 72.48 process.

5 Exit Meeting

The inspectors reviewed the scope and findings of the inspection during a telephonic exit meeting conducted with Mr. Lou Bosch, Plant Manager, and other members of your staff on August 8, 2018.

SUBJECT: CALLAWAY PLANT - INSPECTION OF THE INDEPENDENT SPENT FUEL STORAGE INSTALLATION (ISFSI) - INSPECTION REPORT 05000483/2015008 AND 07201045/2015001

Dear Mr. Diya:

A team inspection was conducted of your Independent Spent Fuel Storage Installation (ISFSI) between May 19, 2015 and September 1, 2015. The purpose of the inspections were to observe your dry fuel storage preoperational testing activities, to independently assess your readiness to load spent fuel into the ISFSI, and to inspect your initial fuel loading operations. The inspections consisted of six separate inspection trips involving multiple inspectors to observe your dry fuel storage preoperational testing and loading activities. The initial loading of the spent fuel into the first dry fuel storage cask occurred between August 24 - September 1, 2015. The results of the inspections were discussed in an exit with Mr. Mark McLachlan, Senior Director of Engineering and other members of your staff on September 17, 2015.

During the inspections, the NRC staff examined activities conducted under your license as they relate to public health and safety to confirm compliance with the Commission’s rules and regulations, and the conditions of your license. Within these areas, the inspection consisted of selected examination of procedures, representative records, observations of activities, and interviews with personnel. The enclosed report presents the results of these inspections. The inspection determined that you had completed all required activities identified in the Holtec Certificate of Compliance #1040 for use of the Holtec HI-STORM UMAX storage system at your site. No violations of significance were identified and no response to this letter is required.

In accordance with 10 CFR 2.390 of the NRC's "Rules of Practice," a copy of this letter, its enclosure, and your response if you choose to provide one, will be made available electronically for public inspection in the NRC Public Document Room or from the NRC's document system (ADAMS), accessible from the NRC Web site at http://www.nrc.gov/reading-rm/adams.html.

To the extent possible, your response should not include any personal, privacy or proprietary information so that it can be made available to the public without redaction.

Should you have any questions concerning this inspection, please contact the undersigned at (817) 200-1191 or Mr. Lee Brookhart at (817) 200-1549.

Sincerely,

/RA/

EXECUTIVE SUMMARY

Callaway Plant and Independent Spent Fuel Storage Installation
NRC Inspection Report 50-483/2015-08 and 72-1045/2015-01

The NRC team conducted an extensive evaluation of Callaway's program for the safe handling and storage of spent fuel at their UMAX ISFSI, observed the pre-operational training demonstrations, and observed the loading of the first spent fuel cask system. The Callaway Plant had selected the Holtec Certificate of Compliance #1040, HI-STORM UMAX cask storage system for use at their site's Independent Spent Fuel Storage Installation (ISFSI). This system consisted of the Multi-Purpose Canisters (MPC-37) that store 37 pressurized water reactor fuel assemblies in a below grade Vertical Ventilated Module (VVM). Callaway had constructed the UMAX ISFSI to hold 48 MPC-37s within the VVMs at the site. The ISFSI location includes space to eventually expand the UMAX to accommodate an additional 96 VVMs, if the site feels that it will be required in the future. The ISFSI was licensed by the NRC under the general license provisions of 10 CFR Part 72, Subpart K. The licensee planned to load six canisters for placement within the UMAX ISFSI during fall of 2015, of which the first canister loading was observed by the NRC.

This inspection report covers six separate inspections conducted between May 19 and September 1, 2015. During the dry run demonstrations and loading activities the inspectors verified compliance with licensing documents: Holtec Certificate of Compliance No. 72-1040 and Technical Specifications, Amendment 0; the UMAX Final Safety Analysis Report (FSAR), Revision 2; the FW FSAR, Revision 3; the NRC's Safety Evaluation Report for 72-1040, Amendment 0. Callaway developed a pre-operational test plan which consisted of five dry run demonstrations encompassing the pre-operational testing and training exercises required by License Condition 8 of the Holtec Certificate of Compliance. The demonstrations were conducted under the observation of the NRC. Twenty- three technical areas were reviewed during the inspections including such topical areas as the overhead crane requirements, loading operations, fuel verification, radiological programs, quality assurance, heavy loads, training, welding, fire protection and others. Subsequent to the site visits, an extensive in-office review was performed of documents provided by the Callaway staff. This effort involved the review of licensee reports, procedures, calculations, training documents, test results, personnel qualification records, safety evaluations, and condition reports to support the conclusion that the licensee had developed and implemented a comprehensive program to support ISFSI activities.

During the inspections, the licensee completed the demonstrations related to the operations of equipment and the implementation of procedures to verify that all operations required by the technical specifications could be performed safely. The programs review conducted by a NRC team of six inspectors, concluded that the licensing requirements related to dry cask storage had been adequately incorporated into the site's programs and procedures. During the various pre-operational demonstrations and first loading, the Callaway workers demonstrated a comprehensive understanding of the technical requirements related to the loading and operations of an ISFSI. Callaway's first cask was placed within the site's UMAX ISFSI on September 1, 2015.

Details related to the technical areas reviewed during this inspection are provided as Attachment 2 "Callaway Inspector Notes" to this inspection report. The following provides a summary of the observations of this inspection.

Canister Drying/Inerting

- Forced helium dehydration dryness limits established in Technical Specification A.3.1.1.1 and Table 3-1 had been incorporated into the licensee's procedures. The licensee planned to use the forced helium dehydration system for drying all canisters loaded at the site. Operation of the forced helium dehydration system was demonstrated during the pre-operational dry run exercises.

- Helium backfill pressure requirements established in Technical Specification A.3.1.1.2 and Table 3-2 had been incorporated into the licensee's procedures.

Crane Design

- The licensee had evaluated their fuel building 125-ton crane against the criteria in NUREG 0554, ASME NOG-1, and CMAA Spec #70-2010 and found the crane to meet the criteria for a single failure proof crane.

- Specific aspects of the crane which included: the bridge and trolley brakes, main hoist safety devices, emergency stop features, crane two-block protection, and dual rope reeving system met the requirements of NUREG 0554 and NUREG 0612.

Crane Inspection

- The 125-ton fuel building crane was subjected to a daily inspection, performed prior to use, that satisfied the requirements of ASME B30.2, Section 2-2.1.2 "Frequent Inspection." On an annual basis the crane was subjected to a more rigorous inspection that met the requirements of ASME B30.2, Section 2-2.1.3 "Periodic Inspection."

- A performance test was completed at Callaway after the new 125-ton trolley and hoist were installed. The site test included hoist raising/lowering at all speeds, trolley travel in both directions at all speeds, bridge travel in both directions at all speeds, and testing of all safety devices.

- The crane's hook was inspected annually as required by ASME B30.10, Sections 10-1.4.2 through 10-1.4.6.

Crane Load Testing

- Callaway's new 125-ton crane's trolley and hoist were dynamically load tested to 100% of the rated load and statically loaded to 125% after installation within the fuel building in June 2014.

- The fuel building 125-ton crane utilized a 150-ton hook which was subjected to a 200% hook load test of 300 tons in February 2014.

Crane Operation

- The maximum weight the 125-ton crane would lift during the cask loading campaign was 123.5 tons when lifting the HI-TRAC VW transfer cask containing the MPC-37 canister loaded with spent fuel out of the spent fuel pool.

- Callaway's qualification requirements for crane operators were consistent with the requirements listed in ASME B30.2.

- The licensee had the ability to manually lower the load and manually move the bridge and trolley if an emergency occurred. These provisions had been incorporated into a licensee procedure.

- The licensee's procedures required brake checks and specified a minimum travel height when lifting the HI-TRAC VW.

Dry Run Demonstration

- The licensee successfully completed all the required pre-operational tests specified by License Condition #8 of the Certificate of Compliance. This included welding, drying, and backfilling of a mock-up canister and the simulated unloading of a sealed canister. A weighted canister was used to demonstrate heavy load activities inside the fuel building, transport between the fuel building and the UMAX ISFSI, and movement back into the fuel handling building for unloading purposes. Inside fuel building dry runs included placement of an empty MPC and HI-TRAC VW into the spent fuel pool and movement of a dummy fuel assembly into the MPC. Additionally, Holtec performed a dry run to demonstrate the removal of the canister lid welds, for unloading purposes, at Holtec Manufacturing Division (HMD).

Emergency Planning

- Emergency planning provisions for the ISFSI had been incorporated into the site-wide emergency plan. This included adding a specific emergency action level for an event damaging a loaded cask. Part 50 emergency action levels applicable to the ISFSI included fires, security threats, and events involving a radiological release from a canister.

Fire Protection

- A Fire Hazards Analysis had been performed specific to the Callaway UMAX ISFSI. Administrative controls were established to limit the quantity of combustible and flammable liquids around the ISFSI and near the transport path during movement of the canister.

- Site specific fire and explosion hazards had been evaluated to determine the effect on the UMAX ISFSI and to confirm that the location of the ISFSI, location of the transport route, and the design of the transportation equipment was adequate. Several nearby facilities were evaluated that included diesel tanks and pipes, lube oil tanks, gasoline tanks, hydrogen tanks, and delivery trucks of flammable liquids.

- Additional fire analysis was required for the use of the tracked vertical cask transporter (VCT), the low profile transporter (HI-PORT), and ancillary equipment to account for the fire loading due to all vehicles' fuel contents and their hydraulic fluids. Holtec provided calculations that showed the postulated fire involving all the equipment would not result in a significant increase in the temperature of the spent fuel inside a loaded canister when being transported.

Fuel Selection/Verification

- For the initial loading campaign, the licensee planned to load only intact fuel assemblies that met the requirements of Technical Specification Appendix B, Section 2.1, Section 2.3, and the associated tables. The fuel assemblies selected for the first canister met the limits for length, width, weight, irradiation cooling time, average burn-up, cladding, decay heat, and fuel enrichment.

- The licensee planned to load fuel in the canisters using the regionalized fuel loading concept allowed in Technical Specification Appendix B, Section 2.3 and Figure 2.3-1. For the initial loading campaign, the licensee selected the option to load cooler spent fuel into the outer canister locations to provide shielding to the hotter fuel assemblies that were placed in the inner locations of the canister.

- The licensee had established provisions for independent verification of the correct loading of spent fuel assemblies into the canister. This included use of an underwater camera to view the fuel assemblies' serial numbers.

General License Requirements

- The licensee evaluated the bounding environmental conditions specified in the Holtec FSAR and Certificate of Compliance No. 1040 Technical Specifications against the conditions at the site. This included: tornados, flood, seismic events, hurricanes/high winds, lightning, burial of the ISFSI under debris, snow/ice, normal and abnormal temperatures, and fires/explosions. The site environmental conditions at Callaway were bounded by the Holtec cask design parameters except for fire, explosions, and tornado driven missiles. Separate analyses showed that the site's ISFSI and dry cask storage transportation operations could withstand Callaway's site specific tornado driven missile, worst postulated fire event, and pressures due to an explosion.

- Projected radiation levels at the ISFSI were calculated for an assumed individual located at the owner controlled area boundary to determine the dose to this individual. The analysis assumed that the ISFSI was fully loaded with all 48 canisters in the UMAX ISFSI with fuel characteristics that bounded the UMAX design basis. The calculation concluded that the dose to any individual would be a small fraction of the regulatory limits. The calculated doses were well below the 10 CFR 72.104 limit of 25 mrem/year.

- The licensee performed an evaluation of the Part 50 reactor programs that could be impacted by the addition of an ISFSI. The evaluation included a review of the radiation protection program, emergency planning program, quality assurance program, training program, reactor technical specifications, and the Part 50 license. Revisions to the programs to incorporate the ISFSI were identified and implemented. None of the

changes required an amendment to the plant's Part 50 operating license or technical specifications.

- The Holtec Certificate of Compliance and FSAR had been reviewed by the licensee to verify that the design basis for the Holtec system and the conditions and requirements in the Certificate of Compliance and FSAR were met.

- Callaway had developed procedures for controlling all work associated with cask handling, loading, movement, surveillance, maintenance, and testing. Procedures had been developed specific to the ISFSI activities. Numerous other procedures developed for the Part 50 reactor programs were being adequately applied to the ISFSI program.

Heavy Loads

- The licensee had incorporated the special requirements related to the ISFSI project into the site heavy loads programs and procedures. Crane operators interviewed were knowledgeable of the special handling requirements related to the spent fuel casks.

- Special lifting device height limits and temperature restrictions during movement of the canisters had been incorporated into the licensee's procedures consistent with the requirements in the Certificate of Compliance and FSAR.

- A safe loads path had been identified and analyzed for moving the spent fuel from the spent fuel pool. Provisions were established in procedures to prevent the crane operators from moving the loaded canister outside the boundaries of the safe load path while in the fuel building.

- The adequacy of the vertical cask transporter (VCT) for the expected weight of a loaded transfer cask and the ability of the transporter to safely perform downloading operations at the UMAX ISFSI was verified by NRC inspectors. The VCT was static load tested to 125% of its rated capacity and was given a 100% performance load test prior to fuel loading operations.

Loading Operations

- Requirements in the FSAR related to pre-operational inspections and annual maintenance of equipment were being implemented through the licensee's procedures.

- Technical specifications and FSAR requirements related to spent fuel boron concentration, fuel cladding not being exposed to air, handling of damaged fuel containers, and time-to-boil limits were implemented in the licensee's procedures.

- During the loading of the first canister beginning August 24, 2015, the NRC provided 24-hour coverage of the loading operations for all the critical tasks. This included fuel movement, heavy lifts of the loaded canister, radiation surveys of the loaded transfer cask and storage cask, welding of the lid and port cover plates, Forced Helium Dehydration (FHD) drying, helium backfill of the canister, and transportation of the canister into the UMAX ISFSI. The first canister was placed into the UMAX ISFSI on September 1, 2015.

Non-Destructive Examination

- The requirements to perform helium leak testing of each canister was incorporated into the licensee's procedures. The helium leak testing equipment used during the initial loading operations was verified to meet the minimum sensitivity level specified in ANSI N14.5.

- A review of the visual and liquid penetrant examination specialists' qualifications identified that they were properly qualified as a Level II examiners.

- The welding contractor, utilized by Callaway for dry cask storage operations, implemented visual and liquid penetrant examination procedures that met all the applicable requirements from ASME Section III, Section IV, and the FSAR in regards to non-destructive examination of welds.

Pressure Testing

- The requirements for canister hydrostatic testing had been incorporated into the licensee's procedure and were consistent with the requirements of ASME Section III Subsection NB, Article NB-6000.

- The hydrostatic testing sequence and criteria described in the FSAR had been incorporated into the licensee's procedures.

Quality Assurance

- The licensee had implemented their approved reactor facility Part 50 quality assurance program for the activities associated with the ISFSI. Selected Quality Assurance (QA) activities were reviewed related to calibrations, operating status, receipt inspections, QA surveillances, and QA audits.

- The FSAR identified structures, systems, and components that were important to safety and categorized each item into one of three levels (A, B, or C) based on safety significance. The licensee incorporated Holtec's safety designations into their classification procedure used to determine the level of quality control to place on the items.

- A corrective action program that documented issues and classified problems according to their impact on quality and safety was being effectively used by the licensee. Selected condition reports were reviewed to verify adequate resolution of the issues.

Radiation Protection

- The licensee had incorporated As Low As Reasonably Achievable (ALARA) planning into the dry cask loading program. This included developing reasonable dose goals, utilizing lessons learned from other sites, and conducting radiation pre-job briefings that identified expected radiological conditions for the different work evolutions.

- Requirements for radiological and contamination surveys described in the FSAR and technical specifications had been incorporated into the licensee's health physics

program for the loading of the canisters. This included decontamination of the transfer cask and canister lid, and performing required surveys of the transfer cask and loaded VVM.

- The licensee incorporated proper neutron dose consideration into the health physics monitoring program for neutrons that would be present around the canister when empty of water. This consideration included the use of appropriate personnel dosimetry that could measure neutron doses and applying a correction factor based on survey readings obtained during the loading campaign.

Records

- The licensee was maintaining the ISFSI records in their quality related records system. Records required for retention by 10 CFR 72.174, 10 CFR 72.212, 10 CFR 72.234, and the FSAR had been identified in the licensee's program as required records for retention. The records were required to be maintained for five years after the transfer of the fuel from the ISFSI.

Safety Reviews

- Changes to the site related to the construction and operation of the ISFSI were being evaluated in accordance with 10 CFR 72.48 and 10 CFR 50.59 requirements. No issues were identified during the review of selected safety screenings and full safety evaluations.

Slings

- The slings used for downloading the MPC and other slings utilized throughout the campaign met the requirements of NUREG 0612. Operations required dual/redundant slings that had a rated capacity of twice the sum of the static and dynamic loads. All slings' proof loading tests were found to meet the requirements of ASME B30.9.

- The sling inspection program complied with ASME B30.9 in regards to daily sling inspections, annual sling inspections, and proof loading.

Special Lifting Devices

- The licensee's special lifting device program complied with ANSI N14.6 in regards to stress design, prior to use inspections, and 300% proof loadings for the lift yoke, lift yoke extensions, HI-TRAC VW Lift Lugs, MPC lift cleats, and the VCT lift links.

Storage Operations

- The inspection of the VVM outlet and inlet air ducts to be free from blockage was placed in the licensee's procedures to be performed daily as required by Technical Specification A.3.1.2.

Unloading

- The licensee procured the equipment and developed procedures to perform gas sampling if a canister was required to be unloaded. The licensee demonstrated the gas sampling process to the NRC during the dry run demonstrations.

- Canister re-flooding for unloading was demonstrated to the NRC during the dry run demonstrations. The procedure controlling canister re-flooding contained all of the applicable requirements from the FSAR and the technical specifications.

Welding

- Requirements for hydrogen monitoring during welding of the canister lid had been incorporated into the licensee's procedures.

- All welding procedures contained the required essential, non-essential, and supplemental variables specified in ASME Section IX for gas tungsten arc welding.

- The welding procedure's qualification test coupons all satisfactorily passed the required bend and tension tests to qualify the welding procedures and thus the lid to shell weld.

- The welder's performance qualification test records were reviewed and documented that the welders had met the qualification testing requirements for manual and machine welding of the canister lid. The testing requirements complied with the requirements of ASME Section IX.

CALLAWAY INSPECTOR NOTES

Category: Canister Drying/Inerting **Topic:** Dryness Levels

Reference: CoC 1040, Tech Spec A.3.1.1.1 and Table 3-1 Amendment 0

Requirement When using the forced helium dehydration (FHD) system for moisture removal, the gas temperature exiting the demoisturizer shall be 21 degrees F or less, for 30 minutes or more, or the gas dew point exiting the canister shall be 22.9 degrees F or less, for 30 minutes or more.

Observation: The procedures used at Callaway for canister sealing exceeded the dryness requirements established by the Certificate of Compliance (CoC). The spent fuel canisters used at Callaway used the forced helium dehydration (FHD) system to ensure that fuel dryness levels were adequately obtained. Certificate of Compliance (CoC) 1040 Technical Specification (TS) surveillance requirement 3.1.1.1 and Table 3-1 required that the gas temperature exiting the demoisturizer be less than or equal to 21 degrees F for 30 minutes or more, or that the gas dew point exiting the canister be less than or equal to 22.9 degrees F for 30 minutes or more. These TS requirements were placed in the Holtec procedure HPP-2253-300 for canister sealing. However, the procedures used at Callaway conservatively exceeded the dryness levels required by the Holtec CoC TSs. The procedure used at Callaway required the temperature leaving the demoisturizer to be no more than 16 degrees F for 30 minutes or more. The gas dew point sensor was utilized by the system earlier in the FHD process at Callaway, but the licensee used the demoisturizer exiting temperature for the TS surveillance to ensure the system was dry.

Documents Reviewed: a) Holtec Procedure HPP-2253-300, "MPC Sealing at Callaway," Revision 7

Category: Canister Drying/Inerting **Topic:** Forced Helium Dehydration System (FHD)

Reference: CoC 1040, Appendix A, Section 3.6.1, Table 3-1 Amendment 0

Requirement For canisters containing one or more fuel assemblies with burnup values greater than 45 GWD/MTU, forced helium dehydration must be used for canister drying. For all other canisters, either forced helium dehydration or vacuum drying may be used for canister drying, unless MPC-37 is loaded using Figure 2.3-12.

Observation: Use of the forced helium dehydration system was planned for all canisters loaded at Callaway. The first canister contained assemblies with a burnup of greater than 45 GWD/MTU. The licensee demonstrated the use of the forced helium dehydration system during the dry run conducted the week of June 2-4, 2015. Procedure HPP-2253-300 provided instructions for use of the system. Use of the forced helium dehydration system was always required in Procedure HPP-2253-300, and as such, the criteria in Technical Specification A.3.6.1 was not specified in the procedure.

Documents Reviewed: a) Holtec Procedure HPP-2253-300, "MPC Sealing at Callaway," Revision 7

Category: Canister Drying/Inerting **Topic:** Helium Backfill Pressure

Reference: CoC 1040, Tech Spec A.3.1.1.2, Table 3-2, et al. Amendment 0

Requirement For the MPC-37 canister with Standard Fuel, backfill pressure shall be as follows: for

cask heat loads less than or equal to 33.88 kW, using canister loading option depicted in Figure 2.3-1 helium backfill shall be equal to or greater than 41.0 psig up to 44.2 psig. The pressure range is at a reference temperature of 70 degree F.

Observation: All canisters loaded at Callaway were restricted to the loading option depicted in CoC Appendix B, Figure 2.3-1 "UMAX MPC-37 Permissible Heat Load Chart 1 for Long-term Storage for Short and Standard Fuel" and a helium backfill pressure range of equal to or greater than 41.0 psig up to 44.2 psig (at 70 degree F) per procedure ETP-ZZ-04020.

Helium backfill pressure requirements were incorporated into Procedure HPP-2253-300 consistent with the requirements in TS A.3.1.1.2 and Table 3-2. Procedure HPP-2253-300, Section 7.10, "FHD Helium Backfill Operation," provided instructions for the helium backfill operations. Step 7.10.7 of Procedure HPP-2253-300 used Attachment 8.6 "FHD Helium Backfill Pressure Chart" to determine the acceptable pressure range at different temperatures based on a 70 degree F reference temperature.

Documents Reviewed: a) Certificate of Compliance No. 1040, "For the HI-STORM UMAX Cask Storage System," Amendment 0; b) Callaway Procedure ETP-ZZ-04020, "Fuel Selection and Cask Loading for Dry Cask Storage," Revision 0; c) Holtec Procedure HPP-2253-300, "MPC Sealing at Callaway," Revision 7

Category: Crane Design **Topic:** Bridge and Trolley Brakes

Reference: NUREG 0554, Section 5.1 Published May 1979

Requirement Bridge and trolley control and holding brakes should be: a) rated at 100% of maximum drive torque that can be developed at the point of application; b) adjusted with one brake in each system leading the other; and c) automatically actuate on interruption of power and overspeed. The holding brakes should be designed so that they cannot be used as foot-operated slowdown brakes. Drag brakes should not be used.

Observation: The bridge and trolley brakes on the single-failure proof crane met the NUREG requirements. The bridge/trolley control and the holding brakes were capable of applying a counter torque that would be 100% of maximum drive torque that could be developed at the point of application. The trolley and bridge brakes were provided in arrangements in accordance with the Crane Manufacturers Association of America (CMAA) Spec #70-2010 with one brake system leading the other. The bridge and trolley motors were provided with spring set, electronically released holding brakes that would automatically apply when power became interrupted. The design of the bridge and trolley holding brakes were such that they cannot be used as a foot-operated slowdown brake and drag brakes were not used for the bridge or trolley drives.

Documents Reviewed: a) American Crane and Equipment Corporation Document REP-2150-003, "NUREG 0554/0612 Compliance/Safety Analysis Report for the Cask Handling Crane Upgrade Holtec International/Ameren's Callaway Energy Center," Revision 0

Category: Crane Design **Topic:** Drum Safety Devices

Reference: NUREG 0554, Section 4.2 Published May 1979

Requirement The hoist drum should be provided with structural and mechanical safety devices to limit

its drop during a shaft or bearing failure. The devices should prevent disengaging from the holding brake.

Observation: The single-failure proof crane at Callaway met the design requirement. The main hoist drum retaining devices were steel structures, which ensured that a shaft or bearing failure would not allow the main hoist drums to disengage from the brakes.

Documents Reviewed: a) American Crane and Equipment Corporation Document REP-2150-003, "NUREG 0554/0612 Compliance/Safety Analysis Report for the Cask Handling Crane Upgrade Holtec International/Ameren's Callaway Energy Center," Revision 0

Category: Crane Design **Topic:** Emergency Stop Feature

Reference: NUREG 0554, Sections 3.3, 6.1, and 6.6 Published May 1979

Requirement An emergency stop feature should be installed at the control station. For cranes remotely operated using radio control stations, a second emergency stop feature should be provided at ground level to remove power from the crane, independent of the controller. Cranes that use more than one control station should be provided with electrical interlocks that permit only one control station to be operated at a time.

Observation: The requirement for an emergency stop button to exist on both the remotely operated overhead crane belly box (both the pendant and radio remote controls) and in another redundant location accessible from the ground floor was visually verified by NRC inspectors during preoperational dry-runs at the Callaway Nuclear Station. The presence and locations of the emergency stop buttons was also detailed in the American Crane NUREG 0554 Compliance Report.

Documents Reviewed: a) American Crane and Equipment Corporation Document REP-2150-003, "NUREG 0554/0612 Compliance/Safety Analysis Report for the Cask Handling Crane Upgrade Holtec International/Ameren's Callaway Energy Center," Revision 0

Category: Crane Design **Topic:** Seismic Events During Cask Movement

Reference: NUREG 0554, Section 2.5 Published May 1979

Requirement The crane should be designed to retain control of and hold the load, and the bridge and trolley should be designed to remain in place on their respective runways with their wheels prevented from leaving the tracks during a seismic event.

Observation: The crane was designed to retain control of and hold the load during a seismic event. The trolley was designed to remain in place on their respective runways with their wheels prevented from leaving the tracks during a seismic event. The new trolley, including main hoist, was designed and fabricated to meet CMAA Specification #70-2010, ASME NOG-1-2004, and NUREG 0554 requirements. The main-hoist was single-failure-proof and designed to maintain control of the maximum rated load during the seismic spectra specifications from the plant's Part 50 Updated Final Safety Analysis Report (UFSAR). This analysis was documented in Calculation CAL-21250-SE-001 "Crane Structural Analysis & Trolley Evaluation" and in the licensee's 50.59 screen MP 14-0014 "Dry Fuel Storage Licensing and Operations Documentation (Heavy Loads Review)."

Documents Reviewed: a) Calculation CAL-21250-SE-001, "Crane Structural Analysis & Trolley Evaluation," Revision 1; b) 50.59 Screen MP 14-0014, "Dry Fuel Storage Licensing and Operations Documentation (Heavy Loads Review)," Revision 0

Category: Crane Design **Topic:** Seismically Induced Load Swing

Reference: NUREG 0554, Section 2.5; Reg Guide 1.29 Published May 1979

Requirement The maximum critical load plus operational and seismically induced pendulum and swing load effects on the crane should be considered in the design of the trolley and should be added to the trolley weight for the design of the bridge.

Observation: The maximum critical load plus the swing load effects due to a seismically induced pendulum was included in the design calculations associated with Callaway's 125-ton fuel building crane. Licensee Calculation CAL-21250-SE-001 "Crane Structural Analysis & Trolley Evaluation" included the crane with the maximum crane load suspended from the trolley at several locations along the bridge and at several heights within the fuel building. A linearly elastic, static finite element analysis was used to obtain operational load analyses and environmental seismic member forces. The computer program used for this calculation was the SAP2000 Version 15.1.0, which was permitted by the Part 50 program's UFSAR. The analyses determined that the trolley members and connections satisfied all allowable stress criteria set forth in CMAA #70-2010 and ASME NOG-1.

Documents Reviewed: a) Calculation CAL-21250-SE-001, "Crane Structural Analysis & Trolley Evaluation," Revision 1; b) 50.59 Screen MP 14-0014, "Dry Fuel Storage Licensing and Operations Documentation (Heavy Loads Review)," Revision 0

Category: Crane Design **Topic:** Single Failure Proof Crane

Reference: NUREG 0554, Section 1.0 Published May 1979

Requirement When reliance for the safe handling of critical loads is placed on the crane system itself, the system should be designed so that a single failure will not result in the loss of the capability of the system to safely retain the load.

Observation: The original cask handling crane in Callaway's fuel handling building was a non-single-proof 150-ton crane. In early 2014, Callaway replaced the 150-ton non-single failure proof crane/trolley with a new 125-ton single-failure proof crane/trolley from American Crane and Equipment Corporation. This new 125-ton single-failure proof crane was designed to meet the requirements of NUREG-0554, NUREG 0612, CMAA #70-2010, ASME B30.2, and ASME NOG-01.

Documents Reviewed: a) American Crane and Equipment Corporation Document REP-2150-003, "NUREG 0554/0612 Compliance/Safety Analysis Report for the Cask Handling Crane Upgrade Holtec International/Ameren's Callaway Energy Center," Revision 0; b) 50.59 Screen MP 14-0014, "Dry Fuel Storage Licensing and Operations Documentation (Heavy Loads Review)," Revision 0

Category: Crane Design **Topic:** Two-Block Protection

Reference: NUREG 0554, Section 4.5 Published May 1979

Requirement The complete hoisting system should have the required strength to resist failure during two-blocking. As an alternative, a system of upper travel limit switches may be used to prevent two-blocking. The system should include two independent travel limit devices of different designs and activated by separate mechanical means. These devices should de-energize the hoist drive motor and the main power supply. The auxiliary hoist, if used for critical lifts, should also be equipped with two independent travel limit switches to prevent two-blocking.

Observation: The requirement for two-block protection was met at Callaway through the design of the main hoist that allowed the crane to two-block without cutting or crushing the wire ropes or causing permanent deformation or damage to the crane. In addition, redundant and independent upper travel limit switches to prevent two-blocking from ever occurring were also incorporated into the design. As such, the Cask Handling Crane used at Callaway had multiple paths of two-block protection.

Documents Reviewed: a) American Crane and Equipment Corporation Document REP-2150-003, "NUREG 0554/0612 Compliance/Safety Analysis Report for the Cask Handling Crane Upgrade Holtec International/Ameren's Callaway Energy Center," Revision 0

Category: Crane Design **Topic:** Wire Rope Breaking Strength

Reference: NUREG 0554, Section 4.1 Published May 1979

Requirement The maximum load (including static and inertia forces) on each individual wire rope in the dual reeving system with the maximum critical load attached should not exceed 10% of the manufacturer's published breaking strength.

Observation: The 125 ton single failure proof crane's wire rope met the NUREG 0554 requirement. The maximum load rating for the main hoist was 125-tons or 250,000 lbs. The wire ropes used on the main hoist were rated for 195,800 lbs. The main hoist utilized two Python Power 9V EEIPS wire ropes that were each 1-1/8" nominal diameter and length of 775 ft through an 8-part reeving system. Therefore the stress in each individual wire rope from the maximum load would be 15,625 pounds (250,000/16). Ten percent of the manufacturer's published breaking stress for the wire rope was 19,580 lbs. Therefore the maximum load on the wire rope at maximum rated load was 15,625 lbs, which is less than 10 percent of the published breaking strength of 19,580 lbs, meeting the NUREG requirement.

Documents Reviewed: a) UNIROPE Test Certificate No 191303 Item #5 Rel #2, Dated 12/12/2013; b) UNIROPE Test Certificate No 191303 Item #2 Rel #2, Dated 12/10/2013

Category: Crane Design **Topic:** Wire Rope Configuration

Reference: NUREG 0554, Section 4.1 Published May 1979

Requirement A dual rope reeving system with individual attaching points and a load balancing system will permit either rope system to hold and transfer the critical load without excessive shock in case of failure of the other rope system. The dual reeving system may be a

single rope from each end of the drum terminating at one of the blocks or equalizer with provisions for equalizing beam-type load and rope stretch, with each rope designated for the total load. Alternatively, a 2-rope system may be used from each drum or separate drums using a sheave equalizer or beam equalizer or other combination that provides two separate and complete reeving systems.

Observation: The single-failure proof crane at Callaway met the NUREG requirement. The 125-ton crane at Callaway used two drums with two ropes, with a balanced dual reeving system with each rope terminating on the drum it originated on.

Category: Crane Inspection **Topic:** Crane Inspection - Frequent

Reference: ASME B30.2; Section 2-2.1.2 Published 1976

Requirement Cranes in regular use shall be subjected to a frequent crane inspection monthly during normal service, weekly to monthly during heavy service, and daily to weekly during severe service. The frequent inspection points shall include: a) operating mechanisms for proper operation daily; b) all limit switches should be checked at the beginning of each work shift by inching, or running at slow speeds, each motion into its limit switch; c) leakage in lines, tanks, valves, pumps, and other parts of the air or hydraulic systems; d) hooks for cracks, more than 15% of normal throat opening, or more than 10 degrees of twist; e) hook latches for proper operation; f) hoist ropes including end clamps; and g) the rope reeving system.

Observation: NRC inspectors verified via procedure review that the frequent cask handling crane inspections performed at Callaway would look for the following items: proper operation of operating mechanisms, limit switch functionality, fluid leaks, hook and latch wear and operation, wire rope end connections, and proper spooling on the drum. The 125-ton crane was daily inspected in accordance with ASME B30.2, Section 2-1.1.2.

Documents Reviewed: a) Callaway Procedure OTS-KE-00016, "Operation of the Cask Handling Crane," Revision 22; b) Job Order #15500182.500, "Semi-Annual Crane Inspection HKE14 (Mechanical)," Revision 3

Category: Crane Inspection **Topic:** Crane Inspection - Periodic

Reference: ASME B30.2; Section 2-2.1.3 Published 1976

Requirement Cranes in regular use shall be subjected to a periodic crane inspection annually during normal and heavy service, and quarterly during severe service. The periodic inspection includes checking for: a) deformed, cracked or corroded members; b) loose bolts or rivets; c) cracked or worn sheaves and drums; d) worn, cracked or distorted pins, bearings, shafts, gears, and rollers; e) excessive brake system wear; f) load, wind, and other indicators over their full range for any significant inaccuracies; g) gasoline, diesel, electric, or other power plants for improper performance; h) excessive drive chain sprocket wear and chain stretch; and i) deterioration of controllers, master switches, contacts, limit switches and pushbutton stations.

Observation: The periodic crane inspection was performed as required. Callaway had implemented three different job orders to inspected the 125-ton fuel building crane. Job Order #14502408.500 "Annual Crane Maintenance and Inspection (HKE14)," contained annual mechanical inspection requirements and was completed on June 20, 2015. Job Order #14502408.321 "Annual Crane Inspection HKE14 (Electrical)," contained electrical inspection requirements and was completed June 25, 2015. Job Order #15500182.500 "Semi-Annual Crane Inspection HKE14 (Mechanical)," contained additional mechanical inspection requirements and was completed June 20, 2015. All ASME B30.2 inspection requirements were captured between the three inspection procedures and were being performed on an annual or semi-annual basis.

Category: Crane Inspection **Topic:** Crane Operational Testing

Reference: ASME B30.2; Sect 2-2.2.1 Published 1976

Requirement Prior to initial use, all new, reinstalled, extensively repaired, or modified cranes shall have the following functions tested: (a) lifting and lowering, (b) trolley travel, (c) bridge travel, (d) limit switches, and (e) locking and safety devices. The trip setting of the hoist limit devices shall be determined by tests with an empty hook traveling in increasing speeds up to the maximum speed. The actuating mechanism of the limit device shall be located so that it will trip the device under all conditions in sufficient time to prevent contact of the hook or load block with any part of the trolley or crane.

Observation: All ASME B30.2 operational testing requirements were tested during the site acceptance test performed in June of 2014 per Procedure REP-21250-007.

Documents Reviewed: a) Procedure REP-21250-007, "American Crane & Equipment Corporation Site Load Test," Revision 1

Category: Crane Inspection **Topic:** Hoist Overload Testing

Reference: NUREG 0554, Section 8.3; NUREG 0612, C-4, (9) Published 1979/1980

Requirement If the hoisting system is designed with adequate strength to resist failure during load hang-up, the hoisting system should be tested by securing the load-block-attaching points to a fixed anchor and applying the maximum critical load. Alternately, if a load cell system, a motor current-sensing device, or a mechanical load-limiting device is provided to prevent load hang-up, the device(s) should be tested to verify operability.

Observation: Testing was performed that met the NUREG requirement. A two-block test of the main hoist was performed during factory functional testing at American Crane & Equipment Corporation's factory on March 27, 2014 per REP-21250-004 and REP-21250-005. The overweight limits on the main hoist were calibrated and tested during the factory load testing. The proper operation of the mechanical slip clutch, which was present to mitigate the effects of two-blocking or load hang-up event, was verified for the 125-ton main hoist.

Documents Reviewed: a) Procedure REP-21250-004, "American Crane & Equipment Corporation Factory Functional Test Procedure," Revision 1; b) Procedure REP-21250-005, "American Crane & Equipment Corporation Factory Load Test Procedure," Revision 1

Category: Crane Inspection **Topic:** Hook Inspections - Frequent/Periodic

Reference: ASME B30.10, Sections 10-1.4.2 and 10-1.4.6 Published 1975

Requirement Hooks shall be inspected monthly during normal service, weekly to monthly during heavy service and daily to weekly during severe service. Hooks should be inspected for: a) distortion such as bending, twisting or increased throat opening; b) wear; c) cracks, severe nicks, or gouges; d) latch engagement, damaged or malfunctioning latch (if provided); and e) hook attachment and securing means. Hooks having any of the following deficiencies shall be removed from service unless a qualified person approves their continued use and initiates corrective action: a) cracks; b) wear exceeding 10% of the original sectional dimension; c) bend or twist exceeding 10 degrees from the plane of an unbent hook; and d) an increase in throat opening of 15% (for hooks without latches).

Observation: NRC inspectors verified via procedure review that Callaway met the hook inspection requirements of ASME 30.10, "Hooks," in its frequent (daily) or periodic (semi-annual) crane hook inspections. This criteria included inspections of the hook attachment points, for distortion, cracks, and wear, and for crane hook latch engagement problems. These requirements were met for both the 125-ton main hoist as well as the 5-ton auxiliary hoist.

Documents Reviewed: a) Callaway Procedure OTS-KE-00016, "Operation of the Cask Handling Crane," Revision 22; b) Job Order #15500182.500, "Semi-Annual Crane Inspection HKE14 (Mechanical)," Revision 3

Category: Crane Inspection **Topic:** Wire Rope Inspection - Frequent

Reference: ASME B30.2, Section 2-2.4.1 (a) Published 1976

Requirement All ropes shall be visually inspected once each working day.

Observation: NRC inspectors verified via procedure review that Callaway met the requirements of ASME B30.10, Section 2-2.4, "Rope Inspection, Replacement, and Maintenance." According to the procedure used at Callaway, the wire rope is to be inspected prior to each shift as part of an operational check. The procedure required that the wire rope be inspected for broken/damaged wire, excessive wear, kinks, distortion, corrosion, and problems with the end clips/rope attachment points.

Documents Reviewed: a) Callaway Procedure OTS-KE-00016, "Operation of the Cask Handling Crane," Revision 22

Category: Crane Inspection **Topic:** Wire Rope Replacement Criteria

Reference: ASME B30.2, Section 2-2.4.2 Published 1976

Requirement Conditions such as the following should be sufficient reason for questioning continued use of the rope, or increasing the frequency of inspection: a) twelve randomly distributed broken wires in one lay; b) wear of one-third of the original diameter of outside

individual wires; c) kinking, crushing, bird caging or any other damage resulting in distortion of the rope structure; d) evidence of heat damage; and e) reduction in diameter in excess of nominal.

Observation: The wire rope on the 125-ton crane was inspected to the ASME B30.2, Section 2-2.4.2 criteria semi-annually per Job Order #15500182.500, "Semi-Annual Crane Inspection HKE14 (Mechanical)." The last semi-annual inspection was conducted on June 20, 2015. Steps 5.1.9 from the Job Order contained the ASME B30.2 Section 2-2.4.2 wire rope inspection requirements.

Documents Reviewed: a) Job Order #15500182.500, "Semi-Annual Crane Inspection HKE14 (Mechanical)," Revision 3

Category: Crane Load Testing **Topic:** Cold Proof Testing

Reference: NUREG 0554, Section 2.4; NUREG 0612, C-2 (8) Published 1979/1980

Requirement Minimum operating temperatures for the crane should be specified to reduce the possibility of brittle fracture of the ferritic load-carrying members of the crane. The minimum temperature can be determined by: 1) a drop weight test per ASTM E-208, 2) a Charpy test per ASTM A-370, or 3) a 125% cold proof test. If the crane is made of low alloy steel such as ASTM A514, cold proof testing should be done. If cold proof testing is omitted, the default minimum crane operating temperature is 70 degrees F. For crane operation at temperatures below 70 degrees F, cold proof testing must be performed and the ambient temperature at which the testing is conducted becomes the minimum crane operating temperature.

Observation: The 125-ton crane's operating temperature was set per procedure requirements to exceed 70 degrees F. The MPC loading procedure in step 5.11 required operators to ensure cask handling crane temperature to be greater than 70 degrees F.

Category: Crane Load Testing **Topic:** Dynamic Load Testing (100%)

Reference: NUREG 0554, Section 8.2 Published May 1979

Requirement After the 125% static load test, the crane should be given a full performance test with 100% of the maximum critical load attached, for all speeds and motions for which the system is designed. This should include verifying all limiting and safety control devices.

Observation: A full performance test with 100% of the maximum critical load attached was performed for all speeds and motions for which the system was designed. The 100% site load test was completed on June 4, 2014. Procedure REP-21250-007 page 12 of 41, documented that the licensee satisfactorily performed the test with a load of 253,100 lbs. All speeds and motions were tested as well as the limiting and safety control devices.

Documents Reviewed: a) Procedure REP-21250-007, "American Crane & Equipment Corporation Site Load Test," Revision 1

Category: Crane Load Testing **Topic:** Hook Load Testing

Reference: NUREG 0554, Sect 4.3; ASME B30.10, Sect 10-1.1.2 Published 1979/1975

Requirement A 200% static load test should be performed for each load-attaching hook. For a duplex (sister) hook, the proof load shall be shared by the two sisters unless the hook is designed for unbalanced loading. Measurements of the geometric configuration of the hooks should be made before and after the test and the acceptance criteria is no permanent increase in throat opening in excess of 0.5% or 0.010 inches (0.25 mm). The load testing should be followed by a nondestructive examination that should consist of volumetric and surface examinations to verify the soundness of fabrication and ensure integrity of the hooks.

Observation: A static hook load test of 200% was performed on the 125-ton main hoist of the fuel building crane. A 150-ton hook was purchased for the new fuel building crane. McKissick Certificate of Conformance No 840554 documented that the 150-ton hook was proof load tested to 600,000 lbs on February 19, 2014.

Documents Reviewed: a) McKissick Certificate of Conformance Test Certificate No 840554, "Certificate of Test and Examinations of Chains, Rings, Hooks, Shackles, Swivels, and Pulley Blocks," dated 03/12/14

Category: Crane Load Testing **Topic:** NDE Exams Following Cold-Proof Testing

Reference: NUREG 0554, Section 2.4 and 2.6 Published May 1979

Requirement Following the 125% cold-proof testing, a nondestructive examination of the welds whose failure could result in the drop of a critical load should be performed. If any of these weld joint geometries would be susceptible to lamellar tearing, the base metal at the joints should be nondestructively examined. Nondestructive examination of critical areas should be repeated at 4-year intervals or less.

Observation: Cold proof testing was performed at Callaway following the 125-ton crane's static load test at 125% of the rated capacity. Non-destructive examination was performed on the critical welds identified by the licensee. The welds examined were documented in Attachment A-1 "Table of Required Inspections, Test, and Documentation" and in Attachment A-2 "Identification of Critical Welds & Brittle Fracture Concerns for Existing Bridge Structure for the Cask Handling Crane Upgrade" of American Crane and Equipment Corporation Document REP-2150-003.

Category: Crane Load Testing **Topic:** Rated Load Marking

Reference: NUREG 0554, Section 8.5; ASME B30.2, Sect 2- Published 1976

Requirement The rated load shall be marked on each side of the crane and, if the crane has more than one hoisting unit, each hoist shall have its rated load marked on it or on its load block.

This marking shall be legible from the ground or floor.

Observation: The rated load of the fuel building overhead crane at Callaway was marked on each side of the crane and on each of the hoists. The fuel building crane was rated as 125 tons. One other hoist was located on the crane as well, a 5-ton hoist.

Documents Reviewed: a) NUREG 0554, "Single Failure Proof Cranes for Nuclear Power Plants," published May 1979

Category: Crane Load Testing **Topic:** Static Load Testing (125%)

Reference: NUREG 0554, Section 8.2 Published May 1979

Requirement The crane should be static load tested at 125 percent of the maximum critical load. The test should be conducted at all positions generating maximum strain in the bridge and trolley structures and other positions as recommended by the designer or manufacturer.

Observation: A static load test at 125% of the maximum critical load attached was performed at Callaway on June 4, 2014. Procedure REP-21250-007, page 23, documented that the licensee satisfactorily performed the test with a load of 318,200 lbs.

Documents Reviewed: a) Procedure REP-21250-007, "American Crane & Equipment Corporation Site Load Test," Revision 1

Category: Crane Operation **Topic:** Brake Test Prior to Lift

Reference: ASME B30.2, Section 2-3.2.3 (g) Published 1976

Requirement The operator shall check the hoist brakes at least once each shift if a load approaching the rated load is to be handled. This shall be done by lifting the load a short distance and applying the brakes.

Observation: This requirement had been adequately incorporated into the lifting procedures at Callaway. Callaway's lifting operations procedure included step 4.2.1.t that described the "lift and hold test" for all lifts performed with the main hoist during fuel building operations. In this step, all loads were lifted to clear the ground or securing device for underwater lifts and the load was held long enough to listen for unusual sounds, check the load on the load indicator, review and inspect the rigging, and to ensure that the load is stable. A similar step was included in the lifting and rigging program procedure in step 4.2.3. The crane operating procedures used at Callaway were compliant with the brake testing criterion of ASME B30.2.

Documents Reviewed: a) Callaway Procedure APA ZZ-00365, Addendum L, "Callaway Lifting Operations," Revision 18; b) Callaway Procedure APA-ZZ-00365, "Callaway Lifting and Rigging Program," Revision 26

Category: Crane Operation **Topic:** Height Limit During Cask Movement

Reference: No Reference Provided

Requirement For single failure proof cranes, the cask height during movement should be sufficiently high to allow for engaging of the brakes during an uncontrolled descent before the load would impact the floor.

Observation: Callaway had placed this requirement into their loading procedures. Procedure HPP-2253-200 contained a Note right above Step 7.7.40 that stated, "The HI-TRAC VW must be maintained greater than 9" above the 2047'-6" deck while not centered over the Cask Loading Pit or Cask Wash Down Pit." The nine inch lift height was conservatively above the manufacturer's recommendations of sufficient height to ensure the main hoist brakes would engage during an uncontrolled lowering event.

Documents Reviewed: a) Holtec Procedure HPP-2253-200 "MPC Loading at Callaway," Revision 9

Category: Crane Operation **Topic:** Hoist Limit Switch Tested Each Shift

Reference: ASME B30.2, Section 2-3.2.4 (a) Published 1976

Requirement At the beginning of each shift, the operator shall try out the upper limit device of each hoist under no-load. Care shall be exercised. The block shall be inched into the limit or run in at a slow speed.

Observation: The Callaway procedure for the cask handling crane listed all of the inspection areas and steps to be performed for daily preoperational testing. Step 5.6.4 (e) of the crane operation procedure tests the upper limit cut-off of the main hoist. This demonstrated that Callaway met the requirements of ASME B30.2, section 2-3.2.4, which required that at the beginning of each shift, the operator shall try out the upper limit device of the hoist under no load.

Documents Reviewed: a) Callaway Procedure OTS-KE-00016, "Operation of the Cask Handling Crane," Revision 21

Category: Crane Operation **Topic:** Qualification For Crane Operator

Reference: ASME B30.2, Sections 2-3.1.2 and 2-3.1.6 Published 1976

Requirement Qualification to operate a cab operated or remote operated crane, requires the operator to pass a written or oral examination and a practical operating examination specific to the type of crane to be operated unless able to furnish evidence of previous qualification and experience. In addition, the operator shall: a) have vision of at least 20/30 Snellon in one eye and 20/50 in the other with or without corrective lenses; b) be able to distinguish colors regardless of their position; c) have sufficient hearing capability for the specific operation with or without hearing aids; d) have sufficient strength, endurance, agility, coordination and reaction speed for the specific operation; e) have evidence of not having physical defects or emotional instability that would interfere with crane operation; and f) not be subject to seizures, loss of control, or dizziness.

Observation: NRC performed an onsite inspection of crane operator qualifications at the Callaway site on August 6, 2015. NRC inspectors reviewed the qualification documents while onsite and returned them to Callaway so that there were no problems with handling personally identifiable information (PII). NRC confirmed the qualifications of the crane operators at Callaway through its review of vertical cask transporter (VCT), HI-PORT, Overhead Crane, Cask Handling Crane Upgrade, and National Commission for the Certification of Crane Operator (NCCO) training course records, among others. All of the crane operators were verified as meeting the requirements listed in ASME B30.2, sections 2-3.1.2 and 2-3.1.6.

Documents Reviewed: a) Various personnel training records for crane operators at the Callaway site (PII)

Category: Crane Operations **Topic:** Maximum Weight of Canister

Reference: FSAR 1040, Section 9.0, Table 3.2.1 Revision 2

Requirement The maximum weight of the transfer cask containing the canister filled with water and fuel (including dynamic loads) that will be lifted by the crane is to be verified to be within the crane's rated capacity.

The handling weights for the Holtec storage system components are provided in Tables 3.2.1 of the FSAR. The user shall implement controls to ensure all critical set points (e.g., lift weights) do not exceed design limits of the specific equipment.

Observation: The licensee had verified that the weight of the Holtec storage system components would not exceed the rated load of the Callaway fuel building crane. Holtec Report No. HI-2146011, Table 7.2 documented the maximum lifted weight during the performance of a HI-STORM UMAX System, loaded at Callaway, would be during the removal of the HI-TRAC VW transfer cask from the spent fuel pool with the neutron water jacket full of water (Case 2 in Table 7.2). Case 2 of Table 7.2 showed a total lift weight of 247,088 pounds (123.5 tons), which was less than the 125-ton rating of the fuel building crane. The individual component weights shown in Table 7.2 were consistent with those in Holtec FSAR.

Documents Reviewed: a) Holtec Report Number HI-2146011, "Cask Handling Weights at Callaway," Revision 1; b) Holtec Report HI-2115090, "Final Safety Analysis Report (FSAR) on the HI-STORM UMAX Canister Storage System," Revision 2

Category: Crane Operations **Topic:** Provisions For Manual Operation

Reference: NUREG 0554, Sections 3.4; 4.9 Published May 1979

Requirement A crane that has been immobilized because of failure of controls or components while holding a critical load should be able to hold the load or set the load down while repairs or adjustments are made. This can be accomplished by inclusion of features that will permit manual operation of the hoisting system and the bridge and trolley transfer mechanisms by means of appropriate emergency devices.

Observation: The American Crane & Equipment Corporation supplied 125-ton single-failure proof crane for Callaway's fuel building included features that permitted manual operation of the hoisting system and the bridge and trolley transfer mechanisms. These features were tested on June 12, 2014 during the Callaway 100% site acceptance test of the crane per Procedure REP-21250-007. Callaway's Engineering group also developed a site procedure that could be utilized to manually lower a suspended load in the event of a crane malfunction. Callaway Procedure OTS-KE-00016, Attachments 4-6 contained steps to allow manual operation to lower a load, manually operate the bridge, and manually operate the trolley.

Category: Dry Run Demonstration **Topic:** Fuel Loading and Verification Demonstration

Reference: CoC 1040, Condition 8.c, d Amendment 0

Requirement The dry run shall include selection and verification of specific fuel assemblies to ensure type conformance and the loading of specific assemblies into the canister (using a dummy fuel assembly), including appropriate independent verification.

Observation: NRC inspectors observed fuel movement operations in the spent fuel pool (SFP) and assembly placement into multiple MPC slots during Callaway ISFSI dry-run #4 demonstration, August 4-6, 2015. Callaway fuel movers demonstrated the ability to access difficult to reach locations of the SFP and most restrictive areas of the MPC, as situated in the cask loading pit. A walk-through of how the independent verification process would be controlled was also demonstrated during the dry run. Fuel handlers at Callaway fully satisfied the CoC 1040 condition during this preoperational demonstration.

Documents Reviewed: a) Callaway Procedure OTS-KE-00012, "Spent Fuel Pool Bridge Crane," Revision 33

Category: Dry Run Demonstration **Topic:** MPC Pressure Test, Drying, and Helium Backfill

Reference: CoC 1040, Condition 8.f Amendment 0

Requirement The dry run shall include pressure testing, draining, moisture removal (by vacuum drying or forced helium dehydration, as applicable), and helium backfilling. A mockup may be used for this dry-run exercise.

Observation: NRC inspectors observed and documented MPC draining, pressure testing, force helium dehydration, and helium backfill activities during Holtec's second dry run demonstration at Callaway on June 2-4, 2015. A part-size mockup was used for these demonstrations, so the time that it took for operations was greatly abbreviated. Holtec successfully demonstrated pressure testing requirements of the MPC and met all of the required dryness and helium backfill levels just as would be required for a full-sized MPC with actual fuel loaded inside.

Documents Reviewed: a) Holtec Procedure HPP-2253-300, "MPC Sealing at Callaway," Revision 7

Category: Dry Run Demonstration **Topic:** MPC Removal from Spent Fuel Pool

Reference: CoC 1040, Condition 8.e Amendment 0

Requirement The dry run shall include remote installation of the canister lid and removal of the canister and transfer cask from the spent fuel pool or cask loading pool.

Observation: NRC inspectors observed the remote installation of the MPC lid and removal of the MPC and HI-TRAC transfer cask from the cask loading pit (inside the spent fuel pool) to the cask wash-down area of the fuel building. This activity was demonstrated during dry-run #4, August 4-6, 2015. The licensee utilized Procedure HPP-2253-200 to perform the dry run. Callaway fully satisfied this preoperational criteria in the Holtec UMAX Certificate of Compliance 1040.

Documents Reviewed: a) Holtec Procedure HPP-2253-200, "MPC Loading at Callaway," Revision 9

Category: Dry Run Demonstration **Topic:** MPC Transfer to UMAX

Reference: CoC 1040, Condition 8.g Amendment 0

Requirement The dry run shall include transfer cask of the MPC from the transfer cask to the UMAX VVM.

Observation: Callaway demonstrated MPC transfer operations to the UMAX VVM during dry run #3 on July 14-16, 2015. NRC inspectors verified successful transfer of a dummy MPC-37 canister to the UMAX VVM at Callaway. Holtec followed procedure HPP-2253-400.

Documents Reviewed: a) Holtec Procedure HPP-2253-400, "MPC Transfer at Callaway," Revision 6

Category: Dry Run Demonstration **Topic:** MPC Welding and NDE

Reference: CoC 1040, Condition 8.f Amendment 0

Requirement The dry run shall include canister welding and non-destructive examination (NDE) of the canister lid.

Observation: NRC inspectors observed MPC closure welding and the non-destructive testing operations (visual, liquid dye penetrant, and helium leak check) of those welds during the Holtec UMAX dry-run #1 on May 19-21, 2015. Holtec and its welding contractor PCI successfully demonstrated welding of the MPC closure lid to shell weld, port cap covers, and closure ring during its first dry run demonstration for NRC. In addition, NDE of those welds and helium leak testing operations were observed during this dry run. Callaway met this CoC 1040 requirement.

Documents Reviewed: a) PCI Project Instruction, PI-CNSTR-OP-CAL-H-01, "Closure Welding of Holtec Multi-Purpose Canisters - UMAX," Revision 0; b) PCI General Welding Standard - 1 (GWS-1), Revision 0; c) PCI General Quality Procedure, GQP-9.2, "High Temperature Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 8; d) PCI General Quality Procedure, GQP-9.7, "Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 11; e) PCI Procedure GQP-9.6, "Visual Examination of Welds," Revision 14

Category: Dry Run Demonstration **Topic:** Placement of MPC in Spent Fuel Pool

Reference: CoC 1040, Condition 8.a, b Amendment 0

Requirement The dry run shall include moving the MPC and the transfer cask into the spent fuel pool or cask loading pool and preparing the HI-STORM UMAX cask system for fuel loading.

Observation: NRC inspectors observed movement of the MPC and HI-TRAC transfer cask into the spent fuel pool cask loading pit during Callaway's ISFSI dry-run #4 demonstration, August 4-6, 2015. The licensee utilized Procedure HPP-2253-200 to perform the dry run. Callaway fully satisfied the Holtec UMAX CoC 1040 condition during this preoperational demonstration.

Documents Reviewed: a) Holtec Procedure HPP-2253-200, "MPC Loading at Callaway," Revision 9

Category: Dry Run Demonstration **Topic:** Unloading a Canister

Reference: CoC 1040, Condition 8.h Amendment 0

Requirement The dry run shall include HI-STORM UMAX system unloading, including flooding the canister cavity and removing canister lid welds. A mockup may be used for this dry-run exercise.

Observation: NRC observed the demonstration of reflooding of a simulated previously loaded MPC during the second dry-run demonstration at Callaway on June 2-4, 2015. Reflooding of the canister was demonstrated after the drying and backfill dry run was completed. Placement of the MPC and HI-TRAC transfer cask back into the spent fuel pool for unloading was demonstrated during the final dry-run on August 4-6, 2015. These operations were successfully demonstrated as part of Callaway's dry run activities leading up to the first loading during the week of August 24, 2015.

Callaway's contractor, Holtec, completed the MPC cutting dry run on July 16-18, 2015. Holtec performed the MPC lid to shell weld cutting dry run at Holtec Manufacturing Division (HMD) located in Turtle Creek, PA. Callaway personnel were in attendance for this dry run and performed oversight activities throughout the operations. NRC inspectors from headquarters also observed the cutting dry run. Holtec utilized Procedure HPP-2253-500 to perform the cutting demonstration. The cutting activities included boring through the cover plate and the MPC vent/drain port covers. Utilization of a cutting machine to remove the lid to shell weld, while purging the area under the lid with argon, monitoring for hydrogen during the duration of the cutting demonstration, and removal of the MPC lid after the cutting was successful. Ultimately, the ability to core bore through the closure ring and vent/drain port cover plates and cut the MPC lid to shell weld was demonstrated. As a result of the demonstration, a number of procedure enhancements to the implementing procedure HPP-2253-500 were documented on Callaway CAR 201501626, Action 7. In addition, a Holtec International Bulletin (HIB)/Lessons Learned addressing shim installation during lid placement prior to lid to shell welding was to be issued and was also documented on the same CAR. All procedure enhancements were successfully completed prior to Callaway's first loading campaign.

Category: Emergency Planning **Topic:** Emergency Drills

Reference: 10 CFR Part 50, App E, Section F.1 Published 2015

Requirement The emergency program shall provide for the training of employees and exercising, by periodic drills, of radiation emergency plans to ensure that employees are familiar with their specific emergency response duties.

Observation: No emergency drills had been conducted at the site, specific to the ISFSI. Training had been provided to site personnel on the new emergency action level scheme in April 2015, which included the emergency action levels for the ISFSI. Site personnel conducted drills annually related to plant operations that included all aspects of an emergency response that would be applicable to the ISFSI including fire, medical response, and

radiological drills.

Documents Reviewed: a) Callaway Plant Radiological Emergency Response Plan (RERP), Revision 46

Category: Emergency Planning **Topic:** ISFSI Emergency Plan

Reference: 10 CFR 72.32(c) Published 2015

Requirement For an ISFSI that is located on the site of a nuclear power plant licensed for operation, the emergency plan required by 10 CFR 50.47 shall be deemed to satisfy the requirements of this section.

Observation: The licensee was using their Part 50 emergency plan for the ISFSI. Radiological Emergency Response Plan, Table 4-1, "Emergency Action Level (EAL) Classification Matrix," had incorporated the ISFSI and identified an unusual event as the classification for a problem at the ISFSI. Procedure EIP-ZZ-00101, Addendum 2 had incorporated the ISFSI into the emergency action level scheme and identified damage to a loaded cask confinement boundary as the initiating event. This damage could come from different issues which included damage due to a dropped or tipped over cask, explosion at the ISFSI, projectile damage, fire damage, or natural phenomena affecting a cask would classify as an unusual event. Several other EALs could be related to the ISFSI. Due to the type of welded canisters in use, there were no specific EALs related to the ISFSI for radiological releases. However, the site area emergency classification could be reached if radiation levels offsite were measured in excess of 100 mrem. If the levels exceeded 1,000 mrem, a general emergency would be declared. These readings would be based on surveys taken in the field. For a security event, a hostile action in the owner controlled area was an alert. A hostile action within the protected area, including the ISFSI protected area, would be a site area emergency.

Category: Fire Protection **Topic:** Fire Accident Response

Reference: FSAR 1040, Section 12.2.1.3 Revision 2

Requirement Upon detection of a fire adjacent to a loaded HI-STORM UMAX VVM, the ISFSI owner shall take the appropriate immediate actions necessary to extinguish the fire. Following the termination of the fire, a visual and radiological inspection of the equipment shall be performed.

Observation: The NRC inspectors reviewed the licensee's prefire plan and associated strategies and fire response procedure. The inspectors found that the immediate response actions by the fire brigade were incorporated into the prefire plan for the ISFSI pad. If a fire occurred on the heavy haul path, procedure HPP-2253-400, Attachment 8.10 required a continuous attendant equipped with a fire extinguisher who could respond. If that individual could not handle the fire, the fire brigade would be available to respond and have been trained on possible ISFSI transport fires since the ISFSI heavy haul path and pad were entirely within the reactor protected area.

Procedure FPP-ZZ-00007 required a visual and radiological inspection after a fire. There were additional requirements in the Holtec FSAR for actions to take after a fire that were not documented in a site procedure. This observation was captured in CAR 201501626 and the licensee performed a revision to OTO-KC-00001 that incorporated the required actions discussed in the FSAR. The inspectors reviewed the revised procedure and verified the FSAR requirements were adequately incorporated.

The inspectors also reviewed the licensee's EALs and determined that the site did classify a fire associated with the ISFSI causing confinement boundary damage as an Unusual Event.

Category: Fire Protection **Topic:** Fire and Explosion Hazards Analysis

Reference: CoC 1040, App. B.3.4.5; FSAR 1040, Sect 2.2.3.3 Amendment 0/Revision 2

Requirement The potential for fire or explosion shall be addressed, based on site specific considerations. This includes the condition that the onsite transporter fuel tank will contain no more than 50-gallons of diesel fuel while handling a loaded storage cask or transfer cask.

Observation: Explosion hazards were analyzed along the haul path and near the ISFSI in Holtec Report HI-2146196. They included hydrogen tanks and lines, gasoline tanks, and hydrogen delivery trucks since they were adequately determined to be the credible explosion hazards. The assumptions used for explosive hazards in the fire hazards analysis appeared reasonable. No credible explosion hazard exceeded the overpressure needed to tip over the HI-TRAC VW during transport operations or the structural limits of the closure lid for the HI-STORM UMAX at the ISFSI. The fire hazards analysis determined the minimum distance from the ISFSI pad and maximum amount for the hydrogen deliveries that the site had incorporated into procedures to ensure the explosion analysis remained bounding. Since the hydrogen deliveries were not analyzed during transfer using the HI-TRAC VW, the licensee incorporated procedural steps in HPP-2253-400 to stop all hydrogen deliveries during transport operations.

Fire hazards were also analyzed along the haul path and near the ISFSI in Holtec Report HI-2146196. They included diesel tanks and pipes, lube oil tanks and equipment, transformers, gasoline tanks, hydrogen tanks and pipes, delivery trucks of flammable liquids, and Class A flammable materials. The assumptions used for fire hazards in the fire hazards analysis appeared reasonable except that a few buildings near the ISFSI pad did not appear to have been evaluated. These buildings were identified during the NRC inspectors' walk down of the haul path. As a result, the licensee evaluated those buildings and found that they were bounded by other fires in the analysis. No credible fire hazard was found to exceed the acceptable heat input to either the HI-TRAC VW or HI-STORM UMAX closure lid. The fire hazards analysis determined the minimum distance from the ISFSI pad and maximum amount for the flammable liquid deliveries

that the site had incorporated into procedures to ensure the fire analysis remained bounding. Since the flammable liquid deliveries were not analyzed for the HI-TRAC on the haul path, the licensee will stop all flammable liquid deliveries during transport operations. The requirement to ensure no deliveries are made during transport operations was verified to be incorporated into site procedures. It is also important to note that the ISFSI pad area was designated as a combustible free zone in site procedures to ensure the analysis remains bounding.

During the review of the 72.212 report, the inspectors reviewed the licensee's analysis of the worst case fire during transport operations to determine whether it was bounded by the analyzed fire in the HI-STORM UMAX FSAR of 50 gallons of diesel fuel from the cask transporter. A piece of equipment named the HI-PORT was used at Callaway to transport the HI-TRAC out of the fuel handling building. Once out of the building, the VCT engaged the HI-TRAC to transport it to the ISFSI pad. The most limiting scenario was when the HI-PORT and VCT were together while the HI-TRAC was being engaged by the VCT. This operation also included the use of an Articulating Boom Lift next to the HI-PORT and VCT. This combined fire hazard included 50 gallons of diesel fuel and 380 gallons of hydraulic fluid from the VCT; 50 gallons of diesel fuel, 130 gallons of hydraulic fluid, and 48 tires with rubber and polyurethane elastomer from the HI-PORT; and a relatively small amount of hydraulic fluid from the boom lift. This fire loading exceeded that of the HI-STORM UMAX FSAR and was specifically evaluated in Holtec Report HI-2156590, "Evaluation of Combined Effect of HI-PORT and VCT Fires on HI-TRAC at Callaway." The evaluation determined that the fuel temperature, MPC component temperatures, and MPC cavity pressure remained well below their limits and the combined fire event did not exceed any FSAR fire accident acceptance criteria. The inspectors determined that the assumptions in the evaluation were reasonable. The inspectors then reviewed the licensee's controls during this operation that would ensure the analysis would remain bounding but did not find it specifically discussed in the applicable procedures. Due to this observation, the licensee updated the procedures to ensure this operation occurred as evaluated and the inspectors verified the revision change to the procedure was adequate. In addition, the inspectors requested the licensee to provide the 72.48 evaluation, since the site-specific fire hazard exceeded what was analyzed in the FSAR. The licensee provided the 72.48 evaluation, which determined this activity did not require NRC prior review and approval. The inspectors found that the 72.48 evaluation was performed adequately.

The inspectors reviewed the Hazards Walkdown Checklist in procedure HPP-2253-400 and performed a walk down of the haul path to ensure adequate controls were in place to limit combustibles along the haul path and all fire and explosion hazards were analyzed. Only the buildings that could contain Class A combustibles or flammable liquids discussed above were found not to have been analyzed, but were ultimately determined to be bounded by other more limiting fire hazards. The inspectors discussed a number of observations with the licensee to clarify and improve the checklist, which were incorporated into a revision of the checklist and associated procedure. The checklist ensured, among other things, that transient combustibles were controlled to adequate distances from the haul route, all "Hot Work" activities near the haul path were suspended, sufficient fire protection equipment was available along the haul route, and there were no fire protection impairments related to the equipment needed to respond to

fires along the haul route or at the ISFSI pad during transportation operations.

Category: Fire Protection **Topic:** Fire Protection Plan

Reference: 10 CFR 50.48(a)(1) Published 2015

Requirement Each operating nuclear power plant must have a fire protection plan that satisfies Criterion 3 of Appendix A to Part 50. This fire protection plan must describe the overall fire protection program for the facility.

Observation: Callaway had incorporated the ISFSI into the applicable fire protection procedures and program documents to ensure it was adequately protected. This included 1) control of combustibles in the vicinity of the ISFSI pad, 2) that transient combustibles were evaluated near the ISFSI, 3) site modifications took into account fire hazards to the ISFSI, 4) delivery of combustible and explosive materials was suspended during cask transport operations, and 5) the quantities of combustible and explosive materials delivered during storage operations were within the limits specified in the site specific fire hazards analysis and Holtec FSAR.

Category: Fuel Selection/Verification **Topic:** Authorized Contents For Storage

Reference: CoC 1040, Appendix B, Section 2.1.1 Amendment 0

Requirement The HI-STORM UMAX system and MPC-37 is authorized for storage of fuel assemblies, fuel debris, and non-fuel hardware meeting the requirements of Appendix B, Section 2.1.1 and Tables 2.1-1 through 2.1-3.

Observation: The licensee had adequately incorporated the authorized contents for storage requirements into their site procedures. For the initial campaign, the licensee planned to limit loading to intact fuel elements only. No damaged fuel would be loaded for dry storage per the acceptance criteria of Section 3.0 of ETP-ZZ-04020. Section 5.4 of the document provided limits for Callaway storage. Page 165 presented limits for comparison with those of Table 2.1-1 through 2.1-3 of the Certificate of Compliance. Other limits in agreement with the CoC were specified in Section 5.1, Precautions and Limitations, which presented limits on MWD/MTU, heat load per cell, cladding type, maximum initial enrichment, post irradiation cooling time, fuel assembly length and width and weight. Section 5.5 of the procedure documented compliance with Note 1 of

Table 2.1-1 of the CoC. The first canister's fuel assemblies information was reviewed by NRC inspectors and was found to meet requirements of Appendix B, Section 2.1.1 and Tables 2.1-1 through 2.1-3.

Documents Reviewed: a) Callaway Procedure ETP-ZZ-04020, "Fuel Selection and Cask Loading for Dry Cask Storage," Revision 0

Category: Fuel Selection/Verification **Topic:** Damaged Fuel Classification

Reference: FSAR 1040, Glossary; ISG-1, Rev. 2 Revision 2

Requirement A damaged fuel assembly is a fuel assembly with known or suspected cladding defects, as determined by review of records, greater than pinhole leaks or hairline cracks, empty fuel rod locations that are not replaced with dummy fuel rods, missing structural components such as grid spacers, whose structural integrity has been impaired such that geometric rearrangement of fuel or gross failure of the cladding is expected based on engineering evaluations, or those that cannot be handled by normal means. Fuel assemblies that cannot be handled by normal means due to fuel cladding damage are considered fuel debris.

Observation: The licensee adequately implemented the damage fuel classification. Damaged fuel was defined in Section 5.4.7 of ETP-ZZ-04020. The section stated that damaged fuel assemblies were those with known or suspected cladding defects, as determined by a review of records, greater than pinhole leaks or hairline cracks, empty fuel rod locations that are not filled with dummy fuel rods, missing structural components such as grid spacers, whose structural integrity had been impaired such that geometric rearrangement of fuel or gross failure of the cladding was expected based on engineering evaluations or that cannot be handled by normal means. Fuel assemblies that cannot be handled by normal means due to fuel failure were considered fuel debris.

Category: Fuel Selection/Verification **Topic:** Decay Heat, Burnup & Cooling Time Limits

Reference: CoC 1040, App. B Table 2.1-1, Table 2.3-1 Amendment 0

Requirement Fuel assemblies stored in the HI-STORM UMAX system canister must meet the decay heat, burnup and cooling time limits specified in Appendix B, Table 2.1-1 and Table 2.3-1 of the Certificate of Compliance.

Observation: Callaway Procedure ETP-ZZ-04020, incorporated the decay heat, burnup, and cooling time requirements from the Certificate of Compliance (Appendix B. 2.1 and 2.3 of CoC). Section 5.1 of the Procedure, outlined precautions and limitations for assemblies to be placed in dry cask storage. It was recognized in the procedure that no damaged fuel is to be loaded at this time. In addition, requirements for assembly burnup and heat load per cell limits agreed with limits established in the CoC. Section 5.4 of the procedure, outlined that only fuel assemblies meeting specific limits are approved for storage. Criteria outlined in Section 5.4 for cladding type (Zr), maximum initial enrichment (5 wt %), post irradiation cooling time (equal to or greater than 3 years), fuel assembly width (equal to or less than 8.54 inches) and fuel assembly weight (equal to or

less than 2050 pounds) are identical to those presented in Table 2.1-1 of the CoC. Acceptance criteria for fuel assembly length of equal to or greater than 114 inches and equal to or less than 168 inches compared with the CoC limit of equal to or less than 199.2 inches. Fuel assembly decay heat values were determined utilizing the Caskloader computer code developed by the Electrical Power Research Institute (EPRI) to assist utilities in the planning, preparation, and execution of loading spent fuel assemblies and core components into dry fuel storage casks. Calculations for regional loading were made by the licensee to comply with Appendix B Section 2.3, Table 2.3-1, utilizing Append B Figure 2.3-1. Non-fuel hardware decay heat values were utilized for particular storage locations.

Documents Reviewed: a) Callaway Procedure ETP-ZZ-04020, "Fuel Selection and Cask Loading for Dry Cask Storage," Revision 0

Category: Fuel Selection/Verification **Topic:** Fuel Loading Error

Reference: CoC 1040, Appendix B, Section 2.2 Amendment 0

Requirement If any loading condition of Appendix B, Section 2.1 is violated, the affected fuel assemblies shall be placed in a safe condition, the NRC Operations Center shall be notified within 24 hrs, and a special report describing the cause of the violation and actions taken to restore compliance and to prevent recurrence shall be submitted to the NRC within 30 days.

Observation: The licensee had requirements in their procedure that noted, if any loading condition is violated, the affected assemblies should be placed in a safe condition and notifications made. Attachment 1 of the APA-ZZ-00520 specified on Item 7, sheet 14 of 24 in sub-item, that the NRC Operation Center will be notified initially within 24 hours if any of the Fuel Specifications or Loading Conditions in Section 2.1 of the HI-STORM UMAX CoC, Appendix B were violated. Sheets 17 and 18 noted that a follow-up notification in the form of a special written report was required within 30 days of initial notification. The report was required to describe the cause of the violation and actions taken to restore compliance and prevent reoccurrence.

Documents Reviewed: a) Callaway Procedure APA-ZZ-00520, "Reporting Requirements and Responsibilities," Revision 44

Category: Fuel Selection/Verification **Topic:** Fuel Shims

Reference: FSAR 1032 Section 1.2.1.1 Revision 3

Requirement The actual length of fuel shims (if required) will be determined on a site-specific and fuel assembly-specific basis.

Observation: Callaway had implemented provisions to ensure adequate shims were installed into the MPCs prior to loading the canisters. Fuel shims were utilized to vertically position fuel assemblies in the canister to ensure the gap between the MPC lid and the top of the fuel insert, or top nozzle of the assembly (with no insert), met the analyzed limits of 1.5 to 2.5 inches. Axial clearance was provided to account for manufacturing tolerances and the irradiation and thermal growth of fuel assemblies. Actual length of the fuel shims were determined based of site-specific and fuel assembly specific bases. Section 7.0 of

the procedure ETP-ZZ-0420 provided the applicable instructions. Step 7.3.2 stated that the licensee must ensure that the specified MPC had been loaded with fuel spacers appropriate for the insert type. Step 7.6.2 noted that the full down position of fuel assemblies will vary based on the insert type (No insert, RCCA, or BP/TP/NSA).

Documents Reviewed: a) Callaway Procedure ETP-ZZ-0420, "Fuel Selection and Cask Loading for Dry Cask Storage," Revision 0

Category: Fuel Selection/Verification **Topic:** Material Balance, Inventory, and Records

Reference: 10 CFR 72.72(a) Published 2015

Requirement Each licensee shall keep records showing the receipt, inventory (including location), disposal, acquisition, and transfer of all SNM with quantities specified in 10 CFR 74.13(a)(1).

Observation: The licensee's Special Nuclear Material (SNM) accountability plan was revised to include fuel transferred from the spent fuel pool to Callaway's ISFSI. Details of the SNM accountability plan were presented in Procedure APA-ZZ-00405. A new Item Control Area was created for the ISFSI in Revision 28 of the procedure.

Category: Fuel Selection/Verification **Topic:** Post Loading Verification

Reference: FSAR 1032, Section 9.2.3.3 Revision 3

Requirement Perform a post-loading visual verification of the assembly identification markings to confirm that the serial numbers match the approved fuel loading pattern.

Observation: The licensee's procedures had incorporated the requirement to perform an independent post-loading visual verification to confirm that the fuel assembly serial numbers matched the loading plan. The post verification requirement was specified in step 7.10 of ETP-ZZ-04020. NRC inspectors observed the licensee perform the post loading verification, utilizing an underwater camera on the first canister loaded during the week of August 24, 2015.

Documents Reviewed: a) Callaway Procedure ETP-ZZ-04020, "Fuel Selection and Cask Loading For Dry Cask Storage," Revision 0

Category: General License **Topic:** Evaluation of Effluents/Direct Radiation

Reference: 10 CFR 72.212(b)(5)(iii) & 10 CFR 72.104(a) Published 2015

Requirement The general licensee shall perform a written evaluation prior to use that establishes that the requirements of 10 CFR 72.104 "Criteria for Radioactive Materials in Effluents and Direct Radiation from an ISFSI" have been met. 10 CFR 72.104 requires the annual dose equivalent to any real individual who is located beyond the controlled area must not exceed 25 mrem to the whole body, 75 mrem to the thyroid and 25 mrem to any other critical organ during normal operations and anticipated occurrences,

Observation: The licensee performed an evaluation to ensure that the requirements of 10 CFR 72.104,

Criteria for Radioactive Materials in Effluents and Direct Radiation from an ISFSI and showed in Section 5.3 of the 72.212 Report, that the dose equivalent to any individual who is located outside the controlled area was a small fraction of the regulatory limits of 25 mrem to the whole body, 75 mrem to the thyroid, and 25 mrem to any other critical organ. No effluent doses, including thyroid doses, would occur with the welded and sealed Holtec canisters used by the Callaway Energy Center. Though there was not a berm on all sides of the ISFSI, for flood control purposes there were berms on two sides, plant south and plant east that contribute to shielding of direct radiation. Further discussion of calculations associated with the doses to the public are provided under the Category: Radiation Protection and the Topic: Controlled Area Boundary Dose Rate Analysis.

Documents Reviewed: a) 10 CFR 72.212 Evaluation Report, "Callaway Plant, Unit 1, Dry Fuel Storage System for Spent Nuclear Fuel Docket 72-1045," Revision 0; b) Callaway Procedure HPCI-15-05, "Evaluation of Direct Radiation Dose to the Member of the Public from the Independent Spent Fuel Storage Installation," Revision 1

Category: General License **Topic:** Flood Conditions

Reference: CoC 1040, Appendix B, Section 3.4.4 Amendment 0

Requirement Verify that the site analysis for flooding does not exceed the Certificate of Compliance limits of 15 fps water velocity and a height of 125 feet of water.

Observation: The UMAX at the Callaway site was evaluated and verified to not exceed the Certificate of Compliance limits for 15 fps velocity of water and a height of 125 feet of water. Section 5.4.1.3 of the 72.212 Evaluation Report documented that all of Callaway's plant safety-related structures and components are located on a plateau 280 feet or more above maximum flood level. The site is higher than the surrounding terrain so natural streams drain away from the plateau so that isolated local flooding will not occur as a result of a probable maximum precipitation event. The GEI calculation CEC-CS 006-01, concluded that the peak water surface elevations resulting from local intense precipitation event does not exceed critical elevations for the Callaway ISFSI site. Section 5.4.1.7 of the 72.212 Evaluation Report, noted that the ISFSI site is located on a slight plateau with no significantly higher ground within five miles of the site.

The HI-STORM UMAX System is flood resistant as discussed in Section 2.4.7 of the UMAX FSAR. Licensee documents noted that the VVM will withstand a hydraulic head of 125 feet of water submergence. Full or partial submergence of the MPC is not of concern as heat removal is enhanced by the presence of water.

Documents Reviewed: a) 10 CFR 72.212 Evaluation Report, "Callaway Plant, Unit 1, Dry Fuel Storage System for Spent Nuclear Fuel Docket 72-1045," Revision 0; b) Consultant Calculation GEI, CEC-CS 006-01, "Callaway Site Evaluation," Revision 0

Category: General License **Topic:** Initial Compliance Evaluation Against CoC

Reference: 10 CFR 72.212(b)(5) Published 2015

Requirement A general licensee shall perform written evaluations, prior to use and before applying the changes authorized by an amended Certificate of Compliance to a cask loaded under the

initial Certificate of Compliance or an earlier amended Certificate of Compliance, which establishes that the cask, once loaded with spent fuel or once the changes authorized by an amended Certificate of Compliance have been applied, will conform to the terms, conditions, and specifications of the Certificate of Compliance or amended Certificate of Compliance listed in 10 CFR 72.214.

Observation: The Callaway 72.212 Evaluation Report evaluated the terms, conditions and specifications in Certificate of Compliance 1040, Amendment 0, and documented that the conditions as set forth had been met at the Callaway site. Section 5.1 of the 72.212 Evaluation Report, provided a detailed comparison of the requirements in the Certificate of Compliance against the procedures and programs established at Callaway. The licensee used a combination of already existing Part 50 programs and procedures and newly developed procedures specifically for the ISFSI.

Vertical Ventilated Modules (VVMs) having a cavity enclosure container (CEC), a cavity enclosure divider shell, a VVM Closure lid, the HI-TRAC VW transfer cask, and the MPC-37 were to be used, at Callaway, to transport and store the pressurized water reactor spent fuel. The MPC-37 canister holds 37 spent fuel assemblies.

Appendix 1 of the 72.212 Evaluation Report provided a detailed list of each of the licensing conditions in the Certificate of Compliance, the technical specifications in Appendix A of the CoC, and the approved contents and design requirements in Appendix B of the CoC and how Callaway complied with these licensing requirements.

License Condition 1 required the licensee to develop written operating procedures for cask handling, loading, movement, surveillance, and maintenance that are consistent with the UMAX FSAR description of these activities. The licensee had developed "pool-to-pad" and other operating procedures that cover all the activities in License Condition 1.

License Condition 2 required that written cask acceptance tests and a maintenance program be established which is consistent with the technical basis in the UMAX FSAR. Compliance with License Condition 2 was demonstrated through Holtec Component Completion Records and CoC's issued for important to safety structures, systems, and components. The required procedures involving Acceptance Criteria and the Maintenance Program for Callaway dry fuel storage operations had been prepared, revised, and issued as necessary.

License Condition 3 required that activities being performed related to structures, systems, and components designated as important to safety be conducted under an NRC approved quality assurance program. Callaway was using their Part 50 approved program for Part 72 activities.

License Condition 4 required that each lift of an MPC or a HI-TRAC VW transfer cask be performed in accordance with existing heavy load requirements and procedures of the licensed facility. Lifts within the Callaway Fuel Building and made by the single failure proof crane were governed by 10 CFR Part 50. Dry Fuel Storage lifts were conducted in accordance with existing heavy loads Procedure APA-ZZ-00365 and other new Dry Fuel Storage heavy load handling procedures which met existing heavy load requirements.

License Condition 5 required that the fuel loaded in the MPC-37 meet the required fuel specification in Appendix B of the Certificate of Compliance 1040. During the NRC inspection, a detailed review of the licensee's program related to fuel selection was completed to verify that processes and procedures had been put in place by the licensee to ensure that only spent fuel consistent with Appendix B of CoC 1040 would be selected for storage. More detail related to selection of the spent fuel is found in the Inspector Notes of this report under the Category "Fuel Selection and Verification."

License Condition 6 required that features and characteristics for the site or system must be in accordance with Appendix B of the CoC. A discussion of each of the design features in Appendix B were discussed in Appendix 1, Table 3 of the 72.212 Evaluation Report. References were often provided to various Callaway procedures and documents to show compliance with the design features listed in Appendix B.

License Condition 7 discussed making changes to the Certificate of Compliance. Only Holtec can make requests to the NRC to change CoC 1040, since they were the certificate holder. Callaway was a general licensee, and therefore cannot make any change requests directly to the NRC.

License Condition 8 lists the required pre-operational testing and training exercises for the UMAX system prior to the first actual use of the storage system. Callaway had completed all the required testing and training exercises. Details related to each of these can be found in the Inspector Notes of this inspection report under the Category "Dry Run Demonstration."

License Condition 9 authorized use of the Holtec HI-STORM UMAX Canister Storage System as a general license if the user possessed a Part 50 license. Callaway will use the UMAX system as a general license licensee and currently holds a Part 50 reactor license for the single unit Callaway Plant under Docket Number 50-483.

The 72.212 Evaluation Report, Appendix 1, Table 2, CoC Appendix A – Technical Specifications evaluated the requirements of the Callaway dry fuel storage program against the technical specifications in Appendix A of the Holtec 1040 license. Each of the technical specification requirements in the CoC, Appendix A were evaluated. Table 2 addressed and discussed each of the technical specification requirements and when required, referenced where the requirement had been incorporated into the Callaway procedures.

The requirements in the CoC, Appendix B for the approved content and design features were compared to the Callaway dry fuel storage program and documented in the 72.212 Evaluation Report, Appendix 1, Table 3, CoC Appendix B – Approved Contents and Design Features. Each of the applicable requirements from Appendix B of the CoC were shown to be incorporated into Callaway procedures or, for site conditions that were required to be met, Callaway had performed the necessary analysis to show compliance and referenced the analysis document in the table. Many of the table sections also referenced back to specific sections of the main body of the 72.212 Evaluation Report.

Documents Reviewed: a) Callaway Plant Updated Final Safety Analysis Report (UFSAR), The Callaway UFSAR has two parts, the UFSAR-SP for the Standard Plant and the UFSAR-SA for the Site Addendum, Dated February 2014; b) 10 CFR 72.212 Evaluation Report, "Callaway Plant, Unit 1, Dry Fuel Storage for Spent Nuclear Fuel," Revision 0; c) Certificate of Compliance 1040, "Holtec International HI-STORM UMAX Canister Storage System," Amendment 0; d) Holtec Report No. HI-2115090, "Final Safety Analysis Report for the HI-STORM UMAX Canister Storage System," Revision 2; e) Callaway Letter to NRC UNLNRC-06180 Subject: Notification Pursuant to 10 CFR 72.140(d) of Intent to Apply Previously Approved Quality Assurance Program to Independent Spent Fuel Storage Installation (ISFSI) at Callaway Plant, Unit 1, dated February 13, 2015

Category: General License **Topic:** Initial Compliance Evaluation Against FSAR

Reference: 10 CFR 72.212(b)(6) Published 2015

Requirement The general licensee shall review the FSAR referenced in the Certificate of Compliance or amended Certificate of Compliance and the related NRC Safety Evaluation Report, prior to use of the general license, to determine whether or not the reactor site parameters, including analysis of earthquake intensity and tornado missiles, are enveloped by the cask design basis considered in these reports. The results of this review must be documented in the evaluation made in 10 CFR 72.212(b)(5).

Observation: The licensee documented the required written evaluations in the 72.212 Evaluation Report as Section 5.4, "10 CFR 72.212(b)(6) Reactor Site Parameters Review of UMAX FSAR and SER." Section 5.4 included site specific analysis of fires and explosions, tornados, floods, hurricanes and extreme winds, earthquakes, lightning, burial under debris, environmental temperatures, and snow/ice. Each topical area was reviewed against the Callaway Updated Final Safety Analysis Report (UFSAR) or other site specific documents. The licensee found that they were bounded by the UMAX FSAR in all areas except for fire, explosions, and tornados. As such, Callaway performed a 72.48 evaluation and additional calculations to show the design basis for each area was still met and did not require Callaway to have the Certificate holder to request a license amendment (See Topic Safety Reviews).

Section 5.2.2 of the 72.212 report documented the review of the ISFSI stability including seismic evaluations. The ISFSI stability was evaluated by examining the liquefaction potential, settlement, bearing capacity, and potential for sliding and overturning. The design base earthquake event for the Callaway site was evaluated to not create an issue with MPC retreivability, subcriticality, and the confinement boundary would not be compromised. Callaway Part 50 UFSAR Figure 3.7(B)-1 and Figure 3.7(B)-2 described the design basis earthquake of the Callaway site as a horizontal and vertical zero period accelerations (ZPAs) of 0.20g for both directions. The ground surface horizontal and vertical ZPA used to seismically analyze the UMAX structure in Section 3.4.4.1.2 of the HI-STORM UMAX FSAR ranged from values of 0.539g to 1.008g, with peak accelerations up to 4.040g. Callaway's design basis earthquake was bounded by the UMAX design basis by a considerable margin.

NRC inspectors reviewed the Callaway's 72.212 evaluation report and supplemental evaluations which demonstrated the site parameters for all environmental conditions

analyzed were enveloped by the HI-STORM UMAX system design bases. No findings or issues were identified during this review.

Documents Reviewed: a) 72.48 Evaluation Log No. 15-01, "MP 14-0014, Dry Fuel Storage Licensing and Operations Documentation," Revision 0; b) Holtec Report HI-2146196, "Evaluation of Plant Hazards at Callaway Energy Center," Revisions 2, 3, and 4; c) Holtec Report HI-2156590, "Evaluation of Combined Effect of HI-PORT and VCT Fires on HI-TRAC at Callaway," Revisions 0 and 1; d) Holtec Report HI-2135677, "Evaluation of Effects of Tracked VCT Fire on HI-STORM FW System," Revision 5; e) 10 CFR 72.212 Evaluation Report, "Callaway Plant, Unit 1, Dry Fuel Storage System for Spent Nuclear Fuel Docket 72-1045," Revision 0

Category: General License **Topic:** Initial Evaluation Against Part 50 License

Reference: 10 CFR 72.212(b)(8) Published 2015

Requirement Prior to use of the general license, determine whether activities related to storage of spent fuel involve a change in the facility technical specifications or require a license amendment for the facility pursuant to 10 CFR 50.59(c). Results of this determination must be documented in the evaluation made in 10 CFR 72.212(b)(8).

Observation: Activities related to the storage of spent fuel under the Callaway 10 CFR Part 72 general license were reviewed in accordance with 10 CFR 50.59 for the required modifications and procedure changes, and none of these reviews resulted in NRC approval being required. Callaway developed Modification Package MP14-0014, Dry Fuel Storage Licensing and Operations Documentation to assess and authorize the dry fuel storage operations at Callaway Unit 1. The purpose of MP 14-0014 was to address all operations for loading spent fuel assemblies into an MPC, drying and sealing of the MPC, transport of the loaded transfer cask to the Callaway UMAX ISFSI, transfer of the loaded MPC from the transfer cask into the UMAX, storage of the spent fuel in the UMAX system at Callaway, and all unloading operations. Other modification packages required for ISFSI implementation, including Callaway ISFSI installation, haul path construction, security modifications, and upgrade of the cask handling crane in the fuel building were located in different modification packages that were listed in Table 5.5 of Callaway 72.212 Evaluation Report. NRC inspectors reviewed many of listed modification packages throughout the construction of the ISFSI, dry run inspections, and first loading inspection. No findings were identified regarding Callaway's 50.59 reviews.

Documents Reviewed: a) 10 CFR 72.212 Evaluation Report, "Callaway Plant, Unit 1, Dry Fuel Storage for Spent Nuclear Fuel," Revision 0; b) 50.59 Screen MP14-0014, "Dry Fuel Storage Licensing and Operations Documentation," Revision 0

Category: General License **Topic:** ISFSI Decommissioning Funding Report

Reference: 10 CFR 72.30 (b) Published 2015

Requirement Each licensee must submit for NRC review and approval a decommissioning funding plan prior to loading fuel into an ISFSI.

Observation: Callaway provided their draft letter to the NRC inspectors for the ISFSI Decommissioning Funding Report to be submitted to the NRC before their initial loading

campaign. CAR 201306666 was tracking this submission with a due date before the initial load commenced. The funding plan letter was ultimately submitted prior to the first loading campaign to the NRC on August 17, 2015 (ML15229A127).

Documents Reviewed: a) Letter from Callaway to NRC, "Docket Numbers 50-483 and 72-1045 Callaway Plant Unit 1 Union Electric Co. Renewed Facility Operating License NPF-30, ISFSI Decommissioning Funding Plan," Dated August 17, 2015 (ML15229A127); b) Draft 10 CFR 72.30 ISFSI Decommissioning Cost Estimate

---

Category: General License **Topic:** Limiting Site Temperatures

Reference: CoC 1040, Appendix B, Section 3.4.1; 3.4.2 Amendment 0

Requirement The maximum average yearly temperature at the site shall be verified as 80 degrees F. The temperature extremes, averaged over a 3-day period, shall be greater than -40 degrees F and less than 125 degrees F.

Observation: The Callaway site is below the maximum average yearly temperature of 80 degree F and within the -40 to 125 degree F temperature extremes, averaged over any 3-day period. The Callaway UFSAR-SA (Site Addendum), Section 2.3.2.1.2.2, "On-Site Temperatures," stated that the annual average temperature in the site area was approximately 55.6°F, and was therefore enveloped by the HI-STORM UMAX Canister Storage System design basis. Table 2.3.6 of the HI-STORM UMAX FSAR specified a design basis normal soil temperature (bounding annual average) not to exceed 77°F. Chapter 11, Page 11.10 of the 2008 ASHRAE Handbook - HVAC Systems and Equipment (Reference f), stated that the average annual air temperature should be used to approximate the average annual soil temperature. As stated above, the annual average air temperature at the Callaway site was approximately 55.6°F, which was less than the 77°F requirement specified in the HI-STORM UMAX FSAR for annual average soil temperature.

The lower bound off-normal temperature limit for the HI-STORM UMAX in the HI-STORM UMAX FSAR, Table 2.3.6, was defined as a 3-day average minimum ambient temperature of -40°F. Callaway UFSAR-SA, Table 2.3-23, showed a lowest extreme minimum temperature of -26°F. Therefore, the Callaway minimum temperature met the -40°F 3-day average minimum design basis temperature limit in the HI-STORM UMAX FSAR.

Table 2.3-22 of the Callaway UFSAR-SA showed 116°F as the highest extreme maximum temperature. This was bounded by the extreme accident level ambient temperature limit of 125°F for which the HI-STORM UMAX VVM was designed.

Documents Reviewed: a) Holtec Report No. HI-2115090, "Final Safety Analysis Report on the HI-STORM UMAX Canister Storage System (HI-STORM UMAX FSAR), Docket 72-1040," Revision 2; b) Callaway Plant Updated Final Safety Analysis Report (UFSAR), The Callaway UFSAR has two parts, the UFSAR-SP for the Standard Plant and the UFSAR-SA for the Site Addendum, dated February 2014; c) Holtec Procedure, HPP-2253-400 "MPC Transfer at Callaway," Revision 2; d) Holtec Procedure HPP-2253-500, "MPC Unloading at Callaway," Revision 1; e) Certificate of Compliance 1040 HI-STORM UMAX Appendix B Section 3.4.1 and 3.4.2, Amendment 0; f) ASHRAE Handbook,

Category: General License **Topic:** Program Review - RP, EP, QA, and Training

Reference: 10 CFR 72.212(b)(10) Published 2015

Requirement The general licensee shall review the reactor emergency plan, quality assurance program, training program, and radiation protection program to determine if their effectiveness is decreased and, if so, prepare the necessary changes and seek and obtain the necessary approvals.

Observation: The Callaway Part 50 emergency plan, quality assurance program, training program, and radiation protection program were evaluated for any potential decreases in their effectiveness associated with the implementation of the dry fuel storage operations and equipment. Callaway had revised the Callaway Part 50 Radiological Emergency Response Plan consistent with NEI-99-01, Methodology for Developing Emergency Action Levels. A new ISFSI Emergency Action Level had been incorporated into their emergency program and implementing procedures. Callaway had revised their 10 CFR 50 Appendix B Operating Quality Assurance Manual to include dry fuel storage activities in accordance with 10 CFR 72. Callaway had applied their Training Program, the associated appendices, and training manuals to dry fuel storage activities. Callaway training program relied on Holtec's approved training program for training on pool-to-pad procedures and operations. The remaining training areas, such as, fuel handling, 72.48 reviews, ISFSI quality assurance, ISFSI emergency plan, ISFSI routine Technical Specification surveillances, and ISFSI maintenance of important-to-safety equipment would be implemented under the Callaway training program.

Callaway reviewed and revised the Callaway Radiation Protection Program and implementing procedures to verify it applies to and adequately controls ISFSI and dry fuel storage activities. Existing procedures had been reviewed and revised to ensure posting requirements, access control, survey requirements, and personnel and environmental monitoring are applied to ISFSI activities consistent with 10 CFR Part 20 and Part 72 requirements. Additionally, numerous new ISFSI radiation protection procedures were developed to implement specific dry fuel storage radiological requirements.

Documents Reviewed: a) 10 CFR 72.212 Evaluation Report, "Callaway Plant, Unit 1, Dry Fuel Storage for Spent Nuclear Fuel," Revision 0; b) Callaway Plant 10 CFR 50.47 Radiological Emergency Response Plan, Revision 46; c) Callaway 10 CFR 50 Appendix B Operating Quality Assurance Manual (OQAM), Revision 31; d) Callaway Procedure APA-ZZ-00925, "Training and Qualification of Plant Personnel," dated 2015

Category: General License **Topic:** Revisions to 72.212 Analysis

Reference: 10 CFR 72.212(b)(7) Published 2015

Requirement The general licensee shall evaluate any changes to the written evaluations required by 10 CFR 72.212(b)(5) and 10 CFR 72.212(b)(6) using the requirements of 10 CFR 72.48(c). A copy of this record shall be retained until spent fuel is no longer stored under the general license issued under 10 CFR 72.210.

Observation: The 10 CFR 72.212 Evaluation Report, Section 4.0 stated that Callaway's 72.212 report would be reviewed, and revised if necessary, at a minimum before each dry fuel storage campaign to identify the applicable CoC amendment, FSAR revision, and any changes to the MPC model, fuel loading requirements, or VVM design changes to be used at the ISFSI. Additionally, the changes would be handled in accordance with 10 CFR 72.212(b)(7) to perform an written evaluation through the 72.48 process.

Documents Reviewed: a) 10 CFR 72.212 Evaluation Report, "Callaway Plant, Unit 1, Dry Fuel Storage System for Spent Nuclear Fuel Docket 72-1045," Revision 0

Category: General License **Topic:** Storage Cask Blocked Inlet or Outlet Air Vents

Reference: CoC 1040, Appendix B, Section 3.4.9 Amendment 0

Requirement For those users whose site specific design basis includes an event that results in blockage of the storage cask inlet or outlet air vents for an extended period of time longer than the completion time in LCO 3.1.2 (i.e. 64 hours for heat loads less than or equal to 28.74 kW and 24 hours for heat loads greater than 28.74 kW), an analysis may be performed to demonstrate adequate heat removal for the duration of the event. If the analysis is not performed or adequate heat removal cannot be verified, alternate methods of cooling must be established.

Observation: The Callaway ISFSI pad had been designed and located such that flooding and burial due to debris would not occur. The 72.212 Evaluation Report, Section 5.4.1.3 "Flooding" and Section 5.4.1.7 "Burial under Debris" discussed the features of the ISFSI pad that made these events very unlikely. The ISFSI pad was located on nearly a level plateau with elevations ranging from 830 to 850 feet. The elevation of the flood plain of the Missouri River nearest the site is about 525 feet with a Probable Maximum Flood level at elevation 559 feet. Flooding of the Missouri River would never reach the ISFSI. The elevation of the Callaway site is higher than the surrounding terrain and since well-developed natural streams drain the plateau, isolated local flooding would not occur on the Callaway site. Even when due to a severe event such as the Probable Maximum Precipitation.

The Callaway ISFSI is not located in the vicinity of unstable slopes. Section 2.7, Landslides, in Calculation HI-2146196, Evaluation of Plant Hazards at Callaway Energy Center, noted that Section 2.3.2.2.1 of the Callaway FSAR-SA, described the Callaway Plant and ISFSI site as being located on a slight plateau with no significantly higher ground within 5 miles of the site. Therefore, the site topography precluded the possibility of a landslide hazard that could collapse and surround a HI-STORM UMAX VVM. Calculation HI-2146196 Section 2.2, Fall Hazards, stated that there were no structures in the vicinity of the Callaway ISFSI that could collapse and surround a HI-STORM UMAX VVM. The controlled area around the Callaway ISFSI precluded the close proximity of substantial amounts of vegetation. Therefore, a burial under debris accident affecting the Callaway ISFSI VVMs was not an anticipated event.

For the Callaway ISFSI, HI-STORM UMAX CoC Appendix B, Approved Contents and Design Features Subsection 3.4.12, required performance of an analysis or evaluation if the site-specific design basis includes an event that resulted in the blockage of any HI-STORM UMAX inlet or outlet air duct for an extended period of time and provisions for

alternate means of cooling be established if the fuel cladding short term temperature cannot be demonstrated to be met or if the analysis or evaluation was not performed.

As described above, flooding was not an issue for the Callaway ISFSI, and the 72.212 report concluded that the burial-under-debris accident event does not affect the safe operation of the HI-STORM UMAX Canister Storage System, if the blockage was removed in the Appendix A Technical Specification 3.1.2 specified time period. Callaway Procedure OSP-ZZ-00001 implemented this Technical Specification requirement. Therefore, Subsection 3.4.12 did not apply to the Callaway ISFSI.

Documents Reviewed: a) Callaway Plant Updated Final Safety Analysis Report (UFSAR), The Callaway FSAR has two parts, the UFSAR-SP for the Standard Plant and the UFSAR-SA for the Site Addendum, Dated February 2014; b) Holtec Calculation HI-2146196, "Evaluation of Plant Hazards at Callaway Energy Center," Revision 4; c) Certificate of Compliance 1040 HI-STORM UMAX Appendix B Section 3.4.12, Amendment 0; d) 10 CFR 72.212 Evaluation Report, "Callaway Plant, Unit 1, Dry Fuel Storage System for Spent Nuclear Fuel Docket 72-1045," Revision 0

Category: Heavy Loads **Topic:** Closure Lid Lift Lugs Inspection

Reference: FSAR 1040 Section 10.4.1 Revision 2

Requirement Prior to each MPC loading, closure lid lift lugs examination shall be inspect for indications of overstress such as cracks, deformation, wear marks, corrosion, ect.

Observation: The Holtec CoC 1040 FSAR requirement for VVM closure lid lifting lug inspection was placed into Callaway's Procedure ETP-ZZ-04021 in Step 7.1.20. This requirement was adequately placed into Callaway's procedure to be completed prior to each loading of an MPC.

Documents Reviewed: a) Callaway Procedure ETP-ZZ-04021, "ISFSI Loading Campaign Performance – IPTE," Revision 1

Category: Heavy Loads **Topic:** Licensed Facility Heavy Loads Requirements

Reference: CoC 1040, License Condition 4 Amendment 0

Requirement Each lift of a canister, transfer cask, or storage cask must be made in accordance with the existing heavy loads requirements and procedures of the licensed facility at which the lift is made. A plant specific review (under 50.59 or 72.48, if applicable) is required to show operational compliance with existing plant specific heavy loads requirements.

Observation: The heavy lifts and crane operations associated with the dry cask storage operations were performed in accordance with the plant's maintenance department procedures for all heavy lifting activities in and outside of the plant. The licensee's 50.59 screen that was performed on use of the Holtec equipment and the ISFSI operations documented that reviews and evaluations were performed to ensure all activities were in compliance with the Callaway Lifting and Rigging Program.

The licensee's crane was rated to 125-tons. The maximum lift weight during the dry cask storage operations was calculated at approximately 123.5 tons. The licensee

performed a 50.59 evaluation to determine if the seismic and structural analyses performed by Holtec met the Callaway Part 50 Updated Final Safety Analysis Report (UFSAR) requirements for the plant. The conclusion of the 50.59 evaluation determined that the analysis performed by Holtec was within the bounds of the Part 50 UFSAR and utilized the site's approved methodologies.

Documents Reviewed: a) 50.59 Screen MP 14-004, "Dry Fuel Storage Licensing and Operations Documentation (Heavy Loads Review)," Revision 0

Category: Heavy Loads **Topic:** Procedures

Reference: NUREG 0612, Section 5.1.1 (2) Published July 1980

Requirement Procedures should be developed to cover load handling operations for heavy loads that are or could be handled over or in proximity to irradiated fuel or safe shutdown equipment. The procedures should include: a) identification of the required equipment; b) inspections and acceptance criteria required before movement of the load; c) the steps and proper sequence to be followed in handling the load; d) defining the safe load path; and e) special precautions.

Observation: The procedures used at Callaway that embody the requirements of NUREG 0612 for a safe load path were implemented into Callaway's procedures for lifting operations, operation of the cask handling crane, and MPC loading. Both Callaway and Holtec had developed procedures that covered load handling operations for heavy loads in close proximity to irradiated fuel and reactor safe shutdown equipment. The procedures included identifying the safe load path, special precautions, and the identification of required equipment, inspection requirements, and proper rigging sequence to observe when handling a load.

Documents Reviewed: a) Callaway Procedure APA-ZZ-00365, Addendum L, "Callaway Lifting Operations," Revision 18 b) Callaway Procedure OTS-KE-00016, "Operation of the Cask Handling Crane," Revision 22; c) Holtec Procedure HPP-2253-200, "MPC Loading at Callaway," Revision 9

Category: Heavy Loads **Topic:** Safe Load Paths

Reference: NUREG 0612, Section 5.1.1 (1) Published July 1980

Requirement Safe load paths should be defined for the movement of heavy loads to minimize the potential for heavy loads, if dropped, to impact irradiated fuel in the reactor vessel and in the spent fuel pool, or to impact safe shutdown equipment. The path should follow, to the extent practical, structural floor members, beams, etc., such that if the load is dropped, the structure is more likely to withstand the impact.

Observation: Callaway had satisfied the requirement that a safe load path be established as required by NRC NUREG 0612, Section 5.1.1 (1). Callaway's cask handling crane procedure, OTS-KE-00016, Attachment 1, clearly delineated the safe load and travel path for the cask handling crane that would apply when moving the transfer cask. The allowed load path showed exclusion areas for both the main hoist and the auxiliary hoist. The load path protects critical safety systems from being impacted in the event of a load drop scenario.

Documents Reviewed: a) Callaway Procedure OTS-KE-00016, "Operations of the Cask Handling Crane," Revision 22

Category: Heavy Loads **Topic:** Site Temperature Limit for Cask Handling

Reference: CoC 1040, Appendix B, Section 3.4.11 Amendment 0

Requirement Loading, transport, and unloading operations shall only be conducted with working area ambient temperatures of 0 degrees F or higher.

Observation: Holtec's MPC transfer procedure required that the ambient temperature for VCT operation be between 0 and 120 degrees F. This matched the requirements of CoC 1040, Appendix B, Section 3.4.11, which required that loading, transport, and unloading operations shall only be conducted when the work area ambient temperature is 0 degrees F or higher.

Category: Heavy Loads **Topic:** Transporter Initial Acceptance Testing

Reference: NUREG 0554, Section 8.2 Published May 1979

Requirement After the 125% static load test, the crane should be given a full performance test with 100% of the maximum critical load attached, for all speeds and motions for which the system is designed. This should include verifying all limiting and safety control devices.

Observation: NRC inspectors reviewed purchase specifications and accepting testing documentation to verify completion of the transporter load testing requirements. According to documents reviewed by NRC, after the 125% static load test was performed, the VCT was given a performance test with a load slightly over its 100% rated capacity, 415,000 lbs. The 100% performance test included verifying the operation of the lift booms, crawler, emergency stop function, measurement of general clearances, VCT travel, redundant drop protection, and lowering of the load using the emergency hydraulic pump. The test procedure and results met all applicable safety requirements for heavy loads and single failure proof lifting devices.

Documents Reviewed: a) Holtec Procedure HSP-199, "VCT Factory Acceptance Test Procedure," dated April 9-10, 2015

Category: Heavy Loads **Topic:** Transporter Initial Acceptance Testing

Reference: NUREG 0554, Section 8.2 Published May 1979

Requirement The VCT should be static load tested at 125 percent of the maximum critical load. The test should be conducted at all positions generating maximum strain in the bridge and trolley structures and other positions as recommended by the designer or manufacturer.

Observation: The VCT delivered to Ameren for use in their fuel loading campaign was static load tested with a weight of 519,630 lbs., just above 125% of the rated load of 415,000 lbs. This load was held for ten minutes at a height of 1 inch. The acceptance test met the applicable requirements.

Documents Reviewed: a) Holtec Procedure HSP-199, "VCT Factory Acceptance Test Procedure," dated April 9 - 10, 2015

Category: Heavy Loads **Topic:** VCT Transportation Evaluation

Reference: CoC 1040, Tech Spec. A.5.2 Amendment 0

Requirement Between the fuel building and the ISFSI pad, The Transfer Cask, when loaded with spent fuel, may be lifted to and carried at any height necessary during transport operations and MPC transfer, provided that a) The metal body and any vertical columns of the lifting equipment are designed to comply with stress limits of ASME Section III, Subsection NF, Class 3 for linear structures and all vertical compression loaded primary members satisfy the buckling criteria of ASME Section III, Subsection NF; b) the horizontal cross beam and any lifting attachments used to connect the load to the lifting equipment were designed, fabricated, operated, tested, inspected, and maintained in accordance with applicable sections and guidance of NUREG-0612, Section 5.1 and ANSI N14.6; and c) the lifting equipment has redundant drop protection features which prevent uncontrolled lowering of the load.

Observation: The Vertical Cask Transporter (VCT) steel load bearing members were designed to comply with the stress limits of ASME Section III, Subsection NF, Class 3 for linear structures, including vertical compression loaded primary members, as specified in Holtec PS-1120, the VCT purchase specification. PS-1120 required that the VCT be designed for both static and dead loads and dynamic seismic loads and invoked the guidance of NUREG-0612, including Section 5.1.6. PS-1120 required that the cross beams and lifting attachments met the stress limits of ANSI N14.6. The VCT employed redundant drop protection features as specified in the purchase specification. The aforementioned features show that the VCT in use at Callaway met the stress limits and compression buckling requirements of ASME Section III, Subsection NF; the cross beam meets the design requirements of NUREG-0612, and the applicable requirements of ANSI N14.6; and the VCT had redundant drop protection features to prevent uncontrolled lowering of a load.

Category: Loading Operations **Topic:** Cask System Annual Maintenance

Reference: FSAR 1040, Tables 10.4.1 and 10.4.2 Revision 2

Requirement The following cask system maintenance shall be performed annually, or prior to use if out of service for greater than 1 year: a) UMAX VVM in-service inspection, b) ISFSI pad inspection, c) UMAX VVM external surface visual examination, d) UMAX VVM inspection of visual markings, and e) HI-TRAC VW pressure relief valve calibration.

Observation: The licensee had incorporated the UMAX FSAR requirements into three annual Preventive Maintenance procedures (PMs) to perform the required UMAX VVM in-service inspection, ISFSI pad inspection, UMAX VVM external surface visual examination, UMAX VVM inspection of visual markings, and HI-TRAC VW pressure relief valve calibration annually, or prior to use if out of service for greater than one year. The licensee utilized PM1008323 to perform the UMAX VVM in-service inspection, UMAX VVM external surface visual examination, UMAX VVM inspection of visual markings, and to perform the ISFSI pad inspection. The licensee utilized PM1008325 to perform the HI-TRAC VW pressure relief valve calibration.

Category: Loading Operations **Topic:** Cask System Inspections Prior to Use

Reference: FSAR 1040, Table 10.4.1 Revision 2

Requirement The following HI-STORM UMAX areas shall be inspected prior to MPC installation: a) CEC cavity visual inspection; b) divider shell visual inspection; c) closure lid examination.

Observation: The licensee had incorporated the UMAX FSAR requirements into their procedures to perform the required inspections prior to MPC loading for; the CEC cavity visual inspection, divider shell visual inspection, and closure lid examination. The licensee utilized Procedure ETP-ZZ-04021 for all three inspections. Procedure ETP-ZZ-04021 contained the inspection requirements listed in FSAR 1040 Table 10.4.1, HI-Storm System Maintenance Program Schedule, for all three components.

Documents Reviewed: a) Callaway Procedure ETP-ZZ-04021, "ISFSI Loading Campaign Performance - IPTE," Revision 1

Category: Loading Operations **Topic:** Fuel Cladding Not Exposed to Air

Reference: CoC 1040, Appendix B, Section 3.4.13 Amendment 0

Requirement Procedures and/or mechanical barriers shall be established to ensure that during loading operations (and unloading) that either the fuel cladding is covered by water or the canister is filled with an inert gas.

Observation: This criteria was met at Callaway. Use of special equipment and procedures ensured the fuel was not exposed to air during loading operations. Procedures for loading and

unloading dry fuel storage canisters at Callaway all included a caution statement to ensure that the water level in the canister was not lowered below the top of the fuel cladding to avoid exposing fuel to the atmosphere, to prevent oxidation and potential fuel damage. In this regard, Holtec/Callaway had established procedures which ensured that during loading operations that either the fuel cladding was covered by water or the canister was filled with an inert gas. Special equipment such as the "dip tube" and flow meters ensured that less than 50 gallons of water would be removed to support welding operations while also preventing the fuel from being exposed to air.

Documents Reviewed: a) Holtec Procedures HPP-2253-200, "MPC Loading at Callaway," Revision 9; b) Holtec Procedure HPP-2253-500, "MPC Unloading at Callaway," Revision 4

Category: Loading Operations **Topic:** Handling Damaged Fuel Containers

Reference: FSAR 1032, Sections 2.1.3 and 6.4.4.1 Revision 3

Requirement Damaged fuel assemblies and fuel debris shall be loaded into damaged fuel containers (DFCs) prior to being loaded into the canister.

Observation: Damaged Fuel Containers were not to be used during the initial loading campaigns. Section 3.0 of the Callaway Procedure ETP-ZZ04020 provided the Acceptance and Functional Criteria for loading operations. The procedure stated that only fuel assemblies meeting the requirements of the HI-STORM, UMAX Certificate of Compliance for undamaged assemblies were to be loaded into spent fuel canisters.

Category: Loading Operations **Topic:** MPC-37 Boron Concentration

Reference: CoC 1014, Tech Spec A.3.3.1 and associated tables Amendment 0

Requirement The boron concentration in the canister shall meet the limits specified in Technical Specification 3.3.1 for the applicable canister model and the most limiting fuel assembly array and class. The boron concentration must be verified within required limits using two independent measurements taken within four hours of filling the canister with water, and every 48 hours thereafter while fuel and water are in the canister.

Observation: The boron concentration sampling requirements specified in the Technical Specification were placed in the implementing procedures for ISFSI loading operations at Callaway. Callaway's loading and unloading procedures HPP-2253-200 and HPP-2253-500 both contained the appropriate steps to sample for boron concentrations when loading fuel assemblies, adding water from the pool during hydrostatic tests, and prior to MPC alternate cooling operations.

Category: Loading Operations **Topic:** Pressure Relief Valves

Reference: FSAR 1032, Table 9.1.1 Revision 3

Requirement Pressure relief valves in the water and gas processing systems limit the canister pressure to acceptable levels.

Observation: Pressure relief valves were required and utilized during water and gas processing system operations at the Callaway site. A review of Holtec's procedure for MPC sealing at Callaway showed two pressure relief valves in the schematic diagram present in Attachment 8.10. NRC inspectors verified the presence of these pressure relief values during the second dry-run, June 2-4, 2015, and during initial fuel loading operations at Callaway. The safety relief valves were set at two different pressure values, 95 and 140 psig. The design pressure of the MPC was 100 psig. The 95 psig pressure relief valve was utilized throughout the canister drying and backfilling process. The 140 psig pressure relief valve was utilized during the hydrostatic testing of the MPC when the pressure of the system was raised to 125 psig.

Documents Reviewed: a) Holtec Procedure HPP-2253-300, "MPC Sealing at Callaway," Revision 7

Category: Loading Operations **Topic:** Time-to-Boil Time Limits

Reference: FSAR 1032, Section 4.5.3 and Table 4.5.4 Revision 3

Requirement Wet transfer operations begin when the lid is placed on the canister in the spent fuel pool and end when the canister is blown down following pressure testing. During wet operations, the water inside the MPC is not permitted to boil. Using the design basis heat load, Table 4.5.4 of the FSAR provides the time-to-boil for various initial water temperatures. If wet transfer operations cannot be completed prior to boiling, a forced water circulation shall be initiated and maintained to remove decay heat from the canister cavity. The minimum water flow rate required to maintain the MPC cavity water temperature below boiling with an adequate subcooling margin is determined using a calculation provided in Section 4.5.3 of the FSAR.

Observation: Callaway had procedure steps in place that adequately calculated and controlled the time to boil limitations put into place by the Holtec FSAR. Holtec's MPC loading procedure for Callaway included a time to boil calculation that was based on the HI-STORM FW FSAR. The HI-STORM FW used the same MPC design as the Holtec UMAX at Callaway. The calculation for the time to boil appeared in Step 7.6.40 of the loading procedure, HPP-2253-200. In addition, the MPC sealing procedure included steps that precluded draining the HI-TRAC/MPC annulus until the MPC blow down was to begin. Adherence to the time to boil clock, assures that the fuel assemblies and cladding would be maintained at acceptable temperatures until just prior to the start of force helium dehydration, which also controlled cladding temperatures until the helium backfill has been completed.

If the time to boil limit could not be met, Callaway's procedure HPP-2253-300 Attachment 8.13, "Contingency Steps for MPC Alternate Cooling," required establishing a forced water circulation with minimum flow rate of 11 gallons per minute that was calculated in accordance with FSAR Section 4.5.3.

Category: Loading Operations **Topic:** Transfer Cask Inspections Prior to Use

Reference: FSAR 1040, Table 10.4.1 Revision 2

Requirement The following HI-TRACK VM transfer cask area shall be inspected prior to use: a) HI-TRAC cavity visual inspection; b) HI-TRAC TAL visual inspection; c) HI-TRAC bottom lid bolts and bolt holes; d) HI-TRAC water jacket visual verification.

Observation: The licensee had incorporated the UMAX FSAR requirements into Procedure ETP-ZZ-04021 and Preventive Maintenance (PM) job order PM 1008270. The documents performed the required HI-TRAC VW cavity visual inspection, HI-TRAC Threaded Anchor Location (TAL) visual inspection, HI-TRAC bottom lid bolts & bolt holes inspection, and HI-TRAC waterjacket visual verification prior to HI-TRAC VW use.

Documents Reviewed: a) Callaway Procedure ETP-ZZ-04021, "ISFSI Loading Campaign Performance - IPTE," Revision 1; b) Callaway Procedure PM1008270, "Perform HI-Trac Inspection per HI-STORM FW FSAR Table 9.2.5 and UMAX FSAR Section 10.4.1," Revision 0

Category: NDE-Helium Leak Testing **Topic:** Helium Leak Test-Vent/Drain Covers

Reference: CoC 1040, Tech Spec A.3.1.1.3 Amendment 0

Requirement The helium leak rate through the canister vent and drain port confinement welds shall meet the leak tight criteria of ANSI N14.5 (1997). This degree of containment is achieved by demonstration of a leakage rate less than or equal to 2 X 10(-7) atm·cc/sec of helium at an upstream pressure of 1 atmosphere (atm) absolute (abs) and a downstream pressure of 0.01 atm abs or less.

Observation: The helium leak test was demonstrated during the welding dry run May 19-21, 2015 consistent with the acceptance standards specified in Certificate of Compliance 1040 and ANSI N14.5-1997. Procedure MSLT-MPC-Holtec, Step 8.1 required that the total leak rate of the vent port plus the drain port be less than or equal to 2 x 10(-7) atm cc/sec helium. Additionally, NRC inspectors witnessed the helium leak rate test on the first canister loaded on September 1, 2015. The leak rate was verified to be below the Technical Specification limit.

Documents Reviewed: a) MSLT-MPC-Holtec, "Helium Mass Spectrometer Leak Test Procedure MPC," Revision Callaway-01

Category: NDE-Helium Leak Testing **Topic:** HMSLD Minimum Sensitivity

Reference: ANSI N14.5, Section 8.4 Published 1997

Requirement The helium mass spectrometer leak detector (HMSLD) shall have a minimum sensitivity of 1/2 the acceptance leak rate. For example, a package with a leak tight acceptance criteria of 1.0 X 10(-7) ref-cc/sec requires a minimum helium mass spectrometer leak detector sensitivity of 5.0 x 10(-8) ref-cc/sec. This sensitivity requirement applies to both the hood and detector probe methods. The helium mass spectrometer leak detector shall be calibrated to a traceable standard.

Observation: The helium mass spectrometer leak detector (MSLD) minimum sensitivity requirement was specified in Callaway's procedure. Procedure MSLT-MPC-Holtec, Step 4.1 required the MSLD sensitivity to be less than 1/2 the acceptance criteria leak rate. The minimum acceptable leak rate was stated in Section 8.2 as 2.0 x 10(-7) atm-cc/sec (He) and referenced Technical Specification 3.1.1.3. Technical Specification 3.1.1.3 required the helium leak rate through the canister vent and drain port confinement welds to meet the leak tight criteria specified in ANSI N14.5-1997. Section 2, "Definitions," of ANSI N14.5-1997 defined leak tight as having a leak rate of 1 x 10(-7) ref-cc/sec of air. A note to the definition stated that 1 x 10(-7) ref-cc/sec of air was equivalent to 2 x 10(-7) atm-cc/sec of helium. A calibration standard traceable to the National Institute of Standards and Technology (NIST) with a leak rate between 10(-6) and 10(-8) atm-cc/sec was required by Step 4.3 of Procedure MSLT-MPC-Holtec. Section 5.0, "MSLD Startup and Instrument Calibration," provided instructions on calibrating the helium mass spectrometer. On September 1, 2015, NRC inspectors observed the qualified non-destructive examiner properly set up the MSLD per Callaway's approved procedure and perform the helium leak test.

Documents Reviewed: a) MSLT-MPC-Holtec, "Helium Mass Spectrometer Leak Test Procedure MPC," Revision Callaway-01

Category: NDE-Liquid Penetrant **Topic:** Acceptance Criteria

Reference: ASME Section III, Article NB-5352 Published 2007

Requirement Only indications with major dimensions greater than 1/16 inch should be considered relevant. The following relevant indications are unacceptable: (1) any cracks or linear indications. Linear indications have a length at least 3 times greater than the width; (2) rounded indications with dimensions greater than 3/16 inch (5 mm); (3) more than four rounded indications in a line, separated by 1/16 inch (1.5 mm) or less edge to edge; and (4) ten or more rounded indications in any 6 square inch area in the most unfavorable location relative to the indications being evaluated.

Observation: The acceptance standards from ASME Section III are found in Appendix A, "Acceptance Standards," of the PCI liquid dye penetrant procedure, GQP-9.2. These criteria were fully met during the welding dry-run at Callaway on May 19-21, 2015 and during the first fuel loading at Callaway, which began on August 24, 2015.

Documents Reviewed: a) PCI General Quality Procedure, GQP-9.2, "High Temperature Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 8; b) PCI General Quality Procedure, GQP-9.7, "Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 11

Category: NDE-Liquid Penetrant **Topic:** Contaminants

Reference: ASME Section V, Article 6, T-641 Published 2007

Requirement The user shall obtain certification of contaminant content for all liquid penetrant materials used on austenitic stainless steels. The certifications shall include the manufacturers batch number and sample results. Sub-article T-642 limits the total halogen (chlorine plus fluorine) content of each agent (penetrant, cleaner and developer) to 1.0 weight percent (wt.%) when used on austenitic stainless steels.

Observation: NRC inspectors reviewed vendor supplied laboratory test results for the liquid dye penetrant, developer, and cleaner used for non-destructive testing at Callaway and verified that the total halogen content of each agent did not exceed the ASME Section V, Article 6, T-641 requirement of 1% (by weight) for use on austenitic stainless steels.

Documents Reviewed: a) Sherwin Incorporated Certification for DUBL-CHEK KO-19, Batch No. 06-B56; b) Sherwin Incorporated Certification for DUBL-CHEK KO-17, Batch No. 07-B54; c) Sherwin Incorporated Certification for DUBL-CHEK D-350, Batch No. 99-L71

Category: NDE-Liquid Penetrant **Topic:** Final Interpretation

Reference: ASME Section V, Article 6, T-676.1 Published 2007

Requirement Final interpretation shall be made after allowing the penetrant to bleed-out for 10-60 minutes under standard temperatures (50 and 125 degrees F). The 10-60 minute clock starts immediately after application of a dry developer.

Observation: PCI's liquid dye penetrant procedure, GQP-9.7, had the requirements of ASME Section V, Article 6, T-676.1 spelled out in step 9.7.1(a). For high temperature uses, procedure GQP-9.2 will be used. GQP-9.2 was used during welding dry-run activities at the Callaway site. The manufacturer's instructions (Sherwin Incorporated) for the high temp penetrant, KO-17, high temperature cleaner, KO-19, and high temperature developer, D-350, listed different developer dwell times based on the surface temperature of the area being examined. The use of the Sherwin high temperature liquid penetrant products was fully qualified by PCI for use during dry fuel storage operations at Callaway. The manufacturer's recommendations supersede general code requirements in situations such as this one.

Documents Reviewed: a) PCI General Quality Procedure GQP-9.7, "Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 11; b) PCI GQP-9.2, "High Temperature Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 8

Category: NDE-Liquid Penetrant **Topic:** Lid-To-Shell Weld PT

Reference: CoC 1040, Appendix B, Table 3-1 Amendment 0

Requirement Only ultrasonic testing or multi-layer liquid penetrant (PT) examination is permitted on the lid-to-shell weld. If PT alone is used, at a minimum, it will include the root and final weld layers and each approximately 3/8 inch of weld depth.

Observation: PCI's Project Instruction called out the requirement that liquid penetrant (PT) examination shall be performed after the root layer and every layer of weld material afterwards. The layer was defined as equal to or less than 3/8 inch thickness (consisting of one or more passes), as referenced in the Holtec CoC 1040, Appendix B, Table 3-1. This requirement was met in the procedure and observed in practice during the welding dry-run activities at Callaway the week of May 18, 2015.

Documents Reviewed: a) PCI Project Instruction PI-CNSTR-OP-H-01, "Closure Welding of Holtec Multi-Purpose Canisters - UMAX," Revision 0

Category: NDE-Liquid Penetrant **Topic:** Minimum Elements

Reference: ASME Section V, Article 6, T-621 Published 2007

Requirement Each liquid penetrant (PT) procedure shall include the requirements listed in Table T-621: (1) type of each penetrant, remover, emulsifier, and developer; (2) Surface preparation (finishing and cleaning, including type of cleaning solvent); (3) Method of applying penetrants; (4) Method of removing excess surface penetrant; (5) Hydrophilic or lipophilic emulsifier concentration and dwell time in dip tanks and agitation time for hydrophilic emulsifiers; (6) Hydrophilic emulsifier concentration in spray applications; (7) Method of applying developer; (8) Minimum and maximum time periods between steps and drying aids; (9) Decrease in penetrant dwell time; (10) Increase in developer dwell time (Interpretation Time); (11) Minimum light intensity; (12) Surface temperature outside 40 degrees F to 125 degrees F or as previously qualified; (13) Performance demonstration, when required; (14) Personnel qualification requirements; (15) Materials, shapes, or sizes to be examined and the extent of examination; and (16) Post-examination cleaning technique.

Observation: The two procedures in use by PCI both contain all of the applicable minimum elements as specified in ASME Section V with the following allowed exceptions: Elements 5 and 6, both dealing with hydrophilic or lipophilic emulsifier concentration, did not apply to the specific types of dye penetrants and developers used for NDE at Callaway. Also, the temperature range of element #12 was not met, 40 to 125 degrees F. Instead, the solvent, dye, and developer used at Callaway by PCI were qualified for use from 50 to 350 degrees F. PCI and Callaway met the code required minimum elements in their liquid dye penetrant procedures.

Documents Reviewed: a) PCI General Quality Procedure GQP-9.2, "High Temperature Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 8; b) PCI General Quality Procedure GQP-9.7, "Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 11

Category: NDE-Liquid Penetrant **Topic:** Removing Excess Penetrant

Reference: ASME Section V, Article 6, T-673.3 Published 2007

Requirement Excess solvent removable penetrants shall be removed by wiping with a cloth or absorbent paper until most traces of the penetrant have been removed. The remaining traces shall be removed by lightly wiping the surface with a cloth or absorbent paper moistened with solvent. Care shall be taken to avoid the use of excess solvent. Flushing the surface with solvent, following the application of the penetrant and prior to developing, is prohibited.

Observation: The PCI Liquid Dye Penetrant procedure was compliant with the requirements of ASME Section V, Article 6, T-673.3, but included provisions for spraying the cleaner solvent directly onto the surface of the area to be inspected. Consultation with the manufacturer's recommendations for Dubl-Chek KO-19 cleaner indicated that this was an acceptable practice. Further consultation with HQ and an industry Level III NDE technician indicated that since KO-19 was applied as a foam, spraying it directly onto the surface to be examined does not constitute "flushing the surface" with solvent. PCI was fully compliant with the ASME requirements and manufacturers recommendations for use and removal of excess dye penetrant.

Documents Reviewed: a) PCI General Quality Procedure, GQP-9.2, "High Temperature Liquid Penetrant Examination and Acceptance Standards for Welds, Base Materials, and Cladding," Revision 8; b) Sherwin Incorporated KO-19 Hi-Temp Remover Technical Data Sheet

---

Category: NDE-Liquid Penetrant **Topic:** Surface Preparation

Reference: ASME Section V, Article 6, T-642 (b) Published 2007

Requirement Prior to each liquid penetrant examination, the surface to be examined and all adjacent areas within one inch must be dry and free of all dirt, grease, lint, scale, welding flux, weld spatter, paint, oil, and other extraneous matter that could obscure surface openings or otherwise interfere with the examination.

Observation: PCI's liquid penetrant procedure included the requirement that the surface to be examined be free of all dirt, grease, link, scale, welding flux, weld spatter, and other contaminants on the surface in step 9.1.1.b. PCI's procedure was fully compliant with the requirements listed in ASME Section V, Article 6, T-642(b).

Category: NDE-Personnel Qualification **Topic:** Certification Records

Reference: SNT-TC-1A, Section 9 Published 1992

Requirement Certification records should contain the name of the certified individual, the certification level and method, the individual's educational background and NDE experience, a statement of satisfactory completion of training per the employer's written practice, visual examination results, evidence of successful completion of examinations including grades, date of certification, and the signature of the employer.

Observation: NRC inspectors reviewed the training, testing, and certification records for two Level II NDE technicians from PCI. One of the technicians was involved in the dry-run activities witnessed during the week of May 18, 2015. The other individual was the one who actually participated at Callaway during their initial dry fuel storage campaign. The records for both individuals were complete and included all of the required information as specified by SNT-TC-1A, Section 9.

---

Category: NDE-Personnel Qualification **Topic:** Level II Exam Grading

Reference: SNT-TC-1A, Section 8 Published 1992

Requirement Level II technicians take 3 examinations: Basic, Method, and Specific. A composite grade should be determined by simple averaging of the results of the 3 examinations. A passing composite grade should be 80% with no examination results below 70%.

Observation: NRC inspectors reviewed the PCI procedure that directs the training, qualification, examination, and certification of NDE personnel. The requirements within the

procedure contained the requirements of SNT-TC-1A, Section 8. NRC inspectors verified that the Level II technician had passed all of his composite and individual examination requirements with an acceptable level of accuracy and proficiency. This requirement was met.

Documents Reviewed: a) PCI GQP-9.0 "Training, Qualification, Examination, and Certification of NDE Personnel in Accordance with SNT-TC-1A and CP-189," Revision 15; b) various NDE VT Level II Personnel Certificates, NDE PT Level II Personnel Certificates, and a Certificate of Inspection, Examination, and Testing Personnel for the individual who performed VT and PT for the welding dry-run at Callaway

---

Category: NDE-Personnel Qualification **Topic:** Level III Candidates

Reference: SNT-TC-1A, Section 6 Published 1992

Requirement A Level III candidate who has completed less than 2 years of engineering or science study must have 4 years of experience comparable to a Level II. A Level III candidate who has completed 2 years of engineering or science study must have 2 years of experience comparable to a Level II. A Level III candidate who has completed 4 years of engineering or science study must have 1 year of experience comparable to a Level II.

Observation: The welding contractor for Callaway, PCI, had these requirements clearly spelled out in its procedure for training and qualification of NDE personnel. Step 7.5.2 of the procedure laid out the education, training, and relevant experience requirements for Level III technicians. PCI had implemented Level III requirements that were fully compliant with SNT-TC-1A, Section 6.

Documents Reviewed: a) PCI Procedure GQP-9.0, "Training, Qualification, Examination, and Certification of NDE Personnel in Accordance with SNT-TC-1A and CP-189," Revision 15

Category: NDE-Personnel Qualification **Topic:** Recertification of Personnel

Reference: SNT-TC-1A, Section 9 Published 1992

Requirement Maximum recertification intervals are 3 years for Levels I and II, and 5 years for Level III. Recertification may be granted without testing provided there is documented continuing satisfactory performance. Without documented continuing satisfactory performance, reexamination is required for those sections deemed necessary by the Level III examiner.

Observation: PCI's procedure, GQP-9.0, for training and qualification of NDE personnel covered recertification requirements in Steps 11.2.1 through 11.2.7. The requirements of SNT-TC-1A, Section 9 were met by PCI's written procedure. PCI's procedure does not address Level I personnel. However, no Level I personnel were supporting dry fuel storage activities at Callaway.

Documents Reviewed: a) PCI Procedure, GQP-9.0, "Training, Qualification, Examination, and Certification of NDE Personnel in Accordance with SNT-TC-1A and CP-189," Rev. 15

Category: NDE-Personnel Qualification **Topic:** Visual Acuity

Reference: SNT-TC-1A, Section 8.2 Published 1992

Requirement The NDE examiner should have natural or corrected near-distance acuity in at least one eye capable of reading Jaeger Number 1 at a distance of not less than 12 inches on a standard Jaeger test chart, or capable of perceiving a minimum of 8 on an Ortho-Rater test pattern. This should be verified annually. The NDE examiner should demonstrate the capability of distinguishing and differentiating contrast among colors used in the applicable method. This should be verified every 3 years.

Observation: PCI Procedure GQP-9.0 required visual acuity examinations for NDE personnel in accordance with SNT-TC-1A. The overarching procedure, GQP-9.0 established the yearly frequency for the visual examination of the NDE personnel. GQP-9.14 established a procedure for carrying out the visual examination which included near and far distance visual acuity and color discrimination. PCI had adequate instructions and procedures in place to support qualification of personnel to perform NDE examinations. NRC also inspected the visual evaluation reports for PCI staff NDE personnel. Dry fuel operations at Callaway met this requirement.

Documents Reviewed: a) PCI General Quality Procedures GQP-9.14, "Visual Acuity Examinations," Revision 2; b) PCI GQP-9.0, "Training, Qualification, Examination, and Certification of NDE Personnel in Accordance with SNT-TC-1A and CP-189," Revision 15; c) PCI Visual Evaluation Report, SAP# 73566

Category: NDE-Visual Examination **Topic:** Acceptance Criteria - Overlap

Reference: ASME Section III, Article NF-5360 (d) Published 2007

Requirement When fusion in the overlap length cannot be verified, an overlap length of greater than 3/8" (10 mm) in any 4" (100 mm) segment, and 1/4" (6 mm) in welds less than 4" (100 mm) long, is unacceptable.

Observation: The overlap acceptance criteria was incorporated into the visual weld examination procedure. Procedure GQP-9.6 Addendum 1 included the requirements of the ASME Section III, Article NF-5360, which was utilized by the NDE inspector during visual examinations to verify the acceptance criteria was met.

Category: NDE-Visual Examination **Topic:** Eye Position and Lighting

Reference: ASME Section V, Article 9, T-952 Published 2007

Requirement Direct visual examinations shall be conducted with the eye within 24" (610 mm) of the surface, at an angle not less than 30 degrees. The minimum light level shall be 100 foot-candles.

Observation: The PCI procedure used at Callaway, Procedure GQP-9.6, was verified by NRC inspectors to contained the ASME Section V, Article 9, T-952 requirement. PCI Procedure GQP-9.6, Step 4.1 stated "Direct visual examinations are those which can be made when access is sufficient to place the eye within 24 inches of the surface and at an angle not less than 30 degrees to the surface to be examined. Mirrors may be used to improve the angle of vision, and aids such as a magnifying lens may be used to assist examinations." Step 6.2 of the procedure stated "For direct visual examination, lighting shall be provided such that the specific part, component, vessel or section thereof, under immediate examination is illuminated to attain a minimum of 100 foot-candles. Illumination may be by any means including a hand held flashlight."

Documents Reviewed: a) PCI Procedure GQP-9.6, "Visual Examination of Welds," Revision 14

Category: NDE-Visual Examination **Topic:** Minimum Elements

Reference: ASME Section V, Article 9, T-921.1 Published 2007

Requirement Each Visual Testing (VT) procedure shall include the: (1) Technique used either direct or remote; (2) Remote visual aids; (3) Personnel performance requirements, when required; (4) Lighting intensity; (5) Configurations to be examined and base material product forms(pipe, plate, forgings, etc.); (6) Lighting equipment; (7) Methods or tools used for surface preparation; (8) Equipment or devices used for a direct technique; (9) sequence of examination; (10) Personnel qualifications.

Observation: The PCI procedure used at Callaway, GQP-9.6, was verified by NRC inspectors to contained the required elements specified by ASME Section V, Article 9, T-921.1 related to visual examination (testing) requirements.

Documents Reviewed: a) PCI Procedure GQP-9.6, "Visual Examination of Welds," Revision 14

Category: NDE-Visual Examination **Topic:** Procedure Validation

Reference: ASME Section V, Article 9, T-921.3 Published 2007

Requirement The procedure shall contain or reference a report of what was used to demonstrate that the examination procedure was adequate. In general, a fine line 1/32" or less in width, or some other artificial flaw located on the surface or a similar surface to that to be examined, may be considered a test method for this demonstration. The line or artificial flaw should be in the least discernible location on the area examined, to prove the procedure.

Observation: NRC inspectors reviewed procedure qualification record for the PCI Procedure GQP-9.6 used at Callaway, that demonstrated the visual examination procedure was adequate. PCI Letter "Visual Examination Demonstration to HSB Global Standards ANI of GQP 9.6 Revision 14," dated December 4, 2013, documented the qualification of PCI's procedure. Attached to the letter was the visual testing examination report form that documented the qualification results.

Category: Pressure Testing **Topic:** Governing Code

Reference: FSAR 1032, Section 10.1.2.2.2 Revision 3

Requirement Pressure testing (hydrostatic or pneumatic) of the canister confinement boundary shall be performed in accordance with the requirements of ASME Code Section III, Subsection NB, Article NB-6000, when field welding of the canister lid-to-shell weld is completed. If hydrostatic testing is used, the canister shall be pressure tested to 125% of design pressure.

Observation: The requirements for the canister hydrostatic testing had been incorporated into Procedure HPP-2253-300 consistent with ASME Code Section III, Subsection NB,

Article NB-6000. The canister design pressure was 100 pounds per square inch-gauge (psig) per Holtec UMAX FSAR, Table 2.3.5 "Design (Maximum Allowable) Pressures." Procedure HPP-2253-300, Section 8.4, "Hydrostatic Test with FHD" provided the instructions for performing the canister hydrostatic test. Procedure HPP-2253-300, Step 7.4.30 required pressurizing the canister to 125.5-129.5 psig. Test results were documented in Step 7.4.41 after the pressure was maintained for 10 minutes. Procedure Step 7.4.42 required an Ameren Representative to witness the hydrostatic test and sign off on the test results.

Documents Reviewed: a) Holtec Procedure, HPP-2253-300 "MPC Sealing at Callaway," Revision 7

Category: Pressure Testing **Topic:** Hydrostatic Testing Sequence

Reference: FSAR 1032, Table 2.2.1, Sections 9.2.5;10.1.2.2.2 Revision 3

Requirement During hydrostatic testing, demineralized water or spent fuel pool water is admitted to the canister through a supply line connected to the drain port RVOA. The canister is pressurized to 125 +5/-0 psig and held for 10 minutes with no pressure drop. Following the 10-minute hold at test pressure, the canister lid to shell weld is examined to confirm no observable water leakage. The canister is then depressurized through a return line connected to the vent port RVOA and routed back to the spent fuel pool or liquid radwaste system. Once the canister is depressurized, the liquid penetrant examination of the canister lid-to-shell weld is repeated. Any evidence of cracking or deformation is cause for rejection.

Observation: NRC inspectors verified that the hydrostatic testing was performed properly with a positive displacement pump. The technician maintained the pressure in the correct pressure range (125.5 – 129.5 psi) for the ten minutes prescribed by the testing procedure. NRC observed the hydrostatic test during dry-run #2 June 2-4, 2015.

Category: Pressure Testing **Topic:** Pressure Gauge Calibration

Reference: ASME Section III, Article NB-6413 Published 2007

Requirement All test gauges shall be calibrated against a standard dead weight tester or a calibrated master gauge. The gauges shall be calibrated before each test or series of tests. A series of tests is that group of tests using the same pressure test gauge or gauges, which is conducted at the same site within a period not exceeding 2 weeks.

Observation: The test gages used to verify compliance for the hydrostatic test of the canister lid weld were required to be calibrated within 2 weeks of use. This requirement was stated in prerequisite Step 5.10 which required the pressure gauges for vent and drain ports to be calibrated within 2 weeks of the next test.

Category: Pressure Testing **Topic:** Pressure Gauge Installation

Reference: ASME Section III, Article NB-6411 Published 2007

Requirement Pressure test gauges shall be connected directly to the component and visible to the operator controlling test pressure.

Observation: Pressure testing of the lid to shell weld at Callaway complied with the ASME requirements. Holtec Procedure HPP-2253-300 Attachment 8.10 "Hydrostatic Test System and Blowdown Setup," required the pressure gages to be directly connected to the Remote Valve Operating Assembly (RVOA), which connects to the vent and drain ports of the MPC. The hydrostatic pump was located next to the MPC in the Cask Washdown Pit making the test gages visible to the operator controlling the test pressure.

Category: Pressure Testing **Topic:** Pressure Gauge Ranges

Reference: ASME Section III, Article NB-6412 Published 2007

Requirement Analog type indicating pressure gauges used in testing shall be graduated over a range not less than 1.5 times nor more than 4 times the test pressure. Digital type pressure gauges may be used without range restriction.

Observation: Only digital pressure gauges were in use at Callaway during the preoperational dry-runs and the initial loading campaign for the Holtec UMAX ISFSI. Therefore, the gauges used at Callaway did not have use restrictions.

Documents Reviewed: a) Holtec Procedures HPP-2253-300, "MPC Sealing at Callaway," Revision 7

Category: Pressure Testing **Topic:** Thermal Expansion

Reference: ASME Section III, Article NB-6126 Published 2007

Requirement If a pressure test is to be maintained for a period of time and the test medium in the system is subject to thermal expansion, precautions shall be taken to avoid excessive pressure.

Observation: Precautions were taken to guard against over-pressurization of the canister during MPC sealing operations at Callaway. The Holtec procedure used at Callaway directed the technician to actively monitor pressure at all times during the hydro-static testing of the MPC lid to shell weld. Procedure steps 7.4.28 through 7.4.42 direct the technician to actively throttle the pressure while maintaining it within a certain acceptable band (125.5 – 129.5 psi) during the pressure test. NRC inspectors interviewed the Holtec cask loading supervisor and loading technician on the technique that would be followed. They both responded that the technician would be holding a throttle valve for the entire pressure test and maintaining the pressure manually. At any point during the test, the technician can release the pressure. The diligence of the technician would thereby limit the pressure to acceptable levels. There was also one relief valves in the line-up during the hydrostatic test, rated at 140 psi.

Category: Quality Assurance **Topic:** Approved QA Program

Reference: 10 CFR 72.140(d) Published 2015

Requirement A QA program previously approved by the Commission as satisfying the requirements of Appendix B to Part 50 will be accepted as satisfying the requirements of Part 72. In filing the description of the QA program required by Part 72.140(c), each licensee shall notify the NRC of it's intent to apply it's previously approved QA program to ISFSI activities. The notification shall identify the previously approved QA program by date of submittal, docket number and date of Commission approval.

Observation: The licensee had incorporated the Part 72 quality assurance requirements into their approved Part 50 quality assurance plan. Callaway sent a letter to the NRC on February 13, 2015, notifying the Commission of their intent to apply the previously approved 10 CFR Part 50 Quality Assurance Program to cover ISFSI activities at their site. Callaway's Operational Quality Assurance Manual (OQAM) Revision 31, was reviewed by inspectors during the programs review week and was found to adequately incorporate the Part 72 ISFSI activities.

Documents Reviewed: a) Callaway's Operational Quality Assurance Manual, Revision 31; b) Letter to NRC "Notification Pursuant to 10 CFR 72.140 (d) of Intent to Apply Previously Approved Quality Assurance Program to the ISFSI at Callaway Plant, Unit 1," dated 02/13/2015

Category: Quality Assurance **Topic:** Corrective Actions

Reference: 10 CFR 72.172 Published 2015

Requirement The licensee shall establish measures to ensure that conditions adverse to quality, such as failures, malfunctions, deficiencies, deviations, defective material and equipment, and nonconformances are promptly identified and corrected. In the case of significant conditions adverse to quality, the measures must ensure that the cause of the condition is determined and corrective action taken to preclude repetition. This must be documented and reported to appropriate levels of management.

Observation: The licensee had incorporated the tracking and addressing conditions adverse to quality of ISFSI activities into their Part 50 approved Corrective Action Program. Callaway Procedure APA-ZZ-00500 described the corrective action process and provided instructions for initiating a Corrective Action Request System (CARS). Plant management was involved in the process of reviewing CARs and periodic reports on the status of open or closed CARs.

Condition reports that had been issued related to the ISFSI activities and the fuel building crane were reviewed during the dry run and first loading inspections to evaluate whether conditions adverse to quality were being appropriately identified and adequately corrected. A large number of CARs written dealing with ISFSI construction, dry runs, programs review, and issues discovered during the first loading were reviewed by the NRC inspectors. The CARs were related to a variety of issues. The CARs reviewed were well documented and properly categorized based on the safety significance of the issue. The corrective actions taken were appropriate for the situations. Based on the comprehensiveness of the corrective action reports, the licensee demonstrated a high attention to detail in regard to the setup, maintenance, and operation of their ISFSI program and the cask handling crane. No NRC safety concerns were identified related to

the condition reports reviewed.

Category: Quality Assurance **Topic:** Important to Safety Components - Ancillaries

Reference: FSAR 1032, Table 9.2.1 Revision 3

Requirement Ancillary equipment shall be classified as important to safety (ITS) in accordance with FSAR Table 9.2.1.

Observation: All Important to Safety (ITS) classifications contained in Table 9.2.1 of the HI-STORM FW FSAR (referenced by the UMAX FSAR) were consistent with the licensee's safety classifications in Holtec Document ID: 2253-C2015-46R2 for ancillary equipment except for the MPC Lifting Slings. Table 9.2.1 classified the lifting slings as ITS Category A while the licensee classified the slings as ITS Category B. An evaluation was performed by Holtec for the lifting slings in Purchase Specification (PS) PS-1234 that provided the justification for the slings as ITS Category B due to an evaluation that demonstrated that a 25 foot MPC drop will not breech the MPC containment boundary. Therefore, failure of a lifting sling would not directly cause loss of containment integrity and classification of the lifting slings as ITS Category B was justified. In addition, the inspectors noted in the FSAR Table 9.2.1 under the MPC Lift Attachments section, it stated, in part, that the ITS classification of the lifting device attached to the attachments may be lower than the attachment itself, as determined site-specifically. The MPC Lift Attachments are classified as ITS Category A equipment.

Category: Quality Assurance **Topic:** Important to Safety Components - Cask System

Reference: FSAR 1032, Table 2.0.2, 2.0.3, 2.0.4, and 2.0.7 Revision 3

Requirement Structures, systems, and components of the HI-STORM UMAX cask system are identified as important to safety (ITS) in accordance with NUREG/CR-6407 "Classification of Transportation and Dry Spent Fuel Storage System Components." Holtec FW FSAR, Tables 2.0.2, 2.0.3, 2.0.4, and 2.0.7 provides a summary of the classification of the structures, systems, and components as important to safety A, B, C, and NTIS (not important to safety).

Observation: Callaway had listed the Important to Safety structures, systems, and components (SSCs) associated with the UMAX/FW systems appropriately in their Quality Assurance Program implementing procedures. Callaway Procedure APA-ZZ-00303 documented that the ITS SSCs associated with the UMAX were defined in Holtec Report HI-2135435. Callaway Procedure APA-ZZ-00303 Appendix 1, documented that the ITS SSCs associated with the MPC, HI-TRAC VW, and other loading equipment was

documented in Holtec Letter 2253-C2015-46R2. The Holtec report and letter were reviewed and were determined to be consistent with the tables in the FSAR and NUREG/CR-6407.

Category: Quality Assurance **Topic:** QA Audits

Reference: 10 CFR 72.176 Published 2015

Requirement The licensee shall carry out a comprehensive system of planned and periodic audits to verify compliance with all aspects of the QA program and to determine the effectiveness of the program.

Observation: The licensee had developed a comprehensive plan for auditing the spent fuel dry cask storage program which was described in Appendix B of Callaway's Operational Quality Assurance Manual, Revision 31. Callaway's quality assurance organization was conducting audits and surveillances of the dry cask storage activities at Callaway and of the cask vendor, Holtec, which included engineering design activities and the cask manufacturing activities.

Selected QA audits and surveillances were reviewed related to the Callaway's dry cask storage program. The documents reviewed included audits and surveillances of Holtec activities, including work being performed at the Holtec Manufacturing Division, as well as activities being conducted by both Holtec and the licensee's staff at the Callaway site. Audit and surveillance findings were adequately categorized, resolved and documented

Category: Radiation Protection **Topic:** ALARA Program

Reference: FSAR 1040, Section 11.1.1 Revision 2

Requirement Licensees using the HI-STORM UMAX cask system will utilize and apply their existing site ALARA policies, procedures and practices for ISFSI activities to ensure that personnel exposure requirements of 10 CFR 20 are met.

Observation: The licensee had expanded their existing ALARA program to apply to ISFSI operations. The radiation protection program document (APA-ZZ-01000) described the ALARA Program. Section 4.4, addressed dose to members of the Public. Section 4.5.1, provided Federal Occupational Limits Guidelines. Section 4.5.2, discussed limits for pregnant workers. Section 4.5.4, outlined Administrative Dose Limits and subparagraph (c) noted that minors may not receive an occupational dose. Routine radiological controls were implemented by means of existing Callaway radiological control procedures associated with operation of the 10 CFR 50 facility. The licensee had reviewed and revised existing procedures to ensure compliance with requirements of 10 CFR 20.

The licensee applied lessons learned from other sites and incorporated suggestions from numerous INPO Reports. Man-hour and Person-rem projections were made using data from the Diablo Canyon ISFSI campaign. The licensee committed to use of low dose waiting areas. Two minute drills were observed during dry runs. Radiation Work Permits were developed. Personnel were encouraged to present ideas for reducing exposure during various evolutions. Radiation protection personnel were trained on the limitations of their survey instrumentation. The radiation protection technicians had participated in the Callaway Energy Site dry run demonstrations performed to meet Certificate of Compliance requirements. Radiation Protection personnel were found to be knowledgeable of the various activities and of the associated dose rates that would be expected. Health physics controls to include use of low dose waiting areas were

implemented during dry run and loading activities.

Documents Reviewed: a) Callaway Procedure APA-ZZ-01000, "Radiation Protection Program," Revision 41 b) General and Specific Radiation Work Permits as follows by prime number and subtitles - 15001753, "TRNSPRT – Move HI-TRAC From Wash down Pit to HI-STORM UMAX;" "CLOSE – Decontaminate, Close and Prepare MPC for Movement of Canister;" "LOAD – Place MPC into Spent Fuel Pool, Load Assemblies and Prepare for Movement to Cask Wash down Decontamination Pit;" "PREPS – Prepare the HiTrac and MPC for Loading"

Category: Radiation Protection **Topic:** Controlled Area Boundary Dose Rate Analysis

Reference: CoC 1040, Tech Spec A.5.3.2 Amendment 0

Requirement Considering the planned number of casks to be deployed and the cask contents, the licensee shall perform an analysis to confirm the dose limits of 10 CFR 72.104(a) will be satisfied under actual site conditions. 10 CFR 72.104(a) states that the annual dose to any real individual located beyond the controlled area must not exceed 25 mrem to the whole body, 75 mrem to the thyroid, and 25 mrem to any other critical organ as a result of direct radiation from the ISFSI during normal operations and anticipated occurrences. The results of the analysis shall be documented in the 10 CFR 72.212 evaluation report.

Observation: Callaway calculations provided in HPCI 15-05, noted that the annual dose to the nearest resident is 1.09E- 02 mrem, well below the 10 CFR 72.104(a) limit of 25 mrem. Holtec Calculation HI-2135879 in Section 5.3.1.2 compared the dose due to normal operations and anticipated occurrences due to the ISFSI to be compliant with limits of 10 CFR 72.104. Table 5.3-2 of the document noted an annual dose at 1600 meters, the approximate site boundary distance, and 2800 meters, the approximate distance to the nearest residence to be a maximum of less than 2 E-02 mrem, well within the limit of 25 mrem. The calculation assumed a maximum number of stored casks, 48. During loading the licensee measured the Transfer Cask and VVM surface neutron and gamma dose rated for comparison with limits and found results to be satisfactory. Because of the design of the welded and sealed canisters, there were no effluent pathways associated with the stored canisters under normal conditions.

The licensee was required by 10 CFR 72.104 to include doses from other nearby fuel cycle activities into the dose calculations. The operating Callaway Energy Center nuclear power plant as a source term was considered in the determination of whether the dose rate was being met. The license reviewed data for 2012, 2013 and 2014. While the data varied somewhat from year to year, the licensee determined that dose rates at the controlled area boundary were not statistically different from background levels.

Documents Reviewed: a) Callaway Procedure HSP-ZZ-0015, "Callaway Site Boundary Dose Evaluation," Revision 0; b) Callaway Calculation HPCI 15-05, "Evaluation of Direct Radiation Dose to the Member of the Public from the Independent Spent Fuel Storage Installation," Revision 1; c) Holtec Calculation HI-2135879, "ISFSI Site Boundary and CoC Dose Rate Calculations for Callaway Plant Site Boundary," Revision 0

Category: Radiation Protection **Topic:** Controlled Area Radiological Doses

Reference: 10 CFR 72.106(a)/(b)/(c) Published 2015

Requirement For each ISFSI, a controlled area must be established. Any individual located on or beyond the nearest boundary of the controlled area may not receive from any design basis accident 5 rem TEDE for accident conditions. Minimum distance from ISFSI to nearest boundary of controlled area must be 100 meters. Controlled area may include roads, railroads or waterways as long as arrangements are made to control traffic and protect public.

Observation: The ISFSI pad was located within the Callaway Energy Center nuclear power plant exclusion zone within the plant's owner controlled area. Holtec Calculation HI-213879 stated that the distance from the ISFSI to the nearest Callaway Plant site boundary is approximately 1600 meters which exceeds the 100 meter required. This calculation presented dose rates for the individual dose rate components (neutron and gamma) at the site boundary (2080 hours/year occupancy) and nearest residence (8760 hours/year occupancy). Results are a fraction of a mrem and well below regulatory limits of 25 mrem. Section 5.0 of Callaway's 72.212 Report stated that the MPC was designed to provide confinement of all radionuclides under normal, off-normal and accident conditions, including natural phenomena. Radioactive materials stored inside the MPC will not escape to the atmosphere over the life of the ISFSI. Therefore the dose rates expected to an individual was anticipated to be well below the regulatory limits.

Documents Reviewed: a) 10 CFR 72.212 Evaluation Report, "Callaway Plant, Unit 1, Dry Fuel Storage System for Spent Nuclear Fuel Docket 72-1045," Revision 0; b) Holtec Calculation HI-213879, "ISFIS Site Boundary and CoC Dose Rate Calculations for the Dry Storage Project," Revision 0

Category: Radiation Protection **Topic:** Dose Rate Survey - Transfer Cask

Reference: CoC 1040, TS A.5.3.3, A.5.3.4 (b) and A.5.3.8.(c) Amendment 0

Requirement The licensee shall establish site specific dose rate limits (gamma and neutron) for the sides of the transfer cask. The licensee shall measure the surface dose rates (gamma + neutron) for each loaded transfer cask. A minimum of 4 dose rate measurements shall taken on the side of the transfer cask at mid-plane, approximately 90 degrees apart around the circumference, and between the radial ribs of the water jacket. The measured dose rate shall not exceed the licensee's site-specific surface dose rate limits as determined from Technical Specification A.5.3.3 or 3500 mrem/hr on the side, whichever is lower.

Observation: Callaway Procedure HDP-ZZ-03000, Step 6.1.1.a.1 listed a maximum average dose rate of 3,500 mrem/hr, neutron and gamma combined, on the side of the HI-TRAC VW transfer cask. Procedure Step 6.1.2.a.1 required that HI-TRAC dose rate measurements be taken at mid-height plane locations approximately 90-degrees apart on the side of the HI-TRAC between the radial ribs of the water jacket. Those procedure steps aligned with the Holtec Certificate of Compliance Technical Specification requirements of A.5.3.3, A.5.3.4 (b), and A.5.3.8(c). NRC inspectors verified this criterion was met through procedure review.

Category: Radiation Protection **Topic:** Neutron Dosimetry

Reference: N/A

Requirement Neutron dose rates to occupational workers should be adequately monitored.

Observation: The licensee had incorporated provisions into the health physics monitoring program to adequately monitor for both thermal and higher energy neutron spectra. The licensee used Eberline NRD Instruments (rem balls) for field neutron dose rate surveys. Mirion DMC 2000GN electronic dosimeters provided for secondary dose monitoring. The dose of record was based on Landauer Optically Stimulated Luminescent (OSL) dosimeters combined with a Neutrak 144 Dual Element CR-39 system. The licensee's calculation and analysis presented results for various dosimeters and calibration spectra related to the HAWK Tissue Equivalent Proportional Chamber (TEPC), the Mirion DMPC 2000GN Electronic Dosimeter, and the Eberline NRD Neutron Dose Rate Survey Meter. The HAWK TEPC served as a reference for true neutron dose rate. This instrument allowed for the application of appropriate International Commission Radiation Protection (ICRP) quality factors to each interaction resulting in a more accurate response. The licensee committed to continued studies during campaigns to further refine correction and calibration factors and validate assumptions and decisions made.

Documents Reviewed: a) Callaway Calculation HPCI 08-02, "Response of Callaway Neutron Dosimeters and Neutron Survey Instruments," Revision 0

Category: Radiation Protection **Topic:** Shielding Effectiveness Test

Reference: FSAR 1040, Section 10.3.ii. Revision 2

Requirement Operational neutron and gamma shielding effectiveness tests shall be performed after the first fuel loading at the host plant site using written and approved procedures. Calibrated neutron and gamma dose rate meters shall be used to measure the actual neutron and gamma dose rates at the accessible surface of the HI-STORM UMAX VVM. The test is performed to identify the expected dose levels around the VVM in order to plan for appropriate radiation protection measures for future cask loadings.

Observation: Callaway had placed the shielding effectiveness test into their site Procedure HDP-ZZ-03000, Appendix H. Procedure HDP-ZZ-03000, Appendix H, Step 6.1.2.b. contained requirements to perform a radiation survey at multiple locations around the VVM closure lid and its outlet vent ducts. Step 6.1.4.b contained instructions to evaluate the VVM survey results to determine if 10 CFR 72.104 limits would be exceeded and if appropriate radiation controls were adequate.

Documents Reviewed: a) Callaway Procedure HDP-ZZ-03000 Appendix H, "Spent Fuel Storage Cask Surveys," Revision 0

Category: Radiation Protection **Topic:** Site-Specific Dose Rate Limits - Storage Cask

Reference: CoC 1040, Tech Spec A.5.3.3 (a), A.5.3.4 (a) Amendment 0

Requirement The licensee shall establish site-specific surface dose rate limits (gamma + neutron) for the top of the VVM. The surface dose rate limits for the storage cask may be set between the dose rate assumed in the 72.104(a) analysis and the dose rate needed to exceed the 72.104(a) dose limits, but shall not be set greater than 30 mrem/hr on the top of the VVM.

Observation: Callaway Procedure HDP-22-03000, Section 6.1.2.b.1.a requires that Tech Spec measurements be made at 4 locations taken against the outlet vent duct screen. The limits are listed in Section 6.1.1.b, combined neutron and gamma dose rates of 30 mrem/hr. Those procedure steps align with the Holtec certificate of compliance technical specification requirements of A.5.3.3 (a) and A.5.3.4 (a). NRC inspectors verified this criterion was met through procedure review.

Documents Reviewed: a) Callaway Procedure HDP-ZZ-03000, Appendix H, "Spent Fuel Storage Cask Surveys," Revision 0

Category: Radiation Protection **Topic:** Transfer Cask Surface Contamination Limit

Reference: CoC 1040, Tech Spec A.3.2.1 Amendment 0

Requirement Removable contamination on the exterior surfaces of the transfer cask and accessible portions of the canister shall not exceed 1,000 disintegrations per minute per 100 square centimeters (dpm/100 square centimeters) from beta and gamma sources and 20 dpm/100 square centimeters from alpha sources. The accessible portion of the canister is the upper portion of the canister external shell wall accessible after the inflatable annulus seal is removed and before the annulus shield ring is installed.

Observation: The contamination limits from TS A.3.2.1 of CoC 1040 had been incorporated into the licensee's procedures. Procedure HPP-2253-200, Step 7.9.11 and 7.9.14 required radiation protection group to perform contamination survey of MPC top lid surfaces and accessible areas on the MPC after the annulus seal was removed to ensure the TS 3.2.1 had been met.

The requirements in the Callaway procedures were consistent with the Holtec FW FSAR, Section 9.2.4.2, which stated that after decontaminating the canister lid top and the shell area above the annulus seal, to deflate the seal and survey the canister lid top surface and the accessible areas of the top three inches of the canister. A "Note" preceding Step 7.9.14 in HPP-2253-200 stated: "The MPC exterior shell survey is performed. Indications of contamination could require the MPC to be unloaded. In the event that the MPC shell is contaminated, users must decontaminate the annulus. If the contamination cannot be reduced to acceptable levels, the MPC must be returned to the spent fuel pool and unloaded. The MPC may then be removed and the external shell decontainінated."

Category: Records **Topic:** Cask Records

Reference: 10 CFR 72.234(d)(2) & (d)(3) Published 2015

Requirement A list of records required for each cask is provided in 10 CFR 72.234(d)(2). The certificate holder is required by 10 CFR 72.234(d)(3) to provide an original of these records to the user.

Observation: The licensee was maintaining the required records in their quality related records system consistent with 10 CFR 72.234. Callaway had implemented retention of ISFSI records into their Part 50 record retention program. Callaway Procedure APA-ZZ-00209 Step 7.18.1.h. required retention of all Quality Assurance records pertaining to Callaway ISFSI Important to Safety structures, systems, and components per 10 CFR 72.174. NRC inspectors reviewed the cask records provided to Callaway per 10 CFR 72.234(d)(2) from Holtec for the first canister planned to be loaded by Callaway. The canister package contained the required information and was easily retrieved through Callaway's record retention program.

Category: Records **Topic:** Record Retention for 72.212 Analysis

Reference: 10 CFR 72.212(b)(5)(iii) Published 2015

Requirement A copy of the 10 CFR 72.212 analysis shall be retained until spent fuel is no longer stored under the general license issued under 10 CFR 72.210.

Observation: Callaway had implemented retention of ISFSI records including the 10 CFR 72.212 Evaluation Report into their Part 50 record retention program. Callaway Procedure APA-ZZ-00209 Step 7.18.1.h. required retention of all Quality Assurance records pertaining to Callaway ISFSI Important to Safety structures, systems, and components per 10 CFR 72.174. Callaway generated a print-out copy of File Plan E430.0002 that documented the ISFSI records shall be retained for additional 5 years after the fuel has been transfer in accordance with 10 CFR 72.72 (d).

Documents Reviewed: a) Callaway Procedure APA-ZZ-00209, "Records Identification, Retention and Destruction," Revision 18; b) File Plans E430.0002, "ISFSI Records Retained for Department of Energy Transfer of Spent Fuel," dated 05/12/15

Category: Records **Topic:** Registration of Casks with NRC

Reference: 10 CFR 72.212(b)(2) Published 2015

Requirement The general licensee shall register the use of each cask with the NRC no later than 30 days after using the cask to store spent fuel.

Observation: The requirement to notify the NRC within 30 days of using a cask to store spent fuel was incorporated into Procedure ETP-ZZ-04021. Step 7.7.8 of the procedure, required the licensee to ensure loaded MPCs have been registered with the NRC no later than 30 days after using the cask to store fuel.

Documents Reviewed: a) Callaway Procedure ETP-ZZ-04021, "ISFSI Loading Campaign Performance IPTE," Revision 1

Category: Safety Reviews **Topic:** Changes, Tests, and Experiments

Reference: 10 CFR 72.48(c)(1) Published 2015

Requirement A licensee can make changes to their facility or storage cask design if certain criteria are met as listed in 10 CFR 72.48.

Observation: The licensee had combined the 72.48 screening and evaluation process with the 50.59 process used at the site. Procedure APA-ZZ-00143 described the screening and evaluation process for both requirements and used several different forms.

The licensee had developed classroom training material and an engineering qualification card for the 10 CFR 72.48 program. The training material provided a good description of the purpose and philosophy of the 10 CFR 72.48 process and how it related to other processes that controlled licensing basis activities at Callaway. Relevant definitions and applicable terms were provided with discussions of what they meant. The training material was well developed and very informative in assisting the user in making decisions related to the 72.48 screening and evaluation process. Examples were provided to further illustrate how to implement the process. The training material included numerous drawings and pictures describing the various components of the dry cask system specific to Callaway to help familiarize the personnel assigned to perform the screenings and evaluations with the key safety components of the various systems. The training module described the forms required and gave examples of what the various screening and evaluation criteria meant. Lessons learned at other sites relevant to the 10 CFR 72.48 process were provided.

As part of the 72.212 Evaluation Report review, NRC inspectors reviewed many 72.48 screens and three full 72.48 evaluations that related to the sites fire hazards analysis, explosion hazards, and the tornado missile analysis. The full evaluations were documented in 72.48 Evaluation Log No 15-01.

The HI-STORM UMAX FSAR documented that the fire accidents for storage were

conservatively postulated to be the results of the spillage and ignition of 50 gallons of combustible transporter fuel. The Callaway site specific analysis evaluated a fire due to the Low Profile Transporter (HI-PORT), tracked Vertical Cask Transporter (VCT), and an Arial Work Platform (JLG) boom lift. The fire specific analysis was documented in Holtec Report HI-2156590. The fire accident was evaluated using the same methodology as in the FSAR. The results of the analysis concluded that the combined combustible liquids from the above listed equipment would not cause fuel assemblies to exceed peak cladding temperatures above the FSAR allowable accident limits of 570 degrees C.

The explosion hazard documented in the FSAR, found the UMAX was qualified to a 10 psi overpressure. Due to the location of the ISFSI within the Protected Area, Callaway requested that the UMAX be reviewed and qualified for an overpressure of 20 psi. The explosion impacts from Callaway were documented in Holtec Report HI-2146196. The Callaway site-specific explosion hazards were evaluated and determined that the overpressure wave did not result in lid separation and that all lid stresses were a fraction of the allowable limits.

The tornado missile analysis contained in the FSAR did not bound all the missiles contained in the Callaway's Part 50 UFSAR Table 3.5-1. As a result, a site specific analysis was performed using a different set of missiles to bound Callaway's design basis missiles. The tornado missile analysis was documented in Holtec Report HI-2146196. The specific analysis utilized the same methodology as performed in the Holtec UMAX FSAR. The kinetic energy generated by the Callaway Part 50 design basis missiles was bounded by the kinetic energy input values generated from the new list of bounding missiles that were presented in the analysis. It was found that the new bounding missiles did not breach the confinement boundary, locally deform the cask such that the retrievability of the MPC was threatened, or deform the cask plastically such that the shielding effectiveness was affected.

All three evaluations were performed using the original methodology and acceptance criteria, and found that the original acceptance criteria was still met. The evaluations documented that the site specific conditions did not result in more than a minimal increase in the frequency or likelihood of any accident or malfunction, or consequences of an accident or malfunction. The site specific evaluations also did not create the possibility of a different type of accident or malfunction, cause a design basis limit for a fission product barrier to be exceeded or altered, or result in a change in methodology. Therefore the 72.48 evaluation concluded the activity can be implemented without requesting a CoC Amendment.

Category: Slings **Topic:** Sling Heavy Load Requirements

Reference: NUREG 0612, Section 5.1.6 (1) (b) Published July 1980

Requirement Dual or redundant slings should be used such that a single component failure or malfunction in the sling will not result in an uncontrolled lowering of the load, OR the load rating of the sling should be twice the sum of the static and dynamic loads.

Observation: Dual and redundant slings were used to download the canister from the transfer cask into the HI-STORM UMAX. The load rating on the slings was twice the weight of the static and dynamic loads of the canister. The slings purchased at Callaway had a vertical rating of 140,000 pounds each. Two of these slings are required for downloading the canister. The fully loaded canister was calculated to be 97,288 pounds per Holtec Document HI-2146011 (Case 6). A conservative static value of 120,000 pounds was used in the calculation of Purchase Specification PS-1234 for purchase of the slings. A dynamic load of 15% was added to the static load providing a total of 140,000 pounds. Redundant slings were used in the vertical formation. The minimum vertical rated capacity of each sling was calculated to be 140,000 pounds. The slings that were purchased by Callaway were rated at 140,000 lb (vertical rated) capacity (TPSE-EE14000 - 62.5ft Twin-Path Spark-eater eye & eye slings).

NRC inspectors reviewed the purchase specifications for the slings utilized in lifting the MPC lid, lifting the gate adapter, lifting the closure lid, and other miscellaneous slings utilized throughout the campaign. Dual and redundant slings were used in all heavy load lifts associated with the loading operations.

Documents Reviewed: a) Holtec Report HI-2146011, "Cask Handling Weights at Callaway," Revision 1; b) Holtec PS-1234, "Purchase Specification for the MPC Downloading Slings for Downloading Using the VCT," Revision 4; c) Holtec PS-3200, "Purchase Specification for the HI-STORM FW System Multi-Purpose rigging system," Revision 3

Category: Slings **Topic:** Sling Identification

Reference: ASME B30.9, Section 9-5.1.6 Published 1990

Requirement Each sling should be permanently marked to show: (a) name or trademark of manufacturer; (b) manufacturer's code or stock number; (c) rated loads (rated capacities) for the types of itches used; (d) type of natural or synthetic material;

Observation: NRC inspectors visually inspected slings during the outside pad operations dry-run, from July 14-17, 2015. All inspected steel wire rope and synthetic fiber slings were tagged with information including manufacturer, rated load capacity, serial number, and type of material.

Documents Reviewed: N/A.

Category: Slings **Topic:** Sling Inspections - Frequent

Reference: ASME B30.9, Section 9-4.7.1 (b) Published 1990

Requirement A visual inspection for damage shall be performed each day or shift the sling is used.

Observation: Callaway's rigging procedure contains the routine inspection criteria for wire rope and synthetic slings. According to the procedure, slings were to be inspected for all manner of wear and tear, including burns, missing tags, holes, cuts, etc on a daily basis. NRC inspectors noted that slings were inspected during dry-run activities and during the initial cask loading operations at Callaway. The licensee had established training and procedures to ensure that slings would be properly inspected prior to use during fuel loading operations for the Callaway ISFSI.

Documents Reviewed: a) Holtec Report No.: HI-2135598, "MPC Lift Sling Operations and Maintenance Manual," Revision 0; b) Callaway Procedure APA-ZZ-00365, Addendum R, "Callaway Rigging Operations," and Attachment 4, "Portable Hoist and Come-along Frequent Inspections," Revision 1

Category: Slings **Topic:** Sling Inspections - Periodic

Reference: ASME B30.9, Section 9-4.7.1 Published 1990

Requirement A complete inspection for damage to the sling shall be conducted at intervals not to exceed one year.

Observation: A complete inspection of slings was completed on an annual basis for the slings utilized in the Callaway loading campaign. All slings and wire ropes utilized in the Callaway loading operations were owned and controlled by Holtec. Holtec Procedure HSP-410 was utilized to perform the annual inspections. The NRC inspector confirmed that all slings used during the first canister loading operations were within their annual inspection dates by visual examination of sling equipment identification tags.

Documents Reviewed: a) Holtec Procedure HSP-410, "NUREG-0612 Periodic Maintenance Program: Control of Slings, Hooks, Misc. Tackle and Structural and Mechanical Lifting Devices," Revision 0

Category: Slings **Topic:** Sling Load Rating

Reference: NUREG 0612, Section 5.1.1 (5) Published July 1980

Requirement In selecting the proper sling, the load used should be the sum of the static and maximum dynamic load. The rating identified on the sling should be in terms of the "static load" which produces the maximum static and dynamic load.

Observation: All slings utilized at Callaway were selected in accordance with the NUREG 0612 requirements. NRC inspectors reviewed the Purchase Specifications for the slings utilized in downloading the MPC, lifting the MPC lid, lifting the gate adapter, lifting the closure lid, and other misc. slings utilized throughout the campaign. The documents demonstrated the slings selected were based on the sum of the static and dynamic loads. NRC inspectors inspected the slings that were utilized in the campaign and confirmed that the slings met the Purchase Specifications.

Documents Reviewed: a) Holtec PS-1234, "Purchase Specification for the MPC Downloading Slings for Downloading Using the VCT," Revision 4; b) Holtec PS-3200, "Purchase Specification for the HI-STORM FW System Multi-Purpose rigging system," Revision 3

Category: Slings **Topic:** Sling Proof Loading

Reference: ASME B30.9, Section 9-5.4 Published 1990

Requirement When specified by the purchaser, slings of all types shall be proof loaded. The proof load for single leg (branch) slings and endless slings shall be two times the vertical rated load (rated capacity).

Observation: Holtec Purchase Specification, Section 8, "Inspections and Testing Requirements," required that a proof test of twice the rated vertical capacity be applied to all load bearing components of the MPC downloading ancillary. The certificate of conformance from I&I Slings showed that two slings, serial numbers P102114094 and P102114095, were proof tested to twice their rated load of 140,000 lbs., in accordance with ASME 30.9 standards. This criteria was satisfactorily demonstrated by documents review by NRC inspectors during dry-run activities and first loading at Callaway for its Holtec UMAX ISFSI.

Documents Reviewed: a) Holtec International Purchase Specification PS-1234, "Purchase Specification for the MPC Downloading Sling for Downloading using the VCT," Revision 4; b) Holtec International COC-14311-002, "Certificate of Conformance," Revision 0

Category: Slings **Topic:** Sling Temperature Limits

Reference: No Reference Provided N/A

Requirement Synthetic slings shall not be used in contact with objects that exceed the temperature limit of the sling.

Observation: NRC inspectors verified that a maximum allowable sling to MPC contact temperature had been established for cask loading operations at the Callaway ISFSI. The synthetic MPC lift slings used at Callaway had a specified maximum contact temperature for the synthetic sling of no more than 300 degrees F in both the Holtec Report and Holtec's procedure for use at Callaway.

Documents Reviewed: a) Holtec Report No.: HI-2135598, "MPC Lift Sling Operations and Maintenance Manual," Revision 0; b) Holtec Procedure HPP-2253-400, "MPC Transfer for Callaway," Revision 7

Category: Slings **Topic:** Synthetic Round Sling Removal from Service

Reference: ASME B30.9, Section 9-4.8 Published 1990

Requirement A synthetic round sling shall be removed from service if any of the following conditions are present: (a) cuts, gouges, badly abraded spots; (b) seriously worn surface fibers or yarns; (c) considerable filament or fiber breakage along the line where adjacent strands meet (light fuzzing is acceptable); (d) particles of broken filament or fibers inside the rope between the strands (inspect inside the rope); (e) discoloration or harshness that may mean chemical damage or excessive exposure to sunlight. Inspect filaments or

fibers for weakness or brittleness; (f) kinks or hockles; (g) melting or charring on any part of the sling; (h) excessive pitting or corrosion, or cracked, distorted or broken fittings; (i) other visible damage that causes doubt as to the strength of the sling

Observation: The synthetic round sling inspection criteria, consistent with the key elements of ASME B30.9, was listed in Procedure HSP-410. All slings and wire ropes utilized in the Callaway loading operations were owned and controlled by Holtec. The Holtec Procedure HSP-410 contained the ASME B30.9 removal criteria in Section 6.3.6. The NRC inspectors confirmed that all slings used during the first canister loading operations were within their annual inspection dates.

Category: Slings **Topic:** Wire Rope Sling Removal From Service

Reference: ASME B30.9, Section 9-2.8.3 Published 1990

Requirement A wire rope sling shall be removed from service if any of the following conditions are present: (a) for strand laid and single part slings ten randomly distributed broken wires in one rope lay, or five broken wires in one strand in one rope lay; (b) severe localized abrasion or scraping; (c) kinking, crushing, birdcaging or any other damage resulting in distortion of the rope structure; (d) evidence of heat damage; (e) end attachments that are cracked, deformed, or worn to the extent that the strength of the sling is substantially affected; (f) severe corrosion of the rope or end attachments;

Observation: The wire rope sling inspection criteria, consistent with the key elements of ASME B30.9, was listed in Procedure HSP-410. All slings and wire ropes utilized in the Callaway loading operations were owned and controlled by Holtec. The Holtec Procedure HSP-410 contained the ASME B30.9 removal criteria in Section 6.3.5. The NRC inspectors confirmed that all slings used during the first canister loading operations were within their annual inspection dates.

Documents Reviewed: a) Holtec Procedure HSP-410, "NUREG-0612 Periodic Maintenance Program: Control of Slings, Hooks, Misc. Tackle and Structural and Mechanical Lifting Devices," Revision 0

Category: Special Lifting Device **Topic:** Lifting Device's Annual Testing

Reference: ANSI N14.6, Sect 7.3.1; Sect 6.3.1 Published 1993

Requirement Annually, not to exceed 14 months, all special lifting devices shall be subjected to a test load equal to 300% of the maximum service load if a single component failure on the device could result in an uncontrolled lowering of the load. If the design for handling the load incorporates a single-failure proof concept, then each path in the dual-load-path device shall be tested to 150% of the load instead of the 300%. After sustaining the load for a period of not less than 10 minutes, critical areas, including major load bearing welds, shall be subject to visual inspection for defects and all components shall be inspected for permanent deformation. In cases where surface cleanliness and conditions permit, the load testing may be omitted and dimensional testing, visual inspection and

nondestructive testing of major load-carrying welds and critical areas shall suffice.

Observation: Callaway/Holtec equipment had recently performed the initial load tests and NDE examinations for the lift yoke, yoke extension, HI-TRAC VW lifting lugs, MPC lift cleats, and the VCT lift links for the current year. NRC inspectors reviewed two worksheets that were produced for recording/tracking future test results for the Callaway owned equipment. Both Callaway owned and Holtec owned equipment's' preventative/routine maintenance procedures had not been fully developed at the time of the initial loading inspection. This will be a follow-up item to be reviewed in future inspections at Callaway.

Documents Reviewed: a) Callaway Worksheets PM15506409, "Lift Yoke Annual Load Test," Revision 0; b) PM15506408, "Lift Yoke Extension Annual Load Test," Revision 0

Category: Special Lifting Device **Topic:** Lifting Device's Initial Acceptance Testing

Reference: ANSI N14.6, Sect 7.3.1; Sect 6.2.1; Sect 6.5 Published 1993

Requirement Prior to initial use, the yoke shall be subjected to a test load equal to 300% of the maximum service load if a single component failure on the yoke could result in an uncontrolled lowering of the load. If the design for handling the load incorporates a dual-load-path concept, then each path in the dual-load-path device shall be tested to 150% of the load instead of the 300%. After sustaining the load for a period of not less than 10 minutes, critical areas, including load bearing welds, shall be subject to nondestructive testing using liquid penetrant or magnetic particle examination.

Observation: NRC inspectors reviewed load test procedures and acceptance testing results for the Lift Yoke, S/N: 702-0872-8851-1000-1; Lift Yoke Extension, S/N: 0929-878+91000-1-A; Lift Lug S/Ns: 723-006 "G" and 723.-010 "H;" and the MPC Lift Cleats and Shielding, S/N: 209-98131000-1. Those load tests included the results of hydraulically simulated loads of 300% the maximum rated load capacity, as specified by Holtec Procedure HSP-706. The inspection criteria included sustaining the simulated load for a minimum of ten minutes followed by dimensional measurements, which were at specified locations, pre and post load test. The inspection also called for visual testing and non-destructive testing of the special lifting devices and those results were also shared with the NRC. The lift yoke, lift yoke extension, both lift lugs, and the MPC lift cleats all passed the load, dimensional, and nondestructive testing that was required by ANSI N 14.6.

Documents Reviewed: a) Holtec Purchase Specification PS-3702, "Purchase Specification for the HI-TRAC VW Lift Yoke," Revision 5; b) Holtec Procedure HSP-706, "HI-TRAC VW Lift Yoke/Lift Lugs Load Test Procedure," Revision 2; c) Holtec Procedure HPP-2253-06, "Lift Yoke Extension Factory Acceptance Test," Revision 0; d) Holtec PS-3701, "Purchase Specification for the HI-TRAC VW Lift Links," Revision 2; e) Holtec Report No: HI-2135597, "MPC Lift Cleats Operation and Maintenance Manual," Revision 0; f) Holtec Procedure HPP-2253-06, "Lift Yoke Factory Acceptance Test," dated January 20, 2015; g) Holtec Procedure HSP-710, "MPC FW Lift Cleat Load Test Procedure," Revision 4

Category: Special Lifting Device **Topic:** Lifting Device's Stress Design -Dual-Load-Path

Reference: ANSI N14.6, Sect 4.2.1.1; Sect 4.1.3; Sect 7.2.3 Published 1993

Requirement For yokes that are single failure proof by having dual-load-path attachments, the load bearing members of the yoke shall be capable of lifting three (3) times the combined weight of the shipping container plus the weight of the intervening components of the special lifting device, without generating a combined shear stress or maximum tensile stress at any point in the device in excess of the corresponding minimum tensile yield strength of the material of construction. They shall also be capable of lifting five (5) times the weight without exceeding the ultimate tensile strength of the materials. The dual load-path attachment points on the yoke shall be designed such that each load path will be able to support a static load of three (3) times the weight of the critical load, including intervening components of the lifting device.

Observation: The lift yoke, as well as, the yoke extension, the HI-TRAC VW Lifting Lugs, the MPC lift cleats, the VCT lift links, and the transporter's pulley system used to download the MPC were all designed in accordance with the ANSI N14.6 standard and NUREG 0612 requirements. Stress reports and design specifications for each lifting device were reviewed to confirm the ANSI and NUREG design requirements were properly specified. Additionally, the NRC inspectors reviewed the bill of materials specified on the design drawing or in the components' documentation packages to confirm the components were fabricated from the same material as specified in the purchase specifications and stress reports.

Category: Special Lifting Device **Topic:** Special Lifting Devices Inspection Prior to Use

Reference: ANSI N14.6, Sect 6.3.6 Published 1993

Requirement The yoke shall be visually inspected by operating personnel for indications of damage prior to each use.

Observation: Prior to use inspections steps were placed in Callaway's loading procedures prior to rigging any of the special lifting devices used during the ISFSI loading operations. This included the yoke, yoke extension, HI-TRAC VW lift lugs, MPC cleats, and VCT lift links.

Documents Reviewed: a) Procedure HPP-2253-200, "MPC Loading at Callaway," Revision 9; b) Procedure HPP-2253-400, "MPC Transfer at Callaway," Revision 7

Category: Special Lifting Device **Topic:** Transporter Initial Acceptance Testing

Reference: ANSI N14.6, Sect 7.3.1; Sect 6.2.1; Sect 6.5 Published 1993

Requirement Prior to initial use, the special lifting device shall be subjected to a test load equal to 300% of the maximum service load if a single component failure on the yoke could result in an uncontrolled lowering of the load. If the design for handling the load incorporates a single-failure proof concept, then each path in the dual-load-path device shall be tested to 150% of the load instead of the 300%. After sustaining the load for a period of not less than 10 minutes, critical areas, including load bearing welds, shall be subject to nondestructive testing using liquid penetrant or magnetic particle examination.

Observation: Review of the factory acceptance test documentation showed that the VCT used by Callaway for its initial ISFSI campaign had met all of the regulatory requirements. The Vertical Cask Transporter (VCT) used at Callaway for transfer of the MPC from the fuel building to the ISFSI pad had its initial acceptance testing performed on April 9 and 10, 2015. NRC inspectors reviewed the test records that documented the 125% static load test, 100% dynamic load and operational test, 150% MPC downloader system test, initial and post-test non-destructive examination (NDE), and others.

Documents Reviewed: a) Holtec Procedure HSP-199, "VCT Factory Acceptance Test Procedure," Attachment 7.1, "FAT [Factory Acceptance Test] and Sign-offs," Revision 2

Category: Special Lifting Device **Topic:** Transporter Inspection - Quarterly

Reference: ANSI N14.6, Sect 6.3.7 Published 1993

Requirement Special lifting devices shall be visually inspected by maintenance or other non-operating personnel at intervals not to exceed three months in length for indications of damage or deformation.

Observation: Callaway's Procedure ETP-ZZ-04021 had included acceptance criteria for vendor owned (Holtec) special lifting devices in Step 7.1.12 for the HI-TRAC lift lugs and Step 7.1.28 for the MPC lid lift cleats, which included making sure that all periodic maintenance and checks had been performed. This procedure also included the Callaway owned special lifting devices of the lift yoke and lift yoke extension in Step 7.1.19. NRC inspectors reviewed the quarterly preventative maintenance worksheets for both the lift yoke and lift yoke extension. NRC verified that all of the proper procedures and supporting documents were in place to support the quarterly visual inspection of special lifting devices or to check to insure that vendor supplied special lifting devices had been properly tested prior to use at Callaway.

Category: Storage Operations **Topic:** Storage Cask Temperature Monitoring

Reference: CoC 1040, Tech Spec A.3.1.2 Amendment 0

Requirement Verify all VVM outlet air ducts are free of blockage from solid debris or floodwater every 24 hours, OR for VVMs with installed temperature monitoring equipment, verify that the difference between the average VVM air outlet temperature and ISFSI ambient temperature is less than or equal to 80 degrees F every 24 hours for storage casks containing PWR canisters.

Observation: The licensee planned to conduct vent screen daily observations per operator rounds procedure ODP-ZZ-0016E, Appendix 1, Point ID OPS 02174. If debris was found, the operator would clear the debris from the vents. If the clearance could not be accomplished by hand, a work order would be created to clear the debris. Results were communicated to a licensed operator who documented the results in OSP-ZZ-00001, Attachment 4 and in the Operator Log. If there was a blockage, OSP-ZZ-00001 directed the operator to review the applicable Technical Specification for applicability.

Documents Reviewed: a) Callaway Procedure ODP-ZZ-0016E Appendix 1, "Inside Operator Rounds," dated 06/29/2015; b) Callaway Procedure OSP-ZZ-00001, "Control Room Shift and Daily Log Readings and Channel Checks," Attachment 4, Revision 85

Category: Storage Operations **Topic:** Thermal Acceptance Test

Reference: FSAR 1040 Section 10.3.iii Revision 2

Requirement A thermal acceptance test shall be performed on the first fully loaded VVM assembly whose aggregate MPC heat load is at least 50% of the Design Basis maximum heat load per the system CoC.

Observation: Callaway placed limits on their first campaign's canisters' heat loads to ensure all MPCs would have a heat load below 50% of the Design Basis maximum. By placing this restriction, Callaway would not be required to perform the Heat Transfer Validation Test. Callaway Procedure ETP-ZZ-04020 Section 5.1, noted that the aggregate heal load of the loaded elements will not exceed 33.88 KW which is 80 percent of the design basis limit of 43.5 kW. A note in the Section 5.1 listed 21.75 kW as the threshold for when a thermal performance test would be required.

Table 8-8H of Procedure ETP-ZZ-04020, provided decay heat load for selected elements including inserts and approved MPC Regions for loading. Attachment 1 to the procedure provided fuel assembly identification numbers, insert identification numbers, decay heat rate per assembly, assembly burnup, spent fuel pool location prior to loading operations, the cell location in the MPC into which the assembly is to be loaded, the decay heat limit for the specified MPC cell, and the MPC cell allowed inserts for the six canisters that were to be loaded in the first campaign.

The licensee completed a two party compliance checklist for each MPC loaded in the campaign. The checklist verified that all assemblies met the MPC cell decay heat limit, that the total heat load was less that 21.75 kW, the all assembly burnups were equal to or less than 68,200 MWD/MTU, that all fuel assemblies are Westinghouse 17X17 Zr clad assemblies, that all assemblies have been discharged for more than 3 years, that all fuel

assemblies are approved for the designated MPC region, the MPC contained no nuclear source assemblies, that RCCAs were only placed in cells 5 through 7, 10 through 14, 17 through 21, 24 through 28 and 31 through 33, that BRPA maximum burnup was 60,000 MWD/MTU and that RCCA and Thimble plug maximum burnup is 630,000 MWD/MTU. Review of the data supplied for each MPC loading indicated that applicable limits were met.

Documents Reviewed: a) Callaway Procedure ETP-ZZ-04020, "Fuel Selection and Cask Loading for Dry Cask Storage," Revision 0; b) Cask Loading Plan, Attachment 1 to ETP-ZZ-04020, Revision 0, for MPC# HGMPC0037,HGMPC0038, HGMPC0039, HGMP0040, HGMP0041, HGMP0042

Category: Storage Operations **Topic:** VVM Vent Screen Inspections

Reference: FSAR 1040, Table 10.4.1 Revision 2

Requirement The VVM vent screens shall be visually examined for damage monthly.

Observation: The licensee incorporated the FSAR requirement to perform monthly visual examinations of the VVM vent screens into the Preventative Maintenance system as PM # 1008329. This maintenance item required a monthly visual check of the VVM screens for damage and accessible VVM areas for long term degradation.

Documents Reviewed: a) Callaway PM #1008329, "VVM Monthly Inspections," Revision 0

Category: Unloading Operations **Topic:** Canister Gas Sampling

Reference: FSAR 1032, Section 9.4.3.4 Revision 3

Requirement During unloading of a cask, gas sampling is performed to assess the condition of the fuel assembly cladding. The gas sample bottle is connected to the vent port RVOA and the RVOA body and sample bottle are evacuated. The vent port cap is then slowly opened using the RVOA, and the gas sample is obtained.

Observation: Callaway demonstrated the ability to draw a gas sample from a canister during the fluid operations dry run that was conducted on June 2-4, 2015. Callaway would utilize Procedure CSP-ZZ-07046 to obtain a gas sample if the licensee was required to unload an MPC. The procedure addressed ALARA concerns that could develop when performing the activity.

Documents Reviewed: a) Callaway Procedure CSP-ZZ-07046, "MPC Boron and Gas Activity," Revision 0

Category: Unloading Operations **Topic:** Canister Reflooding

Reference: FSAR 1032, Section 9.4.3.5.c. Revision 3

Requirement Reflood the canister slowly with a pressure of less than 90 psi through the drain port until bubbling from the vent line has terminated.

Observation: Reflooding of a canister would be performed through the drain port at a pressure of less than 90 psig. Procedure HPP-2253-500, Step 7.10.12 described commencing the reflooding of the canister. A note above that step required monitoring the pressure gage to ensure the MPC remained less than 90 psig. Attachment 8.8 of the procedure

contained the MPC reflood arrangement diagram that showed water would enter the MPC via the drain port.

Documents Reviewed: a) Holtec Procedure, HPP-2253-500 "MPC Unloading at Callaway," Revision 7

Category: Unloading Operations **Topic:** Hydrogen Monitoring

Reference: FSAR 1032, Table 9.1.1 Revision 3

Requirement To preclude the potential for hydrogen ignition during lid cutting, operating procedures require monitoring for combustible gas and purging the space beneath the canister lid with an inert gas.

Observation: Hydrogen monitoring was required during lid cutting operations and was incorporated into the weld cutting dry run that took place at Holtec HMD facility on June 16-18, 2015. NRC inspectors observed the weld cutting dry run and use of the hydrogen monitoring system. Holtec procedure HPP-2253-500 required continuous monitoring for hydrogen during cutting operations in Step 7.13.21. Personnel were required to record the hydrogen levels in Attachment 8.14, "MPC Combustible Gas Monitoring and Argon Purge Log," every 20 minutes during the duration of the cutting evolution until cutting was complete.

Documents Reviewed: a) Holtec Procedure HPP-2253-500, "MPC Unloading at Callaway," Revision 7

Category: Welding **Topic:** Closure Ring, Vent and Drain Port Plate Weld PT

Reference: CoC 1040, Appendix B, Table 3-1 Amendment 0

Requirement A liquid penetrant (PT) examination is required on the root (if more than one weld pass is required) and the final pass on the vent and drain port cover plate welds. The PT examination shall be performed in accordance with NB-5245.

Observation: The PCI project instruction, in the steps under section 9.0, established a process for examining and documenting the acceptability of all levels of welding taking place to secure the closure lid and port vent cap lids to the Holtec Multi-Purpose Canister. Those steps of the instruction direct a liquid dye penetrant test after the root and other closure passes, after hydro testing, and prior to helium leak testing for the drain port cover plates. The NDE examinations for all sections of the final closure welds were spelled out by procedure and instructions. The PCI procedure satisfied the criteria set forth in CoC 1040 regarding PT of the closure lid, rings, and vent port caps.

Documents Reviewed: a) PCI Project Instruction PI-CNSTR-OP-CAL-H-01, "Closure Welding of Holtec Multi-Purpose Canisters – UMAX," Revision 1

Category: Welding **Topic:** Combustible Gas Monitoring

Reference: CoC 1040, Appendix B, Section 3.5 Amendment 0

Requirement During canister lid-to-shell welding operations, combustible gas monitoring of the space under the lid is required to ensure that there is no combustible gas mixture present in the welding area.

Observation: The requirement to monitor the space under the lid for combustible gases (hydrogen)

was covered in the PCI procedure for the closure welding of the MPC in Step 8.3.4 which calls for hydrogen monitoring the be performed until the lid-to-shell weld has been completed. PCI had procedures in place that met the combustible gas monitoring requirement as called out in the Holtec CoC 1040.

Documents Reviewed: a) PCI Project Instruction, PI-CNSTR-OP-CAL-H-01, "Closure Welding of Holtec Multi-Purpose Canisters – UMAX," Revision 1

Category: Welding **Topic:** Control of Weld Filler Materials

Reference: 10 CFR 72.154 Published 2015

Requirement The licensee shall establish measures to ensure that purchased material, equipment, and services conform to procurement documents. These measures must include provisions for source evaluation and selection, objective evidence of quality furnished by the contractor/subcontractor, inspection at the contractor/subcontractor source and examination of product on delivery. Records shall be available for the life of the ISFSI. The effectiveness of the control of quality by contractors/subcontractors shall be assessed at intervals consistent with the importance, complexity and quantity of the product or service.

Observation: PCI had established for Callaway a procedure for control of weld wire and other materials that met the applicable requirements of 10 CFR 72.154. PCI Procedure GQP-7.1 covered the procurement, receipt, storage, and issuance requirements for weld and fill materials to be used in support of dry fuel storage operations at Callaway. WCP-3 implemented the security and storage requirements of NUREG/CR-6314 Section 4.3.2.1.2 (6) (d) in its Section 8, "Storage and Disbursement Areas." This section of the PCI procedure specified how welding filler materials, electrodes, and other materials shall be stored and accessed by PCI welders and others who needed to access these materials.

Documents Reviewed: a) PCI Procedure GQP-7.1, "Procurement, Receipt, Storage, and Issue of ASME III, Subsection NCA 3800 Weld Materials," Revision 7; b) PCI Welding Control Procedure, WCP-3, "Weld Material Control," Revision 0

Category: Welding **Topic:** Minimum Delta Ferrite Content

Reference: ASME Section III, Article NB-2433; Reg Guide 1.31 Published 2007

Requirement A delta ferrite determination must be made for A-No.8 consumable inserts, bare electrode, rod, or wire filler metal. Exceptions: 1) A-No.8 metal used for weld metal cladding; 2) SFA-5.4 and SFA-5.9 metal; 3) Type 16-8-2 metal. The minimum acceptable delta ferrite content is 5 FN and it must be stated in the certification records.

Observation: The ferrite number for all of the inspected certified mill test results (CMTRs) were above the required number of 5 FN. The weld filler material's CMTRs inspected by the NRC all exceeded the minimum code requirements.

Documents Reviewed: a) PCI Certificate of Conformance 907864-01; b) ARCOS Certified Material Test Report for PCI purchase order, PO# 4500651885

Category: Welding **Topic:** Procedure Qualification Record (PQR)

Reference: ASME Section IX, Part QW-200.2 Published 2007

Requirement Each manufacturer or contractor shall prepare a Procedure Qualification Record (PQR) for each procedure. The completed PQR shall document all essential and, when required, all supplementary essential variables of QW-250 through QW-280 for each welding process used during the welding of the test coupon. Non essential variables may be documented at the contractor's option. The PQR shall be certified accurate by the manufacturer or contractor.

Observation: PCI, the welding contractor for Callaway, had prepared the Procedure Qualification Records with the required information for each welding procedure. The procedure qualification records (PQR-062, PQR-063, PQR-600, PQR-864, and PQR-899) for Weld Procedure Specifications (WPS) 8-MC-GTAW and 8 MN-GTAW listed the proper essential, supplementary, and non-essential variables, as specified in ASME Section IX, Part QW-200.2

Documents Reviewed: a) PCI PQR-062, Revision 3; b) PCI PQR-600, Revision 6; c) PCI PQR-864, Revision 2; d) PCI PQR-899, Revision 0; e) PCI PQR-063, Revision 6; f) PCI WPS 8-MC-GTAW, Revision 15; g) PCI WPS 8 MN-GTAW, Revision 3

Category: Welding **Topic:** Procedure Qualification Tests

Reference: ASME Section III, Article NB-4331 Published 2007

Requirement All welding procedure qualification tests shall be in accordance with the requirements of Section IX. ASME Section IX Article II QW-202.2 (b) requires partial penetration groove welds to be qualified in accordance with the requirements of QW-451. QW-202.2 (c) states that welding procedure specification (WPS) qualification for fillet welds may be made on groove-weld test coupons using test specimens specified in (b) above.

Observation: The procedure qualification records (PQR-062, PQR-063, PQR-600, PQR-864, and PQR-899) test coupons, which qualified Welding Procedure Specifications 8-MC-GTAW and 8-MN-GTAW, all satisfactorily passed the required tests per Table QW-451.1 "Groove - Weld Tension Tests and Transverse-Bend Tests."

Documents Reviewed: a) PCI PQR-062, Revision 3; b) PCI PQR-600, Revision 6; c) PCI PQR-864, Revision 2; d) PCI PQR-899, Revision 0; e) PCI PQR-063, Revision 6; f) PCI WPS 8-MC-GTAW, Revision 15; g) PCI WPS 8 MN-GTAW, Revision 3

Category: Welding **Topic:** Tack Welds

Reference: ASME Section III, Article NB-4231.1 Published 2007

Requirement Tack welds used to secure alignment shall either be removed completely when they have served their purpose, or their stopping and starting ends shall be properly prepared by grinding or other suitable means so that they may be satisfactorily incorporated into the final weld. When tack welds are to become part of the finished weld, they shall be visually examined and defective tack welds shall be removed.

Observation: NRC reviewed PCI's general welding procedure and found that it did not explicitly address the incorporation of tack welds into the final weld by grinding or other suitable means. This was taken and placed into the Callaway corrective action program as CAR

201501626. The licensee decided that language would be adopted and placed into the general welding standard to address this shortcoming. Language was added to Step 7.2.5 in Revision 1 of the PCI procedure for closure welding of Holtec MPCs, directing that tack weld starts and stops should be "ground" or "feathered" for suitable incorporation into the final weld.

Documents Reviewed: a) PCI General Welding Standard - 1 (GWS-1), Revision 0; b) PCI Project Instruction PI-CNSTR-OP-CAL-H-01, "Closure Welding of Holtec Multi-Purpose Canisters – UMAX," Revision 1

Category: Welding **Topic:** Weld Repairs - Base Metal Defects

Reference: ASME Section III, Article NB-4132 Published 2007

Requirement Weld repairs exceeding in depth the lesser of 3/8 inch (10 mm) or 10 percent of the section thickness, shall be documented on a report which shall include a chart which shows the location and size of the prepared cavity, the welding material identification, the welding procedure, the heat treatment, and the examination results of the weld repair.

Observation: This requirement was met. PIC Weld Control Procedure, WCP-5, did not reference ASME Section III, Article NB-4132 as a standard, nor did it include the requirements that all weld repairs exceeding 3/8 inch or 10 percent of the section thickness shall be documented on a report that includes a chart showing the location and size of the prepared cavity, weld material identification, procedure and examinations results of the weld repair. This issue was addressed in a revision to PCI Project Instruction PI-CNSTR-OP-CAL-H-01. Revision 1 of the Procedure PI-CNSTR-OP-CAL-H-01 in Step 7.2.6 included wording to align the weld repair criteria at Callaway with the ASME code document. In addition, the base metal and weld repair worksheet, Attachment 10, of that instruction was updated, as well.

Documents Reviewed: a) PCI Project Instruction PI-CNSTR-OP-CAL-H-01, "Closure Welding of Holtec Multi-Purpose Canisters – UMAX," Revision 1; b) PCI Weld Control Procedure WCP-5, "Weld and Base Metal Repair," Revision 0

Category: Welding **Topic:** Weld Types for Canister Lid

Reference: FSAR 1032, Table 7.1.1 Revision 3

Requirement The canister closure welds on the canister lid shall be the following types: (a) canister lid to shell - partial penetration groove (b) vent and drain port cover plates - partial penetration groove (c) closure ring to shell - fillet (d) closure ring to closure ring radial - partial penetration groove (e) closure ring to lid - partial penetration groove.

Observation: PCI had procedures in place that insured all applicable welds listed in the Holtec HI-STORM FW FSAR Table 7.1.1 were accounted for. The types of canister closures welds used for the MPC were documented per the project instruction in Attachment 6, "PCI Energy Services Weld Process Traveler," and Attachment 7, "PCI Energy Services Multiple Weld Data Card." These attachments listed the weld types for each weld made in the process of final closure of the MPC.

Documents Reviewed: a) PCI Project Instruction PI-CNSTR-OP-CAL-H-01, "Closure Welding of Holtec Multi-Purpose Canisters – UMAX," Revision 1

Category: Welding **Topic:** Welder Performance Qualification Test

Reference: ASME Section IX, Part QW-301.2 Published 2007

Requirement The welder performance qualification test shall be welded in accordance with a qualified welding procedure specification (WPS), unless preheat or post weld heat treatment is specified.

Observation: NRC inspectors reviewed the Callaway procedure that provided instructions for qualifying welders, brazers, and brazing operators working under the Callaway's QA program. NRC inspectors also reviewed the welder performance qualification records (WPQs) and welding procedure specifications for the various welding procedures qualified for use during dry cask loading operations at Callaway. Each of the welders present during the welding dry run were qualified to perform the lid to shell, port caps covers, and final closure ring welding for the Holtec MPC. In addition, the qualifications of an additional welder who participated in the first loading campaign was also reviewed by the NRC inspectors.

Documents Reviewed: a) Callaway Procedure MTW-ZZ-WP002, "Welder Performance Qualification," Revision 27 b) PCI Welder Maintenance Logs (numerous); c) PCI ASME Section IX Welding Procedure Specifications for 8 MC-GTAW, Revision 15 and 8 MN-GTAW, Revision 4; d) PCI ASME IX Welding Procedure Qualification Records (numerous)

Category: Welding **Topic:** Welding Operator Performance Qualification

Reference: ASME Section IX, Parts QW-301.4, 361.2, 452.1, 6 Published 2007

Requirement The record of welding operator performance qualification (WOPQ) tests shall include the essential variables listed in QW-360, the type of test and test results, and the ranges qualified in accordance with QW-452. The essential variables for machine welding are: (1) welding process; (2) direct or remote visual control; (3) automatic arc voltage control (GTAW); (4) automatic joint tracking; (5) position qualified; (6) consumable inserts; (7) backing; and (8) single or multiple passes per side. Two side bend tests are required for groove weld test coupons 3/4 inch thick or greater. Groove weld tests qualify fillet welds.

Observation: NRC reviewed the welder performance qualification reports (WPQs) of several welders qualified to support dry cask storage operations at Callaway, including the welders who participated in the welding dry-run activities the week of May 18, 2015. All of the qualification records for welders explicitly addressed all eight essential variables noted in the requirement section, above. The welders performing the welding dry-run activities at Callaway were qualified in the eight essential variables. NRC inspectors also reviewed the performance qualification of an additional welder who participated in the initial loading campaign at Callaway who was not present during the welding dry-run.

Documents Reviewed: a) Numerous PCI Welder Performance Qualification records (WPQs)

Category: Welding **Topic:** Welding Procedure Specification (WPS)

Reference: ASME Section IX, Part QW-200.1 Published 2007

Requirement Each manufacturer or contractor shall prepare written Welding Procedure Specifications for making production welds to code requirements. Welding Procedure Specifications shall include the essential, non-essential, and (when required) supplementary essential variables for each welding process. The variables are listed in QW-250 through QW-280 and are defined in Article IV, Welding Data.

Observation: PCI, the welding contractor for Callaway, had prepared written Weld Procedure Specifications (WPS) 8-MC-GTAW and 8 MN-GTAW. Each WPS listed the proper essential, supplementary, and non-essential variables.

Documents Reviewed: a) PCI WPS 8-MC-GTAW, Revision 15; b) PCI WPS 8 MN-GTAW, Revision 3

CERTIFICATE OF SERVICE

I hereby certify that on July 20, 2020, I electronically filed the foregoing with the Clerk of the Court for the United States Court of Appeals for the Ninth Circuit by using the appellate CM/ECF system.

Participants in the case who are registered CM/ECF users will be served by the appellate CM/ECF system.

Dated: July 20, 2020

HOLTEC INTERNATIONAL

DOCUMENT CATEGORIZATION			
In accordance with the Holtec Quality Assurance Manual and associated Holtec Quality Procedures (HQPs), this document is categorized as a:			
☐	Calculation Package[3] (Per HQP 3.2)	☒	Technical Report (Per HQP 3.2)(Such as a Licensing Report)
☐	Design Criterion Document (Per HQP 3.4)	☐	Design Specification (Per HQP 3.4)
☐	Other (Specify):		

DOCUMENT FORMATTING
The formatting of the contents of this document is in accordance with the instructions of HQP 3.2 or 3.4 except as noted below:

DECLARATION OF PROPRIETARY STATUS					
☒	Nonproprietary	☐	Holtec Proprietary	☐	Privileged Intellectual Property (PIP)
Documents labeled Privileged Intellectual Property contain extremely valuable intellectual/commercial property of Holtec International. They cannot be released to external organizations or entities without explicit approval of a company corporate officer. The recipient of Holtec's proprietary or Top Secret document bears full and undivided responsibility to safeguard it against loss or duplication.					

Notes:

1. This document has been subjected to review, verification and approval process set forth in the Holtec Quality Assurance Procedures Manual. Password controlled signatures of Holtec personnel who participated in the preparation, review, and QA validation of this document are saved in the N-drive of the company's network. The Validation Identifier Record (VIR) number is a random number that is generated by the computer after the specific revision of this document has undergone the required review and approval process, and the appropriate Holtec personnel have recorded their password-controlled electronic concurrence to the document.

2. A revision to this document will be ordered by the Project Manager and carried out if any of its contents is materially affected during evolution of this project. The determination as to the need for revision will be made by the Project Manager with input from others, as deemed necessary by him.

3. Revisions to this document may be made by adding supplements to the document and replacing the "Table of Contents", this page and the "Revision Log".

GLOSSARY OF TERMS USED IN HI-STORM SAFETY ANALYSIS REPORTS

AFR is an acronym for Away from Reactor storage**.**

ALARA is an acronym for As Low As Reasonably Achievable

Ambient Temperature for Short Term Operations (operations involving use of the HI-TRAC, a Lifting device and/ or a on-site transport device) is defined as the 24 hour average of the local temperature as forecast by the National Weather Service.

Ancillary or Ancillary Equipment is the generic name of a device used to carry out "short term operations.

Bottom Lid means the removable lid that fastens to the bottom of the HI-TRAC transfer cask body to create a gasketed barrier against in-leakage of pool water in the space around the MPC.

Bottom MPC Guides are the MPC Guides located in the bottom region of the MPC storage cavity.

BWR is an acronym for Boiling Water Reactor.

Canister means an all-welded vessel containing used fuel that has been qualified to serve as a confinement boundary under the rules of 10CFR 72.

Cavity Enclosure Container (CEC) means a thick walled cylindrical steel weldment that defines the storage cavity for the MPCs.

CG is an acronym for center of gravity.

Closure Lid means the METCON lid that is installed on the MPC storage cavity to provide physical and shielding protection to the stored MPC.

Commercial Spent Fuel or CSF refers to nuclear fuel used to produce energy in a commercial nuclear power plant.

Confinement Boundary means the outline formed by the sealed, cylindrical enclosure of the Multi-Purpose Canister (MPC) shell welded to a solid baseplate, a lid welded around the top circumference of the shell wall, the port cover plates welded to the lid, and the closure ring welded to the lid and MPC shell providing the redundant sealing.

Confinement System means the Multi-Purpose Canister (MPC) which encloses and confines the spent nuclear fuel during storage.

Container Flange means the ring flange that is welded to the upper extremity of the Container shell.

Container Shell means the cylindrical portion of the Cavity Enclosure Container

Controlled Area means that area immediately surrounding an ISFSI for which the owner/user exercises authority over its use and within which operations are performed.

Controlled Low-Strength Material (CLSM) Withheld in Accordance with 10 CFR 2.390

Cooling Time (or post-irradiation cooling time) for a spent fuel assembly is the time between its final discharge from the reactor to the time it is loaded into the MPC.

Critical Characteristic means a feature of a component or assembly that is necessary for the proper safety function of the component or assembly. Critical characteristics of a material are those attributes that have been identified, in the associated material specification, as necessary to render the material's intended function.

DAS is the abbreviation for the Decontamination and Assembly Station. It means the location where the Transfer Cask is decontaminated and the MPC is processed (i.e., where all operations culminating in lid and closure ring welding are completed).

DBE means Design Basis Earthquake.

DCSS is an acronym for Dry Cask Storage System.

Damaged Fuel Assembly is a fuel assembly with known or suspected cladding defects, as determined by review of records, greater than pinhole leaks or hairline cracks, empty fuel rod locations that are not replaced with dummy fuel rods, missing structural components such as grid spacers, whose structural integrity has been impaired such that geometric rearrangement of fuel or gross failure of the cladding is expected based on engineering evaluations, or those that cannot be handled by normal means. Fuel assemblies that cannot be handled by normal means due to fuel cladding damage are considered fuel debris.

Damaged Fuel Container (or Canister) or DFC means a specially designed enclosure for damaged fuel or fuel debris which permits flow of gaseous and liquid media while minimizing dispersal of gross particulates.

Design Basis Load (DBL) is a loading defined in this SAR to bound one or more events that are applicable to the storage system during its service life. Thus, the pressure loading on the cask's lid specified in this SAR is a DBL because it is set substantially above the pressure from accumulated snow set down in the national consensus standard for the 48 contiguous United States.

Design Heat Load or Design Basis Heat Load is the computed heat rejection capacity of the HI-STORM system with a certified MPC loaded with CSF stored in uniform storage with the ambient at the normal temperature and the peak cladding temperature (PCT) at 400ºC. The Design Heat Load is less than the thermal capacity of the system by a suitable margin that reflects the conservatism in the system thermal analysis.

Design Life is the minimum duration for which the component is engineered to perform its intended function set forth in this SAR, if operated and maintained in accordance with this SAR.

Design Report is a document prepared, reviewed and QA validated in accordance with the provisions of 10CFR72 Subpart G. The Design Report shall demonstrate compliance with the requirements set forth in the Design Specification. A Design Report is mandatory for systems, structures, and components designated as Important to Safety. The SAR serves as the Design Report for the HI-STORM UMAX System.

Design Specification is a document prepared in accordance with the quality assurance requirements of 10CFR72 Subpart G to provide a complete set of design criteria and functional requirements for a system, structure, or component, designated as Important to Safety, intended to be used in the operation, implementation, or decommissioning of the HI-STORM UMAX System. The SAR serves as the Design Specification for the HI-STORM UMAX System.

Divider Shell means a cylindrical shell bearing insulation over most of its inner or outer surface that divides the annular space between the MPC and the CEC shell into two discrete regions for down- flow and up-flow of air..

Duct Extension means a removable, non-structural member fastened to the inlet or outlet duct to move the location of air intake or exhaust, as applicable

Enclosure Wall means an optional circumscribing structure installed to mitigate the incursion of groundwater into the subgrade space of the ISFSI.

Enclosure Vessel (or MPC Enclosure Vessel) means the pressure vessel defined by the cylindrical shell, baseplate, port cover plates, lid, closure ring, and associated welds that provides confinement for the helium gas contained within the MPC. The Enclosure Vessel (EV) and the fuel basket together constitute the multi-purpose canister.

Equivalent (or Equal) Material is a material with critical characteristics (see definition above) that meet or exceed those specified for the designated material.

Fracture Toughness is a property which is a measure of the ability of a material to limit crack propagation under a suddenly applied load.

FSAR is an acronym for Final Safety Analysis Report (10CFR72).

Fuel Basket means a honeycombed structural weldment with square openings which can accept a fuel assembly of the type for which it is designed.

Fuel Building is the generic term used to denote the building in which the fuel loading and where a portion of "short-term operations" will occur.

Fuel Debris is ruptured fuel rods, severed rods, loose fuel pellets, containers or structures that are supporting these loose fuel assembly parts, or fuel assemblies with known or suspected defects which cannot be handled by normal means due to fuel cladding damage.

Fuel Shim is a suitably sized metallic part interposed in the space between the fuel and the MPC cavity at either the top or the bottom (or both) ends of the fuel to minimize the axial displacement of the SNF within the MPC due to longitudinal inertia forces.

High Burnup Fuel, or HBF is a commercial spent fuel assembly with an average burn-up greater than 45,000 MWD/MTU.

HI-PORT is a Holtec trade name for an engineered Low Profile Transporter to that maximizes protection of the cask against overturning under seismic conditions.

HI-TRAC is a generic term for the transfer cask used to house the MPC during MPC fuel loading, unloading, drying, sealing, and on-site transfer operations to a HI-STORM storage module or HI-STAR storage/transportation overpack. The HI-TRAC shields and protects the loaded MPC during short term operations.

HI-STORM VVM means the module that receives and contains the sealed multi-purpose canisters containing spent nuclear fuel for long term storage. It provides the gamma and neutron shielding, ventilation passages, missile protection, and protection against natural phenomena and accidents for the loaded MPC.

HI-STORM UMAX system consists of loaded MPCs stored in the HI-STORM UMAX VVM .

HI-STORM 100 System consists of any loaded MPC model placed within any design variant of the HI-STORM overpack in Docket number 72-1014.

Holtite*™*-A is a trademarked Holtec International neutron shield material.

Important to Safety (ITS) means a function or condition required to store spent nuclear fuel safely; to prevent damage to spent nuclear fuel during handling and storage, and to provide reasonable assurance that spent nuclear fuel can be received, handled, packaged, stored, and retrieved without undue risk to the health and safety of the public.

Independent Spent Fuel Storage Installation (ISFSI) means a facility designed, constructed, and licensed for the interim storage of spent nuclear fuel and other radioactive materials associated with spent fuel storage in accordance with 10CFR72.

Intact Fuel Assembly is defined as a fuel assembly without known or suspected cladding defects greater than pinhole leaks and hairline cracks, and which can be handled by normal

means. Fuel assemblies without fuel rods in fuel rod locations shall not be classified as Intact Fuel Assemblies unless dummy fuel rods are used to displace an amount of water greater than or equal to that displaced by the fuel rod(s).

Interim Storage means an autonomous monitored canister storage facility from which the stored canister can be retrieved, if necessary.

Interfacing Components means the weldments certified in other dockets that will be used with the HI-STORM UMAX VVM assemblies for transferring and storing MPCs in HI-STORM UMAX. The MPC is an Interfacing Component

ISFSI Pad means the reinforced concrete pad that provides the support surface for the cask handling device.

License Life means the duration for which the system is authorized by virtue of its certification by the U.S. NRC.

Licensing Drawings or Licensing Drawing Package is an integral part of this SAR wherein the essential geometric and material information on HI-STORM UMAX is compiled to enable the safety evaluations pursuant to 10 CFR 72 to be carried out.

Long-term Storage means the time beginning after on-site handling is complete and the loaded overpack is at rest in its designated storage location on the ISFSI pad and lasting up to the end of the licensed life of the HI-STORM 100 System.

Low Profile Transporter (LPT) is the generic name of the ancillary used to move a loaded or empty cask in a plant's "truck bay" and/or the haul path with the cask directly situated on a low lying platform founded on a structurally robust frame such that an uncontrolled lowering (free fall) of the cask is not credible. The LPT must be sufficiently short to insure that the loaded cask can clear the roll-up door in the truck bay.

Lowest Service Temperature (LST) is the minimum metal temperature of a part for the specified service condition.

Maximum Reactivity means the highest possible k-effective including bias, uncertainties, and calculational statistics evaluated for the worst-case combination of fuel basket manufacturing tolerances.

METAMIC® is a trade name for an aluminum/boron carbide composite neutron absorber material qualified for use in the MPCs and in wet storage applications.

METAMIC-HT is the tradename for the metal matrix composite made by imbedding nano-particles of aluminum oxide and fine boron carbide powder on the grain boundaries of aluminum resulting in improved structural strength properties at elevated temperatures.

METCON□ is a trade name for the HI-STORM overpack. The trademark is derived from the

metal-**con**crete composition of the HI-STORM overpack.

MGDS is an acronym for Mined Geological Disposal System.

Minimum Enrichment is the minimum assembly average enrichment. Natural uranium blankets are not considered in determining minimum enrichment.

Moderate Burnup Fuel, or MBF is a commercial spent fuel assembly with an average burnup less than or equal to 45,000 MWD/MTU.

Multi-Purpose Canister or MPC means the sealed canister consisting of a fuel basket for spent nuclear fuel storage, contained in a cylindrical canister shell (the MPC Enclosure Vessel). The MPC is the confinement boundary for storage conditions.

MPC Guides is a generic term to represent Top or Bottom MPC Guides

MPC Transfer means transfer of the MPC between the storage module and the transfer cask which begins when the MPC is lifted off the HI-TRAC bottom lid and ends when the MPC is supported from beneath by the module (or the reverse).

NDT is an acronym for Nil Ductility Transition Temperature, which is defined as the temperature at which the fracture stress in a material with a small flaw is equal to the yield stress in the same material if it had no flaws.

Neutron Absorber is a generic term used in this SAR to indicate any neutron absorber material qualified for use in the MPCs certified in a HI-STORM docket.

Neutron Shielding means a material used to thermalize and capture neutrons emanating from the radioactive spent nuclear fuel.

Non-Fuel Hardware is defined as Burnable Poison Rod Assemblies (BPRAs), Thimble Plug Devices (TPDs), Control Rod Assemblies (CRAs), Axial Power Shaping Rods (APSRs), Wet Annular Burnable Absorbers (WABAs), Rod Cluster Control Assemblies (RCCAs), Control Element Assemblies (CEAs), Neutron Source Assemblies (NSAs), water displacement guide tube plugs, orifice rod assemblies, Instrument Tube Tie Rods (ITTRs), vibration suppressor inserts, and components of these devices such as individual rods.

Planar-Average Initial Enrichment is the average of the distributed fuel rod initial enrichments within a given axial plane of the assembly lattice.

Plain Concrete is concrete that is unreinforced and is of density specified in this FSAR.

Post-Core Decay Time (PCDT) is synonymous with cooling time.

PWR is an acronym for pressurized water reactor.

Reactivity is used synonymously with effective neutron multiplication factor or k-effective.

Regionalized Fuel Loading is a term used to describe an optional fuel loading strategy used in lieu of uniform fuel loading wherein the storage locations are ascribed to two or more distinct regions each with its own maximum allowable specific heat generation rate.

Regionalized Fuel Storage is a term used to describe an optimized fuel loading strategy wherein the storage locations are ascribed to distinct regions each with its own maximum allowable specific heat generation rate.

Removable Shielding Girdle is an ancillary designed to be installed to provide added shielding to the personnel working in the top region of the transfer cask.

SAR is an acronym for Safety Analysis Report.

Self-hardening Engineered Subgrade (or SES) means CLSM or lean concrete in this FSAR.

Service Life means the duration for which the component is reasonably expected to perform its intended function, if operated and maintained in accordance with the provisions of this FSAR. Service Life may be much longer than the Design Life because of the conservatism inherent in the codes, standards, and procedures used to design, fabricate, operate, and maintain the component.

Short-term Operations means those normal operational evolutions necessary to support fuel loading or fuel unloading operations. These include, but are not limited to MPC cavity drying, helium backfill, MPC transfer, and onsite handling of a loaded HI-TRAC transfer cask.

Single Failure Proof means that the handling system is designed so that all directly loaded tension and compression members are engineered to satisfy the enhanced safety criteria of Paragraphs 5.1.6(1)(a) and (b) of NUREG-0612.

SNF is an acronym for spent nuclear fuel.

Specific Heat Load means the heat emission rate from one fuel assembly. Sum of the Specific Heat loads of all fuel assemblies in a canister is referred to as the Aggregate heat Load or SFSC Heat Load.

SSC is an acronym for Structures, Systems and Components.

STP is Standard Temperature and Pressure conditions.

Support Foundation Pad (SFP) means the reinforced concrete pad located underground on which the CECs are situated.

Subgrade is the lateral space between each CEC, the SFP and the ISFSI Pad.

TAL is an acronym for the Tapped Anchor Location.

Thermal Capacity of the HI-STORM system is defined as the amount of heat the storage system, containing an MPC loaded with CSF stored in *uniform storage,* will actually reject with the ambient environment at the normal temperature and the peak fuel cladding temperature (PCT) at 400ºC.

Thermo-siphon is the term used to describe the buoyancy-driven natural convection circulation of helium within the MPC fuel basket.

Top MPC Guides and Bottom MPC Guides mean the set of radial plates that are shaped to aid in the insertion and withdrawal of MPCs and serve to restrain the MPC's lateral movement during seismic events.

TOG is an acronym for top-of-the-grade of the ISFSI and identified by the by the riding surface of the cask transporter.

Traveler means the set of sequential instructions used in a controlled manufacturing program to ensure that all required tests and examinations required upon the completion of each significant manufacturing activity are performed and documented for archival reference.

Undamaged Fuel Assembly is defined as a fuel assembly without known or suspected cladding defects greater than pinhole leaks and hairline cracks, and which can be handled by normal means. Fuel assemblies without fuel rods in fuel rod locations shall not be classified as Intact Fuel Assemblies unless dummy fuel rods are used to displace an amount of water greater than or equal to that displaced by the fuel rod(s).

Under-grade is the space below the SFP**.**

Uniform Fuel Loading is a fuel loading strategy where any authorized fuel assembly may be stored in any fuel storage location, subject to other restrictions in the CoC, such as those applicable to non-fuel hardware, and damaged fuel containers.

Vertical Cask Transporter or VCT is the generic name for a device that has the ability to raise or lower a cask or a canister with the built-in safety of a redundant drop protection system. A VCT may be designed to be limited in its operation space to the ISFSI pad area and/or it may have the capability to translocate the cask over a suitably engineered haul path.

VVM is an acronym for Vertical Ventilated Module

ZPA is an acronym for zero period acceleration.

ZR means any zirconium-based fuel cladding material authorized for use in a commercial nuclear power plant reactor. Any reference to Zircaloy fuel cladding in this FSAR applies to any zirconium-based fuel cladding material.

FSAR SECTION REVISION STATUS, LIST OF AFFECTED SECTIONS AND REVISION SUMMARY

FSAR Report No.: HI-2115090 | **FSAR Revision Number:** 3

FSAR Title: Final Safety Analysis Report on the HI-STORM UMAX System

This FSAR is submitted to the USNRC in support of Holtec International's application to secure a CoC under 10CFR Part 72.

FSAR review and verification are controlled at the chapter level and changes are annotated at the chapter level.

A section in a chapter is identified by two numerals separated by a decimal. Each section begins on a fresh page. Unless indicated as a "complete revision" in the summary description of change below, if any change in the content is made, then the change is indicated by a "bar" in the right page margin and the revision number of the entire chapter including applicable figures (annotated in the footer) is changed.

A summary description of change is provided below for each FSAR chapter. Minor editorial changes to this FSAR may not be summarized in the description of change.

Chapter 1

Affected Section or Table No.	Current Revision No.	Summary Description of Change
Section 1.0	3	Updated description of underground per ECO
Section 1.0.2		Updated per Amendment 1 changes
Section 1.1		Updated per ECO on shell thickness
Section 1.2.2		Updated VVM description per ECO

HI-STORM UMAX FSAR
TABLE OF CONTENTS

CHAPTER 1: GENERAL DESCRIPTION OF THE HI-STORM UMAX SYSTEM

1.0 GENERAL INFORMATION

This final safety analysis report (FSAR) describes the Holtec International HI-STORM UMAX Canister Storage System (HI-STORM UMAX) and contains the necessary information and analyses to support a United States Nuclear Regulatory Commission (USNRC) licensing review as a spent nuclear fuel (SNF) dry storage cask under the provisions of 10 CFR 72 [1.0.3]. This report, prepared pursuant to 10 CFR 72.230, describes the basis for NRC approval and issuance of a Certificate of Compliance (CoC) on the HI-STORM UMAX System under 10 CFR 72, Subpart L to safely store spent nuclear fuel (SNF) at an Independent Spent Fuel Storage Installation (ISFSI) under the general license authorized by 10 CFR 72, Subpart K.

The HI-STORM UMAX stores a hermetically sealed canister containing spent nuclear fuel in an in-ground Vertical Ventilated Module (VVM). The safety evaluation and regulatory control is maintained in USNRC docket # 72-1040. The annex identifier UMAX is an acronym of Underground MAXimum capacity. HI-STORM UMAX is designed to provide long-term underground∗ storage of loaded multi-purpose canisters (MPC) previously certified for storage by the USNRC in Holtec International ("Holtec") Docket 72-1032 (HI-STORM FW) [1.0.2]. The HI-STORM UMAX VVM is essentially the underground equivalent of the HI-STORM FW overpack certified in Docket# 72-1032. Although the storage cavity dimensions and the air ventilation system in the HI-STORM UMAX VVM have been selected to enable it to also store all MPCs certified in for storage in the HI-STORM 100 overpack (Docket number 72-1014)[1.0.1], this FSAR does not seek to support their certification at this time. Safety analyses and evaluations of the HI-STORM 100 MPCs under (hypothetical) storage in HI-STORM UMAX are nevertheless included in this FSAR, as appropriate, to provide a comparative reference for the licensing-basis analyses of the HI-STORM FW canisters (MPC-37 & MPC-89). Thus while the safety analyses have been carried out in this FSAR for all MPCs presently certified in docket # 72-1014 (HI-STORM 100) and docket # 72-1032 (HI-STORM FW) , the Certificate-of-Compliance sought pursuant to this licensing submittal is *limited to qualifying only MPC-37 and MPC-89 which have been previously certified in the HI-STORM FW docket*. .Inclusion of the smaller MPCs originally certified in the HI-STORM 100 docket serves to underscore the plausible result that the structural and thermal margins are controlled by the larger canister. Specifically, it is found that MPC-37 governs in respect of structural and thermal margins. MPC-37 is therefore designated as the "governing canister". To insure that the CoC for the HI-STORM UMAX system is autonomously complete, the entire body of the latest versions

∗ The term "underground" is used throughout this document to refer to the HI-STORM UMAX System, in which MPCs are stored within a monolithic block, some of which is below grade, instead of within discrete above-ground overpacks. The term underground is not intended to mean that all portions of the system are located below the site grade level. Sites construct the HI-STORM UMAX in accordance with the license requirements and site-specific conditions.

of the Technical Specification pertaining to MPC-37, MPC-89 and HI-TRAC VW is excerpted from the "FW" docket and included in the proposed Technical Specifications for the HI-STORM UMAX storage system. To facilitate convenient access to the referenced material, the latest revision of the HI-STORM FW FSAR has been placed in this docket and a list of "FW " FSAR sections germane to this chapter is provided in a tabular form. Table 1.0.1 provides a listing of the applicable material adopted in this chapter by reference to the HI-STORM FW FSAR.

Except in cases where clarity of presentation calls for reproduction of the HI-STORM FW FSAR material in this FSAR, the safety analyses for the canisters and the transfer cask documented in the HI-STORM FW FSAR, where applicable, are incorporated by reference. *Directly copied FSAR text matter from the "FW" docket is provided in the "Arial" font to identify its provenance*.

HI-STORM UMAX is intended for dry storage of spent nuclear fuel at an Independent Spent Fuel Storage Installation (ISFSI) under 10CFR 72 [1.0.3] Subpart L. The HI-STORM UMAX ISFSI (illustrated in Figure 1.0.1), which may contain any number of UMAX VVMs, may be co-located at a licensed reactor site or at an away-from-reactor (AFR) site such as an interim storage facility. Certain innovative design features of HI-STORM UMAX are subject to patent action by the USPTO under application number 61625869 dated April 18, 2012. A licensing drawing package depicting the essential geometric details of the HI-STORM UMAX is provided in Section 1.5. The licensing drawings for MPC-37, MPC-89 and the HI-TRAC transfer cask are also reproduced in Section 1.5 from the "FW" docket for configuration control. The glossary preceding this chapter contains the definition of terms and acronyms that may be consulted as necessary.

This safety evaluation follows the guidelines of RG 3.61 [1.0.4] and NUREG-1536 [1.0.5] to qualify the MPC-37 and MPC-89 models previously certified in the HI-STORM FW Holtec docket for storage in the HI-STORM UMAX. This report has been prepared in the format and content suggested in NRC Regulatory Guide 3.61 [1.0.4] and NUREG-1536 Standard Review Plan for Dry Cask Storage Systems [1.0.5]. The only deviation in the format from the formatting instruction in Reg. Guide 3.61 is the insertion of a chapter (Chapter 8) on material compatibility pursuant to ISG-15 and renumbering of all subsequent chapters and only deviation from NUREG-1536 is the order of Chapters 5, 6 and 7 which is similar to HI-STORM FW format.

The Glossary contains a listing of the terminology and notation used in this FSAR.

The safety evaluations in this FSAR are intended to bound the conditions that exist in the vast majority of domestic power reactor sites and potential away-from-reactor storage sites in the contiguous United States. This includes the potential fuel assemblies which will be loaded into the system and the environmental conditions in which the system will be deployed. This FSAR also provides the basis for component fabrication and acceptance, and the requirements for safe operation and maintenance of the components, consistent with the design bases and safety analyses documented herein. In accordance with 10CFR72, Subpart K, site-specific implementation of the generically certified HI-STORM FW System requires that the licensee perform a site-specific evaluation, as defined in 10CFR72.212. The HI-STORM UMAX System FSAR identifies a number of conditions that are site-specific and are to be addressed in the licensee's 10CFR72.212 evaluation. These include:

- Siting of the ISFSI and design of the storage and security system. Site-specific demonstration of compliance with regulatory dose limits. Implementation of a site-specific ALARA program.
- An evaluation of site-specific hazards and design conditions that may exist at the ISFSI site or the transfer route between the plant's cask receiving bay and the ISFSI. These include, but are not limited to, explosion and fire hazards, flooding conditions, landslides, and lightning protection.
- Determination that the physical and nucleonic characteristics and the condition of the SNF assemblies to be stored meet the fuel acceptance requirements of the Certificate of Compliance.
- An evaluation of interface and design conditions that exist within the plant's Fuel Building in which canister fuel loading, canister closure, and canister transfer operations are to be conducted in accordance with the applicable 10CFR50 requirements and technical specifications for the plant.
- Detailed site-specific operating, maintenance, and inspection procedures prepared in accordance with the generic procedures and requirements provided in Chapters 9 and 10, and the Certificate of Compliance.
- Performance of pre-operational testing.
- Implementation of a safeguards and accountability program in accordance with 10CFR73. Preparation of a physical security plan in accordance with 10CFR73.55.
- Review of the reactor emergency plan, quality assurance (QA) program, training program, and radiation protection program.

In presenting the bounding generic analyses of this safety report, selected conditions are drawn from authoritative sources such as Regulatory Guides and NUREGs, where available.

Within this report, all figures, tables and references cited are identified by the double decimal system *m.n.i*, where *m* is the chapter number, *n* is the section number, and *i* is the table number. For a complete listing of Tables and Figure please consult the Table of Contents. For example, Figure 1.2.1 is the first figure in Section 1.2 of Chapter 1. Similarly, the following convention is used in the organization of chapters:

a. A chapter is identified by a whole numeral, say *m* (i.e., *m*=3 means Chapter 3)

b. A section is identified by one decimal separating two numerals. Thus, Section 3.1 is section 1 in Chapter 3.

c. A subsection has three numerals separated by two decimals. Thus, Subsection 3.2.1 is subsection 1 in Section 3.2.

d. A paragraph is denoted by four numerals separated by three decimals. Thus, Paragraph 3.2.1.1 is paragraph 1 in Subsection 3.2.1.

e. A subparagraph has five numerals separated by four decimals. Thus, Subparagraph 3.2.1.1.1 is subparagraph 1 in Paragraph 3.2.1.1.

Tables and figures associated with a section are placed after the text narrative. Drawings are controlled separately within the Holtec QA program and have individual revision numbers and are included in Section 1.5.

1.0.1 Engineering Change Orders

The changes authorized by the Holtec ECOs (with corresponding 10CFR72.48 evaluations, if applicable) listed in the following table are reflected in this Revision of the FSAR.

LIST OF ECO'S AND APPLICABLE 10CFR72.48 EVALUATIONS

Affected Item	ECO Number	72.48 Evaluation or Screening Number
MPC-37 Fuel Basket	**102-18**	**1110R0 and R1**

1.0.2 Changes Introduced in this FSAR

This FSAR revision corresponds to Amendment #1 to the CoC of HI-STORM UMAX Canister Storage system. The changes in this FSAR are necessary to increase the intensity of the permitted earthquake hereafter referred to as the "Most Severe Earthquake" (MSE) for the UMAX system. The physical design changes are as follows:

a. Addition of a hold-down system to the Closure Lid to prevent its uplift during MSE.
b. The fill material interstitial space between the CECs, referred to as Space A in Figure 2.4.4, is replaced with plain concrete with a minimum compressive strength of 3000 psi (see Table 2.3.10)
c. The MPC Guides are strengthened to increase their load bearing capacity and their nominal gap with the MPC is engineered to be made vanishingly small.

The design embodiment of HI-STORM UMAX wherein the above changes are incorporated is referred to as "Version MSE."

There are no other upgrades to the design of the "UMAX" ISFSI to meet the loads from the MSE.

1.0.2.1 Change in Design and Applicable Loading

The only significant change contemplated under this CoC Amendment is the introduction of a stronger Design Basis Earthquake (DBE) than that previously approved for the "UMAX" system. The new governing earthquake is quantified in Table 2.3.10 and Table 2.4.5 in Chapter 2.

The seismic analysis to evaluate the admissibility of the more severe DBE is documented in subparagraph 3.4.4.1.2 in Chapter 3.

1.0.2.2 Chapters affected by Amendment 1

The table below lists the locations in this FSAR that contain additions or revisions.

Chapter & Title	Chapter Modified?	Comment/ Justification
1.General Description	Yes	The scope of change applicable to this FSAR revision is summarized in this subsection. The drawing package in Section 1.5 is revised to incorporate the changes mentioned above that together define "Version MSE."
2. Principal Design Criteria	Yes	The intensity of the Design Basis Earthquake is increased as set down in Table 2.3.10. The ISFSI is required to meet the new DBE (termed the Most Severe Earthquake) under five generated earthquakes consisting of statistically independent time histories that all bound the target response spectra per

		SRP3.7.1(see Table 2.4.5).
3. Structural Evaluation	Yes	Additional stress analysis under the so-called Most Severe Earthquake is provided in subparagraph 3.4.4.1.2 in Chapter 3
4. Thermal Evaluation	No	The thermal-hydraulic design of the system is unchanged; hence there is no effect on its thermal characteristics.
5. Shielding Evaluation	No	There is no change in the shielding design features of the system and hence there is no change in its shielding characteristics.
6. Criticality Evaluation	No	There is no change in the MPC or fuel basket design.
7. Confinement Evaluation	No	The design, manufacturing and inspection of the MPC's Enclosure Vessel remains unchanged; therefore, there is no change in the system's confinement capability.
8.Material Evaluation	No	No new material or environmental condition is introduced in this revision.
9.Operating Procedures	No	The loading and unloading procedures remain unchanged.
10. Acceptance Criteria & Maintenance Programs	No	No change
11.Radiation Protection	No	The radiation protection features of the system remain unchanged.
12. Accident Evaluation	No	No new accidents are introduced.
13.Operating Controls and Limits	No	No change in operating controls or limits.
14. Quality Assurance Program	No	The applicable QA program remains unchanged.

As can be seen from the above table, the new text matter and safety evaluation for the proposed change are limited to specific subsections in Chapters 1, 2 and 3. The rest of the FSAR is unaffected by the amendment.

* For convenience of reference, the specific revision of the HI-STORM FW FSAR that is referenced in the safety analysis herein is placed in this docket. Updated versions of the HI-STORM FW FSAR shall be placed in this docket as necessary so as to ensure that the safety analyses on the "UMAX" docket (72-1040) remain aligned with the material referenced in the HI-STORM FW FSAR.

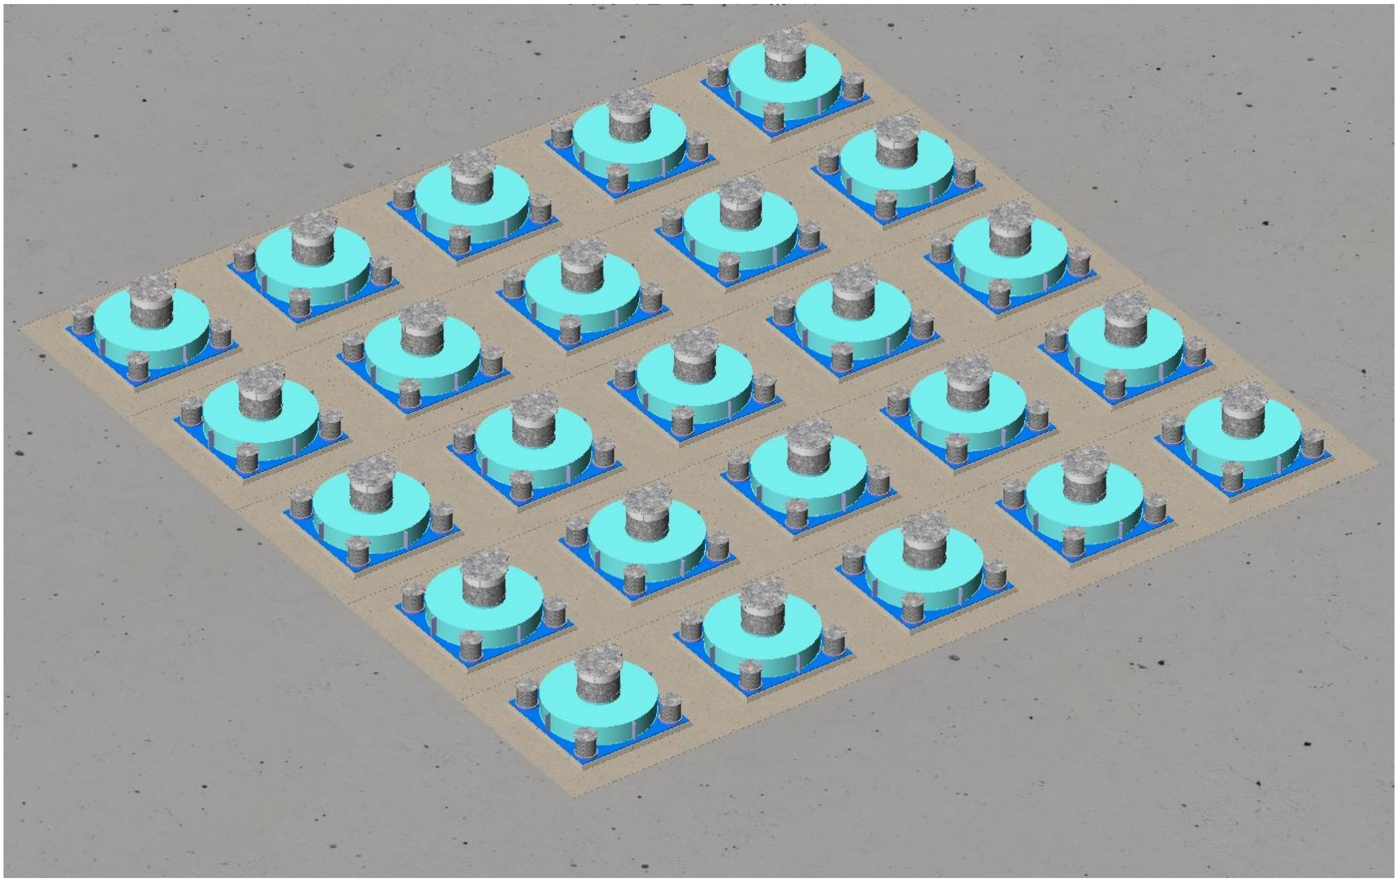

Figure 1.0.1; Pictorial View of a HI-STORM UMAX ISFSI

1.1 INTRODUCTION

HI-STORM UMAX is a dry, in-ground spent fuel storage system consisting of any number of Vertical Ventilated Modules (VVM) each containing one canister. The HI-STORM UMAX is designed to be fully compatible with all HI-TRAC transfer casks and multi-purpose canisters (MPC) presently certified under USNRC Docket No. 72-1014 and 72-1032. Safety analyses documented herein treat all MPCs listed in Table 1.2.1. However, as would be expected, the largest canisters, i.e., those licensed in the HI-STORM FW docket are governing in terms of structural and thermal margins. These largest canisters, namely MPC-37 and MPC-89 are termed "Licensing Basis MPCs" and the certification request for storage in HI-STORM UMAX is limited to these MPCs only. For completeness, the permissible contents from the HI-STORM FW docket are excerpted in Chapter 2 herein and also reproduced in the Technical Specification applicable to the CoC. The safety analyses summarized in this FSAR are intended to demonstrate that the HI-STORM UMAX System can safely store PWR or BWR fuel assemblies, in the MPC-37 or MPC-89, respectively. The MPC is identified by the maximum number of fuel assemblies it can contain in the fuel basket. As presently licensed in the HI-STORM FW docket, the standard MPC external diameters are identical to allow the use of a single overpack design; however the height of the MPC is varied to accord with the SNF to be loaded.

The MPC is an integrally welded pressure vessel designed to meet the stress limits of the ASME Boiler and Pressure Vessel Code, Section III, Subsection NB [1.1.1]. The MPC defines the Confinement Boundary for the stored spent nuclear fuel assemblies. Regardless of the storage cell count, the construction of the MPC is fundamentally the same; the basket is a honeycomb structure comprised of cellular elements. This is positioned within a circumscribing cylindrical canister shell. The egg-crate construction and cell-to-canister shell interface employed in the MPC basket impart the structural stiffness necessary to satisfy the limiting load conditions discussed in Chapter 2 of the HI-STORM FW FSAR. Figures 1.1.1 and 1.1.2 provide cross-sectional views of the PWR and BWR fuel baskets, respectively. Figures 1.1.3 and 1.1.4 provide isometric perspective views of the PWR and BWR fuel baskets, respectively.

The HI-STORM UMAX VVM provides structural protection, cooling, and radiological shielding for the MPC.

The HI-TRAC VW transfer cask (hereafter referred to as HI-TRAC) is required for shielding and protection of the SNF during loading and closure of the MPC and during movement of the loaded MPC from the cask loading area of a nuclear plant spent fuel pool to the storage overpack. Figure 1.1.5 shows a cut away view of the transfer cask. The MPC is placed inside the HI-TRAC transfer cask and moved into the cask loading area of nuclear plant spent fuel pools for fuel loading (or unloading). The HI-TRAC/MPC assembly is designed to prevent (contaminated) pool water from entering the narrow annular space between the HI-TRAC and the MPC while the assembly is submerged. The HI-TRAC transfer cask also allows dry loading (or unloading) of SNF into the MPC in a hot cell.

Design criteria for a forced helium dehydration (FHD) system is provided in Section 2.5.1.

The HI-STORM UMAX is comparable to the HI-STORM 100U ("100U") VVM licensed in NRC Docket No. 72-1014. The major differences between the HI-STORM UMAX and 100U are

that the HI-STORM UMAX VVM cavity is larger in diameter and the HI-STORM UMAX closure lid features a modified outlet ventilation duct system.

The HI-STORM UMAX has all the safety attributes that are attributed to in-ground storage, such as enhanced protection from incident projectiles and threats from extreme environmental phenomena such as hurricanes, tornado borne missiles, earthquakes, tsunamis, fires, and explosions. The HI-STORM UMAX VVM is anatomically similar to the HI-STORM 100U VVM in several respects. In particular, the MPCs are stored in-ground and each storage cavity is isolated from the surrounding environment by a thick cylindrical steel weldment. This steel shell is appropriately coated with surface preservatives or by other means to protect it from corrosion from long-term use.

HI-STORM UMAX differs from HI-STORM 100U in two important respects:

a. The placement of the inlet and outlet ducts in HI-STORM UMAX minimizes the reduction of ventilating air flow rate through HI-STORM VVM under wind conditions which, as is noted in Docket #72-1014, has a small de-rating effect on the thermal performance of the ventilation system in HI-STORM 100U. As shown in Chapter 4, the inlet and outlet locations in HI-STORM UMAX are also found to minimize inter-module flow interactions.

b. The storage cavity in the HI-STORM UMAX VVM is sufficiently large in physical dimensions to accommodate all canisters presently licensed by different designers under different 10CFR72 dockets. Therefore, it is theoretically possible to qualify the entire universe of used fuel canisters presently deployed at the ISFSIs around the country for storage in the HI-STORM UMAX system. This would make it possible to unify the long-term storage of all of the presently deployed nation's dry storage canisters at an Interim Storage site in HI-STORM UMAX VVM assemblies in a monitored and retrievable configuration. The present issue of this SAR, however, is limited to supporting the certification of the HI-STORM FW MPCs listed in Table 1.2.1.

The design and operational attributes of the HI-STORM UMAX, described in the following paragraphs pursuant to the provisions of 10CFR72.24(b), are subject to intellectual property rights in the U.S. and abroad under the patent laws governing the respective jurisdictions.

To summarize, the HI-STORM UMAX System has been engineered to:

- maximize shielding and physical protection for the MPC;
- minimize the extent of handling of the SNF;
- minimize dose to operators during loading and handling;
- require minimal ongoing surveillance and maintenance by plant staff;
- facilitate SNF transfer of the loaded MPC to a compatible transport overpack for transportation;

All HI-STORM UMAX System components (VVM, transfer cask, and MPC) are designated ITS and their sub-components are categorized in accordance with NUREG/CR-6407 [1.1.2].

The principal ancillaries used in the site implementation of the HI-STORM UMAX System are similar to HI-STORM FW System and are summarized in Section 1.2 of the HI-STORM FW FSAR and referenced in Chapter 9 of the HI-STORM FW FSAR in the context of loading operations. A listing of common ancillaries needed by the host site is provided in Table 9.2.1 of the HI-STORM FW FSAR. The detailed design of these ancillaries is not specified in this FSAR. In some cases, there are multiple distinct ancillary designs available for a particular application (such as a forced helium dehydrator or a vacuum drying system for drying the MPC) and as such, not every ancillary will be needed by every site. Ancillary designs are typically specific to a site to meet ALARA and personnel safety objectives.

1.2 GENERAL DESCRIPTION OF HI-STORM UMAX SYSTEM

1.2.1 System Characteristics

The HI-STORM UMAX System consists of interchangeable MPCs, which maintain the configuration of the fuel and is the confinement boundary between the stored spent nuclear fuel and the environment; and a storage overpack that provides structural protection and radiation shielding during long-term storage of the MPC. In addition, a transfer cask that provides the structural and radiation protection of an MPC during its loading, unloading, and transfer to the storage overpack is also subject to certification by the USNRC. Description of MPCs and the HI-TRAC transfer cask are provided in Section 1.2 of the HI-STORM FW FSAR. The key parameters for the UMAX MPCs are provided in Table 1.2.2 of the HI-STORM FW FSAR. The principal materials used in the manufacturing of the MPC are listed in the licensing drawings (Section 1.5) and the acceptance criteria are provided in Chapter 10 of HI-STORM FW FSAR. Alloy X description is provided in Appendix 1.A of the HI-STORM FW FSAR. The principal materials used in the manufacturing of the HI-TRAC transfer cask are listed in the licensing drawings in Section 1.5 and the acceptance criteria are provided in Chapter 10 of the HI-STORM FW FSAR. Table 1.2.6 of the HI-STORM FW FSAR provides applicable code paragraphs for manufacturing the HI-TRAC transfer cask.

All structures, systems, and components of the HI-STORM UMAX system, MPCs and HI-TRACs, which are identified as Important-to- Safety (ITS), are specified on the licensing drawings provided in Section 1.5.

1.2.2 Constituents of the HI-STORM UMAX Vertical Ventilated Module and ISFSI Structures

The HI-STORM UMAX VVM, shown in the licensing drawing in Section 1.5, provides for storage of the MPC in a vertical configuration inside a subterranean cylindrical cavity entirely below the top-of-grade (TOG) of the ISFSI. The key constituents of a HI-STORM UMAX VVM and ISFSI structures (see Figure 1.2.1 and Figure 1.2.2) are:

<u>VVM Components</u>

a. The Cavity Enclosure Container (CEC)

b. The Closure Lid

<u>ISFSI Structures</u>

c. The ISFSI Pad

d. The Support Foundation Pad

e. The Subgrade and Under-grade

f. The Enclosure Walls (optional)

A brief description of each constituent part is provided in the following:

a. The Cavity Enclosure Container:

The Cavity Enclosure Container (CEC) consists of a thick walled shell integrally welded to a bottom plate. The top of the container shell is stiffened by a ring shaped flange which is also integrally welded. The constituent parts of the CEC are made of low carbon steel plate, with stainless steel as an optional material for some components, as specified in the licensing drawing provided in Section 1.5. In its installed configuration, the CEC is interfaced with the surrounding subgrade for most of its height except for the top region where it is girdled by the ISFSI pad.

With the Closure Lid removed, the CEC is a closed bottom, open top, thick walled cylindrical vessel that has no penetrations or openings. Thus, groundwater has no path for intrusion into the interior space of the CEC. Likewise, any water that may be introduced into the CEC through the air passages in the top lid will not drain into the groundwater.

The MPC Bearing surfaces and the Divider Shell, two parts internal to the CEC, are important to the thermal performance of the VVM system. The top surfaces of the MPC support system are made of stainless steel so that the MPC is not resting directly on carbon steel components. The Divider Shell, as its name implies, is a vertical cylindrical shell concentrically situated in the CEC that divides the CEC into an inlet flow downcomer and an outlet flow passage. The Divider Shell divides the radial space between the MPC and the CEC cavity into two annuli. The bottom end of the Divider Shell has cutouts to enable movement of air from the downcomer to the up-flow region around the MPC. The cutouts in the Divider Shell are sufficiently tall to ensure that if the cavity were to be filled with water, the bottom region of the MPC would be submerged for several inches. This design feature is important to ensure adequate thermal performance of the system if flood water would stop air flow. The Divider Shell is not attached to the CEC which allows its convenient removal for decommissioning or for any in-service maintenance that may be required.

As the licensing drawing in Section 1.5 shows, the lower end of the MPC is restrained by a set of radial guides at the MPC's Baseplate elevation. The top lid of the MPC is likewise laterally restrained by a set of radial guides attached to the Divider Shell. The radial guides serve as an aid during insertion of the canister into the CEC and also provide the means to limit the lateral movement of the free-standing canisters during an earthquake. By limiting the lateral movement of the MPC, the guides protect against excessive inertia loads during seismic events.

The cylindrical surface of the Divider Shell is equipped with insulation to prevent significant preheating of the inlet air. The insulation material is selected to be water and radiation resistant as well as non-degradable under accidental wetting.

The chief distinguishing features of the VVM are its low profile and in-ground configuration. The MPC is below the ISFSI Pad for its entire height allowing the earth, ISFSI pad and Closure Lid to provide shielding of the stored fuel.

b. The Closure Lid:

The Closure Lid is a steel structure filled with plain concrete that can withstand the impact of the Design Basis Missiles defined in Chapter 2. Both the inlet and outlet vents are located at the grade level. A set of inlet passage located on top of the CEC provide maximum separation from the large outlet passage which is located in the center of the lid. Using a flue extension, the air exhaust from the outlet passage is set to be several feet higher than the inlet and prevents significant preheating of the incoming air. As shown in Chapter 4, the geometry of the inlet and outlet ducts, as depicted in the licensing drawings, make the HI-STORM UMAX VVM essentially insensitive to the speed of the wind.

The Closure Lid fulfills the following principal performance objectives:

1. Because there are no lateral streaming paths in the VVM body and the outlet air passage is located in the Closure Lid, there is no lateral radiation leakage paths during the MPC lowering or raising operation. Thus, the need for shield blocks (necessary to close off vents in certain aboveground HI-STORM 100 models) is eliminated.
2. The air passages in the Closure Lid are configured in such a manner that the aerodynamics in the system is not significantly affected by the change in the horizontal direction of the wind.
3. The Closure Lid is physically restrained against horizontal movement during a Design Basis Earthquake event or a tornado missile strike.
4. To minimize the radiation emitted from the storage cavity, a portion of the Closure Lid extends into the cylindrical space above the MPC. This cylindrical below-surface extension of the Closure Lid is also made of steel filled with shielding concrete to maximize the blockage of skyward radiation issuing from the MPC.
5. As can be seen from the drawings in Section 1.5, the Closure Lid is substantially larger in diameter than the CEC and the MPC is positioned to be at a significant vertical depth below the top of the Container Flange. These geometric provisions ensure that the Closure Lid will not fall into the MPC storage cavity space and strike the MPC if it were accidentally dropped during its handling. Because the Closure Lid is the only removable heavy load, the carefully engineered design features to facilitate recovery from its accidental drop provide added assurance that a handling accident at the ISFSI will not lead to radiological release. This additional measure against accidental Closure Lid drop does not replace the drop prevention features mandated in this FSAR on heavy load lifting devices (such as the cask transporter) that have been a standard and established requirement in the HI-STORM dockets.

c. The ISFSI Pad:

The ISFSI Pad serves to augment shielding, to provide a sufficiently stiff riding surface for the cask transporter, to act as a barrier against gravity-induced seepage of rain or floodwater around the VVM body as well as to shield against a missile. The ISFSI pad is a monolithic reinforced concrete structure that provides the load bearing surface for the cask transporter. The portion of the ISFSI pad adjacent to the VVM is slightly sloped and thicker than the rest of the ISFSI pad to ensure that rain water will be directed away from the VVM. The appropriate requirements on the structural strength of the ISFSI pad and the applicable industry code are specified in Chapter 2.

d. The Support Foundation Pad:

The Support Foundation Pad (SFP) is the underground pad which supports the HI-STORM UMAX ISFSI. The SFP on which the VVM rests must be designed to minimize long-term settlement. The SFP and the under-grade must have sufficient strength to support the weight of all the loaded VVMs during long-term storage and earthquake conditions. As the weight of the loaded VVM is comparable to the weight of the subgrade which it replaces, the additional pressure acting on the SFP is quite small. The appropriate requirements on the structural strength of the SFP and the applicable industry code are specified in Chapter 2.

e. The Subgrade and Under-grade:

The lateral space between each CEC, the SFP and the ISFSI pad is referred to as the subgrade and is filled with a Controlled Low-Strength Material (CLSM). Alternatively, “lean concrete” may also be used.

CLSM is a self-compacted, cementitious material used primarily as a backfill in place of compacted fill. ACI 229R-99 notes several terms, such as flowable fill, unshrinkable fill, controlled density fill, flowable mortar, flowable fly ash, fly ash slurry, plastic soil-cement and soil-cement slurry to describe CLSMs. ACI 116R-00 defines lean concrete as a material with low cementitious content. CLSM and lean concrete are also referred to as “Self-hardening Engineered Subgrade” (SES).

The subgrade material must meet the shear velocity and density requirements in Chapter 2. The space below the SFP is referred to as the under-grade.

As discussed in Chapters 3 and 8 corrosion mitigation measures commensurate with site-specific conditions are implemented on the below grade external surfaces of the CEC.

f. The Enclosure Wall:

The Enclosure Wall is an optional structure which may be utilized to mitigate groundwater intrusion at sites with a high water table.

Analyses in Chapter 3 show that the Self-hardening Engineered Subgrade (SES) provides a stable lateral support system to the ISFSI under the Design Basis Earthquake. In the absence of an Enclosure wall, the interface between the SES and the native subgrade defines the radiation protection boundary of the ISFSI. As stated in the Technical Specification and demonstrated by the seismic analysis in Chapter 3 of this FSAR, excavation of the sub-grade adjacent to the interface of an operating storage system is permitted but only down to the top of the Support Foundation pad elevation.

1.2.3 Design Characteristics of the HI-STORM UMAX VVM

The minimum depth of the storage cavity is governed by the height of the MPC stored. The nominal gap between the top of the MPC and the bottom of the Closure Lid is specified in the

licensing drawing. All Holtec MPC models certified for storage in Docket 72-1032 can be stored in HI-STORM UMAX. The difference in the MPC diameters is accommodated by different sized MPC guides. The location of the MPC Guides on the divider shell is aligned with the bottom of the MPC lid. The pitch between the CEC cavities allows the Cask Transporter to traverse over any storage cavity and independently access any storage location. Thus, any MPC located in any storage cavity can be independently accessed and retrieved using an already certified transfer cask.

As explained in the chapter on operations, the transfer of the MPCs into or out of the storage cavity will occur in an identical manner to HI-STORM 100U using a certified transfer cask. Screens are installed on the air inlet and outlet openings. The flue in the inlet and outlet plenum is equipped with a rain guard. The flue shell is lightweight and fastened to the outlet duct to allow easy installation and removal.

The essential design and operational features of the HI-STORM UMAX System are:

a. Because of its underground staging in HI-STORM UMAX, tip-over of the canister in storage is not possible.

b. To exploit the biological shielding provided by the surrounding soil subgrade, the MPC is entirely situated well below the top-of-grade level. The open plenum above the MPC also acts to boost the ventilation action of the coolant air.

c. Because the VVM is rendered into an integral part of the subgrade, it cannot be translocated to another ISFSI site. It also cannot be lifted and, therefore, is not subject to the potential for a handling accident.

d. Removal of water from the bottom of the storage cavity can be carried out by the simple expedient use of a flexible hose inserted through the air inlet or outlet passageways.

e. As discussed in Section 3.4, all practical efforts are made to coat exposed surfaces of the VVM with proven low VOC and/or ANSI/NSF Standard 61 [1.2.1] compliant surface preservatives to preclude toxicological effects on the environment to the maximum reasonable extent.

1.2.3.1 Shielding Materials

Steel, concrete, and the subgrade are the principal shielding materials in the HI-STORM UMAX. The steel and concrete shielding materials in the Closure lid provide additional gamma and neutron attenuation to reduce dose rates.

Steel, lead, and water are the principal shielding materials in the HI-TRAC transfer cask. The combination of these three shielding materials ensures that the radiation and exposure objectives of 10CFR72.106 and ALARA are met. The extent and location of shielding in the transfer cask plays an important role in minimizing the personnel doses during loading, handling, and transfer.

The MPC fuel basket structure provides the initial attenuation of gamma and neutron radiation emitted by the radioactive contents. The MPC shell, baseplate, and thick lid provide additional gamma attenuation to reduce direct radiation.

1.2.3.1.1 Neutron Absorber – Metamic HT

Metamic-HT is the designated neutron absorber in the HI-STORM FW MPC baskets. It is also the structural material of the basket. The properties of Metamic-HT and key characteristics, necessary for ensuring nuclear reactivity control, thermal, and structural performance of the basket, are presented in Metamic-HT Sourcebook [1.2.4].

1.2.3.1.2 Neutron Shielding

The HI-TRAC transfer cask is equipped with a water jacket providing radial neutron shielding. The water in the water jacket may be fortified with ethylene glycol to prevent freezing under low temperature operations [1.2.3].

During certain evolutions in the short term handling operations, the MPC may contain water which will supplement neutron shielding.

1.2.3.1.3 Gamma Shielding

In the HI-TRAC transfer cask, the primary gamma shielding is provided by lead. As in the storage overpack, carbon steel supplements the lead gamma shielding of the HI-TRAC transfer cask.

In the MPC, the gamma shielding is provided by its stainless steel enclosure vessel (including a thick lid); and its aluminum based fuel basket and aluminum alloy basket shims.

1.2.3.2 Lifting Devices

Lifting and handling devices used to load or unload an MPC into the HI-STORM UMAX VVM shall be designed per Section 1.2.1 of the HI-STORM FW FSAR (placed in this docket).

The lifting and handling of all heavy loads that are within Part 72 jurisdiction, such as the Closure Lid, to be carried out using single failure proof (see definition in the Glossary) equipment with below-the-hook lifting devices that comply with the stress limits of ANSI N14.6 [1.2.2] and/or slings designed as single failure proof to render an uncontrolled lowering of the Lid a non-credible event.

1.2.3.3 Threaded Anchor Locations

Threaded anchor locations (TALs) are provided in the CEC Flange region of each CEC. These will serve as the anchoring location for the device used for MPC transfer (see Chapter 9). The TALs serve no function during long term storage.

1.2.3.4 Design Life

The design life of the HI-STORM UMAX System is 60 years. This is accomplished by using materials of construction with a long proven history in the nuclear industry, specifying materials known to withstand their operating environments with little to no degradation (see Chapter 8), and protecting material from corrosion by using appropriate mitigation measures.

A maintenance program, as specified in Chapter 10, is also implemented to ensure that the service life will exceed the design life. The design considerations that assure the HI-STORM UMAX System performs as designed include the following:

<u>HI-STORM UMAX VVM and HI-TRAC Transfer Cask</u>

a. Exposure to Environmental Effects
b. Material Degradation
c. Maintenance and Inspection Provisions

<u>MPCs</u>

a. Corrosion
b. Structural Fatigue Effects
c. Maintenance of Helium Atmosphere
d. Allowable Fuel Cladding Temperatures
e. Neutron Absorber Boron Depletion

The adequacy of the materials for the designated design life is discussed in Chapter 8.

1.2.4 Operational Characteristics of the HI-STORM UMAX

Fuel loading operations, MPC preparation, and requirements during the use of the transfer cask are described in the HI-STORM FW Final Safety Analysis Report. The HI-TRAC transfer cask is used for on-site transport of the loaded MPC from the Fuel Building to the ISFSI. Prior to loading the VVM, the Closure Lid or other temporary lid is removed and a suitable device which will connect the transfer cask to the CEC is installed. The cask transporter carrying the transfer cask with the loaded MPC aligns over the top of the CEC and the transfer cask is connected. The MPC inside the transfer cask is lifted slightly by the cask transporter to allow the transfer cask pool lid to be removed. The MPC is slowly lowered into the VVM cavity below. The transfer equipment is removed and the Closure Lid is installed. The principal operational characteristics of short term operations at an ISFSI are:

a. The MPC is kept in the vertical configuration at all times during handling operations. This eliminates the handling risk of down-ending or upending and maintains the thermal performance of the MPC (which is somewhat dependent on its orientation) undisturbed.

b. The vertical insertion (or withdrawal) of the MPC eliminates the risk of gouging or binding of the MPC with the CEC parts.

c. The HI-TRAC transfer cask is mounted on the VVM cavity (with an interposed Mating Device) with large fasteners that are sized to protect the transfer cask from tip over under the site's DBE.

d. All load handling operations are carried out using the Vertical Cask Transporter (VCT) or an equivalent crane that is *single failure proof.*

Details of the generic operational steps involving either installation or removal of the loaded MPC at a HI-STORM UMAX ISFSI are provided in Chapter 9 along with reference to certain recommended safety measures that are known from experience to avert human performance errors. A visual depiction of the required operational steps is also provided in Chapter 9.

1.2.4.1 Design Features

The design features of the HI-STORM UMAX System are intended to meet the following principal performance characteristics under all credible modes of operation:

a. Prevent unacceptable release of contained radioactive material at all times.

b. Minimize occupational and site boundary dose.

c. Permit retrievability of contents (fuel must be retrievable from the MPC under normal and off-normal conditions in accordance with ISG-2 and the MPC only must be recoverable after accident conditions in accordance with ISG-3).

Chapter 11 identifies the many design features built into the HI-STORM UMAX System to minimize dose and maximize personnel safety. Among the design features intrinsic to the system that facilitate meeting the above objectives are:

a. The loaded MPC is always maintained in a vertical orientation during its handling at the ISFSI and is handled using an ANSI N14.6 compliant lift cleats.

b. The height of the HI-STORM UMAX cavity is minimized consistent with the length of the MPCs to optimize the depth of excavation needed to establish the ISFSI.

c. Almost all personnel activities during MPC transfer occur at ground level which helps promote safety and ALARA.

1.2.4.2 Identification of Subjects for Safety and Reliability Analysis

1.2.4.2.1 Criticality Prevention

Criticality is controlled by geometry and neutron absorbing materials in the fuel basket. The entire basket is made of Metamic-HT, a uniform dispersoid of boron carbide and nano-particles of alumina in an aluminum matrix, serves as the neutron absorber. This accrues four major safety and reliability advantages:

(i) The larger B-10 areal density in the Metamic-HT allows higher enriched fuel (i.e., BWR fuel with planar average initial enrichments greater than 4.5 wt% U-235) without relying on gadolinium or burn-up credit.

(ii) The neutron absorber cannot be removed from the basket or displaced within it.

(iii) Axial movement of the fuel with respect to the basket has no reactivity consequence because the entire length of the basket contains the B-10 isotope.

(iv) The larger B-10 areal density in the Metamic-HT reduces the reliance on soluble boron credit during loading/unloading of PWR fuel.

1.2.4.1.2 Chemical Safety

There are no chemical safety hazards associated with operations of the HI-STORM UMAX System. A detailed evaluation is provided in Section 3.4.

1.2.4.2.3 Operation Shutdown Modes

The HI-STORM UMAX System is totally passive and consequently, operation shutdown modes are unnecessary.

1.2.4.2.4 Instrumentation

As stated earlier, the HI-STORM UMAX MPC, which is seal welded, non-destructively examined, and pressure tested, confines the radioactive contents. The HI-STORM UMAX is a completely passive system with appropriate margins of safety; therefore, it is not necessary to deploy any instrumentation to monitor the cask in the storage mode.

1.2.4.2.5 Maintenance Technique

Because of its passive nature, the HI-STORM UMAX System requires minimal maintenance over its lifetime. No special maintenance program is required. Chapter 10 describes the maintenance program set forth for the HI-STORM UMAX System.

1.2.5 Cask Contents

This sub-section contains information on the cask contents pursuant to 10 CFR72, paragraphs 72.2(a)(1),(b) and 72.236(a),(c),(h),(m).

The HI-STORM UMAX System is designed to house both BWR and PWR spent nuclear fuel assemblies. Table 1.2.3 provides key system data and parameters for the MPCs. A description of acceptable fuel assemblies for storage in the MPCs is provided in Section 2.1. This includes fuel assemblies classified as damaged fuel assemblies and fuel debris in accordance with the definitions of these terms in the Glossary. All fuel assemblies, non-fuel hardware, and neutron sources authorized for packaging in the MPCs must meet the fuel specifications provided in Section 2.1. All fuel assemblies classified as damaged fuel or fuel debris must be stored in damaged fuel containers (DFC).

As shown in Figure 2.1.7 (MPC-37) and Figure 2.1.8 (MPC-89), each storage location is assigned an associated cell identification number. A DFC can be stored in the outer peripheral locations of both MPC-37 and MPC-89 as shown in Figures 2.1.1 and 2.1.2, respectively. The permissible heat loads for each cell, and the total canister are given in Tables 2.1.8 and 2.1.9 for MPC-37 and MPC-89, respectively.

1.3 IDENTIFICATION OF AGENTS AND CONTRACTORS

This section contains the necessary information to fulfill the requirements pertaining to the qualifications of the applicant pursuant to 10 CFR72.2(a)(1),(b) and 72.230(a). Holtec International, based in Marlton, NJ, is the system designer and applicant for certification of the HI-STORM UMAX system.

Holtec International is an engineering technology company with a principal focus on the power industry. Holtec International Nuclear Power Division (NPD) specializes in spent fuel storage technologies. NPD has carried out turnkey wet storage capacity expansions (engineering, licensing, fabrication, removal of existing racks, performance of underwater modifications, volume reduction of the old racks and hardware, installation of new racks, and commissioning of the fuel pool for increased storage capacity) in numerous nuclear plants around the world. Over 90 plants in the U.S., Britain, Brazil, Korea, Mexico, China and Taiwan have utilized the Company's wet storage technology to establish their state-of-the-art in-pool storage capacities.

Holtec's NPD is also a turnkey provider of dry storage and transportation technologies to nuclear plants around the globe. The company is contracted by over 45 nuclear units in the U.S. to provide the company's vertical ventilated dry storage technology. Utilities in China, Korea, Spain, Ukraine, the United Kingdom and Switzerland are also active users of Holtec International's dry storage and transport systems.

Four U.S. commercial plants, namely, Dresden Unit 1, Trojan, Indian Point Unit 1, and Humboldt Bay have thus far been completely defueled using Holtec International's technology. For many of its dry storage clients, Holtec International provides all phases of dry storage including: the required site-specific safety evaluations; ancillary designs; manufacturing of all capital equipment; preparation of site construction procedures; personnel training; dry runs; and fuel loading. The USNRC dockets in parts 71 and 72 currently maintained by the Company are listed in Table 1.3.1.

Holtec International's corporate engineering consists of professional engineers and experts with extensive experience in every discipline germane to the fuel storage technologies, namely structural mechanics, heat transfer, computational fluid dynamics, and nuclear physics. Virtually all engineering analyses for Holtec's fuel storage projects (including HI-STORM UMAX) are carried out by the company's full-time staff. The Company is actively engaged in a continuous improvement program of the state-of-the-art in dry storage and transport of spent nuclear fuel. The active patents and patent applications in the areas of dry storage and transport of SNF held by the Company (ca. January 2012) are listed in Table 1.3.2. Table 1.3.3 lists Holtec patents on dry storage technologies that have been published by the US patent office (as of Jan .2012) but not yet granted. Many of these listed patents have been utilized in the design of the HI-STORM UMAX System.

Holtec International's quality assurance (QA) program was originally developed to meet NRC requirements delineated in 10CFR50 [1.3.1], Appendix B, and was expanded to include provisions of 10CFR71 [1.3.2], Subpart H, and 10CFR72, Subpart G, for structures, systems, and components designated as important to safety. The Holtec quality assurance program, which satisfies all 18 criteria in 10CFR72, Subpart G, that apply to the design, fabrication, construction, testing, operation, modification, and decommissioning of structures, systems, and components

important to safety is incorporated by reference into this FSAR. Holtec International's QA program has been certified by the USNRC (Certificate No. 71-0784).

The HI-STORM UMAX System will be fabricated by the Holtec International Manufacturing Division (HMD) located in Pittsburgh, Pennsylvania with subcontract services from the Company's smaller plants in other parts of the country, namely Nanotec Metals Division (NMD) in Lakeland, FL and Orrvilon in Orrville, Ohio. HMD is a long-term ASME N-Stamp holder and fabricator of nuclear components. In particular, HMD has been manufacturing HI-STORM and HI-STAR system components since the inception of Holtec International's dry storage and transportation program in the 1990s. HMD routinely manufactures ASME code components for use in the U.S. and overseas nuclear plants. Holtec International's engineering organization, based in Marlton, NJ and the HMD subsidiary in Pittsburgh, PA have been subject to triennial inspections by the USNRC. If another fabricator is to be used for the fabrication of any part of the HI-STORM UMAX System, the proposed fabricator will be evaluated and audited in accordance with Holtec International's QA program approved by the USNRC.

Holtec International's Nuclear Power Division (NPD) also carries out site services for dry storage deployments at nuclear power plants. Several nuclear plants, such as Trojan and Waterford 3 (both completed) and Comanche Peak (ongoing, ca. January 2012) have deployed dry storage at their sites using a turnkey contract with Holtec International.

1.4 GENERIC CASK ARRAYS

An ISFSI deploying the HI-STORM UMAX System may use an unlimited number of VVM. The preferred embodiment of the VVM array is a rectangular configuration as illustrated in the licensing drawing in Section 1.5. The reference pitch (center-to-center distance between centerlines of adjacent CECs in the two orthogonal directions) between the VVMs is shown on the licensing drawing. In either or both directions, the reference pitch spacing can be adjusted by the site to ensure that any commercially available cask transporters can traverse the VVM arrays to provide autonomous access to each stored MPC. This reference pitch spacing also serves to provide adequate shielding around each storage cavity.

No limit is placed on the maximum spacing between VVMs. If there are multiple VVMs in an ISFSI they should be founded on a continuous SFP, to the extent practicable, to enhance the seismic response characteristics of the ISFSI.

1.5 FIGURES AND DRAWINGS

The licensing drawing for the HI-STORM UMAX System, pursuant to the requirements of 10CFR72.24(c)(3), is provided in this section. The material list on the licensing drawing contains sufficient information to articulate major design features and general operational characteristics of "UMAX". Further, it is intended to serve as the control information to guide the preparation of the documents required to manufacture the components under Holtec's Quality Assurance Program. Holtec's Quality Assurance Program requires that the entire array of manufacturing documents must remain in complete conformance with the Licensing Drawing Package at all times.

The MPC and HI-TRAC drawings listed below are excerpted from the HI-STORM FW docket.

Drawing Package Number	Description	Revision
8446	HI-STORM UMAX Canister Storage System	15
6514	HI-TRAC VW – MPC-37	9
6799	HI-TRAC VW – MPC-89	9
6505	MPC-37 ENCLOSURE VESSEL	15
6506	MPC-37 FUEL BASKET	12
6512	MPC-89 ENCLOSURE VESSEL	17
6507	MPC-89 FUEL BASKET	11

CHAPTER 2: PRINCIPAL DESIGN CRITERIA

2.0 OVERVIEW OF THE PRINCIPAL DESIGN CRITERIA

2.0.1 General

This chapter provides a systematic presentation of the loadings that must be considered for a complete safety evaluation of the HI-STORM UMAX System. As discussed in Chapter 1, this FSAR does not introduce any new MPC or transfer cask model. Rather, it envisages previously approved MPCs under docket 72-1032 [2.0.1] to be stored in a HI-STORM UMAX VVM. The drawings of the previously certified MPC-37 and MPC-89 are reproduced from the HI-STORM FW docket in Section 1.5 herein. Although the safety analyses of these previously certified MPCs are adopted from the HI-STORM FW FSAR by reference, additional safety evaluations are necessary to ensure that their licensed limits set forth in this CoC are not exceeded when they are stored in the HI-STORM UMAX VVM. Likewise, it is necessary to ensure that the licensed limits of the HI-TRAC VW transfer cask, certified along with the MPC-37 and MPC-89 in docket number 72-1032, are not exceeded when it is used to transfer the MPC at the HI-STORM UMAX ISFSI.

Section 1.5 contains the Licensing drawings for the MPC-37, MPC-89 and HI-TRAC VW cask excerpted from the HI-STORM FW docket where it was originally certified.

Design Criteria pertaining to the loadings and components common to the HI-STORM FW and the HI-STORM UMAX systems, such as the MPC and the HI-TRAC, are referenced in this FSAR, as appropriate, to the HI-STORM FW FSAR. To facilitate convenient access to the referenced material, the latest edition of the HI-STORM FW FSAR has been placed in this docket and a list of HI-STORM FW FSAR sections germane to this chapter is provided in a tabular form below.

HI-STORM FW FSAR material referenced in this FSAR		
Location of UMAX FSAR	**Subject of the Reference**	**Location in HI-STORM FW FSAR, Revision 3**
Sub-Section 2.0.1	Design Characteristics of MPC	Sub-Section 1.2.1
Sub-Section 2.0.1	Design Characteristics of HI-TRAC	Paragraph 1.2.1.3
Sub-Section 2.0.2	Structural analysis for qualifying the MPC closure welds	Sub-Section 3.4.3 and sub-Section 3.4.4
Sub-Section 2.0.2	MPC design analyzed for all design basis normal, off-normal and postulated accident conditions	Sub-Sections 2.2.1, 2.2.2, and 2.2.3
Sub-Section 2.0.2	HI-TRAC design analyzed for all design basis normal, off-normal and postulated accident conditions	Sub-Sections 2.2.1, 2.2.2, and 2.2.3
Sub-Section 2.0.3	HI-TRAC designed for off-normal environmental cold conditions	Section 2.2.2
Sub-Section 2.0.3	Evaluation of potential for brittle fracture in structural steel materials	Sub-Section 3.1.2.4 and Table 3.1.9
Sub-Section 2.0.4	HI-TRAC accident condition- loss of water in the water jacket	Sub-Section 5.1.2
Sub-Section 2.0.5	MPC providing criticality control for all design basis normal, off-normal and postulated accident conditions	Section 6.1
Sub-Section 2.0.6	MPC meeting the guidance of ISG-18	Section 7.1
Sub-Section 2.0.8	Acceptance Criteria for manufacturing of MPCs and HI-TRAC	Section 10.1, Tables 10.1.1, 10.1.3 through 10.1.8
Sub-Section 2.0.8	Maintenance Program for MPCs and HI-TRAC	Section 10.2, Table 10.2.1
Sub-Section 2.3.1	Applicable loads to MPC and HI-TRAC	Tables 2.2.6, 2.2.7, 2.2.13 and 3.1.1

HI-STORM FW FSAR material referenced in this FSAR*		
Location of UMAX FSAR	**Subject of the Reference**	**Location in HI-STORM FW FSAR, Revision 3**
Subsection 2.3.4	Confinement Boundary Leakage	Section 7.1
Sub-Section 2.7.2	Inspections and tests to verify integrity of the confinement boundary	Sub-Section 10.1.4

* For convenience of reference, the specific revision of the HI-STORM FW FSAR that is referenced in the safety analysis herein is placed in this docket. Updated versions of the HI-STORM FW FSAR shall be placed in this docket as necessary so as to ensure that the safety analyses on the "UMAX" docket (72-1040) remain aligned with the material referenced in the HI-STORM FW FSAR.

The applicable design criteria for the MPC and the HI-TRAC transfer cask are based on their licensing bases in the HI-STORM FW docket. MPC design criteria information extracted from the HI-STORM FW FSAR is provided in "Arial" font throughout this chapter.

Tables 2.0.1, et.seq. in the HI-STORM FW FSAR contain the ITS designations of the subparts of the MPCs and transfer cask that constitute the components of the HI-STORM UMAX system.

The MPC is engineered for a 60 year design life, while satisfying the requirements of 10CFR72. The adequacy of the MPC to meet the above design life is discussed in Section 3.4 of the HI-STORM FW FSAR. The design characteristics of the MPC are described in Section 1.2 of the HI-STORM FW FSAR.

The HI-TRAC VW transfer cask is engineered for a 60 year design life. The adequacy of the HI-TRAC VW to meet the above design life commitment is discussed in Section 3.4 of HI-STORM FW FSAR. The design characteristics of the HI-TRAC VW cask are presented in Section 1.2 the HI-STORM FW FSAR.

A description of the HI-STORM UMAX VVM is provided in Section 1.2. The applicable loads, affected parts under each loading condition, and the applicable structural acceptance criteria are compiled in this Chapter to provide a complete framework for the required qualifying safety analyses in the rest of the safety analysis report. Information consistent with the regulatory requirements related to shielding, thermal performance, confinement, radiological, and operational considerations is also provided. The licensing drawing of the HI-STORM UMAX VVM in Section 1.5 provides information on the necessary *critical characteristics* that define the HI-STORM UMAX system. The constituents of the HI-STORM UMAX ISFSI fall into two broad categories, namely:

a. VVM components

b. ISFSI structures

The safety analyses address both the VVM components and the ISFSI structures. The VVM components consist of:

a. The Cavity Enclosure Container (CEC)

b. The Divider Shell

c. The Closure Lid

The ISFSI Structures consist of:

a. The Support Foundation Pad (SFP)

b. The ISFSI Pad;

c. The Enclosure Wall (optional)

d. The Subgrade and Under-grade

Figure 1.2.1 denotes the key constituent parts of the HI-STORM UMAX VVM and Figure 2.4.4 depicts the subgrade and under-grade nomenclature for the ISFSI. The analysis basis density and shear wave velocities of sub-grade and under-grade spaces are given in Table 2.3.2. The spaces shown in Figure 2.4.4 are further explained below.

a. Space A is the Self-hardening Engineered Subgrade (SES) below the ISFSI Pad after the construction of the SFP. The candidate materials of SES include Controlled Low-Strength Material (CLSM) and lean concrete.

b. Space B is the lateral subgrade that extends by the amount W around the ISFSI where W is the characteristic dimension of the ISFSI. Space A and Space B may be separated by an Enclosure Wall.

c. Space C is the under-grade below the SFP and extending 100 feet down from the top of grade elevation.

d. Space D is the under-grade surrounding Space C extending 100 feet down from the top of grade elevation.

2.0.2 Structural

MPC Design Criteria

The MPC is classified as important-to-safety. The MPC structural components include the fuel basket and the enclosure vessel. The fuel basket is designed and fabricated to meet a more stringent displacement limit under mechanical loadings than those implicit in the stress limits of the ASME code (see Section 2.2 of the HI-STORM FW FSAR). The MPC enclosure vessel is designed and fabricated as a Class 1 pressure vessel in accordance with Section III, Subsection NB of the ASME Code, with certain necessary alternatives, as discussed in Section 2.2 of the HI-STORM FW FSAR. The principal exception to the above Code pertains to the MPC lid, vent and drain port cover plates, and closure ring welds to the MPC lid and shell, as discussed in Section 2.2 of HI-STORM FW FSAR. In addition, Threaded Anchor Locations (TALs) in the MPC lid are designed in accordance with the requirements of NUREG-0612 for critical lifts to facilitate handling of the loaded MPC.

The MPC closure welds are partial penetration welds that are structurally qualified by analysis in Chapter 3 of the HI-STORM FW FSAR. The MPC lid and closure ring welds are inspected by performing a liquid penetrant examination in accordance with the drawings contained in Section 1.5. The integrity of the MPC lid-to-shell weld is further verified by performing a progressive liquid penetrant examination of the weld layers, and a Code pressure test.

The structural analysis of the MPC, in conjunction with the redundant closures and nondestructive examination, pressure testing, and helium leak testing provides assurance of canister closure integrity in lieu of the specific weld joint configuration requirements of Section III, Subsection NB.

Compliance with the ASME Code, with respect to the design and fabrication of the MPC, and the associated justification are discussed in Section 2.2 of the HI-STORM FW FSAR. The MPC design is analyzed for all design basis normal, off-normal, and postulated accident conditions, as defined in Section 2.2 of the HI-STORM FW FSAR.

The required characteristics of the fuel assemblies to be stored in the MPC are limited in accordance with Section 2.1 of the HI-STORM FW FSAR.

HI-TRAC Design Criteria

The HI-TRAC transfer cask includes both structural and non-structural radiation shielding components that are classified as important-to-safety. The structural steel components of the HI-TRAC are designed to meet the stress limits of Section III, Subsection NF, of the ASME Code for normal and off-normal storage conditions. The threaded anchor locations for lifting and handling of the transfer cask are designed in accordance with the requirements of NUREG-0612 and Regulatory Guide 3.61 for interfacing lift points.

The HI-TRAC transfer cask design is analyzed for all normal, off-normal, and design basis accident condition loadings, as defined in Section 2.2 of the HI-STORM FW FSAR. Under accident conditions, the HI-TRAC transfer cask must protect the MPC from unacceptable deformation, provide continued shielding, and remain in a condition such that the MPC can be removed from it. The loads applicable to the HI-TRAC transfer cask are defined in Tables 2.2.6, 2.2.13 and Table 3.1.1 of the HI-STORM FW FSAR. The physical characteristics of each MPC for which the HI-TRAC VW is designed are presented in Subsection 1.2 of the HI-STORM FW FSAR.

HI-STORM VVM Design Criteria

All required information on the design bases and criteria for the VVM is compiled in this Chapter and fulfills the requirements of 10CFR72.24(c) (3) and 72.44(d). The VVM structure described in Chapter 1 is designed for all applicable normal, off-normal, extreme environmental phenomena, and accident condition loadings pursuant to 10CFR72.24(c), 72.122(b) and 72.122(c).

ISFSI Structure Design Criteria

The SFP and the subgrade under the ISFSI pad are categorized as important-to-safety (ITS) structures and are included in the structural analyses in Chapter 3, and in other chapters, as applicable. ACI-318 (05) [2.6.2] is specified as the reference code for the design qualification of the SFP and the ISFSI pad using the load combinations specified in Table 2.4.3. The seismic qualification of the storage system is performed in Chapter 3.

As discussed in sub-section 1.2.2, the subgrade in Space A in Figure 2.4.4 can be made from lean concrete or CLSM. The required structural properties of the subgrade are provided in Tables 2.3.2 and 3.3.4. Chapter 8 provides additional (non-structural) data on the CLSM to ensure the establishment of a durable structure built to meet the service life expectations for the ISFSI.

MATERIAL TYPES

The material types used in the VVM are identified in Table 2.6.2. Material designations used by ASTM and ASME for various product forms are, however, subject to change as these material certifying organizations publish periodic updates of their standards. Material designations adopted by the International Standards Organization (ISO) also affect the type of steels and steel alloys available from suppliers around the world. Therefore, it is necessary to provide for the ability to substitute materials with equivalent materials in the manufacture of the equipment.

The term Equivalent Material* has a specific meaning in this FSAR (and other FSARs in Holtec dockets listed in Table 1.2.1). Equivalent materials are those that can be substituted for each other without adversely affecting the safety function of the SSC (system, structure, and component) in which the substitution is made.

The equivalence of materials is directly tied to the notion of *critical characteristics*. A critical characteristic of a material is a property whose value must be specified and controlled to ensure an SSC will render its intended function. The numerical value of the critical characteristic invariably enters in the safety evaluation of an SSC and therefore its range must be guaranteed. To ensure that the safety calculation is not adversely affected, material properties such as Yield Strength, Ultimate Strength and Elongation must be specified as *minimum* guaranteed values in VVM Components. However, there are certain properties where both minimum and maximum acceptable values are required. In this category lies specific gravity and thermal expansion coefficient for the VVM components.

Table 2.6.3 lists the array of material properties typically required in safety evaluation of an SSC in dry storage and transport applications. The required value of each applicable property, guided by the safety evaluation defines the critical characteristics of the material. The subset of applicable properties for a material depends on the role played by the material. The role of a material in the SSC is divided into three category types, namely structural, thermal, and radiation compliance. The material properties listed in Table 2.6.4 are the ones that apply to the VVM components.

To summarize, the following procedure shall be used to establish acceptable equivalent materials for a particular application.

Criterion i: Functional Adequacy:

Evaluate the guaranteed critical characteristics of the equivalent material against the values required to be used in safety evaluations. The required values of each critical characteristic must be met by the minimum (or maximum) guaranteed values (MGVs of the selected material).

Criterion ii: Chemical and Environmental Compliance:

* This text matter on Equivalent Materials is adapted from previously approved FSARs [2.0.1, 2.6.3].

Perform the necessary evaluations and analyses to ensure the candidate material will not excessively corrode or otherwise degrade in the operating environment.

A material from another designation regime that meets Criteria (i) and (ii) above is deemed to be an acceptable material, and hence, equivalent to the candidate material.

For ITS materials, recourse to equivalent materials shall be made only in the extenuating circumstances where the designated material is not readily available.

As can be ascertained from its definition in the glossary, the *critical characteristics* of the material used in a subcomponent depend on its function. The Closure Lid, for example, serves as a shielding device and as a physical barrier to protect the MPC against loadings under all service conditions, including the Extreme Environmental phenomena. Therefore, the critical characteristics of steel used in the lid are its strength (yield and ultimate), ductility, and fracture resistance.

The appropriate critical characteristics for structural components of the VVM, therefore, are:

a. Material yield strength, σ_y

b. Material ultimate strength, σ_u

c. Elongation, ε

d. Charpy impact strength at the lowest service temperature for the part, C_i (unless exempted by other provisions in the governing code)

Thus, the carbon steel specified in the drawing package can be substituted with different steel so long as each of the four above properties in the replacement material is equal to or greater than the minimum values used in the qualifying analyses. The above *critical characteristics* apply to all materials used in the structural parts of the CEC.

In the event that one or more of the *critical characteristics* of the replacement material is slightly lower than the original material, then the use of the §72.48 process is necessary to ensure that all regulatory predicates for the material substitution are fully satisfied.

In addition to the design configuration and materials of construction, the maximum magnitude of Design Basis Earthquake for the HI-STORM UMAX ISFSI is also specified. A non-linear time-history solution procedure implemented on LS-DYNA is used in Chapter 3 to qualify the ISFSI including the storage system. This same non-linear time-history solution procedure must be used to perform safety evaluation under 10CFR72.212 at a host site. Likewise, the loadings from the extreme environmental phenomena, defined in this chapter, are considered in Chapter 3. Site specific loadings that deviate from those analyzed in Chapter 3 are subject to §72.212 safety evaluations in the manner of all HI-STORM models. For sites where the topography of the land results in an inclined or otherwise uneven top surface of the sub-grade girdling the ISFSI pad, the ISFSI owner, at his option, may require a site specific soil-structure interaction analysis to be performed as an input to the site's 10CFR72.212 safety evaluation. The seismic event selected for the SSI analysis may be the Design Basis Earthquake or another (more severe) earthquake deemed to be more appropriate or bounding by the ISFSI owner and the analysis methodology

shall be implemented on LS-DYNA approved in this FSAR. The safety criteria set forth in this FSAR and the applicable Technical Specification shall be met.

To serve their intended functions, the CEC and Closure Lid shall ensure physical protection, biological shielding, and allow the retrieval of the MPC under all conditions of storage (10 CFR 72.122(l)). Because the VVM is an in-ground structure, drops and tip-over of the VVM are not credible events and, therefore, do not warrant analysis. The load cases germane to establishing the structural adequacy of the VVM pursuant to 10 CFR 72.24(c) are compiled in Table 2.4.1. The physical characteristics of the MPC intended for storage in the VVM are presented in Chapter 1.

The design bases and criteria provided in this Chapter are intended to quantify the safety margins in the VVM design with respect to all applicable loadings that follow from the provisions of 10CFR72.24(c)(3), §72.122(b) and §72.122(c).

2.0.3 Thermal

MPC Design Criteria

The thermal design and operation of the MPC in the HI-STORM UMAX System meets the intent of the review guidance contained in ISG-11, Revision 3 [2.4.6]. Specifically, the ISG-11 provisions that are explicitly invoked and satisfied are:

i. The thermal acceptance criteria for all commercial spent fuel (CSF) authorized by the USNRC for operation in a commercial reactor are unified into one set of requirements.

ii. The maximum value of the calculated temperature for all CSF under long-term normal conditions of storage must remain below 400ºC (752ºF). For short-term operations, including canister drying, helium backfill, and on-site cask transport operations, the fuel cladding temperature must not exceed 400ºC (752ºF) for high burnup fuel (HBF) and 570ºC (1058ºF) for moderate burnup fuel.

iii. The maximum fuel cladding temperature as a result of an off-normal or accident event must not exceed 570ºC (1058ºF).

iv. For HBF, operating restrictions are imposed to limit the maximum temperature excursion during short-term operations to 65ºC (117ºF) and the number of excursions to less than 10.

To achieve compliance with the above criteria, certain design and operational changes are necessary, as summarized below.

i The peak fuel cladding temperature limit (PCT) for long term storage operations and short term operations is generally set at 400ºC (752ºF). However, for MPCs containing all moderate burnup fuel, the fuel cladding temperature limit for short-term operations is set at 570ºC (1058ºF) because the nominal fuel cladding stress is shown to be less than 90 MPa [2.0.2]. Appropriate analyses have been

performed as discussed in Chapter 4 and operating restrictions have been added to ensure these limits are met.

ii. A method of drying, such as forced helium dehydration (FHD) is used if the above temperature limits for short-term operations cannot be met.

iii. The off-normal and accident condition PCT limit remains unchanged at 570ºC (1058ºF).

The MPC cavity is dried, either with FHD or vacuum drying, and then it is backfilled with high purity helium to promote heat transfer and prevent cladding degradation.

The normal condition design temperatures for the stainless steel components in the MPC are provided in Table 2.3.7.

Each MPC model allows for regionalized storage where every storage location is identified by a unique number as shown in Figures 2.1.7 and 2.1.8. The permissible storage cell heat load limits and total design heat load limits are presented in Tables 2.1.8 and 2.1.9 for MPC-37 and MPC-89, respectively. The decay heat loads in Tables 2.1.8 and 2.1.9 are a result of CoC restrictions limiting the permissible aggregate heat load† to 80% of the design basis heat load limits. This limit on the aggregate decay heat will compensate for the uncertainties associated with the modeling and application errors, which will be determined by validating the analysis methods. Due to lack of experimental data to validate the thermal analysis, a thermal test described in Section 10.3 will be performed which will be used to benchmark the CFD thermal model developed in Chapter 4. Specific requirements, such as approved locations for DFCs and non-fuel hardware are given in Section 2.1.

HI-TRAC Design Criteria

The allowable temperatures for the HI-TRAC transfer cask structural steel components are based on the maximum temperature for material properties and allowable stress values provided in Section II of the ASME Code. The allowable temperatures for the structural steel and shielding components of the HI-TRAC are provided in Table 2.3.7. The HI-TRAC is designed for off-normal environmental cold conditions, as discussed in Subsection 2.2.2 of the HI-STORM FW FSAR. The evaluation of the potential for brittle fracture in structural steel materials is presented in Section 3.1 of the HI-STORM FW FSAR.

The HI-TRAC is designed and evaluated for the maximum heat load analyzed for storage operations. The maximum allowable temperature of water in the HI-TRAC jacket is a function of the internal pressure. To preclude over- pressurization of the water jacket due to boiling of the neutron shield liquid (water), the maximum temperature of the water is restricted to be less than the saturation temperature at the shell design pressure. Even though the analysis shows that the water jacket will not over-pressurize, a relief device is placed at the top of the water jacket shell. In addition, the water is precluded from freezing during off-normal cold conditions by limiting the

† The aggregate heat load is defined as the sum of heat loads of all stored fuel assemblies.

minimum allowable operating temperature and by adding ethylene glycol. The thermal characteristics of the fuel for each MPC for which the transfer cask is designed are defined in Section 2.1. The working area ambient temperature limit for loading operations is limited in accordance with Table 2.3.6.

HI-STORM VVM Design Criteria

The HI-STORM VVM rejects heat from the stored MPCs by delivering cool ambient air to the annular space around the MPC. The ambient air undergoes progressive heating and reduction in density as it rises in the cylindrical space surrounding the MPC through convective heat transfer with the MPC shell, and exits the cell through the vertical flue mounted on the central region of the closure lid. The storage cavities have a constant out flow of air which will tend to retard the deposition of air borne particulates and debris in the storage space. The accumulated solids can be vacuumed out of the storage cavity by standard means. As shown in Chapter 4, the VVMs are designed to reject the maximum allowable heat load as defined below in a reliable and testable manner consistent with its important-to-safety designation (10CFR72.128(a)(4)). The VVM is designed for extreme cold conditions. The safety of structural steel material used for the VVM from brittle fracture is discussed in Chapter 8.

2.0.4 Shielding

The HI-TRAC transfer cask provides shielding to maintain occupational exposures ALARA in accordance with 10CFR20, while also maintaining the maximum load on the plant's crane hook below the rated capacity of the crane. As discussed in Subsection 1.2.1 of the HI-STORM FW FSAR, the shielding in HI-TRAC is maximized within the constraint of the allowable weight at a plant site. The HI-TRAC calculated dose rates for a set of reference conditions are reported in Section 5.1 of HI-STORM FW FSAR. These dose rates are used to perform a generic occupational exposure estimate for MPC loading, closure, and transfer operations, as described in Chapter 11 of the HI-STORM FW FSAR. A postulated HI-TRAC accident condition, which includes the loss of the liquid neutron shield (water), is also evaluated in Chapter 5 of the HI-STORM FW FSAR.

The annular area between the MPC outer surface and the HI-TRAC inner surface can be isolated to minimize the potential for surface contamination of the MPC by spent fuel pool water during wet loading operations. The HI-TRAC surfaces expected to require decontamination are coated with a suitable coating. The maximum permissible surface contamination for the HI-TRAC is in accordance with plant-specific procedures and ALARA requirements (discussed in Chapter 11 of the HI-STORM FW FSAR).

The off-site dose for normal operating conditions to any real individual beyond the controlled area boundary is limited by 10CFR72.104(a) to a maximum of 25 mrem/year whole body, 75 mrem/year thyroid, and 25 mrem/year for other critical organs, including contributions from all nuclear fuel cycle operations. Since these limits are dependent on plant operations as well as on

site-specific conditions (e.g., the ISFSI design and proximity to the controlled area boundary, and the number and arrangement of loaded storage casks at the ISFSI), the determination and comparison of ISFSI doses to these limits are necessarily site-specific. Dose rates from the HI-STORM UMAX System are provided in Chapter 5. The determination of site-specific ISFSI dose rates at the site boundary and demonstration of compliance with regulatory limits is to be performed by the licensee for the specific VVM array in accordance with 10CFR72.212.

The HI-STORM UMAX VVM is designed to limit the dose rates for all MPCs to ALARA values. The VVM is also designed to maintain occupational exposures ALARA during MPC transfer operations, in accordance with 10CFR20. The underground location of the VVMs significantly reduces the radiation from the ISFSI at the site boundary compared to an aboveground cask. The calculated VVM dose rates, including dose rates during site construction next to an operating ISFSI, are discussed in Chapter 5.

2.0.5 Criticality

The MPC provides criticality control for all design basis normal, off-normal, and postulated accident conditions, as discussed in Section 6.1 of the HI-STORM FW FSAR. The effective neutron multiplication factor is limited to k_{eff} < 0.95 for fresh (unirradiated) fuel with optimum water moderation with due consideration of all biases, uncertainties, and manufacturing tolerances.

Criticality control is maintained by the geometric spacing of the fuel assemblies and the spatially distributed B-10 isotope in the Metamic-HT fuel basket, and for the PWR MPC model, the additional soluble boron in the MPC water. The minimum specified boron concentration in the purchasing specification for Metamic-HT must be met in every lot of the material manufactured. The guaranteed B-10 value in the neutron absorber, assured by the manufacturing process, is further reduced by 10% (90% credit is taken for the Metamic-HT) to accord with NUREG/CR-5661. No credit is taken for fuel burnup or integral poisons such as gadolinia in BWR fuel. The soluble boron concentration requirements (for PWR fuel only) based on the initial enrichment of the fuel assemblies are delineated in Section 2.1 consistent with the criticality analysis described in Chapter 6 of the HI-STORM FW FSAR [2.0.1].

The HI-STORM UMAX VVM does not perform any criticality control function. The MPCs provide criticality control for all design basis normal, off-normal and postulated accident conditions.

2.0.6 Confinement

The MPC provides for confinement of all radioactive materials for all design basis normal, off-normal, and postulated accident conditions. As discussed in Chapter 7 of the HI-STORM FW, MPC design meets the guidance in the Interim Staff Guidance (ISG)-18 so that leakage of radiological matter from the confinement boundary is non-credible. Therefore, no confinement dose analysis is required or performed. The confinement function of the MPC is verified through pressure testing, helium leak testing, and a

rigorous weld examination regimen executed in accordance with the acceptance test program in Chapter 10 of the HI-STORM FW FSAR.

The HI-TRAC transfer cask does not perform any confinement function. The HI-TRAC provides physical protection and radiation shielding of the MPC contents during MPC loading, unloading, and transfer operations.

The VVM does not perform any confinement function. Confinement during storage is provided by the MPC and is addressed above.

2.0.7 Operations

There are no radioactive effluents that result from storage of transfer operations. Effluents generated during MPC fuel loading are handled by the plant's radioactive waste system and procedures.

The cask operations unique to the HI-STORM UMAX (and common with the HI-STORM 100U in the HI-STORM 100 docket) begin with the arrival of the loaded transfer cask at the HI-STORM UMAX ISFSI. The cask transporter is typically used to move the loaded transfer cask to the ISFSI and to transfer the MPC into the VVM cavities. Generic operating procedures for the HI-STORM UMAX System are provided in Chapter 9. Detailed operating procedures will be developed by the licensee using the information provided in Chapter 9 along with the site-specific requirements that comply with the 10CFR50 Technical Specifications for the plan, and applicable Certificate(s) of Compliance (CoC).

The following overarching requirements apply to all SSCs used in the HI-STORM UMAX operations:

a. All threaded parts shall have provisions to prevent rust build up.
b. All rigging components shall be inspected for visible indications of damage or degradation prior to use.
c. All ancillaries used in heavy load handling shall comply with the brittle fracture criteria set down for cask components in this FSAR.

2.0.8 Acceptance Tests and Maintenance

The acceptance criteria and maintenance program to be applied to the MPC are described in Chapter 10 of the HI-STORM FW FSAR. The operational controls and limits to be applied to the MPC are discussed in Chapter 13. Application of these requirements will assure that the MPC is fabricated, operated, and maintained in a manner that satisfies the design criteria defined in this chapter.

The acceptance criteria and maintenance program to be applied to the HI-TRAC Transfer Cask are described in Chapter 10 of the HI-STORM FW FSAR. The operational controls and limits to be applied to the HI-TRAC are contained in Chapter 13. Application of these requirements will assure that the HI-TRAC is fabricated, operated, and maintained in a manner that satisfies the design criteria given in this chapter.

The fabrication acceptance bases and maintenance program to be applied to the VVMs are described in Chapter 10. Application of these requirements will assure that the VVMs are fabricated and maintained in a manner that satisfies all applicable design criteria.

2.0.9 Decommissioning

The MPC is designed to be transportable in a HI-STAR overpack and is not required to be unloaded prior to shipment off-site.

Decommissioning considerations for the HI-STORM UMAX System including HI-TRAC are addressed in Section 2.11.

2.1 SPENT FUEL TO BE STORED AND SERVICE LIMITS

2.1.1 Determination of the Design Basis Fuel

A central object in the design of the HI-STORM UMAX System is to ensure that all SNF discharged from the U.S. reactors can be stored in the HI-STORM UMAX MPC upon meeting the burn up, cooling time and content conditions requirements set forth in this FSAR. Publications such as references [2.1.1] and [2.1.2] provide a comprehensive description of fuel discharged from U.S. reactors.

The cell openings in the fuel baskets have been sized to accommodate BWR and PWR assemblies. The cavity length of the MPC will be determined for a specific site to accord with the fuel assembly length used at that site, including non-fuel hardware and damaged fuel containers, as applicable.

Table 2.1.1 summarizes the authorized contents for the HI-STORM UMAX System. Tables 2.1.2 and 2.1.3, which are referenced in Table 2.1.1, provide the fuel characteristics of all groups of fuel assembly types determined to be acceptable for storage in the HI-STORM UMAX System. Any fuel assembly that has fuel characteristics within the range of Tables 2.1.2 and 2.1.3 and meets the other limits specified in Table 2.1.1 is acceptable for storage in the HI-STORM UMAX System. The groups of fuel assembly types presented in Tables 2.1.2 and 2.1.3 are defined as “array/classes” as described in further detail in Chapter 6 of HI-STORM FW FSAR. Table 2.1.4 lists the BWR and PWR fuel assembly designs which are found to govern for three qualification criteria, namely reactivity, shielding, and thermal, or that are used as reference assembly design is those analyses. Additional information on the design basis fuel definition is presented in the following subsections.

2.1.2 Undamaged SNF Specifications

Undamaged fuel is defined in the Glossary.

2.1.3 Damaged SNF and Fuel Debris Specifications

Damaged fuel and fuel debris are defined in the Glossary.

Damaged fuel assemblies and fuel debris will be loaded into damaged fuel containers (DFCs) (Figure 2.1.6) that have mesh screens on the top and bottom. The DFC will have a removable lid to allow the fuel assembly to be inserted. In storage, the lid will be latched in place. DFC’s used to move fuel assemblies will be designed for lifting with either the lid installed or with a separate handling lid. DFC’s used to handle fuel and the associated lifting tools will designed in accordance with the requirements of NUREG-0612. The DFC will be fabricated from structural aluminum or stainless steel. The appropriate structural, thermal, shielding, criticality, and confinement evaluations have been performed to account for damaged fuel and fuel debris and are described in their respective chapters that follow. The limiting design characteristics for damaged fuel

assemblies and restrictions on the number and location of damaged fuel containers authorized for loading in each MPC model are provided in this chapter.

2.1.4 Structural Parameters for Design Basis SNF

The main physical parameters of an SNF assembly applicable to the structural evaluation are the fuel assembly length, cross sectional dimensions, and weight. These parameters, which define the mechanical and structural design, are specified in Subsection 2.1.8. An appropriate axial clearance is provided to prevent interference due to the irradiation and thermal growth of the fuel assemblies.

2.1.5 Thermal Parameters for Design Basis SNF

The principal thermal design parameter for the stored fuel is the fuel's peak cladding temperature (PCT) which is a function of the maximum decay heat per assembly and the decay heat removal capabilities of the HI-STORM UMAX System.

To ensure the permissible PCT limits are not exceeded, Subsection 2.1.9 specifies the maximum allowable decay heat per assembly for each MPC model.

The fuel cladding temperature is also affected by the heat transfer characteristics of the fuel assemblies. The design basis fuel assembly for thermal calculations for both PWR and BWR fuel is provided in Table 2.1.4.

Finally, the axial variation in the heat generation rate in the design basis fuel assembly is defined based on the axial burnup distribution. For this purpose, the data provided in references [2.1.3] and [2.1.4] are utilized and summarized in Table 2.1.5 and Figures 2.1.3 and 2.1.4. These distributions are representative of fuel assemblies with the design basis burnup levels considered. These distributions are used for analyses only, and do not provide a criteria for fuel assembly acceptability for storage in the HI-STORM UMAX System.

2.1.6 Radiological Parameters for Design Basis SNF

The principal radiological design criteria for the HI-STORM UMAX System are the 10CFR72 §104 and §106 operator-controlled boundary dose rate limits, and the requirement to maintain operational dose rates as low as reasonably achievable (ALARA). The radiation dose is directly affected by the gamma and neutron source terms of the assembly, which is a function of the assembly type, and the burnup, enrichment and cooling time of the assemblies. Dose rates are further directly affected by the size and arrangement of the ISFSI, and the specifics of the loading operations. All these parameters are site-dependent, and the compliance with the regulatory dose rate requirements are performed in site-specific calculations. The evaluations here are therefore performed with reference fuel assemblies, and with parameters that result in reasonably conservative dose rates. The reference assemblies given in Table 1.0.4 of the HI-STORM FW FSAR are the predominant assemblies used in the industry.

The design basis dose rates can be met by a variety of burnup levels and cooling times. Table 2.1.1 provides the acceptable ranges of burnup, enrichment and cooling time for all of the authorized fuel assembly array/classes. Table 2.1.5 and Figures 2.1.3 and 2.1.4 provide the axial distribution for the radiological source terms for PWR and BWR fuel assemblies based on the axial burnup distribution. The axial burnup distributions are representative of fuel assemblies with the design basis burnup levels considered. These distributions are used for analyses only, and do not provide a criteria for fuel assembly acceptability for storage in the HI-STORM UMAX System.

Non-fuel hardware, as defined in the Glossary, has been evaluated and is also authorized for storage in the PWR MPCs as specified in Table 2.1.1.

2.1.7 Criticality Parameters for Design Basis SNF

The criticality analyses for the MPC-37 are performed with credit taken for soluble boron in the MPC water during wet loading and unloading operations. Table 2.1.6 provides the required soluble boron concentrations for this MPC.

2.1.8 Summary of Authorized Contents

Tables 2.1.1 through 2.1.3 specify the limits for spent fuel and non-fuel hardware authorized for storage in the HI-STORM FW System. The limits in these tables are derived from the safety analyses described in the following chapters of this FSAR.

2.1.9 Permissible Heat Load for MPC-37 and MPC-89

MPC-89 (BWR) and MPC-37 (PWR) canisters are previously licensed in Docket 72-1032 for storage of spent fuel and are permitted for storage in HI-STORM UMAX with permissible heat loads as specified in Table 2.1.7. As shown in Figures 2.1.7 and 2.1.8 for MPC-37 and MPC-89 respectively, each storage location is associated with a unique cell identification number. The permissible heat loads for each cell in the canister for storage in the HI-STORM UMAX VVM are given in Figure 2.1.19 and Figures 2.1.12 through 2.1.18 for MPC-89 and MPC-37 respectively. The permissible aggregate heat load for storage in MPC-37 and MPC-89 are provided in Tables 2.1.8 and 2.1.9 respectively.

2.1.10 Permissible Heat Load for MPC-24, MPC-32 and MPC-68

The authorized heat loads in the HI-STORM 100 docket for the MPCs certified for storage in the HI-STORM 100 will be used to determine the acceptability of storing them in HI-STORM UMAX. These analyses will be performed to characterize the thermal behavior of the "UMAX" system; they are not intended to secure certification of the MPCs in docket # 72-1014 at this time.

Regionalized loading of SNF in two regions are permitted in MPC-24, MPC-32 and MPC-68 models. The definition of the two regions for each MPC model is provided in Table 2.1.10. The inner region (Region 1) and the outer region (Region 2), shown in Figures 2.1.9, 2.1.10 and

2.1.11 for different MPC types have maximum permitted specific heat loads denoted by q_1 and q_2, respectively. The maximum permitted values of q_1 and q_2 are related through the ratio X, where,

$X = q_1/q_2$.

The special case where q_1 and q_2 are equal (X= 1) is referred to as “uniform storage”. Table 2.1.11 provides the maximum allowable decay heat per fuel storage location for ZR-clad fuel in a uniform fuel loading pattern for each MPC. (Regionalized fuel loading is not permitted in MPC-68F.) The following procedure is specified in Docket # 72-1014 to determine q_1 and q_2 for any chosen value of X:

(i) Choose a value of X in the permissible range ($0.5 \le X \le 3$)

(ii) Calculate q_2 using the following equation:

$$q_2 = \frac{2 \times Q_d}{\left(1 + X^y\right) \times \left(n_1 \times X + n_2\right)}$$

where:

$y = 0.23/X^{0.1}$
q_2 = Maximum allowable decay heat per fuel storage location in Region 2 (kW)
Q_d= Maximum uniform storage MPC decay heat (34 kW)
X = Ratio of q_1 to q_2 chosen in Step (i)
n_1 = Number of fuel storage locations in Region 1 from Table 2.1.10
n_2 = Number of fuel storage locations in Region 2 from Table 2.1.10

(iii) Calculate q_1 using the following equation:

$$q_1 = X \times q_2$$

Additional details of maximum allowable heat load per fuel storage location are provided in Section 2.1.9.1 of the HI-STORM 100 FSAR [2.6.3].

Table 2.1.1*

MATERIAL TO BE STORED

PARAMETER	VALUE (Note 1)	
	MPC-37	MPC-89
Fuel Type	Uranium oxide undamaged fuel assemblies, damaged fuel assemblies, and fuel debris meeting the limits in Table 2.1.2 for the applicable array/class.	Uranium oxide undamaged fuel assemblies, damaged fuel assemblies, with or without channels, fuel debris meeting the limits in Table 2.1.3 for the applicable array/class.
Cladding Type	ZR (see Glossary for definition)	ZR (see Glossary for definition)
Maximum Initial Rod Enrichment	Depending on soluble boron levels and assembly array/class as specified in Table 2.1.6	≤ 5.0 wt. % U-235
Post-irradiation cooling time and average burnup per assembly	Minimum Cooling Time: 3 years Maximum Assembly Average Burnup: 68.2 GWd/mtU	Minimum Cooling Time: 3 years Maximum Assembly Average Burnup: 65 GWd/mtU

*** The text matter in the "arial" font is excerpted from the HI-STORM FW FSAR with minor editorial changes ,as appropriate**

Other Limitations	▪ Quantity is limited to 37 undamaged ZR clad PWR fuel assemblies with or without non-fuel hardware. Up to 12 damaged fuel containers containing PWR damaged fuel and/or fuel debris may be stored in the locations denoted in Figure 2.1.1 with the remaining basket cells containing undamaged ZR fuel assemblies, up to a total of 37. ▪ One NSA. ▪ Up to 30 BPRAs. ▪ BPRAs, TPDs, WABAs, water displacement guide tube plugs, orifice rod assemblies, and/or vibration suppressor inserts may be stored with fuel assemblies in any fuel cell location. ▪ CRAs, RCCAs, CEAs, NSAs, and/or APSRs may be stored with fuel assemblies in fuel cell locations specified in Figure 2.1.5.	Quantity is limited to 89 undamaged ZR clad BWR fuel assemblies. Up to 16 damaged fuel containers containing BWR damaged fuel and/or fuel debris may be stored in locations denoted in Figure 2.1.2 with the remaining basket cells containing undamaged ZR fuel assemblies, up to a total of 89.

Channel Thickness (in.)	≤ 0.055	≤ 0.120	≤ 0.060

Table 2.1.3 (continued)

BWR FUEL ASSEMBLY CHARACTERISTICS

NOTES:

1. All dimensions are design nominal values. Maximum and minimum dimensions are specified to bound variations in design nominal values among fuel assemblies within a given array/class.
2. This assembly is known as "QUAD+." It has four rectangular water cross segments dividing the assembly into four quadrants.
3. For the SPC 9x9-5 fuel assembly, each fuel rod must meet either the 9x9E or the 9x9F set of limits or clad O.D., clad I.D., and pellet diameter.
4. This assembly class contains 74 total rods; 66 full length rods and 8 partial length rods.
5. Square, replacing nine fuel rods.
6. Variable.
7. This assembly contains 92 total fuel rods; 78 full length rods and 14 partial length rods.
8. This assembly class contains 91 total fuel rods; 83 full length rods and 8 partial length rods.
9. One diamond-shaped water rod replacing the four center fuel rods and four rectangular water rods dividing the assembly into four quadrants.
10. These rods may also be sealed at both ends and contain ZR material in lieu of water.
11. Not Used
12. Fuel assemblies classified as damaged fuel assemblies are limited to 4.0 wt.% U-235.
13. Fuel assemblies classified as damaged fuel assemblies are limited to 4.6 wt.% U-235.

Table 2.1.4

DESIGN BASIS FUEL ASSEMBLY FOR EACH DESIGN CRITERION

Criterion	BWR	PWR
Reactivity/Criticality	GE-12/14 10x10 (Array/Class 10x10A)	Westinghouse 17x17 OFA (Array/Class 17x17B)
Shielding	GE-12/14 10x10	Westinghouse 17x17 OFA
Thermal-Hydraulic	GE-12/14 10x10	Westinghouse 17x17 OFA

Table 2.1.5

Table 2.1.6

Soluble Boron Requirements for MPC-37 Wet Loading and Unloading Operations

Array/Class	All Undamaged Fuel Assemblies		One or More Damaged Fuel Assemblies and/or Fuel Debris	
	Maximum Initial Enrichment $\leq$ 4.0 wt% ^{235}U (ppmb)	Maximum Initial Enrichment 5.0 wt% ^{235}U (ppmb)	Maximum Initial Enrichment $\leq$ 4.0 wt% ^{235}U (ppmb)	Maximum Initial Enrichment 5.0 wt% ^{235}U (ppmb)
All 14x14 and 16x16A	1,000	1,500	1,300	1,800
All 15x15 and 17x17	1,500	2,000	1,800	2,300

Note:

1. For maximum initial enrichments between 4.0 wt% and 5.0 wt% ^{235}U, the minimum soluble boron concentration may be determined by linear interpolation between the minimum soluble boron concentrations at 4.0 wt% and 5.0 wt% ^{235}U.

Table 2.1.7

ALLOWABLE HEAT LOAD FOR MPCS ANALYZED* FOR STORAGE IN THE HI-STORM UMAX CANISTER STORAGE SYSTEM

MPC Type	Docket Number	Permissible Heat Load
All	72-1014	36.9 kW Note 2
MPC-89	72-1032	See Table 2.1.9
MPC-37	72-1032 Short Fuel: 128 inches $\leq$ L < 144 inches Standard Fuel: 144 inches $\leq$ L < 168 inches Long Fuel: L $\geq$ 168 inches (Note 1)	See Table 2.1.8

Notes:

1. L means "nominal active fuel length". The nominal, unirradiated active fuel length of the PWR fuel assembly is used to designate it as “short”, “standard” and “long”.
2. The maximum allowable heat load for MPCs from Docket 72-1014 is specified in supporting CoC amendments 5 to 9.

*This issue of the FSAR seeks certification of only MPC-89 and MPC-37, termed as “governing canisters” in HI-STORM UMAX. The analysis performed on other MPCs is for reference purposes only.

TABLE 2.1.8

HI-STORM UMAX MPC-37 PERMISSIBLE HEAT LOADS

Fuel Type (see Table 2.1.7 for length data)	Description	Helium Backfill Pressure Option (Notes 2)	Heat Load per Storage Cell (Note 3)	Permissible Aggregate Heat Load (Note 1), kW
Short Fuel	Heat Load Chart 1	1	Figure 2.1.12	33.88
	Heat Load Chart 2	2	Figure 2.1.14	33.70
	Heat Load Chart 3	1	Figure 2.1.16	33.53

	Heat Load Chart 3	1	Figure 2.1.17	35.30
Long Fuel	Heat Load Chart 1	1	Figure 2.1.13	35.76
	Heat Load Chart 2	2	Figure 2.1.15	35.57
	Heat Load Chart 3	1	Figure 2.1.18	37.06
Short Fuel	Sub-Design Heat Load	3	Figure 2.1.19	34.28
	Threshold Heat Load	3	Figure 2.1.21	33.46
Standard Fuel	Sub-Design Heat Load	3	Figure 2.1.19	34.28
	Threshold Heat Load	3	Figure 2.1.21	33.46
Long Fuel	Sub-Design Heat Load	3	Figure 2.1.20	36.19
	Threshold Heat Load	3	Figure 2.1.21	33.46

Note 1: The aggregate heat load is defined as a sum of all stored fuel assemblies. Thermal evaluations in Chapter 4 are performed with maximum per storage cell heat load in all locations. However, the CoC restricts the permissible aggregate heat load to the value specified in this table.
Note 2: The helium backfill range is in Table 4.4.6.
Note 3: Decay heat limits must be met for all contents in a fuel storage location (i.e., fuel and non-fuel hardware, as applicable).

TABLE 2.1.9

HI-STORM UMAX MPC-89 PERMISSIBLE HEAT LOAD

Permissible Heat Load per Storage Cell	Helium Backfill Pressure Option (Note 2)	Permissible Aggregate Heat Load (Note 1), kW
Figure 2.1.22	1	36.32
Figure 2.1.23	2	36.72
Figure 2.1.24	2	34.75

Note 1: The aggregate heat load is defined as a sum of all stored fuel assemblies. Thermal evaluations in Chapter 4 are performed with maximum per storage cell heat load in all locations. However, the CoC restricts the permissible aggregate heat load to the value specified in this table..
Note 2: The helium backfill range is in Table 4.4.6

Table 2.1.10

MPC FUEL STORAGE REGIONS FOR MPCS LICENSED IN DOCKET 72-1014

MPC	Number of Storage Cells		Storage Cell IDs*	
	Inner Region (n_1)	Outer Region (n_2)	Inner Region	Outer Region
MPC-24/24E/24EF	12	12	4, 5 8 through 11 14 through 17 20 and 21	All other locations
MPC-32/32F	12	20	7, 8, 12 through 15, 18 through 21, 25 and 26	All other locations
MPC-68/68FF/68M	32	36	11 through 14, 18 through 23, 27 through 32, 37 through 42, 46 through 51, 55 through 58	All other locations

* See Figures 2.1.9 through 2.1.11 for storage cell numbering.

2.2 HI-STORM UMAX VVM COMPONENTS AND ISFSI STRUCTURES

The VVM is engineered for below-grade storage of the MPCs for the duration of its design life, and is designed to withstand normal, off-normal, and extreme environmental phenomena as well as accident conditions of storage with appropriate margins of safety. A discussion of measures to ameliorate corrosion of VVM components is presented in Chapter 8.

The structural limit criteria imposed on the VVM Components are specified to comply with the provisions of 10CFR72, with an embedded large margin of safety. Table 2.4.1 provides the principal acceptance criteria applicable to the VVM Components. The specifications of the materials of construction for the load bearing and non-load bearing parts are provided in Table 2.6.2 along with their maximum permissible temperature for different conditions of storage.

The ISFSI Structures in a HI-STORM UMAX ISFSI are:

a. The Support Foundation Pad (SFP)

The structural requirements on the SFP are focused on providing a robust support to the CEC structure (for shear and compression) and to limit the long-term settlement of the SFP. The minimum structural design requirements on the SFP are provided in Table 2.3.2 and the licensing drawing in Section 1.5.

ACI-318(2005) is the prescribed Code for SFP design. As specified in ACI-318(2005), the applicable loads on the SFP are:

- Dead load (from the ISFSI pad, the loaded VVM, and the mass of soil above the SFP).
- Live load (from the loaded vertical cask transporter bearing on the ISFSI pad).
- Seismic load (the additional inertia load in excess of the dead weight, live load transmitted to the SFP from the loaded VVM and the transporter under the ISFSI's DBE event).
- Long-term settlement.

The load combinations for the HI-STORM UMAX structural analysis of the SFP pursuant to ACI-318(2005) are provided in Table 2.4.3.

Of the above loads, the effect of long-term settlement on the SFP is treated together with the Dead load. The standard approach to compute the long-term settlement is provided in [2.4.3].

In the structural qualification of the SFP, the loading from the seismic event is computed using the dynamic elastic modulus corresponding to the minimum shear wave velocity of the subgrade layers specified in Table 2.3.2.

b. The ISFSI Pad

The ISFSI Pad girdles the Container Shell and extends to the underside of the Container Flange to form a rain water-resistant interface, and has a slight slope to direct water away from the CEC. The principal functions of the ISFSI pad are to provide the riding surface for the loaded transporter and also to enable rainwater to be channeled away from the storage arrays and into the ISFSI storm drain system.

The minimum structural design requirements on the ISFSI pad are provided in Table 2.3.2 and the licensing drawing in Section 1.5. The applicable loads on the ISFSI pad are:

- Dead load (Self weight)
- Live load (Weight of a loaded cask transporter)
- Seismic Load (Inertia load from the concrete pad and the transporter under the ISFSI's DBE event)

The applicable load combinations for the structural analysis of the ISFSI pad pursuant to ACI-318(2005) are provided in Table 2.4.3.

Note that the ISFSI pad is not expected to settle relative to the SFP over their Design Life due to the use of CLSM [2.2.1] or lean concrete to refill the space between the SFP and the ISFSI pad (i.e., Space A in Figure 2.4.4).

The design of the ISFSI pad together with the lateral subgrade must also satisfy the allowable bearing capacity requirement of ACI 360R-06 [2.6.5] for slabs on grade. In particular, the total load imparted by the ISFSI pad on the lateral subgrade, including the live load and seismic load from the transporter, shall be less than 50 percent of the allowable bearing capacity thereof when the load is applied uniformly.

c. Enclosure Wall (optional)

The Enclosure Wall, if used to sequester the substrate under the ISFSI pad from the surrounding subgrade, serves to render each VVM group autonomous and, at sites with elevated water table and serves as a means to prevent water intrusion in the VVM subgrade space. The Enclosure Wall does not have a structural function. In other words, as shown in Chapter 3, the Enclosure Wall is not needed to maintain the physical stability of the subgrade under the ISFSI pad under a Design Basis Earthquake in the limiting condition where the adjacent space has been excavated down to the SFP for construction purposes. Likewise it is shown in Chapter 3 that a Design Basis Missile will not reach any CEC in the ISFSI if the missile were to strike laterally through the excavated space adjacent to the ISFSI.

d. Lateral Subgrade and Under-grade

The soil lateral to the CECs (termed Space A in this FSAR) is required to be removed and replaced with a Self-hardening Engineered Subgrade (SES) such as CLSM or lean concrete which imparts enhanced structural characteristics to the ISFSI pad support system improving its ability to support the Cask transporter during MPC transfer operations. The minimum average density and the minimum shear wave velocity in the lateral subgrade surrounding the VVMs have been specified in Table 2.3.2.

In addition, the design of the sub-grade under the ISFSI pad must be demonstrated to meet the following structural criteria under the Design Basis earthquake (Table 2.3.2) and the Design Basis Missile (Table 2.3.3) impact loading events:

a. The subgrade must continue to maintain its physical integrity under the DBE load combination in Table 2.4.3. Maintaining physical integrity means no structural collapse, instability or cracks that produce an unobstructed direct streaming path in the

subgrade for the radiation emanating from the stored fuel, and no constriction of the CEC that may interfere with retrievability of the MPC.

b. In the scenario where the adjacent subgrade has been excavated exposing the lateral surface of the subgrade and a Design Basis Missile (see Table 2.3.3) strikes the exposed surface in the most severe orientation, the sub grade must be capable of stopping the missile before it reaches the MPC.

The Under-grade's minimum properties have also been specified in Table 2.3.2. A structurally inadequate under-grade may be strengthened by suitably engineered pilings.

Version "MSE" which is solely focused on increasing the seismic capability of the "UMAX" system is described in Subsection 1.0.2. To meet increased seismic inertia loads, the strength of the material in the interstitial space between the VVMs (Space A in Figure 2.4.4) is increased by using normal density concrete. The minimum compressive strength of the Space A concrete is provided in Table 2.3.10

2.3 SERVICE CONDITIONS AND APPLICABLE LOADS

2.3.1 Service Conditions

The categories of loads applicable to the HI-STORM UMAX VVM are identified below.

Normal Condition: dead weight, handling of the Closure Lid, soil overburden pressure from subgrade, live load due to cask transporter movement, long-term settlement and snow loads.

Off-Normal Condition: elevated ambient temperature, wind, partial blockage of air inlets, and off-normal pressure.

Extreme Environmental Phenomena and Accident Condition: extreme ambient temperature, handling accidents, fire, tornado, flood, earthquake, explosion, lightning, complete (assumed) blockage of all inlet ducts, burial under debris, and 100% fuel rod rupture.

Short-term Operations: Short-term operation includes those normal operational evolutions necessary to support fuel loading or unloading activities. These include, but are not limited to MPC cavity drying, helium backfill, MPC transfer, and on-site handling of a loaded HI-TRAC VW transfer cask. The peak cladding temperature in the MPC must meet the ISG-11 Rev. 3 limit for short-term operations

Of the above loadings, lightning is considered to be innocuous to the HI-STORM UMAX ISFSI because of its underground configuration and is therefore not considered as a loading that merits safety evaluation.

As can be seen from the above, the loads that are most significant to the storage system's structures and components are either structural or thermal in origin. Accordingly, they are discussed in the two discrete sections in the following Sections 2.4 and 2.5. The design basis magnitudes of the above loads, as applicable to the HI-STORM VVM, are provided in Tables 2.3.1 and 2.3.2. The loads applicable to the MPC and HI-TRAC VM are defined in Tables 2.2.6, 2.2.7, 2.2.13 and 3.1.1 of the HI-STORM FW FSAR.

2.3.2 Loadings Applicable to Normal Conditions of Storage

2.3.2.1 Pressure

The MPC internal pressure is dependent on the initial volume of cover gas (helium), the volume of fill gas in the fuel rods, the fraction of fission gas released from the fuel matrix, the number of fuel rods assumed to have ruptured, and temperature.

The normal condition MPC internal design pressure bounds the cumulative effects of the maximum fill gas volume, normal environmental ambient temperatures, the maximum MPC heat load, and an assumed 1% of the fuel rods ruptured with 100% of the fill gas and 30% of the significant radioactive gases (e.g., H^3, Kr, and Xe) released in accordance with NUREG-1536.

For the storage of damaged fuel assemblies or fuel debris in a damaged fuel container (DFC), it shall be conservatively assumed that 100% of the fuel rods are ruptured with 100% of the rod fill gas and 30% of the significant radioactive gases (e.g., H^3, Kr, and Xe) liberated. For PWR

assemblies stored with non-fuel hardware, 100% of the gases in the non-fuel hardware (e.g., BPRAs) shall be assumed to be released. The accident condition design pressure shall envelop the case of 100% of the fuel rods ruptured.

The MPC internal and external pressures under the normal condition of storage must remain below the respective limits in docket number 72-1032. For convenience of reference, the maximum allowable internal and external pressures common to all MPCs in Table 1.2.1 are provided in Table 2.3.5.

The HI-TRAC transfer cask is not capable of retaining internal pressure due to its open design. Therefore, no analysis is required for the internal pressure loading in HI-TRAC VW transfer cask. However, the HI-TRAC transfer cask water jacket may experience an internal vapor pressure due to the heat-up of the water contained in the water jacket. Analysis is performed in Chapter 3 of the HI-STORM FW FSAR to demonstrate that the water jacket can withstand the design pressure in Table 2.3.5 without a structural failure and that the water jacket design pressure will not be exceeded. To provide an additional layer of safety, a pressure relief device is used to ensure that the water jacket design pressure will not be exceeded.

The HI-STORM UMAX VVM is not capable of retaining internal pressure due to its open design, and therefore no analysis is required or provided for the VVM internal pressure.

2.3.2.2 Environmental Temperatures and Pressures

To evaluate the long-term effects of ambient temperatures on the HI-STORM UMAX System, an upper bound value on the annual average ambient temperature for the continental United States is used. The annual average temperature is termed as normal ambient temperature for storage. The normal ambient temperature specified in Table 2.3.6 is bounding for all reactor sites in the contiguous United States. The normal ambient temperature set forth in Table 2.3.6 is intended to ensure that it is greater than the annual average of ambient temperature at any location in the continental United States. In the northern region of the U.S., the design basis normal ambient temperature will be exceeded only for brief periods, whereas in the southern U.S, it may be straddled daily in summer months. In as much as the sole effect of the normal temperature is on the computed fuel cladding temperature to establish long-term fuel integrity, it should not lie below the time averaged yearly mean for the ISFSI site. Previously licensed cask systems have employed lower normal temperatures (viz., 75^{o} F in Docket 72-1007) by utilizing national meteorological data.

Likewise, within the thermal analysis, a conservatively assumed soil temperature of the value specified in Table 2.3.6 is utilized to bound the annual average soil temperatures for the continental United States. The 1987 ASHRAE Handbook (HVAC Systems and Applications) reports average earth temperatures, from 0 to 10 feet below grade, throughout the continental United States. The highest reported annual average value for the continental United States is 77^{o}F for Key West, Florida. Therefore, this value is specified in Table 2.3.6 as the bounding soil temperature.

Confirmation of the site-specific annual average ambient temperature and soil temperature is to be performed by the licensee, in accordance with 10CFR72.212. Insolation based on 10CFR71.71 input averaged over 24 hours shall be used as the additional heat input under the normal and off-normal conditions of storage.

The ambient pressure shall be assumed to be 760mm of Hg coincident with the normal condition temperature, whose bounding value is provided in Table 2.3.6. For sites located substantially above sea level (elevation > 1500 feet), it will be necessary to perform a site specific evaluation of the peak cladding temperature using the site specific ambient temperature (maximum average annual temperature based on 40 year meteorological data for the site). ISG 11, Revision 3 [2.4.6] temperature limits will be applicable.

All of the above requirements are consistent with those in the HI-STORM 100 and HI-STORM FW FSARs.

2.3.2.3 Design Temperatures

The ASME Boiler and Pressure Vessel Code (ASME Code) requires that the value of the vessel design temperature be established with appropriate consideration for the effect of heat generation internal or external to the vessel. The decay heat load from the spent nuclear fuel is the internal heat generation source for the HI-STORM UMAX System. The ASME Code (Section III, Paragraph NCA-2142) requires the design temperature to be set at or above the maximum through thickness mean metal temperature of the pressure part under normal service (Level A) condition. Consistent with the terminology of NUREG-1536, this temperature is referred to as the Design Temperature for Normal Conditions. Conservative calculations of the steady-state temperature field in the HI-STORM UMAX System, under assumed environmental normal temperatures with the maximum decay heat load shall remain below the maximum permissible temperatures set down in Table 2.3.7. Unless otherwise stated, the maximum permissible temperatures in Table 2.3.7 are thru-wall thickness average values and are intended to insure that the storage system meets the safety criteria applicable to the specific operating condition.

Maintaining fuel rod cladding integrity is a principal design consideration. The fuel rod peak cladding temperature (PCT) limits for all operating conditions shall meet the limits set forth in ISG-11, Revision 3 [2.4.6].

2.3.2.4 Snow and Ice

The HI-STORM UMAX System must be capable of withstanding pressure loads due to snow and ice. Section 7.0 of ANSI/ASCE 7-05 [2.2.2] provides empirical formulas and tables to compute the effective design pressure on the VVM due to the accumulation of snow for the contiguous U.S. and Alaska. Typical calculated values for heated structures such as the HI-STORM UMAX System range from 50 to 70 pounds per square foot. For conservatism, the snow pressure load provided in Table 2.3.1 is set to bound the ANSI/ASCE 7-05 recommendation.

2.3.2.5 Dead Weight

The HI-STORM UMAX System must withstand the static loads due to the weights of each of its components, including the weight of the HI-TRAC VW with the loaded MPC stacked on top the VVM during the MPC transfer.

2.3.2.6 Handling Evolutions

The HI-STORM UMAX System must withstand loads experienced during routine handling. Normal handling includes:

i. Vertical lifting of HI-STORM UMAX Enclosure Lid.
ii. Vertical lifting and handling of the HI-TRAC VW transfer cask containing a loaded MPC.
iii. Lifting of a loaded MPC.

The dead load of the lifted component is increased by 15% in the stress qualification analyses (to meet ANSI N14.6 guidance) to account for dynamic effects from lifting operations as suggested in CMAA #70 [2.3.3].

2.3.2.7 Sustained Wind Conditions

Wind is an environment variable that can be characterized as a normal occurrence. However, it should not be confused with *normal condition of storage* as defined in NUREG-1536. Like the environmental temperature, the wind is a fickle quantity; it changes almost constantly. Normal condition of storage is based on the annual average of a site's ambient temperature, not daily, or weekly or some other short term average. A fixed velocity of wind (i.e., constant in magnitude, direction and sense of action) cannot be expected to persist long enough to allow the cask to reach steady state. To merit being considered a parameter for inclusion for normal condition of storage, its average for the whole year must be considered. Variation in the wind speed and direction, like the ambient temperature, is a fact of life. If the wind is reasonably constant at a site for some periods then it may be possible to identify a three-day average of the wind speed and also specify a fixed direction of action. But average of the wind velocity vector for a whole year for the normal storage case is evidently not meaningful or realistic. It is for the above reason that it is reasonable to consider three-day average wind velocity to be classified as a contributor to the off-normal condition which uses three day temperature average as the reference ambient temperature.

However, in the interest of conservatism, the fictitious annual wind average is treated as a design basis input to the normal condition of storage in this docket.

2.3.3 Loadings Applicable to Off -Normal Conditions of Storage

As the HI-STORM UMAX System is passive, loss of power and instrumentation failures are not defined as off-normal conditions. The off-normal service conditions are defined in this subsection.

A discussion of the effects of each off-normal condition and the corrective action for each off-normal condition is provided in Chapter 12.

2.3.3.1 Pressure

The HI-STORM UMAX System must withstand loads due to off-normal pressure. The off-normal condition for the MPC internal design pressure bounds the cumulative effects of the maximum fill gas volume, normal environmental ambient temperatures, the maximum MPC heat load, and an assumed 10% of the fuel rods ruptured with 100% of the fill gas and 30% of the significant radioactive gases (e.g., H^3, Kr, and Xe) released as suggested in NUREG-1536.

2.3.3.2 Environmental Temperatures

The HI-STORM UMAX System must withstand off-normal environmental temperatures. The off-normal environmental temperatures are specified in Table 2.3.6. For conservatism the lower bound temperature is assumed to occur with no solar loads and the upper bound temperature occurs with steady-state insolation. Each bounding temperature is assumed to persist for a sufficient duration to allow the system to reach steady-state temperatures.

Limits on the peaks in the time-varying ambient temperature at an ISFSI site are recognized in the FSAR in the specification of the off-normal temperatures. The lower bound off-normal temperature is defined as the minimum of the 72-hour average of the ambient temperature at an ISFSI site. Likewise, the upper bound off-normal temperature is defined by the maximum of 72-hour average of the ambient temperature. The lower and upper bound off-normal temperatures listed in Table 2.3.6 are intended to cover all ISFSI sites in the continental U.S. The 72-hour average of temperature used in the definition of the off-normal temperature recognizes the considerable thermal inertia of the HI-STORM UMAX storage system which essentially flattens the effect of daily temperature variations on the internals of the MPC.

2.3.3.3 Design Temperatures

In addition to the normal condition design temperatures, which apply to long-term storage conditions, an off-normal/accident condition temperature pursuant to the provisions of NUREG-1536 and Regulatory Guide 3.61 is also defined. This is the temperature which may exist during a transient event (examples of such an instance is the blockage of the VVM inlet vents or the fire accident). The off-normal/ accident condition temperatures of Table 2.3.7 are selected to bound the maximum (maximum in time and space) value of the thru-thickness average temperature of the structural or non-structural part, as applicable, during the transient event. These enveloping values, therefore, will bound the maximum temperature reached anywhere in the part, excluding skin effects, during or immediately after, a transient event.

The off-normal/accident condition temperatures for stainless steel and carbon steel components are chosen such that the material's ultimate tensile strength does not fall below 30% of its room temperature value, based on published data [2.4.8 and 2.4.13]. This ensures that the material will not be subject to significant creep rates during these short duration transient events.

Additionally, design temperature limits are also defined for short-term normal operating conditions which include but are not limited to MPC drying operations and onsite transport operations. The short-term temperature limits for all the components are specified in Table 2.3.7

2.3.3.4 Leakage of One Seal

The MPC enclosure vessel (in any MPC model listed in Table 1.2.1) does not contain gaskets or seals: All confinement boundary closure locations are welded. Because the material of construction (austenitic stainless steel) is known from extensive industrial experience to lend to high integrity, high ductility and high fracture strength welds, the MPC enclosure vessel welds provide a secure barrier against leakage.

The confinement boundary is defined by the MPC shell, MPC baseplate, MPC lid, port cover plates, closure ring, and associated welds. Most confinement boundary welds are inspected by radiography or ultrasonic examination. Field welds are examined by the liquid penetrant method on the root (if more than one weld pass is required) and final weld passes. In addition to multi-pass liquid penetrant examination, the MPC lid-to-shell weld is pressure tested. The vent and drain port cover plates are also subject to proven non-destructive evaluations for leak detection such as liquid penetrant examination. These inspection and testing techniques are performed to verify the integrity of the confinement boundary.

The HI-STORM UMAX VVM does not serve a confinement function: It does not feature any safety significant seals. Therefore, leakage of one seal is not evaluated for its consequence to the storage system.

2.3.3.5 Malfunction of FHD

The FHD system is a forced helium circulation device used to effectuate moisture removal from loaded MPCs. For circulating helium, the FHD system is equipped with active components requiring external power for normal operation.

Initiating events of FHD malfunction are: (i) a loss of external power to the FHD System and (ii) an active component trip. In both cases a stoppage of forced helium circulation occurs and heat dissipation in the MPC transitions to natural convection cooling.

Although the FHD System is monitored during its operation, stoppage of FHD operations does not require actions to restore forced cooling for adequate heat dissipation. This is because the condition of natural convection cooling evaluated in Section 4.6 of HI-STORM FW FSAR shows that the fuel temperatures remain below off-normal limits. An FHD malfunction is detected by operator response to control panel visual displays and alarms.

2.3.4 Extreme Environmental Phenomena and Accident Conditions

The loadings corresponding to the extreme environmental phenomena and accident events, collectively referred to as Faulted States, are discussed as a part of load combinations.

2.3.4.1 Partial Blockage of MPC Basket Flow Holes

The MPC is designed to prevent reduction of thermosiphon action due to partial blockage of the MPC basket flow holes by fuel cladding failure, fuel debris and crud. The HI-STORM UMAX System maintains the SNF in an inert environment with fuel rod cladding temperatures below accepted values (Table 2.3.7). Therefore, there is no credible mechanism for gross fuel cladding degradation of fuel classified as undamaged during storage in the HI-STORM UMAX. Fuel classified as damaged fuel or fuel debris are placed in damaged fuel containers. The damaged fuel container is equipped with mesh screens which ensure that the damaged fuel and fuel debris will not escape to block the MPC basket flow holes. The MPC is loaded once for long-term storage and, therefore, buildup of crud in the MPC due to numerous loadings is precluded. Using crud quantities for fuel assemblies reported in an Empire State Electric Energy Research Corporation Report [2.2.3] determines a layer of crud of conservative depth that is assumed to partially block the MPC basket flow holes. The crud depth is listed in Table 2.2.8 of the HI-STORM FW FSAR. The flow holes in the bottom of the fuel basket are designed (as can be seen on the licensing drawings) to ensure that this amount of crud does not block the internal helium circulation.

2.3.4.2 Confinement Boundary Leakage

None of the postulated environmental phenomenon or accident conditions identified will cause failure of the confinement boundary. Section 7.1 of the HI-STORM FW FSAR provides the rationale to treat leakage of the radiological contents from the MPC as a non-credible event.

2.3.4.3 Handling Accident

A handling accident in the Part 72 jurisdiction is precluded by the requirements and provisions specified in the HI-STORM FW FSAR. The loaded HI-TRAC VW and MPCs will be lifted in the Part 72 operations jurisdiction in accordance with written and Q.A. validated procedures and shall use special lifting devices which comply with ANSI N14.6-1993 [2.2.2]. Also, the lifting and handling equipment (typically the cask transporter) is required to have a built-in redundancy against uncontrolled lowering of the load. Further, the HI-TRAC VW is a vertically deployed system, and the handling evolutions in *short term operations*, as discussed in Chapter 9, do not involve downending of the loaded cask to the horizontal configuration (or upending from the horizontal state) at any time. In particular, the loaded MPC shall be lowered into the HI-STORM UMAX VVM or raised from it using the HI-TRAC VW transfer cask and a MPC lifting system designed in accordance with ANSI N14.6. Therefore, analysis of a handling accident event involving a HI-TRAC VW or MPC is not required.

2.3.4.4 Non-Mechanistic Tip-Over

Because the HI-STORM UMAX VVM is situated underground and cannot be moved, a tip-over event is not a credible accident for this design.

2.3.4.5 Tornado

The HI-STORM UMAX System must withstand pressures, wind loads, and missiles generated by a tornado. The prescribed design basis tornado and wind loads for the HI-STORM FW System are consistent with NRC Regulatory Guide 1.76 [2.4.9], ANSI 57.9 [2.4.10], and ASCE 7-05 [2.4.11]. Table 2.3.4 provides the wind speeds and pressure drops applicable to the HI-STORM UMAX System.

The continued integrity of the MPC confinement boundary, within the HI-TRAC VW transfer cask, under impact from tornado-generated missiles in conjunction with the wind loadings is demonstrated in Chapter 3 of the HI-STORM FW FSAR.

2.3.5 Short-Term Operations

Short-term operations and their safety considerations are discussed in Chapter 9.

Table 2.3.1

LOADS, CRITERIA, APPLICABLE REGULATIONS, REFERENCE CODES, AND STANDARDS FOR THE VVM

Type	Criteria or Value and Reference Location in the FSAR	Basis, Regulation and Reference Code/Standard
Life:		
Design Life	60 yrs	-
Service Life	100 yrs	-
Licensed Life	20 years	10CFR72.42(a) & 10CFR72.236(g)
Structural:		
Design & Fabrication Codes: Foundation Pad and ISFSI Pad	ACI-318(05)	10CFR 72.24
Unreinforced Concrete Stress Limits (Closure Lid)	Applicable Sections of ACI-318(05)	10CFR72.24(c)(4)
Structural Steel	Section 2.6	10CFR72.24(c)(4)
VVM Closure Lid Dead Weight:	Section 3.2	R.G. 3.61
Design Internal Pressure	Atmospheric	Ventilated Module
Thermal:		
Design Basis Heat Load	Governed by ISG-11, Rev. 3	The permissible heat load is limited by the requirement that the temperature of the fuel cladding and the internal pressure in the MPC do not exceed allowable limits under all thermally significant loadings listed in Section 2.5.
Maximum Design Temperatures:		
Closure Lid Concrete

DESIGN DATA FOR HI-STORM UMAX ISFSI

	Type	Value (minimum or nominal, as applicable)	Comment
8.	Strain compatible effective shear wave velocity in Space C, V	485 ft/sec minimum	This space may be remediated with vertical reinforcement such as pilings to enhance V.
9.	Strain compatible effective shear wave velocity in Space D, V (Figure 2.4.4)	485 ft/sec minimum	This space will typically contain native soil.
10.	Design Basis Earthquake	Top of the Grade (Ground surface) spectra per Figure 2.4.1 with horizontal ZPA, a_H and vertical ZPA, a_V scaled as follows: $a_H = 1.0g$ $a_V = 0.75g$ and foundation surface pad spectra per Figure 2.4.2 with horizontal ZPA, a_H and vertical ZPA, a_V of: $a_H = 0.93g$ $a_V = 0.71g$	Horizontal and vertical spectra shown in Figures 2.4.1 and 2.4.2 are based on 5% damping. Following the Newmark 100-40-40 response combination technique [2.6.7] endorsed by the Regulatory Guide 1.92 [2.4.7], the *resultant ZPA* for a 3-D earthquake site is defined as: $a_R = a_1 + 0.4a_2 + 0.4a_3$, where a_1, a_2 and a_3 are the site's ZPAs in three orthogonal directions and $a_1 \geq a_2 \geq a_3$. Hence, the DBE *resultant ZPAs* at ground surface and foundation surface elevations are 1.3 g's (=1.0×1.0g's + 0.4×0.75 g's) and 1.214 g's (=1.0×0.93g's + 0.4×0.71 g's), respectively.
11.	Permissible long-term settlement of the SFP	0.2 inch maximum	Used as the input value in the strength qualification of the SFP.
12	Density of plain concrete in the Closure Lid (nominal)	150 lb/cubic feet	Used in shielding calculations
13	Reference compressive strength of plain concrete in the Closure Lid	4,000 psi	Used in analysis of mechanical loadings on the Closure Lid
14	Minimum compressive strength of SES in Space A (see Figure 2.4.4)	1,000 psi	Used in tornado missile impact analysis and SSI analysis

DESIGN TEMPERATURES

Component	Normal & Mechanical Accident Condition Design Temperature Limits (°F) (Note 1)	Short-Term Events Temperature Limits (°F) (Note 6)	Off-Normal and Accident Condition Temperature Limits (°F) (Note 2)
HI-TRAC VW radial lead gamma shield	-	350	600

Note1: Column 2 temperature limits apply to normal conditions of storage and to accident conditions that do not involve a thermally adverse condition such as seismic loading.

Note 2: For extreme environmental phenomena and accident conditions which involve heating of the steel structures and no mechanical loading (such as the blocked air duct accident, fire and burial-under-debris), the maximum permissible temperature is set equal to the permissible fuel cladding temperature(see Note 3 for MBF) at which the VVM structure will remain physically stable .

Note 3: Short term operations include but are not limited to MPC drying and onsite transport. The 1058°F temperature limit applies to MPCs containing all moderate burnup fuel. The limit for MPCs containing one or more high burnup fuel assemblies is 752°F.

Note 4: The VVM closure lid concrete, the primary function of which is shielding, will maintain its structural, thermal and shielding properties provided that the temperature limits prescribed.

The Portland Cement Association (PCA) Bulletin ST32 [2.3.1] provides a comprehensive assay of high temperature effects on concrete, stating, "Under certain conditions such as reinforced concrete chimneys, it (concrete) has been successfully used for temperatures of 600 deg. F (315.5°C). Where there is no load, such as chimney linings, it has been successfully used for temperature up to 1000 deg. F (537.8°C)".

The hydrogen loss from closure lid concrete due to high temperature is small because the closure lid concrete is completely enclosed by steel plate.

Note 5: The MPC basket contains stainless steel and Metamic (MPC-24, MPC-32 and MPC-68) or Metamic-HT (MPC-68M, MPC-37 and MPC-89). The neutron absorber material used in MPC baskets for criticality control (Metamic or Metamic-HT) are manufactured with B_4C and aluminum. B_4C is a refractory material that is unaffected by high temperature and aluminum is solid at temperatures in excess of 1200°F [2.3.2]. For conservatism, neutron absorbers temperatures under off-normal and accident conditions are limited to 1058°F.

Note 6: Short term operations include but are not limited to MPC drying and onsite transport. The 1058°F temperature limit applies to MPCs containing all moderate burnup fuel. The limit for MPCs containing one or more high burnup fuel assemblies is 752°F.

Table 2.3.10

DESIGN DATA FOR HI-STORM UMAX VERSION MSE

(Properties listed in Table 2.3.2 remain unchanged except for those listed below, item numbers from Table 2.3.2 used where applicable)

No.	Type	Value (minimum or nominal, as applicable)	Comment
3.	Depth averaged density of subgrade in Space B (see Figure 2.4.4)	130 lb/ft^3	Required for shielding analysis and SSI analysis.
7.	Strain compatible effective shear wave velocity in Space B, V	344 ft/sec	A small value, computed using the site specific data at the San Onofre nuclear plant (documented in the Calculation Package [3.4.1]), used to magnify the inertial response of the system under the MSE.
10.	Design Basis Earthquake	Defined by Reg. Guide 1.60 spectra applied at the elevation of the Support Foundation Pad (SFP) (See Figures 2.4.5 and 2.4.6). The ZPAs of the two horizontal spectra, 1.5g's each, are vectorially combined to give the resultant ZPA of 2.12 g's. The vertical spectra is also Reg Guide 1.60 pegged at 1.0g.	Horizontal and vertical spectra shown in Figures 2.4.5 and 2.4.6 are based on 5% damping. Following the Newmark 100-40-40 response combination technique [2.6.7] endorsed by the Regulatory Guide 1.92 [2.4.7], the *resultant ZPA* for a 3-D earthquake site is defined as: $a_R = a_1 + 0.4a_2 + 0.4a_3$, where a_1, a_2 and a_3 are the site's ZPAs in three orthogonal directions and $a_1 \geq a_2 \geq a_3$. Hence, the DBE *resultant ZPA* at the foundation surface elevations is 2.5 g's (=1.0×1.5g's + 0.4×1.5 g's + 0.4x1.0 g's) This Newmark resultant ZPA is cited as the limiting value authorized for HI-STORM UMAX CoC for Version MSE.
14.	Minimum compressive strength of SES in Space A (see Figure 2.4.4)	3,000 psi	Used in tornado missile impact analysis and SSI analysis

2.4 STRUCTURALLY SIGNIFICANT LOAD COMBINATIONS AND ACCEPTANCE CRITERIA

Where appropriate, for each loading type, a bounding value is selected in this FSAR to impute an additional margin for the associated loading events. Such bounding loads are referred to as Design Basis Loads (DBL) in this FSAR. For example, the Design Basis External Pressure on the MPC, set down in Table 2.3.1, is a DBL, as it grossly exceeds any credible external pressure that may be postulated for an ISFSI site.

The Design Basis structural loads and their combinations applicable to normal, off-normal and accident conditions for the HI-STORM UMAX system are considered in this section and summarized in Tables 2.4.1 and 2.4.3. The qualifying analyses are presented in Chapter 3.

Each loading case in Table 2.4.1 is distinct in respect of the sub-component of the VVM that it affects most significantly. The acceptance criteria for the storage system, pursuant to NUREG-1536, consist of demonstrating that:

a. The radiation shielding in the storage system does not degrade under normal and off-normal conditions of storage.

b. The system does not deform under credible loading conditions in a manner that would jeopardize the subcritical state of the storage system or ready retrievability of the MPC.

c. The MPC maintains confinement of radiological matter. For accident condition loadings, any permissible degradation in shielding must be shown to result in dose rates sufficiently low to permit recovery of the MPC from the damaged VVM, including unloading if necessary, and loss of function must be readily discernible ,i.e., apparent or detectable.

The above overarching acceptance criteria are further particularized in a more conservative form for each applicable loading case explicitly listed in Table 2.4.1 in the following sections.

2.4.1 Load Case 01: Dead Load plus Design Basis Explosion Pressure

The HI-STORM UMAX system must withstand the pressure pulse due to a design basis explosion event. The effect of overpressure due to an explosion near the VVM acting concurrently with the dead load of the system is defined as Load Case 01 and analyzed in Chapter 3. The overpressure design value applied to the Closure Lid outer surface (see Table 2.3.1) is intended to bound all credible explosion events because no combustible material is permitted to be stored near the VVM, and all materials of construction are engineered to be compatible with the operating environment. However, site-specific explosion scenarios that are not evidently bounded by the design basis explosion load considered herein shall be evaluated under the provisions of 10CFR72.212.

The explosion load is stated in Table 2.3.1 in terms of an equivalent static pressure. The affected sub-components are:

a. The Container Shell, subjected to a compressive state of axial stress under the combined effect of dead weight of the Closure Lid and surface pressure on the Closure Lid under the explosion event.

a. The Closure Lid, subject to self-weight and the Closure Lid surface pressure under the explosion event.

Other VVM Components are not in the direct path of this loading. Level D stress limits are applicable to this load case based on applicable metal service temperatures. The explosion pressure also envelops other normal condition mechanical loads such as snow and flood. Load Case 01, therefore, is a bounding load combination that conservatively subsumes other loading types. Acceptance criteria for this load case are provided in Table 2.4.1. Level A stress limits are applicable based on reference metal temperatures that bound all mechanical loading scenarios (Table 2.4.1) when this case is used as an enveloping evaluation for any normal condition.

2.4.2 Load Case 02: Design Basis Missile Loadings

The HI-STORM UMAX System is protected from the effects of a tornado and accompanying missiles by virtue of its underground configuration. The only VVM component that warrants evaluation for the effects of a tornado-induced missile strike is the Closure Lid, which is made of a steel weldment with encased concrete. The prescribed design basis tornado and wind loads for the HI-STORM UMAX System are consistent with NRC Regulatory Guide 1.76 [2.4.9], ANSI 57.9 [2.4.10] and ASCE 7.05 [2.4.11]. Design Basis Missiles are summarized in Table 2.3.3. The HI-STORM UMAX System is inherently stable under tornado missile impact. The impact of a large missile (1800kg Automobile) is evaluated to determine whether the Closure Lid continues to maintain its required shielding function. Penetration and perforation issues associated with the Closure Lid due to intermediate missiles that constitute the Extreme Environmental Phenomena loads for the HI-STORM UMAX system are also addressed. The Closure Lid is analyzed for penetration of a solid steel cylinder traveling at a high speed consistent with the characteristics of the intermediate missile listed in Table 2.3.3. As there is no direct line of sight to the MPC, small missiles are not considered. Also, since a tornado is a short duration event, the effect of tornado winds on the thermal performance of the VVM would be negligible due to the system's thermal inertia. Therefore, the effect of tornado wind on the thermal performance of the HI-STORM UMAX system is not analyzed.

When subject to a tornado missile strike, the Closure Lid must not be dislodged creating a direct line of sight from the top of the MPC to the outside (see Table 2.4.1). For the intermediate missile, the Closure Lid must resist full penetration. Finally, any CEC deformation from the compressive axial impulse due to the missile strike must not prevent MPC retrievability.

2.4.3 Load Case 03: Design Basis Seismic Event and Long-Term Settlement

The DBE and Long-Term Settlement are treated together under Load Case 03 because they are both germane to the qualification of the two pads (SFP and the ISFSI Pad).

a. Design Basis Seismic Event

As required by 10CFR72.102(f), the Design Basis Earthquake for the ISFSI must be specified. For the HI-STORM UMAX system, a generic Design Basis Earthquake is specified with horizontal and vertical ZPAs intended to envelope the site-specific DBEs at all U.S. plant sites (See Table 2.3.2). For purposes of the generic seismic analysis in this FSAR, the Design Basis Earthquake for the HI-STORM UMAX system is defined by two sets of response spectra specified at the ISFSI pad top surface elevation and at the SFP bottom surface elevation, as shown in Figures 2.4.1 and 2.4.2, respectively. These two spectra sets together exhibit the severity of the earthquake experienced by the ISFSI Structures and VVM Components and are henceforth referred to as the governing spectra. The two sets of response spectra are obtained from the two-step SHAKE/LS-DYNA soil seismic response analyses performed using a lower-bound soil shear wave velocity profile (see Figure 2.4.3). This lower bound profile was established in [2.4.1] based on the geotechnical data of typical U.S. nuclear power plant sites. To develop the governing spectra, the input seismic acceleration time history for the SHAKE analysis is derived from the Regulatory Guide 1.60 seismic response spectrum and designated as the rock outcrop motion. The synthetic time history complies with the response spectrum and power density enveloping criteria in SRP 3.7.1 in NUREG-0800, Rev 2. The input acceleration time history is scaled to yield ground surface ZPAs (at the top of grade elevation) as specified in Table 2.3.2. The average strain-compatible shear wave velocities of the soil column obtained from the SHAKE analysis are used to specify the minimum shear wave velocity values in Table 2.3.2.

The soil model for the subsequent LS-DYNA seismic response analysis uses the average strain-compatible wave velocities obtained from the SHAKE analysis (i.e., minimum shear wave velocity values of the native soils in Table 2.3.2) to define the structural characteristics of the soil layers above and below the SFP elevation. The acceleration time history at the soil column bottom surface, also obtained from the above-mentioned SHAKE analysis, is used as the input seismic motion for the LS-DYNA seismic response analysis performed in Chapter 3. The response spectrum plots shown in Figure 2.4.1 and 2.4.2 are the results of the LS-DYNA soil seismic response analysis (in the absence of the ISFSI). The same soil model and input seismic motion used in the LS-DYNA seismic response analysis is used for the LS-DYNA Soil-Structure Interaction (SSI) analysis (with the ISFSI included in the model) in Chapter 3.

The combination of weak soil properties and strong earthquake, as specified in Table 2.3.2 for the structural evaluation of the underground ISFSI, has been selected to ensure that the Design Basis Earthquake response spectra at the ISFSI location will uniformly envelope those at most U.S. nuclear plants and that the Design Basis structural evaluation for the HI-STORM UMAX system is performed conservatively based on the lower bound support from the sub-grade and the under-grade. Thus, the HI-STORM UMAX system can be deployed in most U.S. nuclear power plant sites without the need for a site-specific analysis to satisfy the requirements of 72.212. Specifically, a candidate HI-STORM UMAX ISFSI site will be exempt from a detailed SSI

analysis if the soil seismic response analysis for the site (using SHAKE or similar program) can demonstrate that the following two criteria are met:

- The site's response spectra at both ISFSI pad and SFP elevations are enveloped by the Design Basis Earthquake response spectra shown in Figures 2.4.1 and 2.4.2 at their applicable elevations, respectively;
- The soil properties of the candidate site are greater than the minimum values specified in Table 2.3.2.

In order to satisfy the first criterion, the site must perform a soil seismic response analysis using SHAKE or a similar program. The site's response spectra at both the ISFSI pad and SFP elevations must be bounded by the Design Basis Earthquake response spectra in Figures 2.4.1 and 2.4.2.

For the case where only one of the above two criteria is not satisfied, a site-specific evaluation under 10CFR72.212 is permitted. Typical scenarios that warrant a site specific evaluation are discussed below:

<u>Scenario A</u>: The site's response spectra are not completely enveloped by the respective Design Basis Earthquake response spectra in Figures 2.4.1 and 2.4.2. However, the site's overall earthquake strength, represented by the resultant ZPA (see Table 2.3.2 for definition) is bounded by that of the Design Basis Earthquake at both ISFSI pad and SFP elevations.

While the ZPA represents the strength of the earthquake (in terms of the maximum value of the seismic acceleration time history), the shape of the seismic response spectrum is affected by many factors such as the overall stiffness of the site and the stiffness profile of soil layers. Therefore, for the same input seismic time history at the base of the soil column, a stiffer site could have a peak response that is not enveloped by the Design Basis Earthquake response spectrum (as demonstrated in the SHAKE parametric study results presented in Table 2.4.4, where the only difference between the two analyzed cases is the stiffness (i.e., shear wave velocity) of the soil column). Although it is expected that the HI-STORM UMAX system would exhibit a greater safety margin against the earthquake loading at the stiffer subgrade/under-grade site, a site-specific evaluation under 10CFR72.212 is the appropriate vehicle to confirm the structural integrity in this situation.

<u>Scenario B</u>: The strain compatible wave velocity of the soil in Space B and/or Space D of the ISFSI site (see Figure 2.4.4) is less than the required minimum value specified in Table 2.3.2.

Typically, Spaces B and D (in Figure 2.4.4) contain native soils whose properties are not affected by the ISFSI construction. More importantly, the loaded VVMs are not directly supported by the soil in these two spaces. Therefore, it is reasonable to assume that a small reduction of soil stiffness in these two spaces would not significantly modify the structural response of the VVM system. Structural compliance through a site specific analysis is assured if the ZPA of the DBE is well below the Design Basis value set down in this FSAR (Figure 2.4.1 and 2.4.2).

The site-specific safety analysis, if required, shall follow the methodology set down in Chapter 3. In addition, since the soil and rock configuration varies from site to site, the total depth of the soil model for site-specific analysis shall be determined following the guideline in Paragraph 3.3.3.2 of ASCE 4-98 [2.4.3]. Uncertainties in SSI analysis for a candidate HI-STORM UMAX

ISFSI site shall be accounted for by varying the best estimate low strain shear modulus of the substrates between the best estimate values times (1+c) and the best estimate value divided by (1+c). If sufficient, adequate soil investigation data is available, the mean and standard deviation of the low strain shear modulus shall be established for every soil layer. The value of c may be established so that it will cover the mean plus or minus one standard deviation for every layer; however, the minimum value for c shall be no less than 0.5. If sufficient data is not available to determine a statistically meaningful mean and standard deviation, then the value for c shall be no less than 1.0.

The qualification of the ISFSI under the system's DBE event involves the following safety determinations:

a. Compliance of the VVM Components to the applicable stress/deformation limits specified in Table 2.4.2.

b. Strength compliance of the ISFSI reinforced concrete structures under ACI-318(2005) load combinations listed in Table 2.4.3.

The Design Basis Seismic Event (also referred to as the Design Basis Earthquake (DBE)) is classified as an extreme environmental phenomenon. As such the Level D service condition limits are applicable to the VVM components, such as the MPC Enclosure Vessel, MPC Guides and the MPC shell (Table 2.4.2).

Most Severe Earthquake Applicable to Version "MSE" of HI-STORM UMAX

As explained in Subsection 1.0.2, Version MSE, is strictly focused on further strengthening the VVM structure, where necessary, such that the system can meet the "most severe earthquake" defined by Regulatory Guide 1.60 spectra as set forth in Table 2.3.10. The required changes, as described in Subsection 1.0.2 and shown in the licensing drawings, are quite minimal. The MSE is designated as the "Design Basis Earthquake" for HI-STORM UMAX Version MSE.

Because the seismic qualification of the reference ISFSI under the MSE entails non-linear time history analysis, five sets of statistically independent time histories corresponding to the horizontal and vertical target spectra (Figures 2.4.5 and 2.4.6) [2.4.14] were generated to comply with NUREG 0800, SRP 3.7.1. Table 2.4.5 provides a comparison of the ZPAs of the generated time histories with those of the corresponding target spectra. As can be seen, the generated spectra bound both the ZPAs and peak values of target spectra.

Table 2.4.5 also provides the duration of the earthquake for each time history set. Figures 2.4.7 to 2.4.11 provide the accelerograms corresponding to the five earthquakes generated to perform the seismic analysis. The qualifying analyses under the above earthquakes are summarized in subparagraph 3.4.4.1.2.

Acceptance Criteria Under DBE

The CEC shell is subject to performance-based limits, which require that the deformation of the CEC does not prevent MPC retrievability, does not cause loss of MPC confinement, and that the system remains subcritical. This is accomplished by demonstrating that after the seismic event, permanent ovalization of the Container Shell does not result in a geometry that precludes retrievability of the MPC and that the impact loadings on the MPC due to its rattling inside the CEC do not cause a breach of the MPC confinement boundary.

Finally, because the MPC Enclosure Vessel is designed to meet ASME Section III, Subsection NB (Class 1) stress intensity limits, and the earthquake is categorized as a Level D event, the primary stress intensities in the MPC Enclosure Vessel must meet Level D limits. The primary stress intensity in the MPC shell is the maximum longitudinal flexural stress intensity, which is compared against the primary membrane stress intensity limit for the material (Alloy X) at the applicable service temperature.

The limits on the primary stresses in the MPC confinement boundary for the DBE condition are also applicable to other Level D (faulted) events. Dynamic analysis using a 3-D detailed model of the MPC confinement boundary is the vehicle for performing the structural qualification. In addition to the primary stress limits, the local plastic strain in the Confinement Boundary due to the impact between the MPC and the MPC guides under the Design Basis Earthquake requires evaluation.

b. Long-Term Settlement

At an ISFSI site, depending on the density of the subgrade, there may be a small mismatch between the weight of the excavated native soil above the SFP and the total weight of loaded VVMs and the refilled subgrade, leading to a minor amount of long-term settlement of the SFP. The limiting allowable value of the SFP long-term settlement has been specified in Table 2.3.2 for a conservative stress analysis of the pad under the load combinations of Table 2.4.3. The effect of long-term settlement on the SFP shall be considered as a concurrent load with Dead load. On the other hand, the ISFSI pad is founded on the refilled Self-hardening Engineered Subgrade (i.e., CLSM or lean concrete), which is known to be immune from long term settlement due to its own weight and the dead weight of the ISFSI pad.

2.4.4 Load Case 04: Design Basis Handling and Impact Events

Because the VVM is situated underground and cannot be moved, drop and tip-over events are not credible accidents for this design. The Closure Lid, as can be inferred from the Licensing Drawings, cannot strike the MPC lid if it were to undergo a free fall due to geometry constraints. Further, because the load handling device and lifting equipment are required to meet the defense-in-depth criteria set down in this FSAR, the drop of the Closure Lid or HI-TRAC transfer cask during handling operation is termed non-credible (as is the case for the aboveground HI-STORM system MPC transfer operations at the ISFSI).

The design of the lifting equipment must meet single failure proof criteria to preclude a safety related load handling event during emplacement or removal of the Closure Lid while the CEC contains a loaded MPC. The Closure Lid lifting attachments shall meet the strength limits of ANSI N14.6 for heavy load handling. The metal load bearing parts shall satisfy the requirements of Reg. Guide 3.61 for primary stresses near the lifting locations and shall satisfy ASME NF [2.6.1] Level A limits away from the lifting locations.

Yield and ultimate strength values used in the stress compliance demonstration per ANSI N14.6 shall utilize confirmed material test data through either independent coupon testing or material suppliers' CMTR or CoC, as appropriate.

Lift locations for the CEC are expected to be used for lifting only during construction, and possibly during decommissioning of the VVM with no loaded MPC present; therefore, these lifting locations are not subject to the defense-in-depth measures of NUREG-0612. They are therefore considered as a part of the site construction safety plan, and the site decommissioning plan, as applicable.

2.4.5 Load Case 05: Design Basis Fire Event

The potential of a fire accident near an ISFSI pad is considered to be rendered extremely remote by ensuring that there are no significant combustible materials in the area. The only credible concern is related to a transport vehicle fuel tank fire engulfing the loaded HI-STORM module during the MPC transfer operations or loaded HI-TRAC transfer cask while it is being moved to the ISFSI.

The VVM must withstand the effects of a fire that consumes the maximum volume of fuel permitted to be in the fuel tank of the cask transporter. The duration of the fire for the VVM is conservatively assumed to be the same as that used for the modules in docket numbers 72-1014 and 72-1032. As is the case for aboveground VVMs, the fuel is assumed to spill, surround one storage system and burn until it is depleted. Because the VVM is configured to have a surrounding built-in step or spill barrier, the spilled fuel will collect and burn over the ISFSI pad, also referred to as Top-of-Grade. Therefore, the location of fuel combustion will be physically removed from the CEC. Also, the natural grade in the ISFSI pad surface, engineered to direct the rainwater away from the VVMs, will do the same to the spilled fuel, further ameliorating the thermal consequence of the fire to the stored MPCs.

The sole effect of fire on the VVM structure is to raise the metal temperature of the structural members surrounding the shielding concrete in the Closure Lid. The analysis for the fire event accordingly seeks to establish that the load bearing structure will not be weakened by the rise in its metal temperature (and a consequent reduction in the yield and ultimate strength) and the Closure Lid suffers structural failure or instability.

Therefore, it is required to demonstrate that the structural collapse of the Closure Lid cannot occur due to the reduction of its structural material's (low carbon steel) strength at the elevated temperatures from the fire.

Finally, it is necessary to demonstrate that the internal pressure in the stored MPC will not exceed the accident condition design pressure during or after the fire event.

2.4.6 Load Case 06: Live Load on VVM During MPC Transfer

The VVM must withstand the weight of the loaded HI-TRAC transfer cask and the mating device during MPC transfer operations. Bounding weights for these components are used in the qualifying analysis.

The acceptance criterion for this load case, like all other load cases, is provided in Table 2.4.1.

2.4.7 Load Case 7: Design Basis Flood

The HI-STORM UMAX System is engineered to be flood resistant. Furthermore, the potential water ingress passages are elevated in the HI-STORM UMAX (in contrast to the pad level inlet ducts in typical ventilated VVMs) to prevent intrusion of floodwater in the MPC storage cavities. However, all HI-STORM MPCs are designed to withstand 125 feet of water submergence (Table 2.4.1). The VVM will clearly withstand this static head of water above the surface of the ISFSI because all structural members are either not subject to any pressure differential from the flood or are backed by the subgrade, which resists the flood water directly. Full or partial submergence of the MPC is not a concern from a thermal perspective, as discussed in Chapter 1, because heat removal is enhanced by the floodwater. Submergence of the CEC up to the level of the Container Flange will not result in a significant hydrostatic pressure; therefore, collapse of the CEC or potential for significant stresses is not a concern. Furthermore, the uplift force on the CEC due to buoyancy is less than the downward force due to the system's dead weight; therefore, uplift of the CEC is not a concern.

The analysis of the CEC for submergence under 125 feet of water is presented in Chapter 3.The qualification of the MPC under the Design Basis Flood is documented in the FSAR that supports the CoC of the MPC.

Table 2.4.1

LOAD CASES AND ACCEPTANCE CRITERIA

Load Case I.D.	Bounding Loading	Affected Sub-Component	Applicable Data: Magnitude of Loading	Applicable Data: Reference Coincident Metal Temperature (Deg. F)	Acceptance Criterion
01	Normal operation condition; dead load plus design basis explosion pressure	• Container Shell structure • Closure Lid	Section 3.2 (dead weight);Table 2.3.1 (pressure)	150 350	Primary stresses do not exceed applicable Level A stress limits of ASME Subsection NF for dead weight only (or Level D limits with explosion)
02	Design basis missile	Closure Lid	Table 2.3.3	350	Closure Lid does not collapse, is not dislodged from the cavity, and is not perforated by the missile.
03	Design basis earthquake	Container Shell	Figure 2.4.1 and 2.4.2	150	After the DBE event, MPC retrievability, subcriticality and confinement must not be compromised. Additional criteria for the CEC and its contents are defined in Table 2.4.2
04	Closure lid handling	Lid Lift Lugs; all metal structure in Lid	1.15 x Closure Lid Weight (From Table 3.2.1)	200	ANSI N14.6 limits based on yield or ultimate strength including magnified inertia loads. Meet Reg. Guide 3.61 and Level A limits as applicable.
05	Design basis fire	Closure Lid	Section 2.4.5	800	The Closure Lid structure does not collapse under its dead weight due to elevated metal temperatures.

Table 2.4.1

LOAD CASES AND ACCEPTANCE CRITERIA

Load Case I.D.	**Bounding Loading**	**Affected Sub-Component**	**Applicable Data**		**Acceptance Criterion**
			Magnitude of Loading	**Reference Coincident Metal Temperature (Deg. F)**	
06	VVM loaded by the overhead transfer cask and Mating Device during the transfer operation	Container Shell	-	150	Service A stress limit for NF Class 3 plate and shell structure and buckling stress limits for the VVM shell must be met.
07	Design Basis Flood	Container Shell	125 feet of water head	150	The hoop stress in the Container Shell shall be below the minimum material yield strength without taking credit for the action of the surrounding subgrade.

Note 1. Structural loads and acceptance criteria for each load case are further explained in Section 2.4.

Note 2: Materials of construction are identified in Table 2.6.2.

Note 3: Design attributes of the VVM are explained in Chapter 1 and details are presented in the drawings in Section 1.5.

Note 4: The limiting value of coincident metal temperature is used to establish material properties and allowable stress (or stress intensity) when applicable.

Note 5: Load cases applicable to MPC and HI-TRAC VW are presented in Tables 2.2.6, 2.2.7, 2.2.13 and 3.1.1 of the HI-STORM FW FSAR.

Table 2.4.2

ACCEPTANCE CRITERIA FOR THE HI-STORM UMAX VVM AND INTERNALS UNDER EXTREME ENVIRONMENTAL CONDITIONS

Component	Calculated Value	Allowable Limit
CEC Container Shell	Radial gap between Divider Shell and the MPC after the seismic event	Nominal Gap between the MPC and the Divider Shell must remain open at end of event.
MPC Guides	Maximum compressive load	Minimum of limiting buckling load or ultimate load
MPC Shell	Longitudinal flexural stress intensity in shell wall from bending of the MPC shell as a beam. The local true strain in the MPC shell in the region of MPC guide/MPC Top Lid impact.	ASME Level D primary membrane stress intensity limit The local strain from impact must be less than 10%, which has been established as a conservative limit in [2.4.12].

2.5 THERMALLY SIGNIFICANT LOADS AND ACCEPTANCE CRITERIA

The analyses summarized in this chapter focus on the governing canisters out of the population of MPCs listed in Table 1.2.1. This chapter, however, supports the certification of only MPC-37 and MPC-89 at this time. The analyses reported for smaller canisters are for reference purposes only.

The thermal design and operation of the HI-STORM UMAX System shall meet the intent of the review guidance contained in ISG-11, Revision 3 [2.4.6]. Specifically, the ISG-11 provisions that are explicitly invoked and satisfied are:

a. The thermal acceptance criteria for all commercial spent fuel (CSF) authorized by the USNRC for operation in a commercial reactor are unified into one set of requirements.

b. The maximum value of the calculated temperature for all CSF under long-term normal conditions of storage must remain below 400ºC (752ºF). For short-term operations, including canister drying, helium backfill, and on-site cask transport operations, the fuel cladding temperature must not exceed 400ºC (752ºF) for high burn-up fuel (HBF) and 570ºC (1058ºF) for moderate burn-up fuel.

c. The maximum fuel cladding temperature as a result of an off-normal or accident event must not exceed 570ºC (1058ºF).

d. For HBF, operating restrictions are imposed to limit the maximum temperature excursion during short-term operations to 65ºC (117ºF) and the number of excursions to less than 10.

As stated in Chapter 1, the MPC models designated for storage in the HI-STORM UMAX system are previously certified for use in the HI-STORM FW overpack. For storage in HI-STORM UMAX, additional restriction in the heat load is applicable for certain MPCs and fuel types. Section 2.1 provides the Design Basis Heat Load for storage in HI-STORM UMAX.

The normal condition design temperatures for the materials used in the HI-STORM UMAX system are provided in Table 2.3.7.

Thermally significant loads are characterized by the absence of any significant mechanical loading and are principally applicable to the integrity of the stored fuel. The safety analyses for thermal loadings are contained in Chapter 4. The acceptance criteria for the fuel cladding temperature summarized above, are from ISG 11 Rev 3. The following thermal condition scenarios are applicable to HI-STORM UMAX:

- Normal Ambient Temperature

The HI-STORM UMAX System is analyzed for the same maximum yearly average ambient air temperature as that used for the HI-STORM FW systems (Table 2.3.6) which apply to long-term storage and short-term normal operating conditions (e.g., MPC drying operations and onsite transport operations). Pursuant to NUREG -1536, a certain population of the fuel rods in the MPC is also assumed to have become depressurized due to cladding failure. This normal operating condition temperature bounds all locations in the continental United States.

- Elevated Ambient Air Temperature

The HI-STORM UMAX System must be able to reject the design basis heat load under short-term conditions of elevated ambient air temperature designated as an Off-normal condition pursuant to NUREG-1536.

- Partial Blockage of Inlet Air Plenum

Pursuant to NUREG-1536, 50% of the inlet ducts are assumed to be blocked under an off normal storage condition.

The HI-STORM UMAX System must withstand 50% blockage of the inlet air flow plenum without exceeding allowable temperature and pressure limits specified for the off-normal condition.

- 100% Blockage of Air Inlets by Debris

The HI-STORM UMAX is assumed to be subject to a complete blockage of the inlet ducts. This is assumed to occur as a postulated accident event. Chapter 4 contains the appropriate thermal analysis which serves to establish the ISFSI surveillance program in the CoC for the system.

- 100% Fuel Rod Rupture

The 100% rod rupture event is a *non-mechanistic* postulate intended to define a bounding scenario of rise in the MPC internal pressure. The HI-STORM UMAX System must withstand loads due to 100% fuel rod rupture. For conservatism, 100% of the fuel rods are assumed to rupture with 100% of the fill gas and 30% of the significant radioactive gases (e.g., H^3, Kr, and Xe) released in accordance with NUREG-1536. All of the fill gas contained in non-fuel hardware, such as burnable poison rod assemblies (BPRAs), is also assumed to be released concomitantly.

The acceptance criterion for this loading event is that the accident condition MPC Design Pressure (Table 2.3.5) is not exceeded.

- Wind

Wind is a common environmental condition which is characterized by varying magnitude and direction at all terrestrial locations. Because wind is an ever changing condition, steady state conditions cannot be expected to be reached in the HI-STORM UMAX storage system which has a substantial thermal inertia. However, it is necessary to ensure that the heat rejection function of the system is not significantly impaired by wind. To make this determination, the thermal performance of the system is quantified under a sustained wind (assumed to be of sufficient duration so that steady state conditions are reached) at typical velocities of in the range of 0 to 10 MPH. Sustained wind in a fixed direction for an extended period is not a plausible environmental occurrence event. Because in NUREG-1536, this condition is not specified as one requiring evaluation, this evaluation performed in this FSAR, exceeds the scope specified in NUREG-1536.

- Burial Under Debris

The HI-STORM UMAX vent screens are engineered to prevent accumulation of dust and debris. Siting of the ISFSI pad shall ensure that the storage location is not located over shifting soil.

However, it may be possible for wind borne debris or debris from a collapsing structure in the vicinity of the ISFSI to block the inlet plenum. If burial of an extensive portion of the VVM is a credible event for an ISFSI, then a thermal analysis to analyze the effect of such an accident condition shall be performed for the site using the analysis methodology presented in Chapter 4. The duration of the burial-under-debris scenario will be based on the ISFSI owner's emergency preparedness program. The following acceptance criteria apply to the burial-under-debris accident event:

The fuel cladding temperature shall not exceed the ISG-11, Revision 3 [2.4.6] temperature limits.

The internal pressure in the MPC cavity shall not exceed the accident condition design pressure limit in Table 2.3.5.

The burial-under-debris analysis will be performed if applicable, for the site-specific conditions and heat loads.

- Extreme Environmental Temperature

The HI-STORM UMAX System must withstand extreme environmental temperatures. The extreme accident level temperature is specified in Table 2.3.6. The extreme accident level temperature is assumed to occur with steady-state insolation. This temperature is assumed to persist for a sufficient duration to allow the system to reach steady-state temperatures. As is standard for ventilated systems, extreme environmental temperature is a 3-day average for the ISFSI site.

- Design Basis Fire

The possibility of a fire accident near an ISFSI site is considered to be extremely remote due to the absence of significant combustible materials. The only credible concern is related to a transport vehicle fuel tank fire engulfing the loaded HI-STORM UMAX VVM or loaded HI-TRAC VW transfer cask while it is being moved to the ISFSI.

The HI-TRAC and HI-STORM UMAX VVM must withstand temperatures due to a fire event. The HI-STORM UMAX fire accidents for storage are conservatively postulated to be the result of the spillage and ignition of 50 gallons of combustible transporter fuel (identical to the HI-STORM 100 docket). The HI-STORM UMAX lid external surfaces are considered to receive an incident radiation and forced convection heat flux from the fire. The temperature of fire is assumed to be 1475° F in accordance with 10CFR71.73.

The HI-STORM UMAX System must withstand fire accident without exceeding allowable temperature and pressure limits specified for the accident condition.

- Flood

A potentially severe flood event could happen during the storage period. In that event, the water could enter the inlet ducts and block portion or the entire cooling air flow passageway at the bottom of the cavity, which reduces the air flow ventilating through VVM and causes an elevation of the fuel cladding temperature and system component temperatures.

Chapter 4 contains the appropriate thermal analysis which serves to establish the ISFSI surveillance program in the CoC for the system.

- Jacket Water Loss

The fuel cladding and MPC boundary integrity should be evaluated under a postulated (non-mechanistic) complete loss of water from the HI-TRAC VW water jacket. The HI-TRAC VW must withstand the jacket water loss accident without exceeding allowable temperature and pressure limits specified for the accident condition.

2.5.1 The Forced Helium Dehydrator

The Forced Helium Dehydrator (FHD) is a HI-STORM system ancillary used to remove the remaining moisture in the MPC cavity after all of the water that can practically be removed through the drain line using a hydraulic pump or an inert gas has been expelled in the water blow-down operation. The FHD system is required to be used for MPCs loaded with one or more high burnup fuel assemblies and generating greater than threshold heat loads defined in Chapter 4. The FHD method of moisture removal is optional for all other MPCs.

Expelling the water from the MPC using a conventional pump or a water displacement method using inert gas would remove practically all of the contained water except for the small quantity remaining on the MPC baseplate below the bottom of the drain line and an even smaller adherent amount wetting the internal surfaces. A skid-mounted, closed loop dehydration system will be used to remove the residual water from the MPC such that the partial pressure of the trace quantity of water vapor in the MPC cavity gas is brought down to ≤ 3 torr. The FHD system, engineered for this purpose, utilizes helium gas as the working substance. In comparison to the classical vacuum drying process, the FHD maintains the fuel cladding at a relatively low temperature (substantially below the permissible cladding temperature in ISG-11 Rev 3) which insures that the pressure inside the cladding and hence its hoop stress remains at a moderate level. The design features of the FHD are described in an array of USPTO-issued patents available in the open literature as follows:

- Patent Number 7,096,600B2, Forced Helium Dehydrator, dated August 29, 2006
- Patent Number 7,210,247B2, Forced Gas Flow Canister Dehydration, dated May 1, 2007
- Patent Number 7,707,741B2, Dew Point Temperature Based Canister Dehydration, dated May 4, 2010
- Patent Number 8,067,659B2, Method of Removing Radioactive Materials from Submerged State and/or Preparing Spent Nuclear Fuel for Dry Storage, dated November 29, 2011
- Patent Number 8,266,823B2, Method and Apparatus for Dehydrating High Level Waste Based on Dew Point Temperature Measurements, dated September 18, 2012

2.5.1.1 FHD Design Criteria

The Design of the FHD has been standardized for all HI-STORM/HI-STAR MPCs using the design criteria set forth in the following which have remained unchanged since their first adoption in the HI-STORM 100 FSAR over a decade ago. These design criteria are intended to ensure that design and operation of the FHD system will remove bulk moisture and lower the partial pressure of the residual vapor in the MPC cavity to ≤ 3 torr if the circulating gas reaches

the specified temperature or dew point value and duration criteria. The FHD system is designed to ensure that during normal operation (i.e., excluding startup and shutdown ramps) the following criteria are met:

i. The temperature of helium gas in the MPC shall be at least 15ºF higher than the saturation temperature at coincident pressure. The operating pressure shall be selected to maximize the mass flow rate within the constraints of the pressure rating of the associated pressure parts.

ii. The recirculation rate of helium shall be sufficiently high (minimum hourly throughput equal to ten times the nominal helium mass backfilled into the MPC for fuel storage operations) so as to produce a turbulated flow regime in the MPC cavity.

iii. The partial pressure of the water vapor in the MPC cavity will not exceed 3 torr. This limit will be met if the gas temperature at the de-moisturizer outlet is verified by measurement to remain ≤ 21ºF for ≥ 30 minutes or if the dew point of the gas exiting the MPC is verified by measurement to remain ≤ 22.9ºF for ≥ 30 minutes.

The design of the FHD ancillary and the thermal- hydraulic simulations to insure that it would meet the above design criteria were carried out at the time of its introduction in the HI-STORM 100 system in 2001. A Holtec proprietary report titled “Forced Helium Dehydrator Sourcebook” Holtec Report HI-2022966 documents the design and confirmatory analyses on the FHD. As required by the HI-STORM 100 FSAR (in its Appendix 2.B), the first FHD manufactured and deployed in MPC drying was subjected to acceptance testing. Since then, over 20 nuclear units have opted for the FHD method of drying. Like all ancillaries, the entire body of information on the design, manufacturing and testing of the FHDs is maintained for archival reference in Holtec’s quality assurance system. The FHD has been designated not-important-to-safety (NITS) because its malfunction cannot precipitate a rise in the stored fuel's reactivity, cause increase in the cladding temperature above design limits, cause a significantly elevated dose rate to the crew or lead to release of radioactive matter to the environment. Instrumentation used to ensure that the licensed conditions for operation are met is calibrated by vendors who are on the Holtec Approved Vendors List for Important-to-Safety and Safety Related equipment.

2.6 MATERIALS, CODES, STANDARDS, AND PRACTICES TO ENSURE REGULATORY COMPLIANCE

There is no U.S. or international code that is sufficiently comprehensive to provide a completely prescriptive set of requirements for the design, manufacturing, and structural qualification of the VVM. The various sections of the ASME Codes, however, contain a broad range of specifications that can be assembled to provide a complete set of requirements for the design, analysis, shop manufacturing, and field erection of the VVMs. The portions of the ASME Codes that are invoked for the various elements of the VVM design, analysis, and manufacturing activities are summarized in Table 2.6.1.

The ASME Boiler and Pressure Vessel Code (ASME Code) Section III, Subsection NF Class 3 [2.6.1], is the applicable code to determine stress limits for the metallic structural components of the VVM when required by the acceptance criteria listed in Tables 2.4.1 and 2.4.2. The permitted material types for long-term use are listed in Table 2.6.2. Manufacturing requirements are set down in licensing and design drawings.

Section III Subsection NB of the ASME Boiler and Pressure Vessel Code [2.6.8], is the governing code for the structural design of the MPC. The alternatives to the ASME Code, Section III Subsection NB, applicable to the MPC in Docket Nos. 72-1032 are also applicable to the MPC in the HI-STORM UMAX System, as documented in Table 2.6.5.

The stress limits of ASME Section III Subsection NF [2.6.10] are applied to the HI-TRAC structural parts where the applicable loading is designated as a code service condition.

The fuel basket, made of Metamic-HT, is subject to the requirements in Metamic-HT Sourcebook [1.2.4] and is designed to a specific (lateral) deformation limit of its walls under accident conditions of loading (credible and non-mechanistic) (see Table 2.2.11 of HI-STORM FW FSAR). The basis for the lateral deflection limit in the active fuel region, θ, is provided in [2.6.9].

ACI-318(2005) [2.6.2] is the applicable reference code to establish applicable limits on unreinforced concrete (in the Closure Lid), which is subject to secondary structural loadings. Chapter 8 contains the design, construction, and testing criteria applicable to the plain concrete in the VVM's Closure Lid. The load combinations applicable to the ISFSI pad and the Enclosure Wall, pursuant to ACI-318(05) are summarized in Table 2.4.3 Applicable sections of ACI-318(2005) should be used in the design of the ISFSI pad and the SFP. Reference [2.6.5] should be used as a secondary guidance document in designing the ISFSI pad. The applicable provisions of [2.6.6] are invoked as an aid in defining the subgrade space that should be modeled in the soil/structure interaction simulation.

The selection of the ISFSI site shall be made with due consideration of the potential of liquefaction. The host plant's criteria with respect to liquefaction for siting the Part 50 structures shall be used in evaluating the suitability of a candidate ISFSI location.

As mandated by 10CFR72.24(c)(3) and §72.44(d), Holtec International's quality assurance program requires all constituent parts of an SSC subject to NRC's certification under 10CFR72 to be assigned an ITS category appropriate to its function in the control and confinement of

radiation. The ITS designations for the constituent parts of the HI-STORM UMAX VVM, using the guidelines of NUREG-CR/6407 [2.6.4], are provided in the Licensing drawing package.

The aggregate of the citations from the codes, standards, and generally recognized industry publications invoked in this FSAR, supplemented by the commitments in Holtec's quality assurance procedures, provide the necessary technical framework to ensure that the as-installed VVM s would meet the intent of §72.24(c), §72.120(a) and §72.236(b). As required by Holtec's QA Program docketed with the NRC (Docket Number 71-0784), all operations on ITS components must be performed under QA validated written procedures and specifications that are in compliance with the governing citations of codes, standards, and practices set down in this FSAR. For activities that may be performed by others, such as site construction work to install the VVM, Holtec International requires that all activities be formalized in procedures and subject to the CoC holder's as well as the ISFSI owner's review and approval.

An ITS designation is also applied to the interfacing structures (such as the SFP), which requires that all quality assurance measures set down in Holtec's Quality Assurance Procedure Manual be complied with by the entity performing the site construction work. In this manner, the compliance of the as-built VVMs with its engineered safety margins under all design basis scenarios of loading is assured.

CRITICAL CHARACTERISTICS OF MATERIALS REQUIRED FOR SAFETY EVALUATION OF STORAGE AND TRANSPORT SYSTEMS

Item	**Property**	**Type (Note 1)**	**Purpose**	**Bounding Acceptable Limit**
1.	Minimum Yield Strength	S	To ensure adequate elastic strength for normal service conditions	Min.
2.	Minimum Tensile Strength	S	To ensure material integrity under accident conditions	Min.
3.	Young's Modulus	S	For input in structural analysis model	Min.
4.	Minimum elongation of $\delta_{min.}$, %	S	To ensure adequate material ductility	Min.
5.	Impact Resistance at ambient conditions	S	To ensure protection against crack propagation	Min.
6.	Maximum allowable creep rate	S	To prevent excessive deformation under steady state loading at elevated temperatures	Max.
7.	Insulation Thermal conductivity (maximum averaged value in the range of ambient to maximum service temperature, t_{max})	T	To reduce the transmission of decay heat from the MPC to the down-coming cool air in the annular gap between divider shell and container shell	Max.
8.	Thermal conductivities for basket (minimum averaged value in the range of ambient to maximum service temperature, t_{max})	T	To ensure that the basket will conduct heat at the rate assumed in its thermal model	Min.
9.	Minimum Emissivity	T	To ensure that the thermal calculations are performed conservatively	Min.
10.	Specific Gravity	S (and R)	To compute weight of the component (and shielding effectiveness)	Max. (and Min.)
11.	Thermal Expansion Coefficient	T (and S)	To compute the change in basket dimension due to temperature (and thermal stresses)	Min. (and Max.)
12.	Boron-10 Content	R	To control reactivity	Min.

Note 1: **Technical Area of Applicability**

S - Those needed to ensure structural compliance

T - Those needed to ensure compliance with thermal (temperature limits)

R - Those needed to ensure radiation (criticality and shielding) compliance

Table 2.6.4

CRITICAL CHARACTERISTICS OF EQUIVALENT MATERIALS USED IN THE VVM COMPONENTS

Designated Material	**Item**	**Critical Characteristic**
ASTM A515 or A516, Gr. 70	Yield Strength	Yield strength vs. Temperature data must exceed values from appropriate tables for 515/516 Gr.70 materials in ASME Code, Section II, Part D at all applicable temperatures.
	Ultimate Strength	Ultimate strength vs. Temperature data must exceed values from appropriate tables for 515/516 Gr.70 materials in ASME Code, Section II, Part D at all applicable temperatures.
	Elongation	Elongation must equal or exceed value(s) for 515/516 Gr. 70
	Charpy Impact	Values that measure resistance to impact must equal or exceed corresponding values for 515/516 Gr. 70.

Table 2.6.5

LIST OF ASME CODE ALTERNATIVES FOR MULTI-PURPOSE CANISTERS (MPCS)

MPC Enclosure Vessel	Subsection NCA	General Requirements. Requires preparation of a Design Specification, Design Report, Overpressure Protection Report, Certification of Construction Report, Data Report, and other administrative controls for an ASME Code stamped vessel.	Because the MPC is not an ASME Code stamped vessel, none of the specifications, reports, certificates, or other general requirements specified by NCA are required. In lieu of a Design Specification and Design Report, the HI-STORM FSAR includes the design criteria, service conditions, and load combinations for the design and operation of the MPCs as well as the results of the stress analyses to demonstrate that applicable Code stress limits are met. Additionally, the fabricator is not required to have an ASME-certified QA program. All important-to-safety activities are governed by the NRC-approved Holtec QA program. Because the cask components are not certified to the Code, the terms “Certificate Holder” and “Inspector” are not germane to the manufacturing of NRC-certified cask components. To eliminate ambiguity, the responsibilities assigned to the Certificate Holder in the Code, as applicable, shall be interpreted to apply to the NRC Certificate of Compliance (CoC) holder (and by extension, to the component fabricator) if the requirement must be fulfilled. The Code term “Inspector” means the QA/QC personnel of the CoC holder and its vendors assigned to oversee and inspect the manufacturing process.

Table 2.6.5

LIST OF ASME CODE ALTERNATIVES FOR MULTI-PURPOSE CANISTERS (MPCS)

MPC Enclosure Vessel	NB-1100	Statement of requirements for Code stamping of components.	MPC Enclosure Vessel is designed and will be fabricated in accordance with ASME Code, Section III, Subsection NB to the maximum practical extent, but Code stamping is not required.
MPC basket supports and lift lugs	NB-1130	NB-1132.2(d) requires that the first connecting weld of a non-pressure retaining structural attachment to a component shall be considered part of the component unless the weld is more than 2t from the pressure retaining portion of the component, where t is the nominal thickness of the pressure retaining material. NB-1132.2(e) requires that the first connecting weld of a welded nonstructural attachment to a component shall conform to NB-4430 if the connecting weld is within 2t from the pressure retaining portion of the component.	The lugs that are used exclusively for lifting an empty MPC are welded to the inside of the pressure-retaining MPC shell, but are not designed in accordance with Subsection NB. The lug-to-Enclosure Vessel Weld is required to meet the stress limits of Reg. Guide 3.61 in lieu of Subsection NB of the Code.
MPC Enclosure Vessel	NB-2000	Requires materials to be supplied by ASME-approved material supplier.	Materials will be supplied by Holtec approved suppliers with Certified Material Test Reports (CMTRs) in accordance with NB-2000 requirements.

Table 2.6.5

LIST OF ASME CODE ALTERNATIVES FOR MULTI-PURPOSE CANISTERS (MPCS)

MPC Enclosure Vessel	NB-3100 NF-3100	Provides requirements for determining design loading conditions, such as pressure, temperature, and mechanical loads.	These requirements are subsumed by the HI-STORM FW FSAR, serving as the Design Specification, which establishes the service conditions and load combinations for the storage system.
MPC Enclosure Vessel	NB-4120	NB-4121.2 and NF-4121.2 provide requirements for repetition of tensile or impact tests for material subjected to heat treatment during fabrication or installation.	In-shop operations of short duration that apply heat to a component, such as plasma cutting of plate stock, welding, machining, and coating are not, unless explicitly stated by the Code, defined as heat treatment operations.
MPC Enclosure Vessel	NB-4220	Requires certain forming tolerances to be met for cylindrical, conical, or spherical shells of a vessel.	The cylindricity measurements on the rolled shells are not specifically recorded in the shop travelers, as would be the case for a Code-stamped pressure vessel. Rather, the requirements on inter-component clearances (such as the MPC-to-transfer cask) are guaranteed through fixture-controlled manufacturing. The fabrication specification and shop procedures ensure that all dimensional design objectives, including inter-component annular clearances are satisfied. The dimensions required to be met in fabrication are chosen to meet the functional requirements of the dry storage components. Thus, although the post-forming Code cylindricity requirements are not evaluated for compliance directly, they are indirectly satisfied (actually exceeded) in the final manufactured components.

Table 2.6.5

LIST OF ASME CODE ALTERNATIVES FOR MULTI-PURPOSE CANISTERS (MPCS)

MPC Enclosure Vessel	NB-4122	Implies that with the exception of studs, bolts, nuts and heat exchanger tubes, CMTRs must be traceable to a specific piece of material in a component.	MPCs are built in lots. Material traceability on raw materials to a heat number and corresponding CMTR is maintained by Holtec through markings on the raw material. Where material is cut or processed, markings are transferred accordingly to assure traceability. As materials are assembled into the lot of MPCs being manufactured, documentation is maintained to identify the heat numbers of materials being used for that item in the multiple MPCs being manufactured under that lot. A specific item within a specific MPC will have a number of heat numbers identified as possibly being used for the item in that particular MPC of which one or more of those heat numbers (and corresponding CMTRS) will have actually been used. All of the heat numbers identified will comply with the requirements for the particular item.
MPC Lid and Closure Ring Welds	NB-4243	Full penetration welds required for Category C Joints (flat head to main shell per NB-3352.3)	MPC lid and closure ring are not full penetration welds. They are welded independently to provide a redundant seal.
MPC Closure Ring, Vent and Drain Cover Plate Welds	NB-5230	Radiographic (RT) or ultrasonic (UT) examination required.	Root (if more than one weld pass is required) and final liquid penetrant examination to be performed in accordance with NB-5245. The closure ring provides independent redundant closure for vent and drain cover plates. Vent and drain port cover plate welds are helium leakage tested.
MPC Lid to	NB-5230	Radiographic (RT) or	Only progressive liquid penetrant

Table 2.6.5

LIST OF ASME CODE ALTERNATIVES FOR MULTI-PURPOSE CANISTERS (MPCS)

Shell Weld		ultrasonic (UT) examination required.	(PT) examination is permitted. PT examination will include the root and final weld layers and each approx. 3/8" of weld depth.
MPC Enclosure Vessel and Lid	NB-6111	All completed pressure retaining systems shall be pressure tested.	The MPC vessel is seal welded in the field following fuel assembly loading. The MPC vessel shall then be pressure tested as defined in Chapter 10. Accessibility for leakage inspections preclude a Code compliant pressure test. All MPC enclosure vessel welds (except closure ring and vent/drain cover plate) are inspected by volumetric examination. MPC shell and shell to baseplate welds are subject to a fabrication helium leak test prior to loading. The MPC lid-to-shell weld shall be verified by progressive PT examination. PT must include the root and final layers and each approximately 3/8 inch of weld depth. The inspection results, including relevant findings (indications) shall be made a permanent part of the user's records by video, photographic, of other means which provide an equivalent record of weld integrity. The video or photographic records should be taken during the final interpretation period described in ASME Section V, Article 6, T-676. The vent/drain cover plate and the closure ring welds are confirmed by liquid penetrant examination. The inspection of the weld must be performed by qualified personnel and shall meet the acceptance

Table 2.6.5

LIST OF ASME CODE ALTERNATIVES FOR MULTI-PURPOSE CANISTERS (MPCS)

			requirements of ASME Code Section III, NB-5350.
MPC Enclosure Vessel	NB-7000	Vessels are required to have overpressure protection.	No overpressure protection is provided. Function of MPC enclosure vessel is to contain radioactive contents under normal, off-normal, and accident conditions of storage. MPC vessel is designed to withstand maximum internal pressure considering 100% fuel rod failure and maximum accident temperatures.
MPC Enclosure Vessel	NB-8000	States requirements for nameplates, stamping and reports per NCA-8000.	The HI-STORM FW System is to be marked and identified in accordance with 10CFR71 and 10CFR72 requirements. Code stamping is not required. QA data package to be in accordance with Holtec approved QA program.

2.7 SAFETY PROTECTION SYSTEMS

2.7.1 General

The HI-STORM UMAX System is engineered to provide for the safe long-term storage of spent nuclear fuel (SNF). The HI-STORM UMAX will withstand all normal, off-normal, and postulated accident conditions without release of radioactive material or excessive radiation exposure to workers or members of the public. Special considerations in the design have been made to ensure long-term integrity and confinement of the stored SNF throughout all cask normal and off-normal operating conditions and its retrievability for further processing or ultimate disposal in accordance with 10 CFR 72.122(l) and ISG-2 [2.7.1].

The HI-STORM UMAX System is completely passive requiring no active components or instrumentation to perform its design functions. Temperature monitoring or scheduled visual verification of the integrity of the air passages is used to verify continued operability of the VVM heat removal system, as set down in the system's Technical Specification.

2.7.2 Protection by Multiple Confinement Barriers and Systems

a. Confinement Barriers and Systems

The confinement of the spent fuel is provided by the MPC's Enclosure Vessel. .

Contamination on the outside of the MPC from the fuel pool water is minimized by preventing contact, removing the contaminated water, and decontamination. An inflatable seal in the annular gap between the MPC and HI-TRAC, and the elastomer seal in the HI-TRAC bottom lid (see Chapter 9 of the HI-STORM FW FSAR) prevent the fuel pool water from contacting the exterior of the MPC and interior of the HI-TRAC VW while submerged for fuel loading.

The MPC is a seal welded enclosure which provides the confinement boundary. The MPC confinement boundary is defined by the MPC baseplate, MPC shell, MPC lid, closure ring, port cover plates, and associated welds.

The MPC confinement boundary has been designed to withstand any postulated off-normal operations, accident conditions, or external natural phenomena. Redundant closure of the MPC is provided by the MPC closure ring welds which provide a second barrier to the release of radioactive material from the MPC internal cavity. Therefore, no monitoring system for the confinement boundary is required.

Confinement is discussed further in Chapter 7 of FW FSAR. MPC field weld examinations, helium leakage testing of the port cover plates welds, and pressure testing are performed to verify the confinement function. Fabrication inspections and tests are also performed, as discussed in Chapter 10 of the HI-STORM FW FSAR, to verify the integrity of the confinement boundary.

b. Cask Cooling

To ensure that an effective passive heat removal capability exists for long-term satisfactory performance, several thermal design features are incorporated in the storage system. They are as follows:

The MPC fuel basket is formed by a honeycomb structure of Metamic-HT plates which allows the unimpeded conduction of heat from the center of the basket to the periphery. The MPC cavity is equipped with the capability to circulate helium internally by natural buoyancy effects and transport heat from the interior region of the canister to the peripheral region (Holtec Patent 5,898,747).

The MPC confinement boundary ensures that the inert gas (helium) atmosphere inside the MPC is maintained during normal, off-normal, and accident conditions of storage and transfer. The MPC confinement boundary maintains the helium confinement atmosphere below the design temperatures and pressures stated in Table 2.3.7 and Table 2.3.5, respectively.

The MPC thermal design maintains the fuel rod cladding temperatures below the ISG-11 limits such that fuel cladding does not experience degradation during the long term storage period.

The HI-STORM UMAX is optimally designed, with multiple cooling passages and suitably sized flow annuli, which maximize air flow by ensuring a turbulent flow regime at Design Basis heat loads.

As shown in the licensing drawing package, cooling air to each MPC storage cavity is provided by four independent ducts. Thus, there is a significant level of redundancy in the cooling air delivery system for the HI-STORM UMAX.

As can be observed from the licensing drawings, the air inlet locations are separated from the outlet vent by a significant lateral and vertical distance. This design feature ensures that there is minimal mixing of cold and heated air in the storage system. Calculations summarized in Chapter 4 show that the heat rejection performance of the system is stable under varying wind speed.

2.7.3 Protection by Equipment and Instrumentation Selection

a. Equipment

The HI-STORM UMAX System may include use of ancillary or support equipment for ISFSI implementation. Ancillary equipment and structures utilized at the HI-STORM UMAX ISFSI may be broken down into two broad categories, namely Important-to-Safety (ITS) ancillary equipment and Not Important to Safety (NITS) ancillary equipment. NUREG/CR-6407 provides guidance for the determination of a component's safety classification [2.6.4].

The only ancillary equipment used in conjunction with the MPC loading at an ISFSI consists of the Mating Device (a patented design, see Table 1.3.2) and the load handling device such as the cask transporter.

The MPC transfer is carried out by actuating the Mating Device and moving the MPC vertically to the cylindrical cavity of the recipient VVM cavity. The mating device is actuated by removing the bottom lid of the HI-TRAC transfer cask. The device utilized to lift the HI-TRAC transfer cask to place it on the VVM and to vertically transfer the MPC may be of stationary or mobile

type, but it must have redundant drop protection features. The cask transporter can serve as the load handling device.

b. Instrumentation

As a consequence of the passive nature of the HI-STORM UMAX System, Important-to-Safety instrumentation is not necessary. No instrumentation is required or provided for HI-STORM UMAX storage operations, other than normal security service instruments and dosimeters.

However, in lieu of performing the periodic inspection of the HI-STORM UMAX VVM vent screens, temperature elements may be installed inside the VVM outlet duct and below the bottom of outlet screen to continuously monitor the air temperature. If the temperature elements and associated temperature monitoring instrumentation are used as the sole means of surveillance then they shall be designated as Important-to-Safety.

2.8NUCLEAR CRITICALITY SAFETY

The criticality safety criteria stipulates that the effective neutron multiplication factor, k_{eff}, including statistical uncertainties and biases, is less than 0.95 for all postulated arrangements of fuel within the cask under all credible conditions.

2.8.1 Control Methods for Prevention of Criticality

The control methods and design features used to prevent criticality for all MPC configurations are the following:

- Fuel basket constructed of neutron absorbing material with no potential of detachment, delamination or degradation in long term inert environment of the MPC.
- Favorable geometry provided by the MPC fuel basket.
- A high B-10 concentration (50% greater than the concentration used in the existing state-of-the art designs certified under 10CFR72) leads to a lower reactivity level under all operating scenarios.

Administrative controls shall be used to ensure that fuel placed in the HI-STORM UMAX System meets the requirements described in Chapters 2. All appropriate criticality analyses are presented in Chapter 6 of the HI-STORM FW FSAR.

2.8.2 Error Contingency Criteria

Provision for error contingency is built into the criticality analyses performed in Chapter 6. Because biases and uncertainties are explicitly evaluated in the analysis, it is not necessary to introduce additional contingency for error.

2.8.3 Verification Analyses

In Chapter 6 of the HI-STORM FW FSAR, critical experiments are selected which reflect the design configurations. These critical experiments are evaluated using the same calculation methods, and a suitable bias is incorporated in the reactivity calculation.

2.9 RADIOLOGICAL PROTECTION

a. Access Control

As required by 10CFR72, uncontrolled access to the ISFSI is prevented through physical protection means. A security fence surrounded by a physical barrier fence with an appropriate locking and monitoring system is a standard approach to limit access if the ISFSI is located outside the controlled area. The details of the access control systems and procedures, including division of the site into radiation protection areas, will be developed by the licensee (user) of the ISFSI utilizing the HI-STORM UMAX System.

b. Shielding

The objective of shielding is to assure that radiation dose rates at key locations are as low as practical in order to maintain occupational doses to operating personnel As Low As Reasonably Achievable (ALARA) and to meet the requirements of 10 CFR 72.104 and 10 CFR 72.106 for dose at the controlled area boundary (see Table 2.9.1).

The HI-STORM UMAX is designed to limit dose rates in accordance with 10CFR72.104 and 10CFR72.106 which provide radiation dose limits for any real individual located at or beyond the nearest boundary of the controlled area. The individual must not receive doses in excess of the limits given in Table 2.9.1 for normal, off-normal, and accident conditions.

Three locations are of particular interest in the storage mode:

- immediate vicinity of the cask
- restricted area boundary
- controlled area (site) boundary

Dose rates in the immediate vicinity of the loaded VVM are important in consideration of occupational exposure. Conservative evaluations of dose rate have been performed and are described in Chapter 5 based on Reference PWR fuel.

Consistent with 10 CFR 72, there is no single dose rate limit established for the HI-STORM UMAX System. Compliance with the regulatory limits on occupational and controlled area doses is performance-based, as demonstrated by dose monitoring performed by each cask user.

Design objective dose rates for the HI-STORM UMAX system are presented in Table 2.9.2.

Because of the passive nature of the HI-STORM UMAX System, human activity related to the system after deployment in storage is infrequent and of short duration. Personnel exposures due to operational and maintenance activities are discussed in Chapter 11, wherein measures to reduce occupational dose are also discussed. The estimated occupational doses for personnel provided in Chapter 11 comply with the requirements of 10CFR20. As discussed in Chapter 11, the HI-STORM UMAX System has been configured to minimize both the site boundary dose in storage and occupational dose during short-term operations to the maximum extent possible.

The analyses and discussions presented in Chapters 5, 9, and 11 demonstrate that the HI-STORM UMAX System is capable of meeting the radiation dose limits set down in Table 2.9.1.

c. Radiological Alarm System

The HI-STORM UMAX does not require a radiological alarm system. There are no credible events that could result in release of radioactive materials from the system. Furthermore, direct radiation exposure from the ISFSI is subject to monitoring by the plant's existing dose monitoring system.

Table 2.9.1 RADIOLOGICAL SITE BOUNDARY REQUIREMENTS	
MINIMUM DISTANCE TO BOUNDARY OF CONTROLLED AREA (m)	100
NORMAL AND OFF-NORMAL CONDITIONS:	
-Whole Body (mrem/yr)	25
-Thyroid (mrem/yr)	75
-Any Other Critical Organ (mrem/yr)	25
DESIGN BASIS ACCIDENT:	
-TEDE (rem)	5
-DDE + CDE to any individual organ or tissue (other than lens of the eye) (rem)	50
-Lens dose equivalent (rem)	15
-Shallow dose equivalent to skin or any extremity (rem)	50

Table 2.9.2

DESIGN OBJECTIVE DOSE RATES FOR HI-STORM UMAX

Area of Interest	Dose Rate (mrem/hr)
Inlet Vents	80
Inlet Plenum Region	150
Outlet Vent	60

2.10 FIRE AND EXPLOSION PROTECTION

There are no combustible or explosive materials associated with the HI-STORM UMAX System. Combustible materials will not be stored within the HI-STORM UMAX ISFSI. However, for conservatism, a hypothetical fire accident has been analyzed in Chapter 4 as a bounding condition for HI-STORM UMAX System. The evaluation of the HI-STORM UMAX System fire accident is discussed in Chapter 12.

Explosive material will not be stored within an ISFSI. Small overpressures may result from accidents involving explosive materials which are stored or transported in the vicinity of the site. Explosion as an accident loading condition has been considered in Chapter 12.

2.11 DECOMMISSIONING CONSIDERATIONS

Efficient decommissioning of the ISFSI is a paramount objective of the HI-STORM UMAX System. The HI-STORM UMAX System is ideally configured to facilitate rapid, safe, and economical decommissioning of the storage site. As discussed below, Holtec International has taken appropriate steps to ensure that the necessary equipment designs and certifications shall be available to the user of the HI-STORM UMAX System to expeditiously decommission the ISFSI at the end of the storage facility's required service life.

Towards that end, the loaded MPC has been designed with the objective to transport it in a HI-STAR 190 transportation cask (Figure 2.11.1) Since the loaded MPC is a self-contained Waste Package, no further handling of the SNF stored in the MPC will be required prior to transport to a licensed centralized storage facility or repository.

The MPC which holds the SNF assemblies is engineered to be suitable as a waste package for permanent internment in a deep Mined Geological Disposal System (MGDS). The materials of construction permitted for the MPC are known to be highly resistant to severe environmental conditions. No carbon steel, paint, or coatings are used or permitted in the MPC in areas where they could be exposed to spent fuel pool water or the ambient environment. Therefore, the SNF assemblies stored in the MPC do not need to be removed. However, to ensure a practical, feasible method to defuel the MPC, the top of the MPC is equipped with sufficient gamma shielding and markings locating the drain and vent locations to enable semiautomatic (or remotely actuated) severing of the MPC closure ring to provide access to the MPC vent and drain. The circumferential welds of the MPC closure lid can be removed by semiautomatic or remotely actuated means, providing access to the SNF.

Likewise, the VVM consists of steel and concrete rendering it suitable for permanent burial. Alternatively, the MPC can be removed from the VVM, and the latter reused for storage of other MPCs. In either case, the VVM would be expected to have no interior or exterior radioactive surface contamination. Any neutron activation of the steel and concrete is expected to be extremely small, and the assembly would qualify as Class A waste in a stable form based on definitions and requirements in 10CFR61.55. As such, the material would be suitable for burial in a near-surface disposal site as Low Specific Activity (LSA) material.

If the SNF needs to be removed from the MPC before it is placed into the MGDS, the MPC interior metal surfaces can be decontaminated using existing mechanical or chemical methods to allow for its disposal. This will be facilitated by the smooth metal surfaces designed to minimize crud traps. After the surface contamination is removed, the MPC radioactivity will be diminished significantly, allowing near-surface burial or secondary applications at the licensee's facility.

The HI-STORM UMAX ISFSI will contain MPCs that are readily removable from their storage cavities. The ISFSI will be decommissioned only after all MPCs have been removed from the storage cavities. Removing the Divider Shell does not require any weld removal or unfastening

of bolts. The CEC structure can be removed by excavating the surrounding subgrade. Alternatively, the cavity can be filled with suitable fill materials and the CEC left in place. Even if the decision is made to dispose of all activated material, the VVM, due to differences in its geometry and construction (particularly, use of the native soil as the biological shield to the extent possible) will result in less steel and concrete to be disposed off. In the aggregate, it is estimated that less material will need to be disposed off to decommission a VVM ISFSI in comparison to an ISFSI containing aboveground VVMs.

Finally, the activation estimate in Table 2.4.1 of [2.6.3] for the aboveground VVM inner shell is adopted herein (conservatively) for the VVM steel shell enclosure.

Due to the design of the HI-STORM UMAX System, no residual contamination is expected to be left behind on the concrete ISFSI pad. The base pad, fence, and peripheral utility structures will require no decontamination or special handling after the last VVM is removed.

The long-lived radio-nuclides produced by the irradiation of the HI-STORM UMAX System components are listed in Table 2.11.1. The activation of the HI-STORM UMAX components shall be limited to a cumulative activity of 10 Ci per cubic meter before decommissioning and disposal of the activated item can be carried out.

Table 2.11.1

PRINCIPAL LONG-LIVED ISOTOPES PRODUCED DURING IRRADIATION OF THE HI-STORM UMAX COMPONENTS

Nuclide	MPC Stainless Steel	HI-STORM Steel	HI-STORM Concrete
^{54}Mn	X	X	X
^{55}Fe	X	X	X
^{59}Ni	X	-	-
^{60}Co	X	-	-
^{63}Ni	X	-	-
^{39}Ar	-	-	X
^{41}Ca	-	-	X

Figure 2.11.1: HI-STAR 190 Transportation Overpack and MPC Shown in Exploded, Cut-Away View

2.12 REGULATORY COMPLIANCE

Pursuant to the guidance provided in NUREG-1536, the foregoing material in this Chapter provides:

A complete set of principal design criteria for the VVM as mandated by 10CFR72.24I(1), §72.24(c)(2), §72.120(a) and §72.236(b);

A clear identification of VVM structural parts subject to a fully articulated design subject to certification under 10CFR72 and of interfacing structures;

The required set of limiting critical characteristics of interfacing ISFSI Structures to ensure that the VVM will render its intended function under all design basis scenarios of operation; and

A complete set of requirements premised on well-recognized codes and standards to govern the design and analysis (to establish safety margins) and manufacturing of the VVM.

It is noted that the requirements of 10CFR72 do not preclude the use of an underground storage system such as the HI-STORM UMAX. The underground VVM design, while not specifically mentioned in the regulatory guidance literature associated with implementing the requirements in 10CFR72 (i.e., NUREG-1536) meets and exceeds the intent of the guidance in that it provides an enhanced protection of the stored spent nuclear fuel and a significantly reduced site boundary dose, enables a more convenient handling operation, and presents a much smaller target for missiles/projectiles compared to an aboveground storage system.

CHAPTER 3: STRUCTURAL EVALUATION[1]

3.0 OVERVIEW

In this chapter, the structural safety evaluation of the HI-STORM UMAX Vertical Ventilated Module (VVM) system is performed pursuant to the guidelines of NUREG-1536. The organization of technical information in this chapter mirrors the format and content of Regulatory Guide 3.61 to the extent applicable. The objective of the structural analyses is to ensure that the integrity of the HI-STORM UMAX system is maintained under the normal, off-normal and extreme environmental conditions and accident events listed in Chapter 2. The design basis information contained in the previous two chapters and in this chapter provides the necessary data to permit all needed structural evaluations for demonstrating compliance with the requirements of 10CFR72.24. To facilitate regulatory review, the assumptions and conservatisms inherent in the analyses are identified along with a concise description of the analytical methods, models, and acceptance criteria. A summary of the system's ability to maintain its structural integrity under other effects that may contribute to structural failure, such as fatigue, buckling, and non-ductile fracture is also provided. (An evaluation of the suitability of the materials used in the HI-STORM UMAX VVM system under both slow acting (degenerative) and fast acting (precipitous) loads is presented in Chapter 8.)

The VVM, consisting of the CEC and the Closure Lid, serves as the storage space for the loaded MPC. The CEC is a weldment of the Container Shell, Container Flange, Bottom Plate, Lower MPC Guides, and MPC Bearing Pads. The Closure Lid is a weldment of structural steel encasing plain concrete and arranged to provide an appropriate outlet passage for the heated air issuing from the storage cavity. An insulated Divider Shell with Upper MPC Guides is situated within the CEC and restrained by the Lower MPC Guides at the bottom and by the Container Flange at the top. These individual components are collectively referred to as VVM Components. Interfacing structures that surround and support the VVM, as well as proximate structures, which are collectively referred to as ISFSI Structures, are explained in Chapter 2. Section 1.2 contains a complete description of the VVM components and ISFSI Structures (accompanied by appropriate figures) and their respective functions within the HI-STORM UMAX ISFSI. The essential design details of both the VVM Components and the ISFSI Structures are set down in the Licensing Drawing in Section 1.5. The design basis loadings for the facility are provided in Chapter 2. The applicable codes, standards, and practices governing the structural analysis of the HI-STORM UMAX module, as well as the design criteria, are also presented in Chapter 2. Throughout this chapter, in the context of the VVM components, the term "*safety factor*" is defined as the *ratio of the allowable stress (load) or displacement for the applicable load combination to the maximum computed stress (load) or displacement.*

For the ISFSI Structures, which are made of reinforced concrete, the safety factor is defined as the ratio of the ultimate moment (or shear) capacity to the actual maximum moment (or shear)

1 The analyses summarized in this chapter focus on the governing canisters out of the population of MPCs listed in Table 1.2.1. Specifically, this chapter supports the certification of only MPC-37 and MPC-89 at this time. The analyses reported for smaller canisters are for reference purposes only.

developed under the factored load combination.

The following information germane to safety factors is important to understanding the safety case presented in this chapter:

1. All safety factors are dimensionless.

2. The minimum permissible value of any safety factor to support a positive safety conclusion is 1.0. However, to permit an occasional 10CFR72.48 evaluation that may be required, the HI-STORM UMAX system is designed to ensure that all safety factors in the initial design basis calculations are at least 1.1.

The objective of the structural analyses is to ensure that the integrity of the HI-STORM UMAX system is maintained under all credible loadings under normal, off-normal and extreme environmental conditions as well all credible accident events. Specifically, the design basis information contained in the previous two chapters and in this chapter provides the necessary data to permit all needed structural evaluations for demonstrating compliance with the requirements of 10CFR72.236(a), (b), (d) (e), (f), (g), and (1). To facilitate regulatory review, the assumptions and conservatisms inherent in the analyses are identified along with a concise description of the analytical methods, models, and acceptance criteria. The information presented herein is intended to comply with the guidelines of NUREG-1536 and ISG-21 pertaining to use of finite element codes.

In particular, every Computational Modeling Software (CMS) deployed to perform the structural analyses is identified and its implementation appropriately justified as suggested in ISG-21. The information on benchmarking and validation of each Computational Modeling Software is also provided (in Subsection 3.6.2).

Where appropriate, the structural analyses have been performed using classical strength materials solution. Such calculations are presented in this FSAR in transparent detail.

Finally, the input data and analyses using Computational Modeling Software (CMS) are described in sufficient detail to enable an independent evaluation of safety conclusions reached in this chapter.

The MPC and HI-TRAC are categorized as "interfacing components" in this FSAR because they have been licensed in their host docket (i.e., docket number 72-1032 for HI-STORM FW). Nevertheless, it is necessary to demonstrate in this FSAR that the loads exerted on an interfacing component do not exceed its licensing basis in its docket number 72-1032. For example, the MPC structural integrity has been evaluated in this chapter to ensure that the rattling motion of the MPC inside the VVM storage cavity during the DBE event will not produce a breach in the confinement boundary or subject the MPC to lateral decelerations in excess of the value for which it was qualified in docket number 72-1032.

However, it should be noted without ambiguity that the HI-STORM UMAX system has been designed such that, with the exception of the earthquake induced impact load on its Confinement Boundary,

the MPC stored in HI-STORM UMAX will always be subject to a less severe loading than what would be obtained in the above-ground HI-STORM systems under an identical environmental condition. Furthermore, the following restrictions apply:

1. *The content conditions for an MPC to be stored in HI-STORM UMAX must not exceed the technical specification for HI-STORM UMAX.*
2. *The design specifications for the MPC (and the HI-TRAC cask used to load the MPC that are identified in its licensing basis FSAR) will apply at all times during loading and storage of the MPC. Such specifications include Design Basis external pressure and any acceptable radiation dose limits.*

Table 3.1.1 provides the acceptance criteria that apply to the MPCs listed in Table 1.2.1.

Technical descriptions and safety analyses in this chapter, especially pertaining to the components common to the HI-STORM FW and the HI-STORM UMAX systems are referenced in this FSAR, as necessary to the HI-STORM FW FSAR. To facilitate convenient access to the referenced material, the latest edition of the HI-STORM FW FSAR has been placed in this docket and a list of HI-STORM FW FSAR sections germane to this chapter is provided in a tabular form below.

The safety analyses summarized in this chapter demonstrate acceptable margins to the allowable limits under all design basis loading conditions and operational modes. Minor changes to the design parameters that inevitably occur during the product's life cycle which are treated within the purview of 10CFR72.48 and are ascertained to have an insignificant effect on the computed safety factors may not prompt a formal reanalysis and revision of the results and associated data in the tables of this chapter unless the cumulative effect of all such unquantified changes on the reduction of any of the computed safety margins cannot be deemed to be insignificant. For purposes of this determination, an insignificant loss of safety margin with reference to an acceptance criterion is defined as the estimated reduction that is no more than one order of magnitude below the available margin reported in the FSAR. To ensure rigorous configuration control, the information in the Licensing drawings in Section 1.5 should be treated as the authoritative source for numerical analysis at all times. Reliance on the input data and associated results in this chapter for additional mathematical computations may not be appropriate as they serve the sole purpose of establishing safety compliance in accordance with the acceptance criteria set down in Chapter 2 and in this chapter.

HI-STORM FW FSAR MATERIAL ADOPTED IN THIS FSAR BY REFERENCE [2]		
Location of UMAX FSAR	**Subject of the reference**	**Location in HI-STORM FW FSAR, Revision 3**
Subsection 3.1.3	Structural Qualifications of MPC	Subsections 3.4.3 and 3.4.4
Subsection 3.1.3	Structural Qualifications of HI-TRAC	Subsections 3.4.3 and 3.4.4
Subsection 3.4.4	MPC Qualified for accident conditions of storage	Subsection 3.4.4
Subsection 3.4.4	Stress Analysis for MPCs and HI-TRAC under normal handling conditions	Subsection 3.4.3

2 For convenience of reference, the specific revision of the HI-STORM FW FSAR that is referenced in the safety analysis herein is placed in this docket. Updated versions of the HI-STORM FW FSAR shall be placed in this docket as necessary so as to ensure that the safety analyses on the “UMAX” docket (72-1040) remain aligned with the material referenced in the HI-STORM FW FSAR.

3.1 STRUCTURAL DESIGN

3.1.1 Overview

This chapter presents the structural evaluation of the VVM Components for the applicable load cases summarized in Chapter 2 (Table 2.4.1). In Section 3.4, the safety factors for each load case for the VVM Components are quantified. In addition, the safety evaluation of the ISFSI Structures is carried out using the factored load combinations from ACI-318(2005) [2.6.2] (see Table 2.4.3). Summary tables of bounding safety factors are provided for governing load combination for the ISFSI Structures. The Licensing Drawing for the HI-STORM UMAX VVM is provided in Section 1.5. Section 2.6 provides a summary of the applicable regulations and codes and standards for the VVM Components and the ISFSI structures. The design of the VVM Components and the ISFSI Structures is depicted in sufficient detail in the Licensing Drawing to enable the safety analyses summarized in this chapter to be performed. The applicable Design Basis Earthquake is defined by the response spectra shown in Figures 2.4.1 and 2.4.2.

3.1.2 Design Criteria and Applicable Loads

Consistent with the provisions of NUREG-1536, the central objective of the structural analysis presented in this chapter is to ensure that the HI-STORM UMAX system possesses sufficient structural capacity to withstand normal and off-normal loads and the worst case loads under extreme environmental phenomenon or accident events. Withstanding such loadings implies that the HI-STORM UMAX system must successfully preclude the following:

- unacceptable risk of criticality
- unacceptable release of radioactive materials
- unacceptable radiation levels
- impairment of ready retrievability of the SNF

The above design objectives for the HI-STORM UMAX system can be particularized for individual components as follows:

- The objective of the structural analysis of the MPC is to demonstrate that:

  i. Confinement of radioactive material is maintained under normal, off-normal, accident conditions, and natural phenomenon events.

  ii. The MPC basket does not deform under credible loading conditions such that the subcriticality or retrievability of the SNF is jeopardized.

  As stated previously in Section 3.0, the certification of a new MPC design is not envisaged for this docket. Any MPC that is to be stored in HI-STORM UMAX must have been certified in another docket.

Furthermore, the design of the HI-STORM UMAX VVM has been configured such that it maintains the steady state stresses acting on the MPC at a lower (equal) level than those that would develop at the design basis heat load during storage in the above-ground HI-STORM FW overpack in docket number 72-1032. Among the environmental loadings, the case of earthquakes warrants special attention because the manner of support provided to the MPC in HI-STORM UMAX is quite different from the above ground overpacks. To ensure that the MPC design continues to meet the above safety goals under the earthquake event, acceptance criteria for the MPC in Table 3.1.1 have been provided.

- The objectives of the structural analysis of the storage modules are to demonstrate that:

  i. Large energetic missiles such as tornado-generated missiles (see Subsection 2.4.2) do not compromise the integrity of the MPC Confinement Boundary.

  ii. The radiation shielding remains properly positioned in the case of any normal, off-normal, or natural phenomenon or accident event.

  iii. The flow path for the cooling airflow shall remain available under normal and off-normal conditions of storage and after an extreme environmental phenomenon or an accident event.

  iv. The loads arising from normal, off-normal, and accident level conditions exerted on the contained MPC do not violate the structural design criteria of the MPC.

  v. No geometry changes occur under any normal, off-normal, and accident level conditions of storage that preclude ready retrievability of the contained MPC.

  vi. The inter-cask transfer of a loaded MPC can be carried out without exceeding the structural capacity of the HI-STORM UMAX module.

Design (and acceptance) criteria for the HI-STORM UMAX VVM components and the ISFSI structures are summarized in Tables 2.3.1 and 2.3.2. The acceptance criteria for the MPC are provided in Table 3.1.1.

3.1.2.1 Applicable Loadings

Individual loads, applicable to the HI-STORM UMAX System, are defined in Sections 2.4 and 2.5.

3.1.2.2 Design Basis Loads and Load Combinations

i. Design Basis Loads and Load Combinations for VVM Components

Load combinations are developed by assembling the individual loads that may act concurrently, and possibly, synergistically. Load cases and design basis loads applicable to the VVM Components are summarized in Table 2.4.1. Those load cases in Table 2.4.1 which involve an "interfacing component" (namely the stored MPC and the HI-TRAC transfer cask) are analyzed with an

appropriate model of the interfacing component included in the simulation of the storage system. For example, the evaluation of the design basis earthquake (DBE) loading includes the MPC. Results of the analyses carried out under the Design Basis Loads are compared with their respective allowable limits and/or functional performance criteria, as applicable.

ii. Design Basis Loads and Load Combinations for ISFSI Structures

The HI-STORM UMAX ISFSI consists of plate-type reinforced concrete structures whose minimum section strength properties are defined by Table 2.3.2 and the Licensing Drawings. The ISFSI is supported by the subgrade underneath the SFP, which may include pilings, if required, to meet the effective shear wave velocity in Table 2.3.2. Table 2.4.3 contains load combinations applicable to the ISFSI Structures (reinforced concrete structures) in the HI-STORM UMAX ISFSI. The individual loadings on the ISFSI are:

a. Dead load of the VVM and the concomitant effect of settlement over the Design Life of the system (D in Table 2.4.3). The method to incorporate the effect of long-term settlement of the subgrade underneath the SFP (also referred to as the “undergrade”), described in Section 3.4, is used. This method essentially consists of using the deflection properties of the different layers to define equivalent elastic properties of the subgrade underneath the SFP. In the finite element analysis of the SFP, the equivalent (degraded) elastic properties of the subgrade underneath the SFP are utilized to account for the effect of long-term settlement. The Dead load on the SFP from the weight of the loaded VVMs nearly equals the weight of the earth removed. Therefore, the long-term settlement of the SFP is expected to be quite small. The ISFSI pad will not settle relative to the SFP over its service life since it’s supported by the Self-hardening Engineered Subgrade (SES).

b. Live load from the loaded transporter acts directly on the ISFSI pad. This load also adds to the overall load on the SFP (L in Table 2.4.3). The load from the loaded transporter is the sole live load applicable to the ISFSI structures.

c. Seismic load is computed using the methodology presented in Subsection 3.4.4. This load, denoted as E in Table 2.4.3, is the aggregate of the peak dynamic load exerted on the ISFSI less the dead weight. For conservatism, the load E is applied as a static load in the stress analysis of ISFSI structures even though it is transient in nature.

Finally, the subgrade (the space between the ISFSI pad and the Support Foundation Pad) is designated as ITS Category C (Table 2.6.2) to insure that it renders its intended function under normal as well as extreme environmental conditions. Accordingly, numerical values for the required properties such as (spatial average) minimum density, shear wave velocity (Table 2.3.2) and key structural strength values (Table 3.3.4) are provided to enable a comprehensive stress analysis. The switch to CLSM or lean concrete for the "UMAX" ISFSI is, in contrast to HI-STORM 100U which permitted native soil, motivated by considerations to make the ISFSI a competent structure under design basis earthquake and other environmental loadings. The structural analyses documented in this chapter show that, without crediting an Enclosure Wall (even if present):

1. The subgrade in Space A (Figure 2.4.4) will not collapse or otherwise fail causing streaming of radiation to the environment if the ISFSI were subject to a Design Basis Earthquake or impacted by a Design Basis Missile defined in Chapter 2.
2. The ISFSI will remain stable if subjected to the Design Basis Earthquake and if its external subgrade on any side has been excavated down to the SFP (i.e., no lateral support from the subgrade outside the limits of the ISFSI).
3. Even with the contiguous subgrade excavated down to the support Foundation Pad elevation, a Design Basis Missile impacting the subgrade laterally will fail to access the stored MPC.
4. The MPC will remain retrievable under all design basis loading events.

3.1.2.3 Allowables

The important-to-safety components of the HI-STORM UMAX system are identified on the drawings in Section 1.5. Allowable stresses, as appropriate, are tabulated for these components for all service conditions.

Relationships for allowable stresses and stress intensities for NB [3.1.4] and NF [3.1.5] components are provided in Tables 3.1.11 and 3.1.12, respectively. Tables 3.1.2 through 3.1.8 contain numerical values of the stresses/stress intensities for all MPC and VVM load bearing Code materials as a function of temperature.

In all tables the terms S, S_m, S_y, and S_u, respectively, denote the design stress, design stress intensity, minimum yield strength, and the ultimate strength. Property values at intermediate temperatures that are not reported in the ASME Code are obtained by linear interpolation. Property values are not extrapolated beyond the limits of the Code in any structural calculation.

Additional terms relevant to the stress analysis of the HI-STORM UMAX system extracted from the ASME Code (see Figure NB-3222-1, for example) are listed in Table 3.1.10.

3.1.2.4 Brittle Fracture

HI-STORM UMAX utilizes the same material types as HI-STORM 100 (Docket number 72-1014) and HI-STORM FW (docket number 72-1032). In addition, the material thicknesses used in HI-STORM UMAX do not exceed those in the previously certified HI-STORM modules. Furthermore, in comparison to its above ground counterparts, the lowest material temperatures in the HI-STORM UMAX shell, because of its underground configuration, will not be as severely affected by the cold ambient temperatures in winter months. Therefore, the safety considerations for brittle fracture for the HI-STORM UMAX structural steel materials are informed (and bounded) by those previously used in the above-ground HI-STORM modules (see also Section 8.4). Table 3.1.9 reproduces the applicable fracture toughness test requirements for the HI-STORM UMAX VVM from the HI-STORM FW FSAR.

3.1.2.5 Fatigue

Fatigue is a consequence of a cyclic state of stress applied on a metal part. Failure from fatigue occurs if the combination of amplitude of the cyclic stress, σ_a, and the number of cycles, n_f, reaches a threshold value at which failure occurs. ASME Code, Section III, Subsection NCA provides the σ_a-n_f curves for a number of material types. At $n_f = 10^6$, the required σ_a is referred to as the "Endurance Limit". The Endurance Limit for stainless steel (the material used in the MPC) according to the ASME Code, Section III, Div. 1, Appendices, Table I.9.2, is approximately 28 ksi.

The causative factors for fatigue expenditure in a non-active system (i.e., no moving parts) such as the HI-STORM UMAX system may be:

i. rapid temperature changes
ii. significant pressure changes

The HI-STORM UMAX system is exposed to the fluctuating thermal state of the ambient environment. Effect of wind and relative humidity also play a role in affecting the temperature of the cask components. However, the most significant effects are the large thermal inertia of the system and the relatively low heat transfer coefficients that act to smooth out the daily temperature cycles.

As a result, the amplitude of the cyclic stresses, to the extent that they are developed, remains orders of magnitude below the cask material's Endurance Limit.

The second causative factor, namely, pressure pulsation, is limited to the only pressure vessel in the system – the MPC. Pressure produces several types of stresses in the MPC (see Table 3.1.10); all of which are equally effective in causing fatigue expenditure in the metal. However, the amplitude of stress from the pressure cycling (due to the changes in the ambient conditions) is quite small and well below the Endurance Limit of the stainless steel material.

Therefore, failure from fatigue is not a credible concern for the HI-STORM UMAX system components.

3.1.2.6 Buckling

Buckling is caused by compressive stress acting on a slender section. In the HI-STORM UMAX system, the steel weldment in the overpack is not slender; its height-to-diameter ratio being less than 2. There is no source of compressive stress except from the self-weight of the shell and the overpack weight of the HI-TRAC transfer cask in the stacked condition, which produces a modest state of compressive stress. The state of a small compressive stress combined with a low slenderness ratio makes the HI-STORM UMAX VVM safe from the buckling mode of failure.

The only instance of a significant in-plane load on a HI-STORM UMAX part is the impact load exerted on the MPC Guides by the lateral rattling of the MPC under the DBE event. Calculations have been performed and summarized in this FSAR that demonstrate that the MPC Guides will not

buckle.

3.1.2.7 Consideration of Manufacturing and Material Deviations

Departure from the assumed values of material properties in the safety analyses can, in certain cases, adversely affect the computed safety margins. Likewise, deviations in manufacturing that inevitably occur in custom fabrication of capital equipment may detract from the safety factors reported in this chapter. In what follows, the method and measures adopted to ensure that deviations in material properties or in the fabricated hardware will not undermine the structural safety conclusions are summarized.

It is noted that the yield and ultimate strengths of materials used in the manufacturing of the HI-STORM UMAX components will typically be greater than that assumed in the structural analyses because the ASME Code mandates all Code materials meet the minimum certified property values set down in the Code tables. Holtec International requires the material supplier to provide a Certified Mill Test Report in the format specified in the Code to ensure compliance of all physical properties of the supplied material with the specified Code minimums.

The above measures make the probability of an actual material strength property to be falling below the assumed value in the structural analysis in this chapter to be non-credible. On the contrary, Holtec's manufacturing experience suggests that the actual properties are likely to be uniformly and substantially greater than the assumed values.

A similarly conservative approach is used to ensure that the fabrication processes do not degrade the computed safety margins. Towards this end, the fabrication documents (drawings, travelers and shop procedures) implement a number of pro-active measures to prevent all known sources of development of a strength-adverse condition, such as:

i. All welding procedures are qualified to yield better physical properties than the Code minimums. All essential variables that affect weld quality are tightly controlled.

ii. Only those craftsmen who have passed the welding skill criteria implemented in the shop are permitted to weld.

iii. A rigorous weld material quality over-check program is employed to ensure that every weld wire spool meets its respective Code specification.

iv. All structural welds are specified as minimums: In practice, most exceed the specified minimums significantly. All primary structural welds are subject to Q.C. over-check and sign-off.

In the event of a deviation that may depress the computed safety margin, a non-conformance report is prepared by the manufacturer and subject to a safety analysis by Holtec International's corporate engineering using the same methodology as that described in this FSAR. The item is accepted only

if the safety evaluation musters part 72.48 acceptance criteria. A complete documentation of the life cycle of the NCR is archived in the Company's Permanent Filing System and shared with the designated system user.

The above processes and measures have been in place at the Holtec Manufacturing Division to ensure that an unacceptable reduction in the safety factors due to variation in material properties and manufacturing processes does not occur. The Company's nuclear manufacturing experience over the past 25 years corroborates the effectiveness of the above measures.

3.1.3 Stress Analysis Models and Computer Codes

To evaluate the effect of loads on the HI-STORM UMAX system components, finite element models for stress and deformation analysis are developed. The essential attributes of the finite element models for the HI-STORM UMAX VVM and the MPC, developed for Design Basis earthquake induced impact analyses, are presented in this subsection. All finite element models are three-dimensional and are prepared to the level of discretization appropriate to the problem to be solved. The models are developed using ANSYS and LS-DYNA general purpose codes, which are described in Subsection 3.6.2.

Pursuant to ISG-21, the description of the computational model for each component addresses the following areas:

- Description of the model, its key attributes and its conservative aspects
- Types of finite elements used and the rationale for their selection
- Material properties and applicable temperature ranges
- Modeling simplifications and their underlying logic

In subsequent subsections, where the finite element models are deployed to analyze the different load cases, the presentation includes the consideration of:

- Geometric compliance of the simulation with the physics of the problem
- Boundary conditions
- Effect of tolerances on the results
- Convergence (numerical) of the solutions reported in this FSAR

The input files prepared to implement the finite element solutions as well as detailed results are archived in the Calculation Package [3.4.1] within the Company's Configuration Control System. Essential portions of the results for each loading case necessary to draw safety conclusions are extracted from the Calculation Packages and reported in this FSAR. Specifically, the results summarized from the finite element solutions in this chapter are self-contained to enable an independent assessment of the system's safety. Input data is provided in tabular form as suggested in ISG-21. For consistency, the following units are employed to document input data throughout this chapter:

- Time: second

- Mass: pound

Four commercial computer programs, all with a well-established history of usage in the nuclear industry, have been utilized to perform structural and mechanical analyses documented in this submittal. These codes are described in Subsection 3.6.2.

3.1.3.1 HI-STORM UMAX VVM

The physical geometry and materials of construction of the HI-STORM UMAX modules are provided in Chapter 1 including the drawings in Section 1.5. The HI-STORM UMAX VVM finite element model is developed for the seismic Soil Structure Interaction (SSI) analysis of the standard 5×5 VVM array (see Figure 1.0.1), which is fully loaded with the tallest and heaviest MPC allowed to be stored in this underground storage system. The key attributes of the HI-STORM UMAX VVM LS-DYNA finite element model are:

i. Shell elements are used to model the divider shell and CEC except for the CEC base plate and MPC pedestals, which are modeled using thick shell and solid elements, respectively. The VVM lid model is conservatively simplified as a rigid solid body to maximize the contact force at the lid/CEC interface. The bounding MPC stored in the VVM is conservatively represented by a rigid cylinder to yield bounding stresses in the VVM structural members and bounding loads for the ISFSI structural components.

ii. Based on the experience gained in developing the HI-STORM 100U (docket number 72-1014) VVM model, the HI-STORM UMAX VVM model is meshed sufficiently fine to capture the primary stresses developed under the Design Basis Earthquake condition.

iii. Except for the divider shell, CEC baseplate and MPC pedestal, which are conservatively assumed to behave linear elastically to maximize the predicted impact loads under the seismic condition, the VVM steel members are represented by their applicable nonlinear elastic-plastic true stress-strain relationships, which can be found directly from [3.1.2] or derived from engineering stress-strain data. The methodology used for obtaining a true stress-strain curve from a set of engineering stress-strain data (e.g., strength properties from [3.3.2]) is provided in [3.1.6], which utilizes the following power law relation to represent the flow curve of metal in the plastic deformation region:

$$\sigma = K\varepsilon^n$$

where n is the strain-hardening exponent and K is the strength coefficient. Table 3.1.14 provides the values of K and n used to model the behavior of the structural materials in LS-DYNA.

The key input data of the VVM model is listed in Table 3.1.13.

3.1.3.2 Multi-Purpose Canister (MPC)

The structural qualification of the MPCs is documented in the HI-STORM FW FSAR. The finite element model of the MPC is needed, however, for two reasons:

i. To determine the structural consequences of the impact of the MPC's "hard points", namely the Top Lid and the Baseplate locations, with the radial guides welded to the CEC under the DBE.

ii. To ensure that the maximum deceleration sustained by each MPC due to their impact with the Guides is less than the acceptable value (see Table 3.1.1).

The LS-DYNA finite element model of the MPC is essentially identical to that developed for the non-mechanistic tipover analysis for HI-STORM FW (docket number 72-1032). The contents of the MPC, i.e., fuel assemblies, fuel basket and basket shims, are explicitly modeled to account for the interaction between the MPC shell and the MPC contents. Moreover, the MPC model employs a refined element grid in the impact regions of the canister. Additional attributes of the finite element model are:

i. The MPC shell and fuel basket are modeled using LS-DYNA thick shell elements while the MPC lid, baseplate and each fuel assembly are modeled using solid elements. The MPC lid-to-shell weld is also explicitly modeled using solid elements. The finite element discretization of the MPC is sufficiently detailed to accurately articulate the primary membrane and bending stresses as well as the secondary stresses at locations of impact.

ii. The material properties of the MPC components are taken based on the calculated bounding temperatures under normal storage condition. The fuel basket is divided into four regions based on the temperature distribution of the basket in order to use more realistic material properties for the finite element analysis; the same approach was used in the HI-STORM FW tipover analysis.

iii. Except for the fuel assembly model, which is assumed to behave linear elastically, all other MPC structural members are characterized by the true stress-strain relationship of the material to accurately determine the actual plastic deformation in the MPC enclosure vessel for the confinement evaluation of the MPC under impact condition.

The key input data of the MPC enclosure vessel model is listed in Table 3.1.15.

3.1.3.3 HI-TRAC Transfer Cask

The structural qualification of the transfer casks is contained in the HI-STORM FW FSAR. There are no new loads that arise from the operations described in Chapter 9. Therefore, no additional analysis of the transfer cask is performed in this chapter. In the LS-DYNA SSI analysis, the loaded HI-TRAC, along with the transfer cask transporter, is represented as a rigid body in the finite element model for conservatism.

Table 3.1.1

ACCEPTANCE CRITERIA FOR MPCs FOR DEPLOYMENT IN HI-STORM UMAX

	ITEM	Limiting Value	**Source**
1.	Maximum permissible deceleration under seismic or mechanical loading condition	There is no design basis deceleration limit on the MPC. However, the computed value (i.e., 61.75 g's) for the non-mechanistic tip-over event in the HI-STORM FW docket can be conservatively used for the safety evaluation.	Section 3.4 of the HI-STORM FW FSAR
2.	Maximum local plastic strain in the confinement boundary shell	0.1	Reference [3.1.3]

2. The average primary shear strength across a section loaded in pure shear may not exceed 0.42 S_u.
3. Stress classification per NB-3220.
4. P_m, P_L, and P_b are defined in Table 3.1.10.

Table 3.1.9

FRACTURE TOUGHNESS TEST REQUIREMENTS

Material	Test Requirement	Test Temperature	Acceptance Criterion
Ferritic steel with nominal section thickness of 5/8" or less	Not required per NF-2311(b)(1)	-	-
A516 Gr. 70 (greater than 5/8”) used for CEC base plate, CEC containment shell, CEC baffle plate, inlet plenum cover plate, inlet plenum corner gusset, inlet plenum side gusset, inlet plenum air-intake flange (see Note 2), MPC pedestal bearing pad, divider shell flange, divider shell flange gusset, lower and upper MPC guides, closure lid shear ring, closure lid strongback, closure lid bottom plate, closure lid outer shell, closure lid cover plate.	Not required per NF-2311 (b)(7)		
Weld material	Test per NF-2430 if: (1) either of the base materials of the production weld requires impact testing, or; (2) either of the base materials is A516 Gr. 70 with nominal section thickness greater than 5/8”.	See Note 1	Per NF-2330

Note:
1. Required NDT temperature = -40 deg. F for all materials in the HI-STORM UMAX VVM “NF” materials.
2. The optional A105/SA350 LF2 materials are exempted from impact testing per NF-2311(b)(7).

Table 3.1.10

ORIGIN, TYPE AND SIGNIFICANCE OF STRESSES IN THE HI-STORM UMAX SYSTEM

Symbol	Description	Notes
P_m	Primary membrane stress	Excludes effects of discontinuities and concentrations. Produced by pressure and mechanical loads. Primary membrane stress develops in the MPC Enclosure Vessel shell. Limits on P_m exist for normal (Level A), off-normal (Level B), and accident (Level D) service conditions.
P_L	Local membrane stress	Considers effects of discontinuities but not concentrations. Produced by pressure and mechanical loads, including earthquake inertial effects. P_L develops in the MPC Enclosure Vessel wall due to impact between the VVM guides and the MPC (near the top of the MPC) under an earthquake (Level D condition). However, because there is no Code limit on P_L under Level D event, a limit on the local strain consistent with the approach in the HI-STORM FW docket is used.
P_b	Primary bending stress	Component of primary stress proportional to the distance from the centroid of a solid section. Excludes the effects of discontinuities and concentrations. Produced by pressure and mechanical loads, including earthquake inertial effects. Primary bending stress develops in the top lid and baseplate of the MPC, which is a pressurized vessel. Lifting of the loaded MPC using the so-called "lift cleats" also produces primary bending stress in the MPC lid. Similarly, the top lid of the HI-STORM UMAX module, a plate-type structure, withstands the snow load or pressure loading from explosion by developing primary bending stress.
P_e	Secondary expansion stress	Stresses that result from the constraint of free-end displacement. Considers effects of discontinuities but not local stress concentration (not applicable to vessels). It is shown that there is no interference between component parts due to free thermal expansion. Therefore, P_e does not develop within any HI-STORM UMAX component.
Q	Secondary membrane plus bending stress	Self-equilibrating stress necessary to satisfy continuity of structure. Occurs at gross structural discontinuities. Can be caused by pressure, mechanical loads, or differential thermal expansion. The junction of MPC shell with the baseplate and top lid locations of gross structural discontinuity, where secondary stresses develop as a result of internal pressure. Secondary stresses would also develop at the two extremities of the MPC shell if a thermal gradient were to exist. However, because the top and bottom regions of the MPC cavity also serve as the top and bottom plenums, respectively, for the recirculating helium, the temperature field in the regions of gross discontinuity is essentially uniform, and as a result, the thermal stress adder is insignificant and neglected .
F	Peak stress	Increment added to primary or secondary stress by a concentration (notch), or, certain thermal stresses that may cause fatigue but not distortion. Because fatigue is not a credible source of failure in a passive system with gradual temperature changes, the cumulative damage factor from fatigue is not computed for HI-STORM UMAX components.

Table 3.1.11

MPC CONFINEMENT BOUNDARY STRESS INTENSITY LIMITS
FOR DIFFERENT LOADING CONDITIONS (ELASTIC ANALYSIS PER NB-3220)†

Stress Category	Design	Level A	Level D††
Primary Membrane, P_m	S_m	S_m	AMIN ($2.4S_m$, $.7S_u$)
Local Membrane, P_L	$1.5S_m$	$1.5S_m$	150% of P_m Limit
Membrane plus Primary Bending	$1.5S_m$	$1.5S_m$	150% of P_m Limit
Primary Membrane plus Primary Bending	$1.5S_m$	N/A	150% of P_m Limit
Membrane plus Primary Bending plus Secondary	N/A	$3S_m$	N/A
Average Shear Stress††††	$0.6S_m$	$0.6S_m$	$0.42S_u$

† Stress combinations including F (peak stress) apply to fatigue evaluations only.
†† Governed by Appendix F, Paragraph F-1331 of the ASME Code, Section III.
†††† Governed by NB-3227.2 or F-1331.1(d).

Definitions:

S = Allowable Stress Value for Table 1A, ASME Section II, Part D.
S_m = Allowable Stress Intensity Value from Table 2A, ASME Section II, Part D
S_u = Ultimate Stress

† Under accident conditions, the cask must maintain its physical integrity, the loss of solid shielding (concrete, steel, as applicable) shall be minimal and the MPC must remain retrievable.

Table 3.1.13

KEY INPUT DATA FOR FINITE ELEMENT MODEL OF HI-STORM UMAX VVM

Item	Value
Overall height of HI-STORM UMAX VVM (including Closure lid) from bottom of SFP to top of ISFSI pad	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
Height of CEC shell cavity including the top surface of the flange	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
Height of top lid above top of grade	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
Inside diameter of HI-STORM UMAX storage cavity (CEC shell) (See Note 1)	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
Outside diameter of Closure Lid	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
CEC shell thickness	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
Thickness of CEC flange	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
Lifting rib (in the Closure Lid outlet pipe) thickness	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
CEC Baseplate thickness	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
Material of construction	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
Ref. temperature for material properties	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]
Concrete density(reference) †	[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]

Notes

1. UMAX System may have an MPC with increased shell thickness with corresponding increased MPC outside diameter and UMAX storage cavity inside diameter. Such systems are equivalent to or bounded by the existing structural analysis for the UMAX VVM listed in this table.

† The ISFSI Pad may have a dry density of 135 lb/ft,^{3} and the SFP may have a dry density of 120 lb/ft^3; however, using 150 lb/ft^3 as a reference dry density for all of the concrete is conservative.

Table 3.1.14

VALUES OF "K" AND "n" USED TO MODEL ELASTIC-PLASTIC BEHAVIOR OF HI-STORM UMAX COMPONENTS IN LS-DYNA

CEC Shell	A516 Gr. 70	150ºF	1.124×10^5	0.171
Fuel Basket	Metamic-HT	644ºF	1.764×10^4	0.060
		617ºF	1.879×10^4	0.056
		572ºF	2.116×10^4	0.051
		392ºF	2.712×10^4	0.075

† K and n are defined in Subsection 3.1.3.1.

Table 3.1.15

KEY INPUT DATA FOR LS-DYNA MODEL OF GOVERNING MPC ENCLOSURE VESSEL

Item	Value
Overall Height of MPC	213 in (for maximum length fuel)
Outside diameter of MPC	75.5 in (see Notes 1 and 2)
MPC upper lid thickness	4.5 in
MPC lower lid thickness	4.5 in
MPC shell thickness (see Note 2)	0.5 in
MPC baseplate thickness	3.0 in
Material	Austenitic stainless steel (Alloy X in Docket # 72-1014)
Ref. temperature for material properties	[3.1.7]

Notes:

1. Input value is slightly less than the outside diameter (75.75 in) of the MPC-37 and MPC-89 per the Licensing drawings in Section 1.5. The use of a smaller diameter is conservative because it increases the clearance gap between the MPC and the MPC guide plates, which results in higher lateral impact loads between them during the Design Basis Earthquake.

2. UMAX System may have an MPC with increased shell thickness with corresponding increased MPC outside diameter and UMAX Divider and Container Shell inner diameters. Such systems are bounded by the existing structural analysis for the governing MPC listed in this table because of the increased structural capacity of the thicker shell in addition to the reasons provided in Note 1 above.

3.2 WEIGHTS AND CENTERS OF GRAVITY

Table 3.2.1 provides bounding weight data of the movable components (Closure lid, MPC, HI-TRAC and the transporter) required for the structural analysis of the HI-STORM UMAX. The weight data is selected to bound all types of MPCs, HI-TRACs and transporters that may be employed with the HI-STORM UMAX system.

Table 3.2.2 provides limiting (maximum and minimum) dimensional data that bound the MPC types certified in docket number 72-1032.

Because the HI-STORM UMAX is immovable and is situated underground, its CG data is not germane to safety evaluation. The Closure Lid is essentially a radially symmetric structure and, as such, its center-of-gravity is closely aligned with its axis of symmetry.

Table 3.2.1

HI-STORM MPC, LID, HI-TRAC AND TRANSPORTER WEIGHT & PRESSURE DATA USED IN STRUCTURAL ANALYSES

Item	Bounding Weight or Value
Closure Lid	35,000 lb
Loaded Transfer cask	270,000 lb (Note 1)
MPC	110,000 lb (Note 1)
LOADED TRANSPORTER DATA (Note 2)	
• Weight of empty Transporter plus rigging (used to carry the loaded transfer cask)	180,000 lbs
• Reference length and width of each load patch (two load patches per transporter)	197.1875 inch long × 29.5 inch wide (Note 2)
• Computed average normal pressure (based on loaded transporter weight and calculated area of two load patches)	38.68 psi

Notes:

1. Maximum MPC weight and HI-TRAC weights are intended to bound all MPCs (listed in Table 1.2.1) and transfer casks that may be used to load fuel in the HI-STORM UMAX VVM.
2. Transporter reference data is based on typical transporters being used at Holtec ISFSI sites.

Table 3.2.2

LIMITING PARAMETERS

	Item	PWR	BWR
1.	Minimum unirradiated fuel assembly length (nominal), inch	157	171
2.	Maximum unirradiated fuel assembly length (nominal), inch	199.2	181.5[1]
3.	Maximum MPC length, inch	213	195
4.	Minimum MPC length, inch	171	185

[1] Maximum fuel assembly length for the BWR fuel assembly refers to the maximum fuel assembly length plus an additional 5” to account for a Damage Fuel Container (DFC).

3.3 MECHANICAL PROPERTIES OF MATERIALS

This section provides the mechanical properties used in the structural evaluation of the HI-STORM UMAX VVM. The properties include yield stress, ultimate stress, modulus of elasticity, Poisson's ratio, weight density, and coefficient of thermal expansion. Values are presented for a range of temperatures which envelope the maximum and minimum temperatures under all service conditions applicable to the HI-STORM UMAX system components.

The materials selected for use in the HI-STORM UMAX VVM are presented on the drawings in Section 1.5. In this chapter, the materials are divided into two categories, structural and nonstructural. Structural materials are materials that act as load bearing members and are, therefore, significant in the stress evaluations. Materials that do not support mechanical loads are considered nonstructural. For nonstructural materials, the principal property that is used in the structural analysis is weight density. In local deformation analysis, however, such as the study of penetration from a tornado-borne missile, the properties of plain concrete in the HI-STORM Closure Lid are included.

Table 2.6.2 lists applicable codes, materials of construction, and ITS designations for the functional parts in the HI-STORM UMAX system.

3.3.1 Structural Materials

Tables 3.3.1 and 3.3.2 provide the numerical values of the material properties needed for structural analysis.

a. Reinforced concrete is used in the construction of the concrete ISFSI Structures, namely, the ISFSI pad, the SFP, and possibly the optional Enclosure Wall. All reinforced concrete load bearing structures in the HI-STORM UMAX ISFSI will conform to stress criteria of ACI-318(2005). Table 3.3.4 provides the required properties for reinforced concrete.

b. Weld materials: All weld materials utilized in the welding of the Code components comply with the provisions of the appropriate ASME subsection (e.g., Subsection NB for the MPC enclosure vessel) and Section IX. All non-code welds will be made using weld procedures that meet Section IX of the ASME Code. The minimum tensile strength of the weld wire and filler material (where applicable) will be equal to or greater than the tensile strength of the base metal listed in the ASME Code.

c. Subgrade material: As described in subsection 1.2.2, the subgrade material in Space A in Figure 2.4.4 serves a structural function under certain design basis loading events, namely the Design Basis Earthquake (DBE) and the Design Basis Missile (DBM) impact events. Therefore, it is classified as ITS Category C material. The critical characteristics assumed for qualifying the "UMAX" ISFSI under the above mentioned design basis loadings are summarized in Table 3.3.4.

3.3.2 Nonstructural Materials

Plain concrete used in the Closure lid and the non-organic insulation used on the outside surface of the Divider shell are the two non-structural materials used in the HI-STORM UMAX VVM assembly.

The primary function of the unreinforced concrete in the VVM Closure Lid is shielding. Unreinforced concrete is not considered as a primary load-bearing (structural) member. However, its ability to withstand compressive, bearing and penetrant loads under the design basis and various service conditions is analyzed. Chapters 2 and Chapter 8 provide requirements on plain (unreinforced) concrete. The compressive strength, bearing stress limit and the reference dry density applicable to the Closure Lid plain concrete is specified in Table 3.3.3 herein. The allowable bearing strength of plain concrete for normal loading conditions is calculated in accordance with ACI-318 (2005) [3.4.6]. The procedure specified in ASTM C-39 [3.3.1] is utilized to verify that the assumed compressive strength will be realized in the actual in-situ pours.

3.3.3 ISFSI Materials

The mechanical properties of reinforced concrete, subgrade and undergrade required for stress and strength analysis are provided in Tables 3.3.4 and 3.3.5.

Table 3.3.1A

RELEVANT MATERIAL PROPERTIES FOR HI-STORM UMAX
YIELD, ULTIMATE, LINEAR THERMAL EXPANSION,
YOUNG'S MODULUS

Temp. (Deg. F)	**A516 and A515, Grade 70**			
	S_y	S_u	α	**E**

Table 3.3.5

SOIL PROPERTIES, COMPUTED SETTLEMENT, AND CORRESPONDING ELASTIC MODULUS FOR THE UNDERGRADE

	Item	**Value**
1.	Water Content ‘w_n’ Soil Parameter ‘a’ Soil Parameter ‘b’ Poisson’s Ratio	14% 0.18 0.13 0.45
2.	Derived Properties for the Undergrade (Notes 1 and 3): Computed Long-Term Settlement (in) (Note 2) Computed Elastic Modulus (psi)	 < 0.12 6,230
3.	Values used in the Structural Analyses Model for Undergrade: Limiting Long-Term Settlement (in) Corresponding Elastic Modulus (psi)	 From Table 2.3.2 3,200

Note 1: The substrate characteristics are obtained using the density data from Table 2-3 and Table 5-1 of reference [3.3.3]. The soil compaction index ‘Cc’ is a direct function of soil parameters w_n, a, and b per [3.3.3]. The long-term settlement and the elastic modulus are derived using the relationships in [3.3.4].

Note 2: See Table 2.3.2 for the values of settlement (greater than those computed here for conservatism) used as the Design Basis data for qualification of the ISFSI structures.

Note 3: The Design Basis settlement has been set at a higher value than that computed for the SFP to allow for the variation in the soil parameters at a host site.

3.4 GENERAL STANDARDS FOR CASKS

3.4.1 Chemical and Galvanic Reactions

The potential of chemical and galvanic action in the HI-STORM UMAX VVM assembly is evaluated in Chapter 8 of this FSAR.

3.4.2 Positive Closure

The confinement boundary of the HI-STORM UMAX system is seal welded in its entirety. The only access to the MPC storage cavity is through the VVM Closure Lid, which weighs well over 16 tons and must be lifted vertically a substantial distance before it can be separated from the VVM body. Furthermore, the removal of the lid requires the use of a special lifting device. Thus inadvertent opening of the VVM cavity is not feasible or credible.

3.4.3 Lifting Devices

3.4.3.1 Identification of Lifting Devices and Required Safety Factors

The only component in the HI-STORM UMAX system requiring lifting and handling is the Closure Lid. The Closure Lid is equipped with a four point lift system that meets the stress requirement of ANSI N14.6 [3.4.3] and Regulatory Guide 3.61 [1.0.4].

As required by Reg. Guide 3.61, lifting operations applicable to the VVM Closure lid are analyzed. Because of the nature of the HI-STORM UMAX system, lid placement or removal may occur with loaded MPCs inside the VVM cavity. Therefore, a stress analysis to demonstrate compliance with ANSI N14.6 to provide the assurance that a structural failure will not occur during lifting is summarized in this chapter.

The governing requirement for the lifting component itself (the lift lug plates) is that they must meet the primary stress limits prescribed by ANSI N14.6-1993 [3.4.3]; the welds in the load path, near the lifting holes, are required to meet the condition that stresses remain below yield under three times the lifted load (per Reg. Guide 3.61). Further, for additional conservatism, away from the lifting location, the ASME Code limit for the Level A service condition applies. Only the lifting component itself is the "significant-to-handling" (STH) part.

The lifting analysis is performed by conservatively assuming that the dead load is amplified by 15%.

3.4.3.2 Analysis of Lifting Scenarios- HI-STORM UMAX VVM Closure Lid Lifting Analysis (Load Case 04 in Table 2.4.1)

The Closure Lid is an axi-symmetric plate-type structure filled with concrete to provide radiation shielding. As shown in the Licensing Drawings, three lift lug plates with four orthogonally situated lift holes are welded together to lift and handle the Closure Lid. The diameter of the Closure Lid is much larger than the CEC shell I.D. which eliminates the risk of the lid falling into the cavity and striking the MPC stored below. Nevertheless, the Closure Lid lifting points and the Lid itself are required herein to meet the most stringent stress criteria from the regulatory literature, as follows:

1. The primary stresses at the lifting points must meet the limits in ANSI N14.6 with the dead load amplified by 15% to incorporate dynamic effects. The allowable stress per ANSI N14.6 is lesser of 1/10th of the ultimate strength or 1/6th of the material Yield Strength.

2. The average stress in the welds joining the lift lug plates for Closure Lid handling under the amplified dead load must meet the limit set down in Regulatory Guide 3.61, which limits the stress to 1/3rd of the material's Yield Strength.

3. The primary stresses in the lid structure under the amplified dead load must meet Level A stress limits in the ASME Code, Subsection "NF" for class 3 linear structures.

Because of the simplicity of the Closure Lid configuration, the lifting analysis is performed using strength of material approach. The details of the calculations are presented in the calculation package [3.4.1] supporting this FSAR. Lifting slings that attach to the lugs shall be sized to meet the safety factors set forth in ANSI B30.3 [3.4.2].

Table 3.4.1 summarizes key results obtained from the lifting analyses for the limiting HI-STORM UMAX VVM Closure Lid design (i.e., the stainless steel lid design) for a bounding set of input design loads.

It is concluded that all structural integrity requirements are met during a lift of the HI-STORM UMAX VVM Closure Lid. All factors of safety are greater than 1.0.

3.4.3.3 Safety Evaluation of Lifting Scenarios

As can be seen from the above, the computed factors of safety have a large margin over the allowable (of 1.0) in every case. In the actual fabricated hardware, the factors of safety will likely be much greater because of the fact that the actual material strength properties are generally substantially greater than the Code minimums. Minor variations in manufacturing, on the other hand, may result in a small subtraction from the above computed factors of safety. A 10CFR72.48 safety evaluation will be required if the cumulative effect of manufacturing deviation and use of the CMTR (or CoC) material strength in a manufactured hardware renders a factor of safety to fall below the above computed value. Otherwise, a 10CFR72.48 evaluation is not necessary. The above criterion applies to all lift calculations covered in this FSAR.

3.4.4 Heat

The evaluation of the HI-STORM UMAX system under thermally significant conditions listed in Section 2.5 is reported in Chapter 4.

a. Summary of Pressures and Temperatures

Required input data for the structural analysis of the HI-STORM UMAX VVM assembly is contained in Tables 2.3.1, 2.3.2 and the Licensing Drawings.

b. Differential Thermal Expansion

i. Normal Hot Environment

All clearances between the MPC and the HI-STORM UMAX VVM are considerably larger than the thermal expansion that may occur during system operations. Therefore, no interferences between the MPC and the HI-STORM UMAX VVM will occur due to thermal expansion of the loaded MPC. The interfaces that may potentially be subject to interference and their reference dimensions from the Licensing Drawings are provided below:

Interfacing Parts	Engineered Gap in Inches (shown in Licensing Drawings)
MPC-to-Divider Shell (diametral clearance)	10.25
MPC-to-Closure Lid (vertical clearance)	23.5
MPC-to-MPC Top Guide Plates (diametral clearance)	0.5
MPC-to-MPC Bottom Guides (diametral clearance)	0.5
Closure Lid-to-CEC Flange (diametral clearance)	1.0

Simplified calculations summarized in Section 4.4 (Chapter 4) show that the engineered gap in the system for each of the above listed interfaces is an order of magnitude (or more) greater than its reduction from thermal expansion under the operating condition corresponding to the maximum temperature differential scenario between the mating parts that form the interface.

ii. Design Basis Fire Event (Load Case 05 in Table 2.4.1)

The thermal analysis of the Design Basis Fire event is documented in Chapter 4 and evaluated in Chapter 12 for its safety consequence. It is shown in Chapter 4 that the fire accident has a small effect on the MPC temperatures because of blocking action of the underground storage system and the short duration of the fire event. Therefore, a structural evaluation of the MPC under the postulated fire event is not required for HI-STORM UMAX.

Likewise, it is shown that the load bearing components in the HI-STORM UMAX assembly will remain well below the temperature that may induce a significant structural deformation or collapse.

3.4.4.1 Safety Analysis

3.4.4.1.1 Design Basis Flood (Load Case 07 in Table 2.4.1)

Unlike free standing casks, moving flood water is not an event of safety consequence to HI-STORM UMAX: The buried configuration of the HI-STORM UMAX system renders it immune from sliding (that is germane to above ground freestanding casks) under the action of a design basis flood.

3.4.4.1.2 Design Basis Earthquake (Load Case 03 in Table 2.4.1)

The treatment of Load Case 03 (Design Basis Earthquake) for the HI-STORM UMAX system, including the model and analysis methodology, is provided below. The parallel analysis for the structurally strengthened design of "UMAX," termed Version MSE in Subsection 1.0.2, under the Most Severe Earthquake event (Table 2.3.10) is provided at the end of this sub-paragraph.

The HI-STORM UMAX system, plus its contents, may be subject to the Design Basis Earthquake (DBE) defined by the response spectra in Figures 2.4.1 and 2.4.2. As explained in Chapter 2, the DBE has been defined for the HI-STORM UMAX ISFSI to ensure that the operative spectra (Figures 2.4.1 and 2.4.2) essentially envelope the corresponding site DBE spectra at virtually all US sites. Because the VVM is buried in the substrate, tip-over of the MPC is not possible.

Under the action of lateral seismic loads, the CEC Container Shell globally acts as a beam-like structure supported on a foundation driven by the site seismic accelerations. During a seismic event, the lateral loading on the CEC consists of:

2. Inertia force from CEC self-weight

3. Inertia forces from the Closure Lid self-weight

4. Interface forces from the rattling of the MPC within its confines of the CEC and the rattling of the contents inside the MPC

5. Interface forces from the subgrade and from the SFP

The CEC Container Shell may develop longitudinal stresses as it bends like a beam to resist the input seismic loads. In addition, the CEC Container Shell and the Divider Shell are subject to ovalizing action from the loads. Both effects are captured in the seismic analysis.

The seismic analysis consists of three discrete steps, namely:

A. Develop the Design Basis Seismic Model (DBSM) for the HI-STORM UMAX ISFSI and perform the Design Basis Earthquake Soil-Structure Interaction (SSI) analysis.

B. Seismic Qualification of the VVM Components based on the SSI analysis results.

C. Stress analysis of the ISFSI structures using the dynamic loads obtained from the LS-DYNA SSI analysis using DBSM.

A. Design Basis Seismic Model and SSI Analysis

As discussed in Section 2.4, based on the lower bound shear wave velocity profile of US nuclear power plants (Figure 2.4.3) and the input seismic acceleration time history derived from the Regulatory Guide 1.60 seismic response spectrum, a two-step soil seismic response analysis using the computer code SHAKE2000 [3.4.4] and LS-DYNA [3.4.5] is performed to establish a bounding seismic loading condition for the HI-STORM UMAX underground fuel storage system. The 1-D SHAKE analysis model consists of 21 native soil layers of the HI-STORM UMAX ISFSI site with a total thickness of 101 ft; the top of the 7^{th} soil layer is aligned with the bottom of the SFP. The total soil depth of the SSI Model is about five times the height of the underground ISFSI. Figure 3.4.1 shows the LS-DYNA soil model for the seismic response analysis. It is noted that the lateral dimension of the ISFSI soil model is significantly greater than that of the ISFSI. The periphery nodes of the soil model space at the same elevation are constrained to move together to simulate the seismic response of the semi-infinite space of soil. According to the numerical study on various lateral boundary conditions of the finite element soil model [2.4.1], this lateral boundary condition, also known as a "slave boundary condition", is appropriate to predict the soil response in a seismic event. The same soil model and input seismic motion used in the LS-DYNA soil seismic response analysis is used later in the DBSM developed to perform SSI analyses for the HI-STORM UMAX ISFSI.

The object of the DBSM is to obtain conservative values of the loads on the ISFSI structures under the Design Basis Earthquake, which is defined as the response spectra at both the ground surface and the ISFSI foundation elevations as shown in Figures 2.4.1 and 2.4.2 (obtained from the two-step SHAKE/LS-DYNA soil seismic response analysis). Since some of the HI-STORM UMAX steel members (i.e., the closure lid, the Divider Shell, and the CEC) have carbon steel and stainless steel design options, the heavier carbon steel design option is considered in the DBSM to yield conservative SSI analysis results. Following the approach used in the safety evaluation of HI-STORM 100U, the reference VVM assemblage used in the seismic qualification is a 5 by 5 array.

The actual array size, as noted in the HI-STORM 100U (docket number 72-1014) may be much larger. The essential attributes of the DBSM are:

1. The DBSM is developed using the finite element code LS-DYNA; this HI-STORM UMAX ISFSI soil-structure model consists of loaded VVMs, concrete pads, and soil spaces with properties as defined in Table 2.3.2. The HI-STORM UMAX VVM Model is discussed in detail in Paragraph 3.1.3.1.

2. The model has the capability to remove the lateral subgrade all the way down to the bottom of the SFP (which conservatively represents an excavated configuration during additional site construction such as to extend the ISFSI).

3. The model has the ability to simulate a loaded cask transporter arrayed on top of the ISFSI pad to enable the stability of the transporter and the structural margin of safety in the ISFSI pad to be determined.

4. The MPC is represented by a solid rigid cylinder of mass equal to its total mass. This means that all internal masses will move in unison and the inertia forces of the MPC are maximized, which will conservatively result in greater impact loads applied to MPC guides and the CEC base plate.

5. The ISFSI pad and SFP are simulated as a flexible plate-type structure represented by layered solid elements. Proper contact interfaces are defined among the ISFSI pad, the SFP, the ISFSI subgrade and undergrade. For conservatism, the optional enclosure wall is not considered in the DBSM.

6. The VCT, along with the carried transfer cask, is modeled as a freestanding rigid body.

7. The ISFSI pad is characterized by an LS-DYNA inelastic concrete model (MAT_PSEUDO_TENSOR) to account for energy dissipation in the concrete due to the impact loading from the loaded VCT. The SFP and soil are modeled using the LS-DYNA elastic material model. For the case where cracking of the concrete needs to be considered, the Young's Modulus of the SFP is reduced to 50% of its nominal value per the guidance in Section 3.4 of [3.4.15].

8. Proper element size and time step controls in the dynamic model are implemented following the guidance in references [3.4.14] and [3.4.15].

The previously described DBSM is used to perform SSI analyses for the four applicable HI-STORM UMAX ISFSI loading scenarios identified and listed in Table 3.4.2. Figures 3.4.2 and 3.4.3 show the corresponding LS-DYNA models of the two ISFSI configurations considered in the four SSI analyses. In each case, the Design Basis Earthquake is applied to the bottom of the LS-DYNA model using the acceleration time histories obtained from the previously described 1-D SHAKE seismic response analysis.

Table 3.4.3 lists the peak ISFSI interface loads obtained from the LS-DYNA SSI simulations of the four loading scenarios listed in Table 3.4.2. These dynamic peak interface loads will be used in the structural qualification of the ISFSI. In addition to the ISFSI interface loads, the SSI analyses also demonstrate that the exposed SES due to excavation for ISFSI expansion can remain intact during the DBE event without the lateral support from the optional enclosure wall. Figure 3.4.4 shows the maximum tensile stress experienced by the SES. The SES has a much greater tensile capacity (see Table 3.3.4) and the safety factor of the SES against rupture is calculated as

$$\begin{aligned} Safety\ Factor &= \frac{Rupture\ strength}{Maximum\ computed\ tensile\ stress\ \ from\ Figure\ 3.4.4} \\ &= \frac{158.1 psi}{77.91 psi} = 2.03 \end{aligned}$$

Finally, the stability of the loaded VCT is confirmed by the LS-DYNA SSI analyses.

B. <u>Seismic Qualification of VVM Components</u>

In addition to the SSI analysis, a governing MPC to MPC guide impact analysis is performed. Figure 3.4.5 shows the MPC to guide impact model, where the MPC guide is fixed at its base and the loaded MPC rotates about the bottom pivot point with an angular velocity to result in an impact force that significantly bounds, or more precisely is over 2 times, the load capacity of the MPC guide (see Table 3.4.4 and Figure 3.4.6a). The MPC enclosure vessel and its contents are explicitly modeled with sufficiently fine mesh density, following the conclusion obtained from the mesh sensitivity study performed for the MPC shell in Docket number 72-1014, to capture the high stress gradient at the impact location. Results obtained from the MPC-to-guide impact analysis and those from the above mentioned SSI analyses are used to structurally qualify HI-STORM VVM components herein.

The CEC Components and parts of the MPC subject to significant loadings during the DBE event are:

a. Divider and CEC shell (subject to ovalization)
b. MPC shell (bending of the shell as a beam, resulting in axial membrane stress in the shell)
c. MPC top and bottom guides (subject to buckling)
d. Lateral loading on the fuel basket panels (must meet the g-load limit).
e. Localized strain in the MPC shell (due to impact of the MPC with the MPC guides if excessive, may cause breach of confinement)

The focus of safety analysis of each component under the DBE event is somewhat different as summarized below:

a. CEC and Divider Shell: These shells are subject to ovalizing forces which may, in theory, cause them to deform and impede future retrievability of the loaded MPC. Since the SES between the ISFSI pad and the SFP is much stiffer than the subgrade material in the HI-STORM 100U design (the SES modulus of elasticity is at least 6.76 times the value of 100U subgrade based on the required shear wave velocity values), ovalization is not a credible concern for HI-STORM UMAX VVM given the very high safety factor (>18) in the 100U design.

b. Primary stress in the MPC shell: The maximum stress intensity in the MPC shell is compared against the allowable stress intensity for the Level D condition. The safety factor is computed as the ratio of the allowable stress intensity under Level D service condition for "NB" components to the maximum computed longitudinal flexural stress intensity in the MPC shell. Figure 3.4.6b shows the distribution of maximum shear stress (i.e., ½ of the stress intensity) in the MPC shell under the bounding impact condition. As documented in the calculation package [3.4.1], the safety factor of the MPC shell against primary stress is well above 1.0.

c. Top and Bottom MPC Guides: The MPC guides are subject to in-plane rattling loads from the lateral movement of the MPC under the inertia loading from the earthquake. The maximum in-plane load bearing capacity of the longest MPC guide permitted by the system design (see Licensing Drawings) is computed and compared with the maximum dynamic loads obtained from the LS-DYNA analysis. The safety factor is calculated as the ratio of the in-plane load bearing capacity and the actual maximum load computed by the LS-DYNA analysis. The analyses summarized in the Calculation Package [3.4.1] shows that the minimum safety factor from the array of dynamic simulations is greater than 1.0.

d. Loading on the Fuel Basket panel: The minimum lateral g-load to which all of the MPCs listed in Table 1.2.1 have been qualified is shown in Table 3.1.1 (corresponding to the non-mechanistic tip-over event). As shown in Figure 3.4.7, the maximum fuel g-load predicted by the LS-DYNA simulation, conservatively measured at the top lid of the MPC, is significantly smaller than the minimum permitted value for the array of MPC types that may be stored in the HI-STORM UMAX system. Although the calculated fuel basket peak temperature under the HI-STORM UMAX normal storage condition with wind (see Table 4.4.15) is slightly higher (32 ºC) than the fuel basket temperature considered in the MPC to MPC guide impact analysis, which leads to approximately 12% reduction in the yield strength of the fuel basket material, the much smaller MPC impact loading (less than half of the acceptable loading) ensures that the structural integrity of the fuel basket in the HI-STORM UMAX system is less challenged compared with the that in the above ground HI-STORM systems.

e. Maximum Local Strain in the Confinement Boundary in the Impact Region: The MPCs are constrained from uncontrolled lateral motion by the radial guide plates located at their baseplate and top lid elevations. Even a small clearance between the MPCs and the

MPC guides can lead to a high localized strain in the region of the shell where the impact from rattling of the canister under a seismic event occurs. Based on the parametric study performed from HI-STORM 100 U, the extent of local strain from impact is minimized by locating the MPC top guide in the vertical direction such that the mid-height of the impact footprint is aligned with the lower surface of the MPC lid in the HI-STORM UMAX design. Thus the location of impact is removed from the lid-to-shell weld junction. Figure 3.4.8 shows the maximum MPC shell maximum plastic (true) strain obtained for the bounding MPC-to-guide impact simulation. The plastic strain developed in the MPC shell is only a small fraction of the acceptable value based on the very conservative recommendation in [3.1.3]. Therefore, the integrity of the confinement boundary is assured.

Table 3.4.4 summarizes the seismic qualification analysis results for VVM components.

To reduce the occupational and site boundary dose rates, an optional divider shell shield ring (attached to the divider shell) can be implemented. The drawings provided in Chapter 1 give more information about this shield ring specification. The optional divider shell shield ring has no adverse effect on the structural performance of the VVM. The attachment welds between the optional ring and the divider shell have been sized appropriately so that they can support the amplified self-weight of the optional shield ring under seismic loading.

C. Strength Qualification of the ISFSI Structure

Under the Design Basis Earthquake (Figures 2.4.1 and 2.4.2), the loads exerted on the Support Foundation Pad and the ISFSI Pad are obtained from the LS-DYNA SSI simulations listed in Table 3.4.2. Table 3.4.3 lists the peak ISFSI interface loads obtained from various LS-DYNA runs listed in Table 3.4.2. In order to incorporate an additional margin of safety in the ISFSI structural analysis, these unfiltered dynamic bounding interface loads are directly used for the structural evaluation of ISFSI components. The use of the bounding loads is in keeping with a similarly bounding value of settlement specified for the strength analysis of the SFP and the ISFSI pad (see Table 2.3.2).

The SFP and ISFSI pad are required to meet the minimum structural requirements set down in Table 2.3.2 and the Licensing Drawings. The ISFSI pad is required to satisfy ACI-318 (2005) [3.4.6] strength limits under all applicable load combinations (Table 2.4.3).

Table 2.4.3 specifies the load combinations used in the strength analysis of the ISFSI structures. The following discrete analyses are required:

(i) Compute the long-term settlement of the undergrade supporting the SFP assuming all VVM locations are loaded for the entire Design Life: Determine the "effective" elastic modulus of the subgrade under the SFP to simulate the effect of settlement in the structural analyses model. As discussed previously, the long-term settlement of the undergrade from the loaded VVMs and the dead weight of the SFP are very small because the combined equivalent density of the loaded VVM's and the SFP is nearly equal to the density of the excavated

subgrade.

This methodology of settlement computation is based on classical soil mechanics and is summarized below.

1. Compute the total long-term settlement, "d", of the subgrade under the SFP (Space C) over the Design Life assuming that the total load "P" (modeled as a uniform pressure at the top of the subgrade) is equivalent to that produced by the SFP fully populated with loaded VVMs for the entire life using the methodology in [3.4.7].

2. Determine an "effective" elastic spring constant "K" of Space C that emulates the cumulative settlement:

$$K = P/d.$$

3. Using the spring constant computed above, which accounts for the effect of long-term settlement under static loading, an appropriate elastic modulus is defined for the soil column under the SFP. The degraded soil modulus so defined is used in the finite element model of the SFP to evaluate the pad flexure under the factored dead load.

The maximum permitted settlement of the subgrade below SFP is limited to the value specified in Table 2.3.2. If the Table 2.3.2 limit cannot be met, remedial measures such as pilings must be used, unless a site-specific analysis is performed using the same methodology described in Paragraph 3.4.4.1 to qualify the ISFSI structure for the increased settlement.

(ii) Prepare a finite element model of the pads in ANSYS and determine the stress field under the factored Dead and Live loads with the settlement based "degraded" elastic moduli.

(iii) Compute the stress field in the pads under factored seismic loads using dynamic elastic modulus corresponding to the minimum shear wave velocity of the subgrade specified in Table 2.3.2.

(iv) Use the bounding peak loads obtained from the dynamic analysis to compute the stress fields in the pads (SFP and ISFSI pad).

(v) Combine the factored loads and determine the total stress resultants. Compare with the respective section strengths to establish the factors of safety for the SFP and the ISFSI pad.

(vi) Compute the bearing stress (or load) on the subgrade under the ISFSI pad using the combined factored loads from the transporter and the ISFSI pad and compare with the corresponding allowable limit to establish the safety factor for the subgrade under the ISFSI pad.

A summary of the analyses and the associated margins of safety are discussed below:

The structural evaluation of the HI-STORM UMAX ISFSI is performed using the commercial computer code ANSYS [3.1.1]. The constituents of the ISFSI, namely the Support Foundation Pad (SFP), the subgrade under the support foundation pad (the undergrade), the ISFSI pad and the subgrade lateral to the CEC under the ISFSI pad are all modeled using linear elastic SOLID45 elements. The element mesh is intentionally kept fine in the areas of load application on the SFP and the ISFSI pad. The lateral subgrade adjacent to the HI-STORM UMAX ISFSI (Spaces B and D in Figure 2.4.4) is included in the FE model and extends laterally a distance that exceeds the overall depth of the FE model considered for structural analysis. For convenience of load application, the footprint of the CEC base on the SFP is carefully articulated in the finite element model. The substrate under the SFP is terminated at approximately 101.0 ft below the ISFSI pad, which is consistent with the Design Basis Seismic Model discussed previously. The “base” model (Simulation Model I) considers that all the storage locations in ISFSI are populated and experience identical peak vertical seismic loading from Table 3.4.3, which bounds the peak result obtained from the LS-DYNA SSI solution as discussed previously. Because of the symmetric geometry and loading, a quarter symmetric finite element model is sufficient to represent the fully loaded ISFSI. Figure 3.4.9 shows the finite element model of HI-STORM UMAX ISFSI. For a non-symmetric model as in case of Simulation Model II, a full FE model of the HI-STORM UMAX ISFSI as shown in Figure 3.4.10 is used. The “degraded” elastic modulus of the subgrade under the SFP is appropriately computed to account for the long-term settlement effects as described in the foregoing. Table 3.3.4 lists the bounding subgrade characteristics and the concomitant elastic moduli effective under dynamic loading.

To address different loading patterns on the ISFSI and for completeness, additional partially loaded ISFSI configurations are considered in the evaluations. The partial loaded configurations include a two row loaded ISFSI, a single row loaded ISFSI (the middle row of VVM locations is loaded) and a single VVM loaded ISFSI (a single VVM location centered near the periphery of the ISFSI is loaded). Figures 3.4.14, 3.4.16 and 3.4.18 illustrate the partial loading configurations for the ISFSI. These loading configurations are hereinafter referred to as Simulation Models II, III, and IV, respectively. The effects of exposed Self-hardening Engineered Subgrade between the ISFSI pad and SFP are evaluated in a fifth Simulation Model (Simulation Model V), which is shown in Figure 3.4.11. In this model, the lateral subgrade is completely removed from one side to bound any future excavation activities associated with the construction of a new underground ISFSI. For Simulation Model V, all VVM locations are assumed to be loaded and thus the transporter load is excluded.

To simulate the material continuity at the extreme boundary surface of the substrate under the SFP, translations are constrained at the lateral face of the subgrade. The extreme bottom surface of the model is fixed representing the bedrock (or competent soil) elevation.

The following individual load steps are considered in the analysis:

1. Bounding peak load transmitted by the VVM as determined from the LS-DYNA SSI analysis is applied as an effective pressure on the footprint of the CEC base at all VVM locations.

2. The load from the transporter is applied as a normal pressure (see Figures 3.4.12 and 3.4.16) over the transporter load patch on the ISFSI pad. The transporter is assumed to be positioned over the central VVM cavity.

3. The dead weight from 11’×11’ square ISFSI pad region that is centered above each VVM location (see Licensing Drawing in Section 1.5) is applied as a normal pressure on the SES elements directly beneath the ISFSI pad.

4. To simulate the self-weight of the modeled portion of the ISFSI pad, a 1g gravity load is applied. The densities of the various constituents are appropriately input in the model to accurately reflect the individual component weights.

It must be noted that the structural analysis of the ISFSI conservatively considers the peak dynamic loads from the LS-DYNA SSI analysis. However, it is permissible to use equivalent static loads obtained by removing high frequency components that would not contribute to the structural response using appropriate filters.

Since the peak loads from the LS-DYNA SSI analyses are substantially larger in comparison to the dead and live loads, the load combination LC-3 from Table 2.4.3 governs for the ISFSI structural evaluation. However, the analyses are carried out for load combinations LC-2 and LC-3, and the corresponding results substantiate that the load combination LC-3 is governing.

Figures 3.4.13a through 3.4.21c depict the maximum in-plane stresses in the ISFSI concrete structures for the governing load combination LC-3 for all the ISFSI configurations analyzed. The in-plane axial and bending stress on the SFP and the ISFSI pad elements are post-processed to compute the equivalent moments. The induced moments are compared to the respective moment capacities to determine the corresponding factor of safety. Table 3.4.5 summarizes the results for the SFP and the ISFSI pad respectively for all ISFSI configurations analyzed. The safety factors listed in Table 3.4.5 show that the ISFSI pad contains a substantially greater strength reserve than that required by the ACI code. In establishing the safety factors, no credit has been taken the Dynamic Increase Factor of 25% for flexure and 10% for shear permitted by [3.4.8] in the strength qualification of reinforced concrete under the impactive loadings that are intrinsic to the seismic event.

Table 3.4.6 summarizes the punching shear safety factor for the SFP and the ISFSI pad. The minimum punching shear safety factor under the governing condition (when the loaded transporter is positioned on the ISFSI pad) is found to be well above 1.0.

The peak transporter load on the ISFSI pad from the LS-DYNA SSI analyses plus the load from the ISFSI pad are used to compute the maximum bearing stress in the substrate surface under the ISFSI pad. According to ACI-360 [3.4.9], the bearing stress can be calculated by uniformly distributing the load over the entire bearing area of the pad. The maximum computed bearing stress in the

subgrade below the ISFSI pad (Table 3.4.7) meets the minimum safety factor of 2.0 (suggested by the ACI code [3.4.9]) with ample margin.

Detailed calculations for qualifying the HI-STORM UMAX ISFSI structures are documented in [3.4.17].

Structural Qualification Under the Most Severe Earthquake (MSE)

As described in Subsection 1.0.2, a structurally reinforced version of HI-STORM UMAX has been developed to withstand a substantially stronger earthquake than that analyzed in the foregoing and permitted by the original CoC. The structural reinforcement necessary to maintain robust margins under the stronger earthquake are quite modest as detailed in the licensing drawing package (Section 1.5) wherein the buttressed VVM/ISFSI structure is identified as "Version MSE". The governing earthquake for Version MSE for the long term storage condition is defined by Table 2.3.10. The information presented below seeks to demonstrate that Version MSE can withstand the new DBE event (referred to as the Most Severe Earthquake or MSE) meeting all of the acceptance criteria set forth in Table 2.4.2.

The Design Basis Seismic Model (DBSM) described in the foregoing is utilized to perform the required safety evaluations under the MSE except that, because the earthquake is applied at the base of the Support Foundation Pad (SFP), the SSI model does not include the under-grade (Spaces C and D shown in Figure 2.4.4).

In order to perform the SSI analysis for HI-STORM UMAX Version MSE, five earthquakes, each consisting of statistically independent set of three acceleration time histories (see Table 2.4.5 and Figures 2.4.7 to 2.4.11) are generated. The details on the compliance of the generated earthquakes with the guidelines of SRP 3.7.1 (NUREG-0800) are archived in [2.4.14]. Similar to the SSI analysis performed previously for the DBE condition, the resultant horizontal acceleration time history is used in the SSI analysis for the MSE condition since the DBSM is a symmetric half model. The SSI analysis and subsequent evaluations performed to establish the structural adequacy and safety of Version MSE are summarized below:

i. Strain Compatible Soil Properties: To characterize the structural properties of the subgrade that is suitably conservative for general certification, the properties of the soil from the grade to the Support Foundation Pad elevation at the San Onofre' Nuclear Generating Station (SONGS) are used. The numerical data is provided in the unnumbered table below.

Input Soil Data of the SHAKE Analysis performed for the Most Severe Earthquake						
Soil Layer (numbered from the top surface)	1	2	3	4	5	6
Soil Layer Thickness (ft)	4.5	4.5	4.5	4.5	3	4
Density (lb/ft^3)	130	130	130	130	130	130
Shear Wave Velocity (ft/s)	1000	1100	1200	1300	1440	1500

The 1-D seismic response program SHAKE is used to establish the strain compatible dynamic soil properties for the HI-STORM UMAX underground fuel storage site at the San Onofre' Nuclear Generating Station (SONGS) under the MSE condition. The results obtained for SONGS are adopted as the generic bounding value of the strain compatible soil shear modulus corresponding to the MSE. Since SHAKE solutions for strong earthquake conditions (ZPA>1.0g's) are questionable, a conservative approach is used to determine the dynamic soil properties under the MSE condition for the soil layers above the SFP. First, four discrete SHAKE analyses are performed for Reg. Guide 1.60 earthquakes whose horizontal ZPAs are 0.25g's, 0.5g's, 0.75g's and 1.0g's. Figure 3.4.23 shows the relationship between the average dynamic shear strain of the soil and the earthquake ZPA which is obtained from the four SHAKE analyses. With a resultant horizontal ZPA of 2.121g's, the average soil shear strain under the MSE condition is predicted to be 0.809 in/in based on the extrapolated curve in Figure 3.4.23. Next, the dynamic shear modulus of the soil under the MSE condition is obtained from the shear modulus-shear strain relationship used by SHAKE and shown in Figure 3.4.24. At the predicted shear strain of 0.809 in/in, the modulus reduction factor is approximately 0.075. The corresponding shear wave velocity reduction factor is therefore approximately 0.274 (square root of 0.075). Based on the measured average static shear wave velocity of 1257ft/s at the SONGS, this reduction factor leads to the "best estimated" strain compatible dynamic shear wave velocity of 344 ft/s (1257ft/s × 0.274 = 344ft/s). The uncertainty of the soil shear modulus is considered in the SSI analysis by multiplying the best estimate value by a factor of 1.5 and 1/1.5 to establish the upper bound value and lower bound value, respectively, per ASCE 4-98.

ii. Sensitivity Study on the Lateral Extent of the SSI Model: It is recalled that the SSI model of the ISFSI structure (Space B) has a circular boundary with 700 feet radius. Recognizing that certain sites, such as SONGS, don't have such a large land mass around the ISFSI, a sensitivity analysis on the size of the ISFSI SSI model was performed using the time history set identified as THS #1 in Table 2.4.5. Figure 3.4.25 and Figure 3.4.26 show the "large" Space B SSI model (i.e., Space B size is identical to that used in the initial qualification) and the "small" Space B SSI model (i.e., the Space B lateral boundary is set at 100 feet away from the ISFSI pad), respectively. The key seismic response parameters obtained from the

two models using an identical boundary condition (transmitting boundary) are summarized in Table 3.4.10 wherein the case identifier contains the letter L or S to indicate the "large" and "small" model, respectively. These SSI results (i.e., the results for Cases 1L and 1S) demonstrate that the large model yields a uniformly greater response. Therefore, it is concluded that, regardless of the size of the ISFSI land area at a site, it is conservative to use the "large" model. The analyses summarized below accordingly utilize the "large" ISFSI SSI model.

iii. Governing MPC Storage Condition: A perusal of the results presented in the foregoing for the SSI model under the DBE event listed in Table 2.3.2 showed that the storage scenario wherein all storage cavity locations are occupied by loaded MPC-37s provides the largest response. Therefore, the same loading state is used in the qualification analyses for the MSE event.

iv. Effect of Concrete Cracking: The effect of the SFP concrete cracking was evaluated previously for the DBE condition following the guidelines from ASCE 4-98 [3.4.14] and ASCE/SEI43-05 [3.4.15]. Table 3.4.2 lists both the cracked scenarios (i.e., Scenarios 2 and 4) and the corresponding uncracked scenarios (i.e., Scenarios 1 and 3) considered in the LS-DYNA SSI analysis for the DBE event. The DBE analysis results summarized in Table 3.4.3 consistently demonstrate that the key seismic response (i.e., the seismic impact loading on the SFP) under the uncracked condition is bounding. Therefore, the LS-DYNA SSI analysis performed for the MSE event only considers the governing uncracked concrete condition.

v. SSI Analysis Base Runs: The Design Basis Seismic Model used in the original certification and the governing MPC storage condition along with the established "best estimate" soil properties identified above are used to analyze the response of the representative "UMAX Version MSE" array under the five earthquakes composed of statistically independent time histories shown in Figures 2.4.7 to 2.4.11(i.e., Cases 1L, 2L, 3L, 4L and 5L in Table 3.4.10). These five discrete seismic analyses using LS-DYNA are referred to as "base runs".

vi. Uncertainty in the Subgrade (Space B) Properties: The uncertainty of the soil properties is studied through two additional SSI simulations for the 2nd earthquake, which has the largest horizontal ZPA per Table 2.4.5, by using the calculated lower bound and upper bound modulus values. The object of the parametric runs is to determine the extent that the key response parameters are affected by the change in the subgrade modulus. Specifically, the ratio of each response parameter for the upper and lower bound soil modulus to its base run value is obtained. The largest value of the ratio for each response parameter is referred to as its amplification factor. If a particular response parameter is governed by the best estimate soil properties (i.e., response is less for upper and lower bound properties), the amplification factor is set equal to 1.0. The two additional SSI simulations, i.e., Cases 2LL and 2LU in Table 3.4.10 with the last letter in the case number indicating L (for lower bound soil property) and U (for upper bound), provide the needed information to ascertain the amplification factor (due to the uncertainty in the subgrade property) for each response

parameter. These amplification factors are applied to the results from the base run to establish the bounding response parameter for the structural qualification analysis of the HI-STORM UMAX Version MSE array. In this manner the effect of uncertainty in the subgrade modulus is incorporated in the safety evaluation.

vii. Determination of Governing Seismic Response Parameters: The amplification factor determined based on the soil property variation for each seismic response parameter is listed in Table 3.4.11. The averaged peak seismic response parameters obtained from the SSI analyses using the "best estimate" soil properties for the five earthquakes (i.e., the averaged values of Cases 1L through 5L) are also listed in that table. The governing seismic response parameters, which provide the input data for the HI-STORM UMAX Version MSE structural qualification analysis, are then determined by multiplying the averaged values with the corresponding amplification factors.

viii. Structural Evaluations: Structural analyses are performed for HI-STORM UMAX Version MSE by using the same analysis methods as those employed in the initial HI-STORM UMAX qualification. Detailed calculations are documented in [3.4.1] and [3.4.17]. As before, the safety analysis focuses on the following parts deemed to be most severely stressed in the system, namely, (a) The Top and Bottom MPC Guide plates and Guide Ring, (b) The MPC Shell (primary stress from beam-bending action), (c) Local stress in the MPC Shell from impact with the Guide Plate, (d) The uplift load in the Closure lid hold-down structure and (e) The flexural stress in the Support Foundation Pad from the amplified vertical inertia load during the MSE event. The summary evaluations, synopsized from the respective Calculation Packages, are presented below:

a. Top & Bottom MPC Guide Plates and Guide Ring: As shown in the licensing drawing package (Section 1.5), the Top and Bottom Guide Plates Guide Ring are configured to close their gap with the MPC surface and thus eliminate impact loads from rattling action of the MPC during the earthquake. Despite this measure, the maximum MPC horizontal acceleration is in excess of 8 G's and the maximum compressive load on the Guide Plate (the top Guide Plate load controls) is approximately 470 kips, as reported in Table 3.4.11. The computed capacity of the Guide Plates under the worst direction of compressive loading, as reported in Table 3.4.12, is greater than 530 kips resulting in a factor of safety in excess of 1.1.
b. The maximum MPC shell primary stress computed from the LS-DYNA analyses, reported in Table 3.4.11, likewise shows a positive margin of safety even without accounting for the strength increase of the stainless steel material under dynamic conditions.
c. The local strain in the impacted region of the MPC shell, reported in Table 3.4.12, is also only a fraction of the limit set forth in Table 3.1.1.
d. The hold-down structure, illustrated in the licensing drawing in Section 1.5, is computed to have a large factor of safety (Table 3.4.12).
e. The factor of safety in the Support Foundation Pad, computed by simply proportioning the maximum vertical load for the previously analyzed DBE event and

the MSE event, as shown in Table 3.4.13, is likewise large for reinforced concrete structures. The values shown in Table 3.4.13 are valid since the analysis approach used to determine the seismic demand loads for the MSE condition is conservative as compared to the original analysis for the DBE condition. Specifically, in the DBE analysis the earthquake motion is deconvoluted from the free field surface down to the bedrock level (100 ft below grade) using the computer code SHAKE2000. The deconvoluted earthquake motion obtained from SHAKE2000 is then applied as the control motion at the bedrock level in the LS-DYNA soil-structure interaction (SSI) model. In the MSE analysis, the free field acceleration is applied directly to the SFP level (25 ft below grade) without considering any decrease in earthquake strength due to deconvolution. Recognizing that the calculated seismic demand loads for the MSE condition are conservative relative to the original results for the DBE condition, and that the ANSYS model used to evaluate the reinforced concrete ISFSI structure is linear, the minimum factors of safety for the SFP for the MSE condition are obtained by linearly scaling the previous results for the DBE condition according to the seismic demand ratio.

f. The ovalization of the Cavity Enclosure Container CEC) shell is negligible.

Safety Conclusions:

The above analyses show that the Version MSE of HI-STORM UMAX meets all applicable structural acceptance criteria. In particular, it is shown that:

a. The MPC retrievability subsequent to the MSE event is maintained with a large margin.
b. The maximum primary stress in the MPC shell remains well below the Level D primary stress intensity limit for Class 1 “NB” pressure vessels.
c. The local impact strain in the MPC enclosure vessel is a small fraction of the local strain limit for stainless steel specified in Table 3.1.1.
d. The bottom and top MPC guide plates remain functional during the MSE condition.
e. The maximum MPC deceleration is less than the acceptable value listed in Table 3.1.1.
f. The structural strength of the ISFSI slab (Table 2.4.3) is not exceeded.
g. The puncture strength of the ISFSI slab is not exceeded.
h. The structural capacity of the VVM lid to CEC top flange connection is not exceeded which ensures that the Closure Lid will not, even temporarily, lift off the ISFSI pad.

3.4.4.1.3 Design Basis Missile Loading (Load case 02 in Table 2.4.1)

3.4.4.1.3.1 Tornado Missile Strike on VVM Closure Lid (Load Case 02 in Table 2.4.1)

Design basis tornado missiles are specified in Table 2.3.3. The Closure Lid is the only component of the VVM that is accessible to a tornado missile; therefore, missile impact analyses focus on this component. The impact a large missile is evaluated to determine whether the Closure Lid can maintain its required shielding function. Because of its size and the steel cross structure in the central pipe of the Closure Lid, the large missile can only deliver its kinetic energy to the side and

top surface of the lid and with no penetration. The medium missile, however, is able to pass through the top opening in the Closure Lid, impacting what is termed the "Lid Extension", a concrete filled steel weldment.

The formula from "Topical Report – Design of Structures for Missile Impact", BC-TOP-9A, Rev. 2, 9/74 [3.4.12]] is used to establish appropriate pressure-time data. For the speed and mass associated with the large missile, the impact force-time curve has the form

$$F(t) = 0.625 \text{ sec/ft} \times 184.8 \text{ ft/sec} \times 4000 \text{ lb} \times \sin(20t) = 462{,}000 \text{ lb} \times \sin(20t) \text{ for } t < 0.0785 \text{ sec.}$$
$$= 0 \text{ for } t >= 0.0785 \text{ sec.}$$

This representation of the large missile impact load is appropriate as demonstrated by the result of a modern passenger vehicle full-scale impact testing. Figure 3.4.22 shows the force-time history from the full-scale test of a full-size Ford passenger vehicle [3.4.11]. The test was performed at an impact speed of 35 mph and the vehicle had approximately the same weight as the design basis large deformable missile. Since the force is directly proportional to the pre-impact momentum, an estimate of the peak force at 126 mph for the vehicle is obtained by a simple ratio of the impact velocities and missile mass. Estimating the peak value from the plot produces a resulting peak force is found to be in good accord with the peak value predicted from [3.4.12], which provides a good confirmation of the methodology in [3.4.12]. Because of the simple geometric configuration of the Closure Lid, the large missile impact is evaluated using strength of materials approach. The calculation results indicate that the large missile event will neither cause the collapse of the Closure Lid nor dislodge the lid from the CEC cavity. Moreover, the lid concrete bearing capacity will not be exceeded by the large missile impact. The details of this calculation are found in [3.4.1].

The analyses performed for the intermediate missile (i.e., a rigid 275 lb 8" diameter cylindrical steel bar) and the small missile (i.e., a 1" diameter solid steel sphere) are based on the energy approach previously used in the missile impact analyses for HI-STORM 100 and HI-STORM FW storage systems. No credit for the central steel "cross" shaped structure is taken and the impact on the "Lid Extension" is also considered in the analysis. Analysis results demonstrate that the intermediate and small missiles will not penetrate the steel weldment and encased concrete of the Closed Lid or cause the drop of the Extended Lid to threat the stored MPC.

A summary of results are presented in Table 3.4.8. Thus, the assessment of all missile impact scenarios leads to the conclusion that the postulated missile strikes will not preclude MPC retrievability, will not cause loss of confinement, and will not affect criticality.

3.4.4.1.3.2 Tornado Missile Protection During Construction

The scenario of an excavation near the ISFSI has been considered. The optional Enclosure Wall on the exposed side of the ISFSI is not considered in the tornado missile analysis. The impact of the exposed lean concrete by the Design Basis Missiles (Table 2.3.3) using the methodology documented in [3.4.10] shows that the MPC storage cavities remain beyond the reach of the missiles.

3.4.4.1.4 Non-Mechanistic Tipover

Tipover is not an applicable load case for HI-STORM UMAX. The VVM is situated underground and cannot be moved; therefore, drop and tipover events are not credible accidents for this design configuration.

3.4.4.1.5 Maximum Temperature and Internal Pressure under Normal and Off-Normal Conditions

The HI-STORM UMAX VVM is open to the environment; therefore, it is not subject to any internal pressure.

The MPCs authorized for storage in HI-STORM UMAX (listed in Chapter 1) have been analyzed and qualified for normal and off-normal conditions of storage in their host docket (i.e., docket number 72-1032 for HI-STORM FW). Calculations in Chapter 4 show that the internal operating temperature in every MPC at its permissible maximum heat load when stored in HI-STORM UMAX is less than the value used in the stress analysis in docket number 72-1032. Because the internal pressure in the MPC bears a proportional relationship to the average internal temperature in the MPC cavity, it follows that the internal pressure in the MPC when stored in HI-STORM UMAX will be less than that assumed in the stress analysis of the MPC in docket number 72-1032. Therefore, the stress values computed for the MPC under normal and off normal operating conditions in docket number 72-1032 will envelope their corresponding values for storage in HI-STORM UMAX.

3.4.4.1.6 Maximum Temperature and Internal Pressure Under Accident Conditions

HI-STORM UMAX, being an open to environment cask, does not experience any internal pressure under accident conditions.

The MPCs authorized for storage in HI-STORM UMAX (listed in Chapter 1) have been analyzed and qualified for accident conditions of storage in their host docket (i.e., docket number 72-1032 for HI-STORM FW). Calculations in Chapter 4 show that the internal operating temperature in every MPC at its permissible maximum heat load when stored in HI-STORM UMAX is less than the value used in the stress analysis in docket number 72-1032. Because the internal pressure in the MPC bears a proportional relationship to the average internal temperature in the MPC cavity, it follows that the internal pressure in the MPC when stored in HI-STORM UMAX will be less than that assumed in the stress analysis of the MPC in docket number 72-1032. Therefore, the stress values computed for the MPC under accident conditions in docket number 72-1032 will envelope their corresponding values for storage in HI-STORM UMAX.

3.4.4.1.7 Handling of Components

The stress analyses of the HI-STORM UMAX VVM under normal handling conditions are presented in Subsection 3.4.3. The stress analyses of the MPC and the HI-TRAC transfer cask under

normal handling conditions are presented in their host docket (i.e., docket number 72-1032 for HI-STORM FW).

3.4.4.1.8 Snow Load

Load Case 01 in Table 2.4.1, presented later in this section, is a bounding load combination that conservatively subsumes a number of normal and extreme environmental phenomena loads including snow load.

3.4.4.1.9 Transfer Cask and Mating Device Loading on VVM Container Shell (Load Case 06 in Table 2.4.1)

During HI-STORM UMAX system loading, a HI-TRAC transfer cask with a fully loaded MPC is placed over a HI-STORM UMAX VVM using a specially designed transporter and a lifting device meeting ANSI N14.6 stress margin requirements. The transfer cask is connected to the CEC using an ancillary mating device (see Chapter 9). Although the Self-hardening Engineered Subgrade will not settle relative to the SFP during the entire service time of the ISFSI, the CEC shell is evaluated herein by conservatively assuming that the entire weight of the transfer cask and the mating device is supported by the shell and that neither the ISFSI pad nor the SES provides any support to the CEC shell. Based on a conservatively assumed total weight (400 kips) of the transfer cask and mating device, the compressive stress of the CEC shell is compared with the Level A service stress limit for NF Class 3 plate and the critical buckling stress for thin-walled cylindrical shell. Results presented in Table 3.4.9 demonstrate that the CEC shell can support the total weight of transfer cask and mating device with large margins.

3.4.4.1.10 Dead Load plus Design Basis Explosion Pressure on VVM Components (Load Case 01 in Table 2.4.1)

The VVM Closure Lid rests on the CEC and resists vertical loads, arising from dead weight, and from induced loadings from explosions, from seismic accelerations, and from tornado missile impact. In this subsection, the analysis considers only the normal loading condition plus a steady pressure that bounds the explosion pressure (see Table 2.3.1). Due to the simple configuration of the lid, the strength of materials method is used perform the evaluation. The stresses from the solution are compared, per the criteria in Table 2.4.1, with allowable stress values for plate and shell structures as provided in ASME Section III Code, Subsection NF. The allowable stress intensity is per Table 3.1.6 for Level D conditions.

As demonstrated in the structural calculation package [3.4.], the combined load from dead weight and the design basis explosion pressure is bounded by the maximum missile vertical impact force applied to the lid. Moreover, it's impossible for the CEC shell to deform under the design basis explosion pressure since it is directly against the SES with a bearing capacity of at least 10 times the design basis explosion pressure. It is therefore concluded that there is a large margin of safety in the HI-STORM UMAX Closure Lid and CEC Container Shell against the lateral pressure from Design Basis Explosion.

3.4.4.1.11 Design Basis Fire on VVM Closure Lid (Load Case 05 in Table 2.4.1)

With respect to the fire event (Load Case 05 in Table 2.4.1), where the Closure Lid steel temperature is conservatively assumed to rise to the limit set in Table 2.4.1, it is noted from Tables 3.1.4 and 3.3.1 that the Level A stress limit is reduced to 0.60 of the room temperature value, the yield strength is reduced to 0.67 of its room temperature value, and the ultimate strength is reduced to 0.92 of its room temperature value. From the stress values obtained in the lid (even with the explosion 10 psi surface pressure load included), it is evident that a structural collapse of the lid due to reduction of the ultimate strength because of the heat of the fire is not possible.

3.4.5 Cold

Due to its subterranean configuration, the structural components of the VVM are relatively protected from extremes in the ambient temperature in comparison to the above ground HI-STORM certified in docket number 72-1032. Therefore, no new analyses are identified for the HI-STORM UMAX system.

3.4.6 Miscellaneous Evaluations

None.

3.4.7 Service Life of HI-STORM UMAX VVM

The term of the 10CFR72, Subpart L C of C, granted by the NRC is 20 years; therefore, the License Life (see Glossary) of all components is 20 years. The principal design considerations that bear on the adequacy of the storage module for the service life are addressed as follows:

Exposure to Environmental Effects

All exposed surfaces of the HI-STORM UMAX Cavity Enclosure Canister that are made from ferritic steels are painted and protected from corrosion on the outside by appropriate means as described in Chapter 8. The inside surface of the CECs is protected by paint or the CEC is made of stainless steel. The Divider Shells are protected by paint or are made of stainless steel. In addition, one side of the Divider Shell is further protected by insulation. Concrete, which serves strictly as a shielding material in the Closure lid, is completely encased in steel. Under normal storage conditions, the bulk temperature of the HI-STORM UMAX system will, because of its large thermal inertia, change very gradually with time. Therefore, material degradation from rapid thermal ramping conditions is not credible for the HI-STORM UMAX system. The configuration of the storage modules assures resistance to freeze-thaw degradation. In addition, the storage modules are specifically designed for a full range of enveloping design basis natural phenomena that could occur over the 60-year design life of the storage system. Chapter 8 provides further discussion on chemical and galvanic reactions, material compatibility and operating environments pertaining to HI-STORM UMAX.

Material Degradation

As discussed in Chapter 8, the relatively low neutron flux to which the storage modules are subjected is insufficient to produce measurable degradation of the cask's material properties and impair its intended safety function. Exposed carbon steel components are coated to prevent corrosion. The controlled environment of the ISFSI storage pad mitigates damage due to direct exposure to corrosive chemicals that may be present in other industrial applications.

Maintenance and Inspection Provisions

The requirements for periodic inspection and maintenance of the storage VVM throughout the 60-year design life are defined in Chapter 10. These requirements include provisions for routine inspection of the inlet plenums and periodic visual or camera aided verification that the air flow paths are free and clear of debris. ISFSIs located in areas subject to atmospheric conditions that are particularly aggressive should be evaluated by the licensee on a site-specific basis to determine the frequency for such inspections to assure long-term performance. In addition, the HI-STORM UMAX system is designed for easy retrieval of the MPC from the storage VVM should it become necessary for any reason.

In summary, the VVM is engineered for a 60 year design life and a 100 year service life, while satisfying the conservative design requirements defined in Chapter 2. For information supporting the 60 year design life addressing chemical and galvanic reactions as well as other potentially degrading factors, reference is made to Chapter 8. Requirements for periodic inspection and maintenance of the HI-STORM UMAX VVM throughout the 60-year design life are defined in Chapter 10. The VVM is designed, fabricated, and inspected under the comprehensive Quality Assurance Program discussed in Chapter 14 and docket number 71-0784 (The service life of a system may exceed its design life if the system is maintained in accordance with the supplier's O&M manual).

The above findings supporting the HI-STORM UMAX service life are consistent with those of the NRC's Waste Confidence Decision Review [3.4.13], which concluded that dry storage systems designed, fabricated, inspected, and operated in accordance with such requirements are adequate for a 100-year service life while satisfying the requirements of 10CFR72.

Table 3.4.1

KEY STRESS RESULTS FOR HI-STORM UMAX CLOSURE LID
NORMAL HANDLING

Item	Calculated Value (ksi)	Allowable Limit (ksi)	Safety Factor
Lifting Hole Tearout Stress	1.464	1.52	1.04
Lifting Hole Bearing Stress	3.833	4.56	1.19
Governing Weld Joint Stress	2.530	3.04	1.20

Table 3.4.2

SEISMIC LOADING SCENARIOS ANALYZED FOR HI-STORM UMAX

Scenario 1	All storage locations loaded with maximum weight MPCs, and a loaded VCT is placed at the center of the ISFSI.
Scenario 2	Same as Scenario 1 except that the Young's Modulus of the SFP concrete is reduced to one-half of its nominal value.
Scenario 3	Same as Scenario 1 except that the subgrade adjacent to one side of SES (Space A) is excavated down to the SFP and that the VCT is not considered.
Scenario 4	Same as Scenario 3 except that the Young's Modulus of the SFP concrete is reduced to one-half of its nominal value.

Table 3.4.3

ISFSI INTERFACE LOADS OBTAINED FROM LS-DYNA SSI SIMULATIONS

Interface Load	Scenario 1	Scenario 2	Scenario 3	Scenario 4
CEC to SFP Impact Load[1], lbf	7.7191×10^5	7.1945×10^5	7.1505×10^5	6.6774×10^5
Transporter to ISFSI Pad Contact Load per Track[2], lbf	8.6014×10^5	8.0838×10^5	NA	NA

Notes:
1. A bounding value of 8.0×10^5 lbf is conservatively used in the strength qualification of ISFSI structure reported in subparagraph 3.4.4.1.2;
2. A bounding value of 1.0×10^6 lbf is conservatively used in the strength qualification of ISFSI structure reported in subparagraph 3.4.4.1.2.

Table 3.4.4

HI-STORM UMAX VVM COMPONENTS SEISMIC QUALIFICATION ANALYSIS RESULTS

Item	Calculated Value	Allowable Limit	Safety Factor
Ovalization of VVM Shells	Not a credible concern; see discussion in subparagraph 3.4.4.1.2		
MPC Shell Primary Stress, ksi	25.88	42.0	1.62
MPC Guide Impact Load, lbf	2.1161×10^{5}†	2.368×10^{5}	1.12
MPC Peak Impact Deceleration, g's	27.854	Table 3.1.1	2.2.2
Local Plastic Strain of MPC Shell, in/in	0.028	0.1	3.57

† This is the maximum impact load obtained from the four SSI runs listed in Table 3.4.2 and is bounded by the corresponding impact force (see Figure 3.4.6a) in the governing MPC to MPC guide impact analysis.

Table 3.4.5

MOMENT RESULTS AND CORRESPONDING MINIMUM SAFETY FACTORS FOR THE ISFSI STRUCTURES

ISFSI Load Configuration	Moment Induced (lbf-in/in)	Axial Force (lbf/in)	Corresponding Moment Capacity (lbf-in/in)	Minimum Safety Factor
Support Foundation Pad (SFP) ‡				
Simulation Model I	84,841	3095.8	207,792	2.449
Simulation Model II	94,625	-584.9	254,460	2.689
Simulation Model III	110,480	993.9	235,770	2.134
Simulation Model IV	96,271	770.3	238,750	2.479
Simulation Model V	78,835	4,502	189,080	2.398
ISFSI Pad ‡				
Simulation Model I	94,265	-39855	274,688	2.914
Simulation Model II	89,244	-14741	339,910	3.808
Simulation Model III	88,090	-31496	323,170	3.668
Simulation Model IV	87,086	-27938	343,800	3.947
Simulation Model V	62,025	4150	171,970	2.773

‡ The moment capacities for the SFP and ISFSI pad are calculated using axial-force-moment interaction diagram corresponding to the axial force and moment induced in the limiting element. Figure 3.4.13a through 3.4.21c also capture the stress plots for the governing load combination (LC-3 in Table 2.4.3) for all the ISFSI loading configurations analyzed.

Note that the flexural safety factors calculated above are based on the maximum moment induced in a single element, which is very conservative. Averaging over a width of the loaded section would result in much higher safety factors.

Table 3.4.6

MINIMUM SAFETY FACTORS AGAINST PUNCHING SHEAR FAILURE FOR THE ISFSI STRUCTURES

ISFSI Structure	Punching Shear Safety Factor
SFP	2.8
ISFSI Pad	1.5

Table 3.4.7

BEARING STRESS OF SUBGRADE UNDER THE ISFSI PAD

Computed Bearing Stress (psi)	Allowable Bearing Stress (psi)	Safety Factor	Minimum Safety Factor Required per [3.4.9]
38.7	100†	2.58	2.0

† Table 3.3.4 lists the actual bearing stress capacity, which is much greater than this conservatively specified allowable bearing stress.

Table 3.4.8

MISSILE IMPACT ANALYSIS RESULTS

Missile Type – Impact Location	Item	Calculated Value	Allowable Limit	Safety Factor
Large Missile – Impact on HI-STORM UMAX Closure Lid	Horizontal impact load that may dislodge the Closure lid, lbf	4.856×10^5	1.574×10^6	3.24
	Vertical impact load that may lead to the collapse of the Closure lid, lbf	3.237×10^5	1.077×10^6	3.33
Intermediate Missile – Impact on HI-STORM UMAX Closure Lid	Penetration, in	3.346	20	5.98
	Vertical impact load that may lead to the drop of the "extended lid", lbf	3.237×10^5	1.203×10^6	3.71
Small Missile – Impact on HI-STORM UMAX Closure Lid	Penetration, in	0.266	20	75.2
Large Missile – Impact on Exposed SES surface	Penetration, ft	0.177	10	56.5
Intermediate Missile – Impact on Exposed SES surface	Penetration, ft	0.544	10	18.4
Small Missile – Impact on Exposed SES surface	Penetration, ft	0.112	10	89.3

Table 3.4.9

BOUNDING STRESS AND BUCKLING ANALYSIS RESULTS OF THE SHELL DURING MPC TRANSFER OPERATION

Item	Calculated Value ksi	Allowable Limit ksi	Safety Factor
Compressive Stress of CEC Shell	1.698	Compression: 16.7	9.8
		Buckling: 252.4	148.7

Table 3.4.10

KEY RESULTS OF LS-DYNA SSI ANALYSES FOR HI-STORM UMAX VERSION MSE UNDER THE MOST SEVERE EARTHQUAKE CONDITION

Case (1)	Maximum MPC Guide Plate Force (kips)	Maximum SFP Load (kips)	SES Maximum Horizontal Acceleration (g's)	Closure Lid Maximum Accelerations (g's) (2)	MPC Maximum Horizontal Accelerations (g's)
1S	326.62	625.9	5.14	6.93 (H) 1.815 (V)	6.4
1L	374.06	808.0	5.89	7.27 (H) 1.51 (V)	7.30
2L	394.57	1,061.2	6.22	8.18 (H) 2.46 (V)	7.99
3L	349.12	875.08	5.57	6.04 (H) 1.88 (V)	7.16
4L	388.49	942.44	6.01	8.20 (H) 1.59 (V)	8.65
5L	446.76	1,232.8	6.64	8.34 (H) 2.48 (V)	7.99
2LL	426.96	933.58	7.13	9.39 (H) 2.39 (H)	8.00
2LU	475.89	999.73	6.96	7.94 (H) 1.63 (V)	9.02

Notes: (1) The SSI analysis case name consists of a number and one or two letters and follows the following convention: The number shows which of the five earthquakes is considered; the first letter "L" or "S" identifies if the "large" or "small" soil" model is considered."Best estimate" soil properties are used unless a second letter "L" or "U" is used in the case identifier to indicate if the "lower" (L) or "upper" (U) bound soil properties are considered. (2) (H) and (V) respectively denote lid accelerations in horizontal and vertical directions.

Table 3.4.11

GOVERNING SSI RESPONSE PARAMETERS UNDER THE MOST SEVERE EARTHQUAKE CONDITION

Item	Maximum Impact Force on the MPC Guide Plate (kips)	Maximum Compression Load on the Support Foundation Pad (SFP) (kips)	Maximum Horizontal Acceleration in the Concrete in Space A (g's)	Closure Lid Maximum Accelerations (g's)	MPC Maximum Horizontal Accelerations (g's)
Averaged Response of 5 Earthquakes	390.60	984.10	6.07	7.61 (H) 2.07 (V)	7.76
Amplification factor	1.21	1.0	1.15	1.15 (H) 1.0 (V)	1.13
Governing Response Parameters	471.10	984.10	6.95	8.73 (H) 2.07 (V)	8.76

Table 3.4.12

STRUCTURAL QUALIFICATION ANALYSIS RESULTS OF HI-STORM UMAX VVM COMPONENTS UNDER THE MSE CONDITION

Item	Calculated Value	Specified Limit for Safety Evaluation	Safety Factor
Ovalization of VVM Shells	Not a credible concern; due to the upgraded SES material (3,000 psi concrete) for the MSE condition		
MPC Shell Primary Stress, ksi	35.92	42.0	1.17
MPC Guide Impact Load, lbf	4.711×10^{5} (1)	5.352×10^{5} (2)	1.14
MPC Peak Impact Deceleration, g's	44.609 (3)	61.75 (4)	1.38
Local Plastic Strain of MPC Shell at the Impact Location in the Lid Region, in/in	0.025	0.1 (See Table 3.1.1)	4.0
Closure Lid Hold-Down Structure Uplift Load, kips	31.0	99.6(5)	3.21

Notes: (1) This is the maximum impact load obtained from the governing seismic response results listed in Table 3.4.11 and is bounded by the corresponding impact force (see Figure 3.4.27) obtained in the bounding MPC to MPC guide impact LS-DYNA analysis. (2) Minimum value of the allowable limits of the top MPC guide plate and the bottom MPC guide ring. (3) Conservatively taken as the peak MPC deceleration in the bounding MPC to MPC guide impact LS-DYNA analysis. (4) The limit on the MPC peak deceleration utilizes the computed value for the non-mechanistic tip-over event in the HI-STORM FW docket. (5) Based on the capacity of the weakest component in the lid hold-down structure.

Table 3.4.13

MINIMUM SAFETY FACTOR OF THE SUPPORT FOUNDATION PAD UNDER THE MSE CONDITION

Seismic Condition	Peak Seismic Load Applied to the SFP Through A Loaded MPC (kips)	Minimum SFP Safety Factor
Design Basis Earthquake	800.0	2.13 (1)
Most Severe Earthquake	984.1	1.73 (2)

Notes: (1) The minimum SFP safety factor taken from Table 3.4.5; (2) The SFP minimum safety factor under the MSE condition is conservatively obtained by multiplying the minimum safety factor computed previously under the DBE condition (in the initial qualification) by the ratio of the maximum seismic load on the SFP under DBE to the corresponding load computed under MSE.

CERTIFICATE OF SERVICE

I hereby certify that on July 20, 2020, I electronically filed the foregoing with the Clerk of the Court for the United States Court of Appeals for the Ninth Circuit by using the appellate CM/ECF system.

Participants in the case who are registered CM/ECF users will be served by the appellate CM/ECF system.

Dated: July 20, 2020

Respectfully submitted,
ALSTON & BIRD LLP

3.5 FUEL RODS

The regulations governing spent fuel storage cask approval and fabrication (10 CFR 72.236) require that a storage cask system "will reasonably maintain confinement of radioactive material under normal, off-normal, and credible accident conditions" (§72.236(l)). Since fuel rod cladding is not considered in the design criteria for the confinement of radioactive material under normal, off-normal, or accident conditions of storage, no specific analysis or test results for the fuel rod cladding are required to demonstrate cladding integrity.

3.6 SUPPLEMENTAL DATA

3.6.1 Calculation Packages

In addition to the calculations presented in Chapter 3, supporting calculation packages have been prepared to document other information pertinent to the analyses. Supporting calculation packages back up the summary results reported in the FSAR. The Calculation Packages are referenced in the body of the FSAR and are maintained as proprietary documents in Holtec's Configuration Control system.

3.6.2 Computer Programs

Computer programs used in this FASR are summarized in this chapter.

i. ANSYS

ANSYS is a public domain code, well benchmarked code, which utilizes the finite element method for structural analyses. It is a self contained analysis tool incorporating pre-processing (geometry creation, meshing), solver, and post processing modules in a unified graphical user interface. It can simulate both linear and non-linear material and geometric behavior. It includes contact algorithms to simulate surfaces making and breaking contact, and can be used for both static and dynamic simulations. ANSYS has been independently QA validated by Holtec International and used for structural analysis of casks, fuel racks, pressure vessels, and a wide variety of SSCs, for over twenty years.

ii. LS-DYNA

LS-DYNA is a general purpose finite element code for analyzing the large deformation static and dynamic response of structures including structures coupled to fluids. The main solution methodology is based on explicit time integration and is therefore well suited for the examination of the response to shock loading. A contact-impact algorithm allows difficult contact problems to be easily treated. Spatial discretization is achieved by the use of four node tetrahedron and eight node solid elements, two node beam elements, three and four node shell elements, eight node solid shell elements, truss elements, membrane elements, discrete elements, and rigid bodies. A variety of element formulations are available for each element type. Adaptive re-meshing is available for shell elements. LS-DYNA currently contains approximately one hundred constitutive models and ten equations-of-state to cover a wide range of material behavior.

In this safety analysis report, LS-DYNA is used to analyze all loading conditions that involve short-time dynamic effects.

LS-DYNA is maintained in a QA-validated status in Holtec's Configuration Control system.

iii. Shake 2000 [3.4.4]

SHAKE 2000, QA validated in [3.6.1] under Holtec International's quality program, has been used to characterize the transformation of the components of an earthquake as they traverse through layers of soil. SHAKE 200 is a linear ,elastic wave propagation code based on a 1972 report by P.B. Schnabel, Lysmer, J. and H.B. Seed at the Earthquake Engineering Research Center entitled "SHAKE: A Computer Program for Earthquake analysis of Horizontally Layered Sites", EERC report number 71-12. SHAKE 2000 has been used in this FSAR to define the earthquake response spectra at the TOG and at the SFP levels consistent with the assumed properties of the subgrade and the undergrade.

The above mentioned computer codes have been benchmarked and QA-validated to establish their veracity. The compliance matrix in Table 3.6.1 below provides the necessary information to document their validation status, and the measures employed pursuant to ISG-21 and Holtec's QA program, to ensure error-free solutions.

Table 3.6.1

ISG-21 AND QA COMPLIANCE MATRIX FOR COMPUTER CODES

	Item	ANSYS	LS-DYNA	Shake 2000
1.	Benchmark and QA-validation are documented in Holtec Report No.(s) (Proprietary Reports)	HI-2012627	HI-961519	HI-2022827 HI-2104792
2.	Computer Program Type (Public or Private Domain)	Public Domain	Public Domain	Public Domain
3.	Does Holtec maintain a system evaluating error notices if any are issued by the Code provider to evaluate their effect on the safety analyses carried out using the Code, including Part 21 notification? (Yes/No)	Yes	Yes	Yes
4.	Is the use of the Code restricted to personnel qualified under the Company's personnel qualification program? (Yes/No)	Yes	Yes	No
5.	Has benchmarking been performed against sample problems with known independently obtained numerical solutions (Yes/No)	Yes	Yes	Yes
6.	Have element types used in the safety analyses herein also employed in the benchmarking effort? (Yes/No)	Yes	Yes	N/A
7.	Are the element types used in this FSAR also used in other Holtec dockets that support other CoCs? (Yes/No)	Yes	Yes	N/A
8.	Is each update of the Code vetted for backwards consistency with prior updates? (Yes/No)	Yes	Yes	Yes
9.	Is the use of the Code limited to the range of parameters specified in the User Manual provided by the Code Developer? (Yes/No)	Yes	Yes	Yes
10.	Are the element aspect ratios, where applicable, used in the simulation model within the limit recommended by the Code Developer or Holtec's successful experience in other safety analyses? (Yes/No)	Yes	Yes	N/A
11.	Are element sizes used in the simulation models consistent with past successful analyses in safety significant applications? (Yes/No)	Yes	Yes	N/A
12.	Was every computer run in this chapter free of an error warning (i.e., in hidden warnings in the Code that indicate a possible error in the solution? (Yes/No)	Yes	Yes	Yes
13.	If the answer to the above is No, then is the annotated warning discussed in the discussion of the result in this report?	N/A	N/A	N/A

3.7 COMPLIANCEWITH THE STRUCTURAL REQUIREMENTS IN PART 72

Supporting information to provide reasonable assurance with respect to the adequacy of the HI-STORM UMAX system to store spent nuclear fuel in accordance with the stipulations of 10CFR72 is presented throughout this FSAR. The following statements are applicable to an affirmative structural safety evaluation:

- The design and structural analysis of the HI-STORM UMAX System is in full compliance with the provisions of Chapter 3 of NUREG-1536 as appropriate for a vertical ventilated module assembly (see Table 3.7.1).

- The HI-STORM UMAX structures, systems, and components (SSC) that are important to safety (ITS) are identified in the Licensing Drawings in Section 1.5. The Licensing Drawings present the HI-STORM UMAX SSCs in adequate detail and the explanatory narratives in this chapter provide sufficient textual details to allow an independent evaluation of their structural effectiveness.

- The requirements of 10CFR72.24 with regard to information pertinent to structural evaluation are provided in Chapters 2, 3, and 12.

- Technical Specifications pertaining to the structures of the HI-STORM UMAX system have been provided in Chapter 13 herein pursuant to the requirements of 10CFR72.26.

- A series of analyses to demonstrate compliance with the requirements of 10CFR72.122(b) and (c), and 10CFR72.24(c)(3) have been performed which show that SSCs in the HI-STORM UMAX VVM designated as ITS possess an adequate margin of safety with respect to all load combinations applicable to normal, off-normal, accident, and natural phenomenon events. In particular, the following information is provided:

    i. Load combinations for the HI-STORM UMAX VVM and the ISFSI structures for normal, off-normal, accident, and natural phenomenon events have been provided.

    ii. Stress limits applicable to the Code materials can be found in Section 3.3.

    iii. The stress and displacement response of the MPC Enclosure vessel, and the HI-STORM UMAX VVM for all applicable loads, have been computed by analysis and reported in Subsections 3.4.3 and 3.4.4. Descriptions of stress analysis models are presented in Subsection 3.1.3.

- The criticality safety of the stored MPCs is ensured by demonstrating that the maximum g-load sustained by the MPC stored inside the HI-STORM UMAX VVMs is less than their licensing basis value. This conclusion satisfies the requirement of 10CFR72.124(a), with respect to structural margins of safety for SSCs important to nuclear criticality safety.

- Structural margins of safety during handling, packaging, and transfer operations, under the provisions of 10CFR Part 72.236(b), imply that the lifting and handling devices be engineered to comply with the stipulations of ANSI N14.6, NUREG-0612. The requirements of the governing standards for handling operations are summarized in Subsection 3.4.3 herein. Factors of safety for all ITS components under lifting and handling operations are summarized in tables in Section 3.4, which show that adequate structural margins exist in all cases.

- Consistent with the requirements of 10CFR72.236(i), the confinement boundary for the HI-STORM UMAX System has been engineered to maintain confinement of radioactive materials under normal, off-normal, and postulated accident conditions. This assertion of confinement integrity is made on the strength of the MPC's licensing basis in docket number 72-1032 and the following information provided in this FSAR.

- The information on structural design included in this FSAR complies with the requirements of 10CFR72.120 and 10CFR72.122.

- The structural design features in the HI-STORM UMAX VVM (along with the previously certified MPCs) are in compliance with the specific requirements of 10CFR72.236(e), (f), (g), (h), (i), (j), (k), and (m).

Table 3.7.1

NUREG-1536 COMPLIANCE MATRIX FOR 10CFR72.120 AND 10CFR72.122 REQUIREMENTS

Item	Compliance	Notes
i. Design and fabrication to acceptable quality standards	All ITS components designed and fabricated to recognized Codes and Standards: • Enclosure Vessel: Subsection NB, loc. cit. • HI-STORM UMAX Structure: Subsection NF, loc. cit.	Subparagraph 3.1.2.3
ii. Erection to acceptable quality standards	• Concrete in HI-STORM UMAX closure lid meets requirements of: ACI –318 (2005)	Subsection 3.3.2
iii. Testing to acceptable quality standards	• All non-destructive examination of structural components utilizes Section V of the ASME Code. • Testing for radiation containment per provisions of NUREG-1536 • Concrete testing	Chapter 8
iv. Adequate structural protection against environmental conditions and natural phenomena.	Analyses presented in Chapter 3 demonstrate that the confinement boundary will preserve its integrity under all postulated off-normal and natural phenomena events listed in Chapter 2.	Subparagraph 3.4.4.1 Chapter 11
v. Adequate protection against fires and explosions	• The extent of combustible (exothermic) material in the vicinity of the cask system is procedurally controlled (the sole source of hydrocarbon energy is diesel in the tow vehicle). • Analyses show that the heat energy released from the postulated fire	Subsections 12.3.20 and 12.3.21 Subsection 11.2.4

Table 3.7.1

NUREG-1536 COMPLIANCE MATRIX FOR 10CFR72.120 AND 10CFR72.122 REQUIREMENTS

Item	Compliance	Notes
	accident condition surrounding the cask will not result in impairment of the confinement boundary and will not lead to structural failure of the VVM. The effect on shielding will be localized to the external surfaces directly exposed to the fire without a significant change in HI-STORM UMAX VVM. • Explosion effects are shown to be bounded by the Code external pressure design basis and there is no adverse effect on ready retrievability of the MPC.	Subparagraph 3.4.4.1
vi. Appropriate inspection, maintenance, and testing	Inspection, maintenance, and testing requirements set forth in this FSAR are in full compliance with the governing regulations and established industry practice.	See Chapters 1 and 2.
vii. Adequate accessibility in emergencies.	The HI-STORM UMAX closure lid can be removed to gain access to the multi-purpose canister. All HI-TRAC transfer cask models have removable bottom and top lids.	Chapter 9 Chapter 9
viii. A confinement barrier that acceptably protects the spent fuel cladding during storage.	The peak temperature of the fuel cladding at design basis heat duty of each MPC has been demonstrated to be maintained below the limits specified in ISG-11 Revision 3. The confinement barriers consist of highly ductile stainless steel alloys. The multi-purpose canister is housed in the VVM, built from a steel structure whose materials are selected and examined to maintain protection against brittle fracture under off-normal ambient (cold) temperatures (minimum of -40ºF).	Section 4.4 Subsection 3.1
ix. The structures are compatible with the appropriate monitoring systems.	The HI-STORM UMAX VVM with openings that are designed to prevent radiation streaming while enabling complete access to temperature monitoring probes, if used.	Section 1.5

Table 3.7.1

NUREG-1536 COMPLIANCE MATRIX FOR 10CFR72.120 AND 10CFR72.122 REQUIREMENTS

Item		Compliance	Notes
x.	Structural designs are compatible with ready retrievability of fuel.	The VVMs are designed to withstand accident loads without suffering permanent deformations of their structures that would prevent retrievability of the MPC by normal means. It is demonstrated by analysis that there is no physical interference between the MPC and the enveloping HI-STORM VVM under all postulated Design Basis loads.	Section 3.4
xi.	Adequate heat removal without active cooling systems.	Thermal analyses presented in Chapter 4 show that the HI-STORM UMAX System will remove the decay heat generated from the stored spent fuel by strictly passive means and maintain the system temperature within prescribed limits.	Section 4.4
xii.	Storage of spent fuel for a minimum of 20 years.	The service life of the storage modules is engineered to be in excess of 60 years.	Subsection 3.4.7
xiii.	Conspicuous and durable marking.	The exterior envelope of the VVM is marked in a conspicuous manner as required by 10CFR 72.236(k).	N/A
ix.	Compatibility with removal of the stored fuel from the site, transportation, and ultimate disposal by the U.S. Department of Energy.	The MPCs used in the HI-STORM UMAX System are intended to serve as a transportable waste package.	N/A

CHAPTER 4: THERMAL EVALUATION

4.0 OVERVIEW

HI-STORM UMAX is an underground vertical ventilated module (VVM) with openings for air ingress and egress and internal air flow passages for ventilation cooling of loaded MPC. The licensing drawing package for the HI-STORM UMAX is provided in Section 1.5. Thermal design requirements are presented in Section 2.5. The analyses summarized in this chapter focus on the governing canisters out of the population of MPCs listed in Table 1.2.1. This chapter, however, supports the certification of only MPC-37 and MPC-89 at this time. The analyses reported for smaller canisters are for reference purposes only.

Section 1.2 provides a summary description of the HI-STORM UMAX system. The MPC types considered for evaluating storage in HI-STORM UMAX VVMs are listed in Table 1.2.1. In this chapter, compliance of HI-STORM UMAX system's thermal performance to 10CFR72 requirements for storage at an ISFSI using 3-D thermal simulation models is established. The analyses consider passive rejection of decay heat from the stored SNF assemblies to the environment under normal, off-normal, and accident conditions of storage. In particular, the thermal margins of safety for long-term storage of both moderate burnup (up to 45,000 MWD/MTU) and high burnup spent nuclear fuel (greater than 45,000 MWD/MTU) in the HI-STORM UMAX system are quantified. The HI-STORM UMAX deploys MPCs and HI-TRAC transfer casks that have been previously certified in HI-STORM FW FSAR and CoC (USNRC Docket 72-1032). Safe thermal performance during fuel loading, unloading and on-site transfer operations, collectively referred to as "short-term operations" utilizing the HI-TRAC VW transfer cask for MPC-37 and MPC-89 is also evaluated. The cases of normal, off-normal and accident conditions of storage, enumerated in Chapter 2 are also evaluated for the MPC designs in Table 1.2.1 to establish an acceptable safety case for their long term storage in the HI-STORM UMAX VVMs.

The thermal evaluation of HI-STORM UMAX follows the guidelines of NUREG-1536 [4.0.1] and ISG-11 [4.0.2]. These guidelines provide specific limits on the permissible maximum cladding temperature in the stored commercial spent fuel (CSF)* and other Confinement Boundary components, and on the maximum permissible pressure in the confinement space under certain operating scenarios. Specifically, the requirements are:

1. The fuel cladding temperature must meet the temperature limit appropriate to its burnup level and condition of storage / handling set forth in NUREG-1536 [4.0.1] and ISG-11 [4.0.2].

2. The maximum internal pressure of the MPC should remain within its design pressures for normal, off-normal, and accident conditions set forth in Table 2.3.5.

---

* Defined as nuclear fuel that is used to produce energy in a commercial nuclear reactor (See Glossary).

3. The temperatures of the cask materials shall remain below their allowable limits set forth in Table 2.3.7 under all scenarios.

Section 2.5 of this FSAR contains a listing of all thermal analysis cases that warrant analysis. Section 2.1 in Chapter 2 provides the Design Basis heat loads (maximum permissible heat loads in storage cells). As demonstrated in this chapter, the HI-STORM UMAX system is designed to comply with all of the thermal criteria defined in Chapter 2.

Sections 4.1 through 4.3 describe thermal analyses and input data that are common to all conditions of storage, handling and on-site transfer operations. All required thermal analyses to evaluate normal conditions of storage in a HI-STORM UMAX storage module are described in Section 4.4. The thermal performance of the system is also evaluated under sustained wind conditions in Section 4.4. Thermal analyses to evaluate on-site transfer in a HI-TRAC transfer cask are considered in Section 4.5 and the evaluations to establish compliance under off-normal and accident conditions are summarized in Section 4.6.

To facilitate convenient access to the referenced material, the latest edition of the HI-STORM FW FSAR has been placed in this docket and a list of "FW" FSAR sections germane to this chapter is provided in a tabular form. The HI-STORM FW FSAR will be maintained in a configuration controlled status in this docket as a mandatory supplement to this FSAR. Table 4.0.1 provides a listing of the material adopted in this chapter by reference to the HI-STORM FW FSAR.

The safety analyses summarized in this chapter demonstrate acceptable margins to the allowable limits under all design basis loading conditions and operational modes. Minor changes to the design parameters that inevitably occur during the product's life cycle which are treated within the purview of 10CFR72.48 and are ascertained to have an insignificant effect on the computed safety factors may not prompt a formal reanalysis and revision of the results and associated data in the tables of this chapter unless the cumulative effect of all such unquantified changes on the reduction of any of the computed safety margins cannot be deemed to be insignificant. For purposes of this determination, an insignificant loss of safety margin with reference to an acceptance criterion is defined as the estimated reduction that is no more than one order of magnitude below the available margin reported in the FSAR. To ensure rigorous configuration control, the information in the Licensing drawings in Section 1.5 should be treated as the authoritative source for numerical analysis at all times. Reliance on the input data and associated results in this chapter for additional mathematical computations may not be appropriate as they serve the sole purpose of establishing safety compliance in accordance with the acceptance criteria set down in Chapter 2 and in this chapter.

Table 4.0.1

HI-STORM FW FSAR MATERIAL GERMANE TO THE EVALUATIONS IN THIS FSAR *

* For convenience of reference, the specific revision of the HI-STORM FW FSAR that is referenced in the safety analysis herein is placed in this docket. Updated versions of the HI-STORM FW FSAR shall be placed in this docket as necessary so as to ensure that the safety analyses on the "UMAX" docket (72-1040) remain aligned with the material referenced in the HI-STORM FW FSAR.

4.1 DESIGN BASIS HEAT LOAD AND GOVERNING MPC FOR THERMAL ANALYSIS

As stated in Section 2.0, the HI-STORM UMAX system has been designed to store all previously certified MPCs under NRC dockets No. 72-1014 and 72-1032. Therefore it is necessary to identify the governing MPC from the list in Table 1.2.1 along with its governing heat load. The governing MPC and its heat load combination are defined as the one that yields the maximum PCT. For this purpose, it is helpful to consider two fundamental facts relevant to the thermal performance of VVMs; namely,

a. Smaller the size of the flow annulus, smaller the air flow rate and a correspondingly lesser extent of heat extraction from the MPC surface and hence greater the PCT in the stored fuel.
b. Larger the heat load, greater the PCT. It must be noted that both the total heat load and per assembly heat load distribution must be considered.

Because the inside diameter of HI-STORM UMAX VVM is fixed, it is readily deduced that the larger diameter MPCs previously licensed in the HI-STORM FW docket [4.1.2] will have a smaller axial flow annulus compared to those in the HI-STORM 100 docket [4.1.1]. The DBHL is also substantially greater in the HI-STORM FW system compared to the HI-STORM 100 system. The input data for all MPCs previously licensed in HI-STORM FW docket, i.e. MPC-37 with short, standard and long fuels under various heat load charts (see Table 2.1.8) and MPC-89 (see Table 2.1.9) are summarized in Table 4.1.1. The maximum peak cladding temperature results are calculated and reported in Table 4.1.2. The results demonstrate that MPC-37 with the short fuel under Heat Load Chart 1 produces the highest PCT and it is therefore designated as the governing thermal scenario.

It is noted that the MPCs in Docket # 72-1014 are smaller in diameter and are certified to lower DBHLs. Nevertheless, the hottest MPC from the HI-STORM 100 docket also warrants analysis because the stainless steel fuel baskets in it are less conductive than their counterparts in the HI-STORM FW docket (that contain METAMIC-HT fuel baskets). As noted in the HI-STORM 100 FSAR, MPC-32 under X=3* regionalized loading scenario (see Section 2.1.10) results in the highest PCT. Therefore it is the governing case among all MPCs in the HI-STORM 100 docket [4.1.1] and therefore is also selected as a candidate MPC type (with regionalized loading scenario X=3) for thermal analysis in HI-STORM UMAX. The case of X=0.5 (see Sub-Section 2.1.10), which is the other limit of regionalization ratio, is also included for completeness.

All the thermal scenarios for MPC-37 and MPC-89 are defined in Table 4.1.1. The limiting thermal scenario for an MPC-32 is defined based on the information in its existing host docket and summarized in Table 4.1.1. The thermal problem is then analyzed using the solution methodology approved in [4.1.1] and [4.1.2]. The temperatures presented in Tables 4.1.2 show

* X is defined in the HI-STORM 100 FSAR [4.1.1] as the ratio of maximum permissible storage per cell heat load in the inner and outer regions.

that the ISG-11 Rev 3 limits are satisfied with comfortable margins.

The maximum peak cladding temperature results for MPC-37, MPC-89 and MPC-32, reported in Table 4.1.2, show that MPC-37 with short fuel under Heat Load Chart 1 produces the highest PCT. Therefore, MPC-37 with short fuel under Heat Load Chart 1 fulfills the criterion for designation as the governing thermal configuration. This governing thermal configuration is used to perform the thermal safety analyses that are reported in the subsequent sections in this chapter.

Note 1: MPC-32 bounds MPC-68, 68M and MPC-24 as noted in HI-STORM 100 Docket 72-1014.

Note 2: All heat load charts for MPC-37 and MPC-89 provided in Section 2.1.9 are evaluated.

Note 3: UMAX System may have an MPC with increased shell thickness with corresponding increased MPC external diameter and UMAX Divider and Container Shell inner diameters. Such systems are equivalent to or bounded by the existing thermal analysis for an MPC listed in this table.

Table 4.1.2

PEAK CLADDING TEMPERATURE RESULTS FOR LONG-TERM NORMAL STORAGE FOR MPC-32, MPC-37 AND MPC-89 IN HI-STORM UMAX SYSTEM**

MPC Types		**Fuel Cladding Temperature ^{o}C (^{o}F)**
MPC-37 (Heat Load Chart 1)	Short Fuel	**367 (693)***
	Standard Fuel	357 (675)
	Long Fuel	351 (664)
MPC-37 (Heat Load Chart 2)	Short Fuel	363 (685)
	Standard Fuel	355 (671)
	Long Fuel	346 (655)
MPC-37 (Heat Load Chart 3)	Short Fuel	359 (678)
	Standard Fuel	364 (687)
	Long Fuel	353 (667)
MPC-89		357 (675)
MPC-32 (X=3)		366 (691)

* Based on the results in this table, MPC-37 with short fuel under Heat Load Chart 1 is selected as the governing thermal configuration and is used to perform all the licensing basis calculations for HI-STORM UMAX System.
** The PCT results documented in this table are for normal storage conditions under quiescent (no wind) conditions.

4.2 SUMMARY OF THERMAL PROPERTIES OF MATERIALS

The thermo-physical properties listed in the tables in this section are identical to those used in the HI-STORM FW FSAR [4.1.2] and in the HI-STORM 100 FSAR [4.1.1]. Materials present in the MPCs listed in Table 1.2.1 include Alloy X*, Metamic-HT, aluminum, and helium. Materials present in the HI-STORM UMAX storage overpack include carbon steel, stainless steel, insulation, and concrete (in the Closure Lid). In Table 4.2.1, a summary of references used to obtain cask material properties for performing all thermal analyses is presented.

Tables 4.2.2 and 4.2.3 provide numerical thermal conductivity data of materials at several representative temperatures. Table 4.2.4 provides the data on emissivity.

In Table 4.2.5, the heat capacity and density of the MPC, overpack and CSF materials are presented. These properties are used in performing transient (i.e., 32 hours inlet duct block and hypothetical fire accident condition) analyses. The temperature-dependent values of the viscosities of helium and air are provided in Table 4.2.6.

To minimize heating of the air in the intake down flow passage, the overpack divider shell is thermally insulated. The density and specific heat of the insulation material are conservatively assumed to be the same as air. The upper bound insulation conductivity is specified in Table 4.2.7.

The properties listed in the tables in this section are consistent across all previously established HI-STORM dockets.

* Alloy X is defined in [4.1.1] to designate a group of stainless steel alloys permitted for use in the HI-STORM MPCs. In this chapter the terms Alloy X and stainless steel are used interchangeably.

4.3 SPECIFICATIONS FOR COMPONENTS

Permissible temperatures for the HI-STORM UMAX system materials and components designated as “Important to Safety” (i.e., required to be maintained within their safe operating temperature ranges to ensure their intended function) are summarized in Table 2.3.7. Long-term integrity of SNF is ensured by the HI-STORM UMAX system thermal evaluation which demonstrates that fuel cladding temperatures are maintained below design basis limits.

Compliance to 10CFR72 requires, in part, identification and evaluation of short-term, off-normal and hypothetical accident conditions. The inherent mechanical characteristics of cask materials and components ensure that no significant functional degradation is possible due to exposure to short-term temperature excursions outside the normal long-term temperature limits. Fuel temperature limits specified in ISG-11 [4.0.2] are compiled in Table 2.3.7 for evaluation of cladding integrity under normal, short term operations, off-normal, and accident conditions.

4.4 THERMAL EVALUATION FOR NORMAL CONDITIONS OF STORAGE

The HI-STORM UMAX System thermal evaluation is performed in accordance with the guidelines of NUREG-1536 [4.0.1] and ISG-11 [4.0.2]. Table 1.2.1 lists the canister types and their host dockets where their thermal qualifications are performed. The candidate canisters and the heat load charts are identified and summarized in Table 4.1.1. These candidate thermal configurations, as mentioned in Section 4.1, are analyzed using the FLUENT model described below to identify the "governing thermal configuration", defined as the one that yields the highest PCT.

4.4.1 FLUENT Thermal Model

The thermal analysis model for the HI-STORM UMAX system utilizes the MPC models for MPC-37 and MPC-89 described in reference [4.1.2] and that for MPC-32 described in [4.1.1]. The effective properties of the fuel storage cells used in the thermal analysis of MPC-37 and MPC-89 in the HI-STORM UMAX System are conservatively 10% lower than those reported in the HI-STORM FW FSAR [4.1.2]. A geometrically accurate 3D thermal model of the HI-STORM UMAX VVM is constructed in the manner of HI-STORM 100U in Docket number 72-1014 for analysis. The VVM closure lid, inlet and outlet duct, the inner and outer annulus, the U-turn and the air plenum above the MPC are explicitly modeled.

The airflow through the cooling passages of the VVM is modeled **[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]** recommended in the Holtec-proprietary benchmarking report [4.4.1]. This is the *same* modeling approach as used in docket numbers 72-1014 and 72-1032. The underside of the VVM Support Foundation Pad is assumed to be supported on a subgrade at an isothermal surface temperature (see Table 4.1.1). The VVM thermal models are constructed using the same modeling platform used for aboveground analysis (FLUENT version 6.3).

4.4.2 Grid Sensitivity Studies

To insure fully converged CFD results, a grid sensitivity study was performed. **[**

PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390
].

A number of grids were generated to study the effect of mesh refinement on the component temperatures. All sensitivity analyses were carried out for the case of MPC-37 with short fuel under Heat Load Chart 1, which is determined to be the governing thermal configuration in Section 4.1. Table 4.4.1 gives a brief summary of the different sets of grids evaluated and PCT results.

Table 4.4.1 shows that Mesh 3 and Mesh 5 report essentially the same results. Therefore it can be concluded that Mesh 3 is reasonably converged [4.4.7]. To provide further assurance of convergence, the uncertainty of CFD result was evaluated in accordance with the ASME V&V 20-2009 for control of numerical accuracy [4.4.2]. The Grid Convergence Index (GCI), which is a measure of the solution uncertainty, is computed to be 1.068% for Meshes 1, 3 and 5. This provides further assurance of grid convergence.

[

PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390

]

It is noted that Mesh 3 (moderate mesh size) yields a slightly higher PCT than Mesh 5 (largest mesh size). Considering the computational cost and available PCT margin, the Mesh configuration 3 was conservatively used in all thermal analyses reported herein.

4.4.3 Test Model

The HI-STORM UMAX thermal analysis is performed on the FLUENT [4.4.3] Computational Fluid Dynamics (CFD) program. To ensure a high degree of confidence in the HI-STORM UMAX thermal evaluations, the FLUENT code has been benchmarked using data from tests conducted with casks loaded with irradiated SNF ([4.4.4], [4.4.6]). The benchmark work is archived in QA validated Holtec reports ([4.4.1], [4.4.5]). These evaluations show that the FLUENT solutions are conservative in all cases. In view of these considerations, additional experimental verification of the thermal design is not necessary. Furthermore, FLUENT has been relied to secured certification in all Holtec International Part 71 and Part 72 dockets.

4.4.4 Maximum and Minimum Temperatures

i. Maximum Temperatures

A comprehensive set of thermal analyses of all candidate “thermal configurations” (meaning the combination of canister type, regionalized loading pattern and fuel type that may produce highest fuel cladding temperature) were performed using the FLUENT model described in Section 4.4.1 to quantify their thermal margins under long term storage conditions. Thermal analyses of the following cases are performed:

A. MPC-37 with short, standard and long fuel and MPC-89 under conditions described in Table 4.1.1*.
B. Docket # 72-1014: MPC-32 under two extreme regionalized loading scenarios (X=0.5 and X=3) described in Table 4.1.1.

The maximum spatial values of the computed temperatures of the fuel cladding, the fuel basket material, the divider shell, the closure lid concrete, the MPC lid, the MPC shell and the average air outlet for all cases are summarized in Table 4.4.2. It can be seen that the governing case is that of MPC-37 with short fuel under heat load chart 1.

The following conclusions are reached from the solution data:

a. The PCT is below the temperature limit set forth in NUREG-1536 [4.0.1] and ISG-11 [4.0.2].
b. The maximum temperatures of all MPC and VVM constituent parts are below their respective limits set down in Table 2.3.7.

It is therefore concluded that the HI-STORM UMAX system provides a thermally acceptable storage environment for the eligible MPCs listed in Table 1.2.1 and that the governing thermal

* Design basis heat load scenario bounds sub-design basis and threshold heat load scenarios defined in Tables 4.4.3, 4.4.4 and 4.4.5 (See Section 4.4.5).

configuration corresponds to the case of MPC-37 with short fuel (Heat Load Chart 1): All other thermal configurations yield a lower PCT result.

ii. Minimum Temperatures

In Table 2.3.6 of this report, the minimum ambient temperature condition for the HI-STORM UMAX storage overpack and MPC is specified to be -40 deg. F. If, conservatively, a zero decay heat load with no solar input is applied to the stored fuel assemblies, then every component of the system at steady state would be at a temperature of -40 deg. F. Low service temperature (-40^{o}F) evaluation of the HI-STORM UMAX is provided in Chapter 8. All HI-STORM UMAX storage overpack and MPC materials of construction will satisfactorily perform their intended function in the storage mode under this minimum temperature condition.

4.4.5 Maximum Internal Pressure in the MPC

The MPC is initially filled with dry helium after fuel loading and drying prior to installing the MPC closure ring. In the MPC host docket (72-1014), the different helium backfill pressure specifications are allowed according to the different CoC amendments. For each type of MPC in Docket 72-1014, the specification of helium backfill pressure for HI-STORM UMAX System envelop all allowed specifications defined in the MPC host docket. The helium backfill pressure for the MPCs authorized to be stored in HI-STORM UMAX are presented in Table 4.4.6.

To provide additional helium backfill range for less than design basis heat load, the following Sub-Design-Basis (SDB) heat load scenarios are allowed for MPC-37 and MPC-89:

(i) MPC-37 under 90% of Heat Load Chart 1 (see Table 4.4.3)
(ii) MPC-89 under 90% of Design Heat Load (see Table 4.4.4)
(iii) MPC-37 under threshold heat load (see Table 4.4.5)
(iv) MPC-89 under threshold heat load (see Table 4.4.5)

The storage cell and MPC heat load limits under the 90% of Design Heat Load scenarios mentioned above are obtained by multiplying 0.9 to the individual storage cell of design heat load, and reported in Tables 4.4.3 and 4.4.4. The storage cell and MPC heat load limits under the threshold heat load scenario in the HI-STORM UMAX are provided in Table 4.4.5.

The helium backfill pressure limits supporting these scenarios are summarized in Table 4.4.6. These backfill limits maybe optionally adopted by a cask user if the decay heats of the loaded fuel assemblies meet the SDB decay heat limits stipulated above.

The heat load of SDB scenarios (i) thru (iv) are bounded by the Design Heat Load scenarios. However, since the helium backfill specifications for SDB scenarios are different from the design basis heat load scenarios, confirmatory analysis under UMAX storage are required. Considering that MPC-37 loaded with short fuel yields the highest temperatures, explicit calculations under threshold heat load and 90% of design basis heat load are performed. The

principal results are reported in Table 4.4.10. The results comply with the temperature and pressure limit Tables 2.3.7 and 2.3.5. The results support the conclusion that threshold heat load and SDB scenarios are bounded by Chart 1 Design Heat Load scenario.

During normal storage, the gas temperature within the MPC rises to its maximum operating basis temperature. The gas pressure inside the MPC will also increase with rising temperature. The pressure rise is determined using the ideal gas law. The MPC gas pressure is also subject to substantial pressure rise under hypothetical rupture of fuel rods and large gas inventory non-fuel hardware (PWR BPRAs).

The MPC maximum gas pressure is computed for a postulated release of fission product gases from fuel rods into this free space. For these scenarios, the amounts of each of the release gas constituents in the MPC cavity are summed and the resulting total pressures determined from the ideal gas law. A concomitant effect of rod ruptures is the increased pressure and molecular weight of the cavity gases with enhanced rate of heat dissipation by internal helium convection and lower cavity temperatures. As these effects are substantial under large rod ruptures the 100% rod rupture accident is evaluated with due credit for increased heat dissipation under increased pressure and molecular weight of the cavity gases. Based on fission gases release fractions (NUREG 1536 criteria [4.0.1]), rods' net free volume and initial fill gas pressure, the maximum gas pressures with 1% (normal), 10% (off-normal) and 100% (accident condition) rod rupture are given in Table 4.4.7 for all thermal scenarios analyzed in Section 4.4.4. The maximum calculated gas pressures reported in Table 4.4.7 are all below the MPC internal design pressures for normal, off-normal and accident conditions specified in Table 2.3.5.

4.4.6 Engineered Clearances to Eliminate Thermal Interferences

Thermal stress in a structural component is the resultant sum of two factors, namely: (i) restraint of free end expansion and (ii) non-uniform temperature distribution. To minimize thermal stresses in load bearing members, the HI-STORM UMAX system is engineered with adequate gaps to permit free thermal expansion of the fuel basket and MPC in axial and radial directions. In this subsection, differential thermal expansion calculations are performed for the governing thermal configuration, i.e. MPC-37 with short fuel under Heat Load Chart 1, to demonstrate that engineered gaps in the HI-STORM UMAX System are adequate to accommodate thermal expansion of the fuel basket and MPC.

The following gaps are evaluated:

a. Fuel Basket-to-MPC Radial Gap
b. Fuel Basket-to-MPC Axial Gap
c. MPC-to-Divider Shell Radial Growth
d. MPC-to-VVM Closure Lid Axial Growth

The FLUENT thermal model provides the 3-D temperature field in the HI-STORM UMAX system from which the changes in the above gaps are directly computed. Table 4.4.8 provides the nominal gaps and their corresponding value during long-term storage conditions. Significant margins against restraint to free-end expansion are indicated by the data in Table 4.4.8.

4.4.7 Effect of Elevation

The reduced ambient pressure at site elevations significantly above the sea level will act to reduce the ventilation air mass flow, resulting in a net elevation of the peak cladding temperature. However, the ambient temperature (i.e., temperature of the feed air entering the overpack) also drops with the increase in elevation. Because the peak cladding temperature also depends on the feed air temperature (the effect is one-for-one within a small range, i.e., 1°F drop in the feed air temperature results in ~1°F drop in the peak cladding temperature), the adverse ambient pressure effect of increased elevation is partially offset by the ambient air temperature decrease. The table below illustrates the variation of air pressure and corresponding ambient temperature as a function of elevation.

Elevation (ft)	Pressure (psia)	Ambient Temperature Reduction versus Sea Level
Sea Level (0)	14.70	0°F
2000	13.66	7.1°F
4000	12.69	14.3°F

A survey of the elevation of nuclear plants in the U.S. shows that nuclear plants are situated near about sea level or elevated slightly (~1000 ft). The effect of the elevation on peak fuel cladding temperatures is evaluated by performing calculations for a HI-STORM UMAX system situated at an elevation of 1500 feet. At this elevation the ambient temperature would decrease by approximately 5°F (See Table above). The peak cladding temperatures are calculated under the reduced ambient temperature and pressure at 1500 feet elevation for the MPC-37 with the short fuel under heat load chart 1. The results are presented in Table 4.4.9.

These results show that the PCT, including the effects of site elevation, continues to be well below the regulatory cladding temperature limit of 752°F. In light of the above evaluation, it is not necessary to place ISFSI elevation constraints for HI-STORM UMAX deployment at elevations up to 1500 feet. If, however, an ISFSI is sited at an elevation greater than 1500 feet, the effect of altitude on the PCT shall be quantified as part of the 10 CFR 72.212 evaluation for the site using the site ambient conditions.

4.4.8 Burnup Effects on Thermal Performance of HI-STORM UMAX System

[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390]

[PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390] Thermal conductivities of fresh UO_2 were used to determine the effective thermal properties of the fuel storage cells. However, it is known that the thermal conductivity of the fuel pellet (UO_2) will reduce with increasing burn-ups. The progressive buildup of fission products with increasing fuel burnup in the fuel pellets progressively reduces its thermal conductivity [4.4.9]. The effect of reduction in the fuel pellet thermal conductivity with fuel burnup and therefore, on the effective planar thermal conductivities of the rodded region is evaluated in [4.4.8]. **[**

PROPRIETARY INFORMATION WITHHELD IN ACCORDANCE WITH 10 CFR 2.390

]

For heat transfer in the axial direction, the thermal conductivity of the fuel storage cells is determined via an area weighted mean of the fuel cladding and helium conductivities. Axial conduction heat transfer in the fuel pellets is ignored per the guidance provided in NUREG-1536 [4.0.1]. Therefore, a change in thermal conductivity of UO_2 will have no effect on the axial (or longitudinal) thermal conductivity of the fuel storage cells.

The effective properties of the fuel storage cells used in the thermal analysis of MPC-37 and MPC-89 in the HI-STORM UMAX System are conservatively 10% lower than that reported in HI-STORM FW FSAR [4.1.2]. Since the decrease in effective thermal conductivity of fuel due to high burnup effects is bounded by the values used in the licensing basis analysis, no further thermal evaluations of HI-STORM UMAX System are warranted.

4.4.10 Evaluation of System Performance for Normal Conditions of Storage

The HI-STORM UMAX System thermal analysis is based on a detailed 3-D heat transfer model that conservatively accounts for all modes of heat transfer in the MPC and overpack. The thermal model incorporates conservative assumptions that render the computed temperature results for long-term storage to be conservative. The computed temperatures in “UMAX” under the governing thermal scenarios show that in each case:

a. The peak cladding temperature is below the ISG-11 Rev 3 limit.
b. The temperatures of structural members in the VVM, which are made of either carbon steel or stainless steel, is well below their allowable values set down in the Chapter 2 (presented in Table 2.3.7).
c. The temperature of shielding concrete mass and insulation (both non-structural members) are also well within their stipulated limits set forth in Table 2.3.7

The modest metal temperatures reached in “UMAX” insure that the components of the system will not suffer long term degradation from elevated temperature effects such as creep, alloy

phase transformation, recrystallization of the materials' grain structure, and the like. Therefore, safety of long term storage from the thermal standpoint is assured.

4.4.11 Effects of Optional Shielding

To reduce the occupational dose during loading operation, an optional stainless steel ring can be implemented. The location and specification of shielding ring are given in the drawing package listed in Section 1.5. To study the effect of this optional shielding ring, MPC-37 with short fuel under heat load chart 1, is re-evaluated for normal long-term storage condition under quiescent conditions. The PCT, maximum component temperatures of MPC and HI-STORM UMAX VVM are reported in Table 4.4.18. The MPC cavity pressure is also reported in Table 4.4.12. These results comply with the temperature and pressure limits reported in Tables 2.3.7 and 2.3.5, respectively. Comparing Table 4.4.18 with the MPC-37 in Table 4.4.2 shows that the impact of this shielding ring is insignificant.

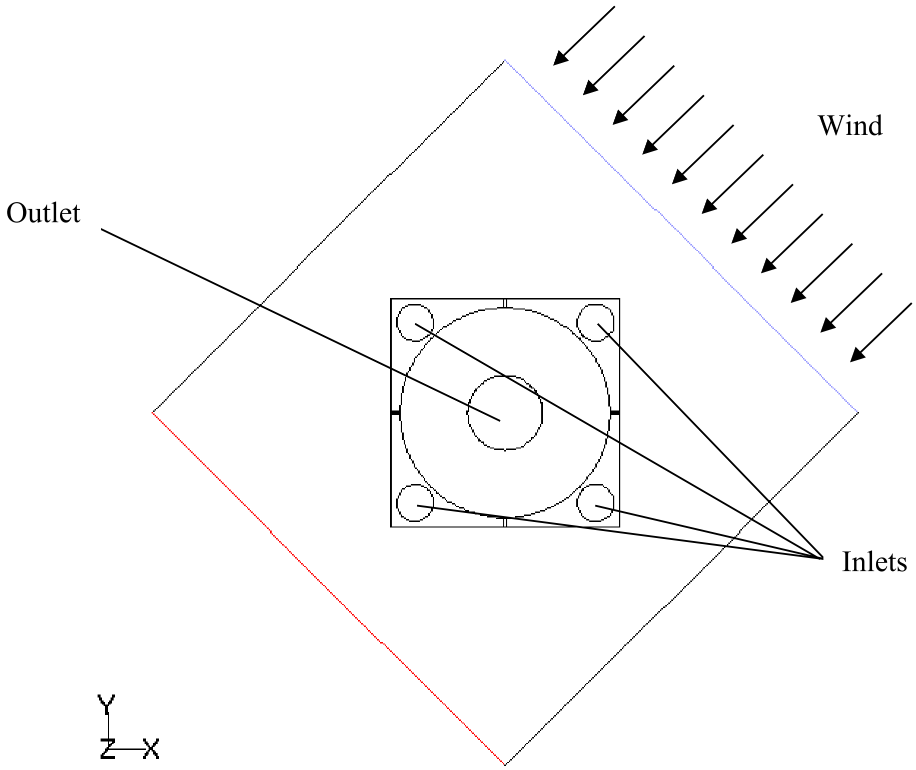

Figure 4.4.1: Schematic of the Analysis Condition - HI-STORM UMAX Full Model (Oblique Flow)

4.5 SHORT-TERM OPERATIONS

Short-Term Operations are those activities that are required to load and package the fuel in a waste package (i.e., a multi- purpose canister) and to place it in long term storage at an ISFSI. In the regulatory literature, all activities that originate in the plant's spent fuel pool and culminate in the MPC emplaced on the ISFSI pad in a passive storage mode or vice-verse from ISFSI to pool under the unlikely scenario requiring fuel unloading are collectively referred to as Short Term Operations. These include operations that occur inside the part 50 facility such as dewatering, drying, and backfilling the canister, establishing the confinement boundary by welding the lid and the Closure Ring and those that occur outside of it, namely transporting the canister to the ISFSI and transferring the MPC to the storage module. All of the short term operations have one common feature: They all involve the transfer cask. In fact, the beginning and end of Short Term Operations can be identified by the moment the fuel enters the MPC inside HI-TRAC to the time when the MPC is delivered to the storage module. The qualification of Short Term Operations, therefore, is integral to the certification of the transfer cask. This FSAR envisages using MPCs and their associated transfer casks certified in the HI-STORM FW FSAR [4.1.2]. The transfer operation of MPC-37 and MPC-89 in HI-TRAV VW is evaluated in the following.

The operational steps that occur during MPC transfer operations include the Mating Device installed and the drawer closed. As explained below this operational step must be performed in an expeditious manner to avoid excessive heating of the MPC and fuel (See Section 9.2). As the Mating Device in the closed drawer position blocks air flow it must be opened to establish air cooling. In the event of equipment malfunction that results in the blockage of air flow, corrective actions must occur within the time limits of the 100% blocked duct accident condition evaluated in Section 4.6. During MPC transfer operation from HI-TRAC to the UMAX (or reverse operation to support fuel unloading), air flow through the VVM cavity will be completely stopped under a complete closure of the Mating Device drawer. This scenario is same as the all inlet duct blockage condition analyzed in Section 4.6.2.3. Therefore, the temperature rise of fuel with time under this event, as shown in Figure 4.6.1 is applicable to evaluation of the closed drawer event. The maximum allowable time duration to ensure temperature limits of limiting fuel (high burnup fuel) remain within short term limits is computed as 4 hours. The time limit computed herein is for an example case of design basis heat load and MPCs containing one or more high burnup fuel assemblies. Additional site-specific analysis may be performed to compute applicable time limits under less than design-basis loadings.

4.5.1 Thermally Limiting Evolutions During Short-Term Operations

Except for MPC-to-UMAX transfer operations evaluated in Section 4.5 herein thermally limiting evolutions under short-term operations defined in the HI-STORM FW FSAR Section 4.5.1 [4.1.2] are incorporated by reference.

4.5.2 HI-TRAC VW Thermal Model

The HI-TRAC VW transfer cask is used to load and unload the HI-STORM UMAX concrete

storage overpack, including onsite transport of the MPCs from the loading facility to an ISFSI pad. The HI-TRAC VW 3-D thermal model is exactly the same as that used for evaluation of the thermal state of a loaded canister during all short-term operations defined in the HI-STORM FW FSAR Section 4.5.2 [4.1.2] except for the following enhancements:

1. The emissivity of fuel basket and aluminum basket shims is based on the values tabulated in Table 4.2.4.

The HI-TRAC VW thermal model is evaluated under the limiting scenario of fuel storage in the minimum height MPC-37 (See Section 4.4.1.5) and limiting Chart 1 heat load (See Section 4.4.4) specified in Chapter 2. Results of on-site transfer analyses are provided in Subsection 4.5.4.

4.5.3 Maximum Time Limit During Wet Transfer Operations

Time limits evaluated under wet transfer operations in the HI-STORM FW FSAR Section 4.5.3 [4.1.2] are incorporated by reference.

4.5.4 Analysis of Limiting Thermal States During Short-Term Operations

4.5.4.1 Vacuum Drying

Vacuum drying evaluations for MPC-37 is exactly the same as that in HI-STORM FW FSAR Section 4.5.4.1 except for the following major additional changes:

1. Vacuum drying of MPCs containing high burnup fuel assemblies is permitted up to threshold heat loads defined in Table 4.4.5.

2. A flattened axial heat generation distribution for PWR fuel assemblies shown in Table 2.1.5 is replaced by a center biased power distribution defined in Table 4.5.1. The center biased power distribution is conservative and results in higher peak cladding temperatures.

The results from the analysis performed for this condition, using the 3-D Fluent model, are provided in Table 4.5.2. The results provide a sufficiently comfortable cushion against the 400^{o}C (752^{o}F) limit.

Vacuum drying evaluations for MPC-89 in the HI-STORM FW FSAR Section 4.5.4.1 [4.1.2] are incorporated by reference.

4.5.4.2 Forced Helium Dehydration

Forced Helium Dehydration in the HI-STORM FW FSAR Section 4.5.4.2 [4.1.2] are incorporated by reference.

4.5.4.3 Normal On-site Transfer

An MPC-37 situated inside a HI-TRAC VW is evaluated under the limiting thermal scenario i.e. short fuel under heat load Chart 1. This scenario is analyzed using the same 3D FLUENT model of the HI-TRAC VW transfer cask in HI-STORM FW FSAR with due recognition of the changes discussed in Section 4.5.2 above.

While the duration of onsite transport is generally short to preclude the MPC and HI-TRAC VW from reaching a steady-state, a conservative approach is adopted herein by assuming steady state maximum temperatures are reached. The principal objectives of the HI-TRAC VW analyses are to demonstrate:

i) Cladding integrity
ii) Confinement integrity
iii) Neutron shield integrity

The appropriate criteria are provided in Tables 2.3.5 (pressure limits) and 2.3.7 (temperature limits).

The results of thermal analyses tabulated in Table 4.5.3 show that the cladding temperatures are below the ISG-11 temperature limits of High and Moderate Burnup Fuel (Table 2.3.7). Actual margins during HI-TRAC VW operations will be much larger due to the many conservative assumptions incorporated in the analysis.

The predicted temperatures and MPC cavity pressure in Tables 4.5.3 are still bounded by the respective counterpart temperatures reported for normal on-site transfer in Section 4.5 of HI-STORM FW FSAR [4.1.2]. Therefore, the accident conditions pertaining to HI-TRAC discussed in HI-STORM FW FSAR remain bounding as well and no additional analysis is warranted in this FSAR.

4.5.5 Cask Cooldown and Reflood During Fuel Unloading Operation

Cask cooldown and reflood evaluation in the HI-STORM FW FSAR Section 4.5.5 [4.1.2] is incorporated by reference.

4.5.6 Maximum Internal Pressure

After fuel loading and vacuum drying, but prior to installing the MPC closure ring, the MPC is initially filled with helium. During handling and on-site transfer operations in the HI-TRAC VW transfer cask, the gas temperature will correspond to the thermal conditions within the MPC analyzed in Section 4.5.4.3. Based on this analysis the MPC internal pressure is computed under the assumption of maximum helium backfill specified in Table 4.4.6 and confirmed to comply

with the short term operations pressure limit in Table 2.3.5. The results are tabulated in Table 4.5.3.

TABLE 4.5.1

NORMALIZED PWR DISTRIBUTION BASED ON A CENTER BIASED BURNUP PROFILE

Interval	**Axial Distance From Bottom of Active Fuel (% of Active Fuel Length)**	**Normalized Distribution**
1	0% to 4-1/6%	0.78

4.6 OFF-NORMAL AND ACCIDENT EVENTS

The safety evaluation of off-normal and accident conditions described in Section 2.5 is presented in this section. Thermal analysis of the HI-STORM UMAX System is performed for the "governing thermal configuration", i.e. MPC-37 with short fuel under heat load Chart 1, identified by the analysis in Section 4.1.

4.6.1 Off-Normal Events

4.6.1.1 Off-Normal Environmental Temperature

To evaluate the effect of off-normal weather conditions, an off-normal ambient temperature (Table 2.3.6) is postulated to persist for a sufficient duration to allow the HI-STORM UMAX system to reach steady state conditions. Because of the large mass of the HI-STORM UMAX system, with its corresponding large thermal inertia and the limited duration for the off-normal temperatures that arise in real life, this assumption is conservative. Starting from a baseline condition evaluated in Section 4.4 (normal ambient temperature and limiting fuel storage configuration) the temperatures of the HI-STORM UMAX system are conservatively assumed to be elevated by the difference between the off-normal and normal ambient temperatures. The HI-STORM UMAX extreme ambient temperatures computed in this manner are reported in Table 4.6.1. The co-incident MPC pressure is also computed (Table 4.6.5) and compared with the off-normal design pressure (Table 2.3.5), which shows a positive safety margin. The results are confirmed to be below the corresponding limits in Chapter 2.

4.6.1.2 Partial Blockage of Air Inlets

The HI-STORM UMAX system is designed with debris screens installed on the inlet and outlet openings. These screens ensure the air passages are protected from entry and blockage by foreign objects. However, as required by the design criteria presented in Chapter 2, it is postulated that the HI-STORM UMAX air inlet vents are 50% blocked. The resulting decrease in flow area increases the flow resistance of the inlet ducts. The effect of the increased flow resistance on fuel temperature is analyzed assuming that steady state conditions have been reached for the "governing thermal configuration" established by a series of thermal analyses in Section 4.4 in the foregoing. The computed temperatures and pressures are reported in Tables 4.6.1 and 4.6.5 respectively. The results are confirmed to be below the allowable limits for both internal pressure and temperature limits presented in Tables 2.3.5 and 2.3.7 respectively.

4.6.1.3 Off-Normal Pressure

This event is defined as a combination of (a) maximum helium backfill pressure permitted, (b) 10% fuel rods rupture, (c) governing thermal configuration, and (d) normal ambient temperature defined in Table 2.3.6. The principal objective of the analysis is to demonstrate that the MPC off-normal design pressure (Table 2.3.5) is not exceeded. Table 4.4.7 provides the computed pressures for the off-normal event as defined above which show that all applicable pressure

limits are met with positive margins.

4.6.1.4 FHD Malfunction

FHD malfunction evaluated in the HI-STORM FW FSAR Section 4.6.1 [4.1.2] is incorporated by reference.

4.6.2 Accident Events

4.6.2.1 Fire Accident

(a) HI-STORM UMAX Fire
The Design Basis Fire event for HI-STORM UMAX, described in Section 2.5, is identical to that of HI-STORM FW[4.1.2] and HI-STORM 100 [4.1.1]. The fire evaluation for limiting MPC-37 with short fuel stored in HI-STORM UMAX is bounded by the analysis reported in the HI-STORM FW FSAR [4.1.2], due to the following facts:

- The initial PCT and component temperatures of MPC stored in HI-STORM UMAX system are lower than that of the same MPC in the HI-STORM FW system.
- HI-STORM UMAX system has much lesser surface directly exposed to fire than that of above-ground system.

Consequently, the conclusion that PCT and components' temperatures and MPC pressure are below temperature and pressure limits for the Design Basis Fire event drawn in HI-STORM FW FSAR [4.1.2] will remain valid for the HI-STORM UMAX system.

(b) HI-TRAC VW Fire
The thermal evaluation of normal on-site transfer in HI-TRAC VW discussed in Sub-Section 4.5.4 is bounded by the normal on-site transfer evaluation of HI-TRAC VW in the HI-STORM FW FSAR Section 4.5.4 [4.1.2]. Therefore, HI-TRAC VW fire evaluated in the HI-STORM FW FSAR Section 4.6.2 [4.1.2] is incorporated by reference.

4.6.2.2 Extreme Environmental Temperatures

To evaluate the effect of extreme weather conditions, an extreme ambient temperature (Table 2.3.6) is postulated to persist for a sufficient duration to allow the HI-STORM UMAX system to reach steady state conditions. Because of the large mass of the HI-STORM UMAX system, with its corresponding large thermal inertia and the limited duration for the extreme temperatures that arise in real life, this assumption is conservative. Starting from a baseline condition evaluated in Section 4.4 (normal ambient temperature and limiting fuel storage configuration) the temperatures of the HI-STORM UMAX system are conservatively assumed to be elevated by the

difference between the extreme and normal ambient temperatures. The HI-STORM UMAX extreme ambient temperatures computed in this manner are reported in Table 4.6.6. The co-incident MPC pressure is also computed (Table 4.6.10) and compared with the accident design pressure (Table 2.3.5), which shows a positive safety margin. The results are confirmed to be below the corresponding limits in Chapter 2.

4.6.2.3 100% Blockage of Air Inlets

This event is defined as a postulated complete blockage of all inlet ducts for a specified duration. The immediate consequence of a complete blockage of the air inlets is that the normal circulation of air for cooling the MPC is interrupted. A small amount of heat will continue to be removed by localized air circulation patterns in the VVM annulus and outlet ducts, and the MPC will continue to dissipate heat to the relatively cooler subgrade. As the temperatures of the MPC and its contents rise, the rate of heat rejection will increase correspondingly. Nevertheless, under this condition, the temperatures of the storage system including the MPC and the stored fuel assemblies will rise monotonically as a function of time.

As a result of the considerable inertia of the storage overpack, a significant temperature rise is possible if the inlets are substantially blocked for extended durations. This accident condition is, however, a short duration event that is identified and corrected through scheduled periodic surveillance. Nevertheless, this event is conservatively analyzed assuming a substantial duration of blockage. The inlet ducts in the HI-STORM UMAX thermal model are assumed to have become impervious to air flow for 100% air inlet blockage. Using this model, a transient thermal solution of the HI-STORM UMAX system starting from normal storage conditions is obtained. The results of the 32 hours blocked ducts transient analysis are presented in Table 4.6.7 and compared against the accident temperature limits (Table 2.3.7). The history of PCT increasing during the early time stage is plotted in Figure 4.6.1 to provide guideline for fuel loading operation. The co-incident MPC pressure (Table 4.6.10) is also computed and compared with the accident design pressure (Table 2.3.5). All computed results are found to remain well below their respective limits under the postulated 32 hours blockage duration.

4.6.2.4 Burial Under Debris

Burial of the HI-STORM UMAX system under debris is not a credible accident. During storage at the ISFSI there are no structures that loom over the casks whose collapse could completely bury the casks in debris. Minimum regulatory distances from the ISFSI to the nearest ISFSI security fence precludes the close proximity of substantial amount of vegetation. Thus, even though there is no credible mechanism for the HI-STORM UMAX system to become completely buried under debris, the scenario of complete burial under debris is analyzed herein to quantify the system's resistance to such an event.

Thus, burial under debris is a postulated accident scenario that is analyzed in this FSAR to determine the length of time that is available to the plant's emergency response organization to remedy the condition. The generic burial-under-debris analysis is performed under the following

assumptions:

a. The ISFSI is assumed to be populated with the limiting MPC type containing the most adverse thermal loading, i.e. MPC-37 with short fuel under heat load chart 1.

b. The burial medium serves as a perfect insulation blocking off any conductive or convective means for heat rejection to the environment.

c. The burial is assumed to affect all VVMs at the ISFSI. Thus no heat transmission path to the adjacent subgrade is available.

d. Heat rejection to the under-grade is also assumed to be (non-mechanistically) lost.

Under the above scenario, the contents of the HI-STORM UMAX system will undergo a transient heat up under adiabatic conditions. The minimum available time ($\Delta\tau$) for the fuel cladding to reach the accident limit depends on the following: (i) thermal inertia of the cask, (ii) the cask initial conditions, (iii) the spent nuclear fuel decay heat generation and (iv) the margin between the initial cladding temperature and the accident temperature limit. To obtain a *lower bound* on $\Delta\tau$, the HI-STORM UMAX VVM's thermal inertia (item i) is understated, the cask initial temperature (item ii) is maximized, decay heat overstated (item iii) and the cladding temperature margin (item iv) is understated. A set of conservatively postulated input parameters for items (i) through (iv) are summarized in Table 4.6.8. Using these parameters $\Delta\tau$ is computed as follows:

$$\Delta\tau = \frac{m \times c_p \times \Delta T}{Q}$$

where:

$\Delta\tau$ = minimum available burial time (hr)
m = Mass of HI-STORM UMAX System (lb)
c_p = Specific heat capacity (Btu/lb-^{o}F)
ΔT = Permissible temperature rise (^{o}F)
Q = Decay heat load (Btu/hr)

Substituting the parameters in Table 4.6.8, the minimum available burial time is computed as 22.7 hours. This is an example calculation for the short fuel. The same methodology can be adopted to estimate the time for other MPC types and fuel assemblies. The co-incident MPC pressure (see Table 4.6.10) is also computed and compared with the accident design pressure (Table 2.3.5). These results indicate that HI-STORM UMAX has a substantial thermal heat sink capacity to withstand a complete burial-under-debris event.

The above simplified computation may be used to compute the permissible burial-under-debris time for a VVM cavity corresponding to its actual content conditions. The available time to

restore full ventilation in a loaded VVM is computed above for guiding the Emergency Response plan for an ISFSI for which a burial-under-debris event can be credibly postulated.

4.6.2.6 Jacket Water Loss

The thermal evaluation of normal on-site transfer in HI-TRAC VW discussed in Sub-Section 4.5.4 is bounded by the normal on-site transfer evaluation of HI-TRAC VW in the HI-STORM FW FSAR Section 4.5.4 [4.1.2]. Therefore, HI-TRAC VW jacket water loss accident evaluated in the HI-STORM FW FSAR Section 4.6.2 [4.1.2] is incorporated by reference.

4.7 REGULATORY COMPLIANCE

The thermal compliance pursuant to the provisions of NUREG [4.0.1] and ISG-11 [4.0.2] of the MPCs requested for certification (MPC-37 and MPC-89) in the HI-STORM UMAX system has been considered in this chapter. NUREG-1536 [4.0.1] and ISG-11 [4.0.2] define several thermal acceptance criteria that must be applied to evaluations of normal conditions of storage. These items are addressed in Sections 2.5 and 4.1. Each of the pertinent criteria and the conclusion of the evaluations are summarized here.

As required by ISG-11 [4.0.2], the fuel cladding temperature at the beginning of dry storage is maintained below the anticipated damage-threshold temperatures for normal conditions for the licensed life of the HI-STORM UMAX System. Maximum fuel cladding temperatures for long-term storage conditions are reported in Section 4.4.

As required by NUREG-1536 [4.0.1], the maximum internal pressure of the canister remains within its design pressure for normal conditions, assuming rupture of 1 percent of the fuel rods. Assumptions for pressure calculations include release of 100 percent of the fill gas and 30 percent of the significant radioactive gases in the fuel rods. Maximum internal pressures are reported in Section 4.4 and shown to remain below the normal design pressures specified in Table 2.3.5.

As required by NUREG-1536 [4.0.1], all VVM components and fuel materials are maintained within their minimum and maximum temperature for normal and off-normal conditions in order to enable components to perform their intended safety functions. Maximum and minimum temperatures for normal, off-normal and accident long-term storage conditions are reported in Sections 4.4 and 4.6 which are shown to be well below their respective Design temperature limits summarized in Table 2.3.7.

As required by NUREG-1536 [4.0.1], the system ensures a very low probability of cladding breach during long-term storage. For long-term normal conditions, the maximum CSF cladding temperature is shown to be below the ISG-11 [4.0.2] limit of 400°C (752°F).

As required by NUREG-1536 [4.0.1], the system is passively cooled. All heat rejection mechanisms described in this chapter, including conduction, natural convection, and thermal radiation, are completely passive.

As required by NUREG-1536 [4.0.1], the thermal performance of the system is within the allowable design criteria specified in SAR Chapters 2 and 3 for normal conditions. All thermal results reported in Section 4.4 are within the design criteria under all normal conditions of storage.

The thermal compliance of short term operations (such as MPC drying, lid welding and transport on the haul path) is presented in Section 4.5 wherein complete compliance with the provisions of

ISG-11 [4.0.2] is demonstrated. In particular, the ISG-11 requirement to ensure that maximum cladding temperatures under all fuel loading and short-term operations be below 400°C (752°F) for high burnup fuel and below 570°C (1058°F) for moderate burnup fuel is demonstrated.

As required by NUREG-1536 [4.0.1], the maximum internal pressure of the MPC is evaluated and shown to remain within its off-normal and accident design pressure, assuming rupture of 10 percent and 100 percent of the fuel rods, respectively. Assumptions for pressure calculations include release of 100 percent of the fill gas and 30 percent of the significant radioactive gases in the fuel rods.

It is therefore concluded that all applicable regulatory requirements and guidelines germane to the integrity of the stored fuel and the "UMAX" storage system have been addressed and satisfied in this chapter.

CHAPTER 5: SHIELDING EVALUATION OF THE HI-STORM UMAX SYSTEM

5.0 INTRODUCTION

This chapter contains a shielding safety analysis of the loaded HI-STORM UMAX VVMs pursuant to the guidelines in NUREG-1536 [5.0.1]. The objective of the analyses summarized in this chapter is to demonstrate that the loaded underground VVM will provide sufficient dose blockage to enable an on-site ISFSI to be operated at a fraction of the controlled area boundary dose limits in 10CFR72**.** The analyses presented in this chapter focus on two representative multipurpose canisters, viz. MPC-37 and MPC-32, out of the population of MPCs listed in the Table 1.2.1. A technical justification of the basis for selecting these two representative canisters is provided later in this section. This chapter, however, only supports the certification of the MPC-37 and MPC-89. The analyses reported for the smaller diameter canister are for reference purposes only. The sections that follow demonstrate that the design of the HI-STORM UMAX dry cask storage system fulfills the following acceptance criteria outlined in the Standard Review Plan, NUREG-1536:

Acceptance Criteria

1. The minimum distance from each spent fuel handling and storage facility to the controlled area boundary must be at least 100 meters. The “controlled area” is defined in 10CFR72.3 as the area immediately surrounding an ISFSI or monitored retrievable storage (MRS) facility, for which the licensee exercises authority regarding its use and within which ISFSI operations are performed.

2. The system designer must show that, during both *normal operations and anticipated occurrences*, the radiation shielding features of the proposed dry cask storage system are sufficient to meet the radiation dose requirements in Section 72.104(a). Specifically, the vendor must demonstrate this capability for a typical array of casks in the most bounding site configuration. For example, the most bounding configuration might be located at the minimum distance (100 meters) to the controlled area boundary, without any shielding from other structures or topography.

3. Dose rates from the cask must be consistent with a well-established “as low as reasonably achievable” (ALARA) program for activities in and around the storage site.

4. After a design-basis accident, an individual at the boundary or outside the controlled area shall not receive a dose greater than the limits specified in 10CFR72.106.

5. The proposed shielding features must ensure that the dry cask storage system meets the regulatory requirements for occupational and radiation dose limits for individual members of the public, as prescribed in 10CFR Part 20, Subparts C and D.

Consistent with the guidelines provided in the Standard Review Plan, NUREG-1536, this chapter contains the following information:

- A description of the shielding features of the HI-STORM UMAX System.
- A description of the source terms.
- A general description of the shielding analysis methodology.
- A description of the analysis assumptions and results for the HI-STORM UMAX system.
- Analyses to show that the 10CFR72.106 controlled area boundary radiation dose limits are met during accident conditions of storage for non-effluent radiation at a minimum distance of 100 meters.

Since only representative dose rate values for normal conditions can be presented herein, compliance with the radiation and exposure objectives of 10CFR72.104, of necessity, must be performed as part of the site specific evaluations.

In this chapter, analyses are presented for two representative MPCs, namely MPC-32 and MPC-37, previously used to qualify peer-certified HI-STORM systems (MPC-32 in HI-STORM 100 in Docket Number 72-1014 [5.0.2], and MPC-37 in HI-STORM FW in Docket Number 72-1032 [5.0.3]) showing that the radiation dose rates follow As-Low-As-Reasonably-Achievable (ALARA) principle. MPC-32 and MPC-37 are selected as they represent two different classes of MPCs from the outer dimensions perspective. The smaller diameter of the MPC-32 compared to that of the MPC-37 results in a larger gap between the MPC enclosure shell and CEC. Additionally, MPC-32 is slightly longer than MPC-37. Both of these attributes may cause slightly higher dose rates for the HI-STORM UMAX system loaded with MPC-32 compared to MPC-37. As stated at the beginning of this section, the MPC-32 dose evaluations are for reference purpose only. Besides the MPC-37, this chapter also supports the certification of the MPC-89 in the HI-STORM UMAX system. However, the MPC-89 specific shielding analyses are not performed as the results presented in the HI-STORM FW FSAR show that results for the MPC-89 are similar to those for the MPC-37. Additionally, it is noted that site specific analyses need to use the site specific MPC (MPC-37 or MPC-89) for controlled area boundary dose calculations to show the site's compliance with 10 CFR 72.104 and 10 CFR 72.106.

The design basis zircaloy clad fuel assemblies used for calculating the dose rates presented in this chapter is the Westinghouse (W) 17x17 PWR fuel (see Table 5.0.1). The burnup and cooling times used for the shielding evaluation are consistent[‡‡] with those in [5.0.3]. Use of identical MPC and similar source term data enables a one-to-one comparison between the

[‡‡] Only difference is the cooling time: FW uses 4.5 years which is more representative for the side of the MPC, whereas UMAX uses 5 years which is more representative for the top of the MPC.

shielding capacity of "HI-STORM UMAX" and its aboveground counterpart, the HI-STORM FW MPC storage system.

The principal sources of radiation in the HI-STORM UMAX System are:

- Gamma radiation originating from the following sources:
  1. Decay of radioactive fission products
  2. Secondary photons from neutron capture in fissile and non-fissile nuclides
  3. Hardware activation products generated during core operations

- Neutron radiation originating from the following sources:
  1. Spontaneous fission
  2. α,n reactions in fuel materials
  3. Secondary neutrons produced by fission from subcritical multiplication
  4. γ,n reactions (this source is negligible)

10CFR72 contains two sections that set down main dose requirements: §104 for normal and off-normal conditions, and §106 for anticipated occurrences and accident conditions. The relationship of these requirements to the safety analyses documented herein, are as follows:

- 10CFR72.104 specifies the dose limits from an ISFSI (and other operations) at a site boundary under normal and off-normal conditions. Compliance with §104 can therefore only be demonstrated on a site-specific basis, since it depends not only on the design of the cask system and the loaded fuel, but also on the ISFSI layout, the distance to the site boundary, and possibly other factors such as the terrain around the ISFSI. The purpose of this chapter is therefore to present the analysis methodology and illustrate its application to obtain the dose rates at locations of interest using a reference problem. The analysis carried out on the "HI-STORM UMAX" geometry is also intended to aid the user in applying the ALARA considerations and planning of the ISFSI. To accomplish the above objectives, it is appropriate to present reasonably conservative dose rate values, based on a reasonable conservative choice of burn-ups and cooling times of the assemblies (Table 5.0.1).
- For the accident dose limit in 10CFR72.106 it should be noted that the governing accident condition for the HI-STORM FW system, namely loss of shielding water in the Transfer cask, is analyzed in Reference [5.0.3]. Reference [5.0.3] contains the shielding analysis for accidental loss of water in HI-TRAC VW. Likewise, the HI-STORM 100 docket (Docket Number 72-1014) contains the equivalent accident analysis for HI-TRAC 125 and 100 models used to transfer MPC-32, MPC-68, and other models licensed in [5.0.2], which can be used as references for ISFSI planning. Therefore, the classical accident analysis considered in deploying the HI-STORM system are pre-empted by the evaluations in Reference [5.0.3], making it unnecessary and redundant to perform them in this FSAR. In addition, a Design Basis Missile (defined by Tables 2.3.3 and 2.3.4) strike to the exposed radiation protection space boundary (defined in Chapter 1), created by the excavation adjacent to it, has been analyzed in Chapter 3 and found to cause about 5.5 feet penetration

through the subgrade. It is to be noted that the optional enclosure wall was not considered in the missile penetration calculations, and while the radiation protection space provides at least 10.75 feet of subgrade in the radial direction from the outer metal surface of the VVM to the radiation protection space boundary, only 6.5 feet of subgarde is conservatively utilized for this accident condition dose calculation. Hence, the impact of a tornado missile penetrating a 6.5 feet subgrade creating a horizontal hole extending 5.5 feet from the external surface of the subgrade is considered as an accident condition for the shielding evaluations.

The shielding analyses were performed with MCNP5 [5.0.4] developed by Los Alamos National Laboratory (LANL). The source terms for the design basis fuels were calculated with the SAS2H and ORIGEN-S sequences from the SCALE 5 system [5.0.5][5.0.6]. A detailed description of the MCNP models and the source term calculations are presented in Sections 5.3 and 5.2, respectively.

To facilitate convenient access to the referenced material, the latest edition of the HI-STORM FW FSAR has been placed in this docket and a list of "FW" FSAR sections germane to this chapter is provided in a tabular form. The HI-STORM FW FSAR will be maintained in a configuration controlled status in this docket as a mandatory supplement to this FSAR. The table below provides a listing of the material adopted in this chapter by reference to the HI-STORM FW FSAR.

The safety analyses summarized in this chapter demonstrate that under accident conditions, acceptable margins to allowable limits exist under all design basis loading conditions. For normal and off-normal conditions, the analyses in this chapter simply provide a generic evaluation that demonstrates that the dose requirements as specified in 10CFR72.104 can be met under site specific conditions. Minor changes to the design parameters that inevitably occur during the product’s life cycle which are treated within the purview of 10CFR72.48 and are ascertained to have an insignificant effect on the computed dose rates in this chapter may not prompt a formal reanalysis and revision of the results and associated data in the tables of this chapter unless the cumulative effect of all such unquantified changes cannot be deemed any more to be insignificant. For accident conditions, the dose limit as specified in 10CFR72.106 is 5 rem. The only accident which impacts dose rates is the loss of water in the water jacket for the HI-TRAC VW. For the purposes of determining if the changes to the HI-TRAC VW are insignificant, an insignificant loss of margin with reference to the 5 rem acceptance criteria is defined as the estimated reduction that is no more than one order of magnitude less than the available margin reported in the FSAR. For normal and off-normal conditions, site specific dose evaluations are required to demonstrate compliance with 10CFR72.104. Incorporating any minor changes into those site specific evaluations is only warranted if it would be expected, on a site specific basis, that those changes could result in a situation where the limits are no longer met and where therefore other compensatory measures are required, such as a change in the loading plan or the closure lid concrete density. Incorporating changes into the analyses in this chapter for normal and off-normal conditions will only be performed under extenuating circumstances, e.g. major changes to the shielding design, in order to provide an updated template for the site specific dose analyses.

To ensure rigorous configuration control, the information in the Licensing drawings in Section 1.5 should be treated as the authoritative source for numerical analysis at all times. Reliance on the input data and associated results in this chapter for additional mathematical computations may not be appropriate as they serve the sole purpose of establishing safety compliance in accordance with the acceptance criteria set down in Chapter 2 and in this chapter.

5.1 SHIELDING FEATURES, DESIGN OBJECTIVE AND RESULTS

5.1.1 Shielding Features

The essentials of the HI-STORM UMAX System are described in Section 1.2. The design details are laid out in the licensing drawings in Section 1.5. As can be seen from the Licensing drawings, the underground HI-STORM UMAX System differs from all aboveground HI-STORM overpacks certified in Dockets 72-1014 and 1032 in that the used fuel is stored well below the ISFSI's top of grade (TOG). HI-STORM UMAX, however, is completely fungible with the HI-STORM FW overpack model in that it can store the MPC-37 and MPC-89 certified to be stored in the FW system. Furthermore, the HI-TRAC VW transfer cask used to perform the *short-term operations* to prepare and install the MPCs in the storage system is identical to that used in the HI-STORM FW system [5.0.3]. In fact, the MPC's content conditions and the loading operations up to the time the loaded transfer cask arrives at the ISFSI are identical to the HI-STORM FW system. Therefore, all shielding safety analyses governing the HI-TRAC VW transfer cask are already provided in Reference [5.0.3] and no further calculations involving the HI-TRAC VW transfer cask are necessary or presented in this chapter.

As shown in the Licensing drawings, the HI-STORM UMAX ISFSI consists of a set of vertically disposed thick-walled steel containers founded on a thick reinforced concrete pad (denoted as the Support Foundation pad, located over 20 feet below TOG) and embedded in a subgrade made of a Self-hardening Engineered Subgrade. The top region of the steel container is reinforced by a thick plate-type flange that rests on a reinforced concrete pad denoted as the ISFSI pad. The top opening in the container is the only location of access into the cavity and potential path of emission of radiation to the environment. To provide maximum blockage to the radiation issuing from the fuel, "HI-STORM UMAX" utilizes both mass and distance as barriers. The Closure Lid, made as an over-40 inch thick steel weldment filled with concrete, provides a massive body in the path of the radiation emanating from the fuel. The shielding action of the lid is further aided by ensuring that the top of the MPC (itself equipped with a > 9inch thick lid) is at least about 2 feet below the bottom of the VVM Closure lid. With such a massive blockage arrayed against the stored fuel, the dose levels at the top of the ISFSI pad are expected to be very low, which the analyses in this chapter will be seen to corroborate.

However, aside from the magnitude of shielding, the shielding mechanism in the HI-STORM UMAX VVM is similar to the aboveground overpack designs certified in [5.0.2] and [5.0.3] with gamma shielding provided by the concrete and the steel of the module, and neutron shielding provided by the ISFSI concrete. However, because the VVM is located below grade, a significant reduction in the dose at the directly accessible surface of the VVM compared to the aboveground storage modules is realized. Dose rates from a HI-STORM UMAX VVM at the site boundary are therefore significantly lower than, and bounded by, the corresponding dose rates from the peer aboveground HI-STORM systems.

It should be noted that the material and thickness of some parts are optional in the HI-STORM UMAX drawings provided in Chapter 1. Site specific chosen options will be considered in performing site specific shielding calculations to show the compliance with the regulatory limits.

5.1.2 Design Objective

In accordance with ALARA practices, design objective dose rates are established for the HI-STORM UMAX system and presented in Table 2.9.2.

Chapter 12 discusses the potential off-normal conditions and their effect on the HI-STORM UMAX system. None of the off-normal conditions have any impact on the shielding analysis. Therefore, off-normal and normal conditions are identical for the purpose of the shielding evaluation.

The 10CFR72.104 criteria for radioactive materials in effluents and direct radiation during normal operations are:

1. During normal operations and anticipated occurrences, the annual dose equivalent to any real individual who is located beyond the controlled area, must not exceed 25 mrem to the whole body, 75 mrem to the thyroid, and 25 mrem to any other critical organ.

2. Operational restrictions must be established to meet As-Low-as-Reasonably-Achievable (ALARA) objectives for radioactive materials in effluents and direct radiation.

10CFR20 Subparts C and D specify additional requirements for occupational dose limits and radiation dose limits for individual members of the public. Chapter 11 specifically addresses these regulations.

5.1.3 Results

Figure 5.1.1 identifies the locations of the dose points referenced in Tables 5.1.1 and 5.1.2 for HI-STORM UMAX loaded with MPC-32 and MPC-37, respectively. Dose Points #1 represents the side of the closure lid shell on top of the inlet plenum. Dose Point #1 is also the location of the highest dose rate on the lid in the final storage configuration. However, there is a substantial dose rate reduction at 1 meter from Dose Point #1. The maximum dose rate is reported for the side surface of the lid shell, while the dose rate value reported at 1 meter is taken at the middle of the lid shell. Dose Point #2 is the location of the surface of the outlet duct. Dose Point #3 is positioned on the closure lid cover plate. Dose Points # 4 and #5 (#5 not seen in Figure 5.1.1) are the locations of the outlet and inlet vents (top surface), respectively. Dose Point #6 is located over a tube that would be required for the ICCPS test station if an ICCPS is used. Dose Point #7 is located over an empty VVM located adjacent to a loaded VVM. Dose Point #7 is used to calculate the potential radiation streaming through an empty cavity surrounded by 4 loaded VVMs.

The tube for the ICCPS test station is modeled as a cylindrical hole that extends from the VIP down to the base plate of the MPC. The tube is modeled with a diameter of 4 inches, located about 5.5 feet from the center of the VVM. If the actual tube has characteristics that could result in higher dose rates, i.e. is larger or closer to the VVM than modeled here, the actual tube

characteristics should be considered in the site specific dose calculations. Depending on the results of those calculations, additional measures, such as added shielding at the top of the tube, may be required.

A comparison between the dose rates in Table 5.1.2 and the corresponding dose rates presented in Section 5.1 of the HI-STORM FW FSAR [5.0.3] show that the maximum dose rate for the HI-STORM UMAX module with a loaded MPC is well below the maximum dose rate for the HI-STORM FW with the identically loaded MPC. The generally lower dose rate in HI-STORM UMAX compared to HI-STORM FW would suggest that the dose rate contribution at the site boundary will be accordingly exiguous. Nevertheless, calculations were performed for both MPC-32 and MPC-37 under normal condition to determine the annual dose rate from the HI-STORM UMAX system at a distance of 100 meters. These results, which are presented in Table 5.1.3, indicate that the HI-STORM UMAX meets the requirements of 10CFR72.104 at 100 meters with large margins. Comparing these results to the results in Section 5.1 of the HI-STORM FW FSAR demonstrates that the off-site dose from the HI-STORM UMAX is a small fraction of the off-site dose from an aboveground overpack.

The bounding accident condition is identified in Chapter 3 to be the impact of a tornado missile with a diameter of 8 inches. This missile would penetrate the soil about 5.5 ft. This is the bounding condition since smaller missiles have less energy, and larger missiles (automotive) have a much larger impact area thus resulting in a much smaller indentation of the soil. Under the bounding condition, the maximum dose over a period of 30 days at a distance of 100 m from the VVM is presented in Table 5.1.4. As discussed in Section 5.0, only 6.5 feet of subgrade in the radial direction from the outer metal surface of the VVM is applied for this accident condition dose evaluation. Table 5.1.4 demonstrates that the accident condition dose is in compliance with the 10CFR72.106 and much lower than the dose reported for HI-TRAC accident condition in Reference [5.0.3].

5.2 SOURCE SPECIFICATION

The design basis fuel used for the reference shielding analyses is identical, and the burnup, cooling time and enrichment combination is consistent** with what was used in the HI-STORM FW FSAR [5.0.3]. However, to enhance readability and to assist the reviewer, excerpt from the source specification section, Section 5.2 of Chapter 5, of the HI-STORM FW FSAR is presented here.

††The neutron and gamma source terms, decay heat values, and quantities of radionuclides available for release were calculated with the SAS2H and ORIGEN-S modules of the SCALE 5 system [5.0.5][5.0.6]. SAS2H has been extensively compared to experimental isotopic validations and decay heat measurements. References [5.2.1] through [5.2.8] present isotopic and decay heat comparisons for PWR and BWR fuels. All of these studies indicate good agreement between SAS2H and ORIGEN-S and measured data.

A description of the design basis fuel for the source term calculations is provided in Table 5.2.1. Subsection 5.2.4 discusses the rationale in the determination of the design basis fuel assemblies.

In performing the SAS2H and ORIGEN-S calculations, a single full power cycle was used to achieve the desired burnup. This assumption, in conjunction with the above-average specific powers listed in Table 5.2.1 resulted in a conservative source term calculation.

5.2.1 Gamma Source

Tables 5.2.2 provides the gamma source in MeV/s and photons/s as calculated with SAS2H and ORIGEN-S for the design basis zircaloy clad fuel at the burnups and cooling times used for the shielding analyses in this chapter.

Previous analyses were performed for the HI-STORM 100 system to determine the dose contribution from gammas as a function of energy [5.0.2]. The results of these analyses have revealed that, due to the magnitude of the gamma source at lower energies, photons with energies as low as 0.45 MeV must be included in the shielding analysis, but photons with energies below 0.45 MeV are too weak to penetrate the HI-STORM overpack or HI-TRAC. The effect of gammas with energies above 3.0 MeV, on the other hand, was found to be insignificant. This is due to the fact that the source of

** Only difference is the cooling time: FW uses 4.5 years which is more representative for the side of the MPC, whereas UMAX uses 5 years which is more representative for the top of the MPC.
†† The text matter in the "Arial" font is excerpted from the HI-STORM FW FSAR with minor editorial changes, as appropriate.

gammas in this range (i.e., above 3.0 MeV) is extremely low. Therefore, all photons with energies in the range of 0.45 to 3.0 MeV are included in the shielding calculations.

The primary source of activity in the non-fuel regions of an assembly arises from the activation of ^{59}Co to ^{60}Co. The primary source of ^{59}Co in a fuel assembly is impurities in the steel structural material above and below the fuel. The zircaloy in these regions is neglected since it does not have a significant ^{59}Co impurity level. Reference [5.2.9] indicates that the impurity level in steel is 800 ppm or 0.8 gm/kg. Therefore, inconel and stainless steel in the non-fuel regions are both assumed to have the same 0.8 gm/kg impurity level.

Some of the PWR fuel assembly designs (B&W and WE 15x15) utilized inconel in-core grid spacers while other PWR fuel designs use zircaloy in-core grid spacers. In the mid 1980s, the fuel assembly designs using inconel in-core grid spacers were altered to use zircaloy in-core grid spacers. To take that into account, the gamma source for the PWR zircaloy clad fuel assembly includes the activation of the in-core grid spacers.

The masses in Table 5.2.1 were used to calculate a ^{59}Co impurity level in the fuel assembly material. The grams of impurity were then used in ORIGEN-S to calculate a ^{60}Co activity level for the desired burnup and decay time. The methodology used to determine the activation level was developed from Reference [5.2.10] and is described here.

1. The activity of the ^{60}Co is calculated using ORIGEN-S. The flux used in the calculation was the in-core fuel region flux at full power.

2. The activity calculated in Step 1 for the region of interest was modified by the appropriate scaling factors listed in Table 5.2.3. These scaling factors were taken from Reference [5.2.10].

Table 5.2.4 presents the ^{60}Co activity utilized in the shielding calculations for the non-fuel regions of the assemblies in the MPC-37 and the MPC-32.

In addition to the two sources already mentioned, a third source arises from (n,γ) reactions in the material of the MPC and the overpack. This source of photons is properly accounted for in MCNP when a neutron calculation is performed in a coupled neutron-gamma mode.

5.2.2 Neutron Source

It is well known that the neutron source strength increases as enrichment decreases, for a constant burnup and decay time. This is due to the increase in Pu content in the fuel, which increases the inventory of other transuranium nuclides such as Cm. The gamma source also varies with enrichment, although only slightly. Because of this effect and in

order to obtain conservative source terms, low initial fuel enrichments of 3.6 wt% were chosen for the PWR design basis fuel assemblies under.

The neutron sources calculated for the design basis fuel assembly are listed in Tables 5.2.5 in neutrons/s for the selected burnup and cooling times used in the shielding evaluations. The neutron spectrum is generated in ORIGEN-S.

5.2.3 Non-Fuel Hardware

Burnable poison rod assemblies (BPRAs), thimble plug devices (TPDs), control rod assemblies (CRAs), axial power shaping rods (APSRs), and neutron source assemblies (NSAs)) are generally termed as non-fuel hardware and can be stored as an integral part of a PWR fuel assembly. Non-fuel hardware storage restrictions as applicable for a particular MPC in the certification of its host docket are also applicable in the HI-STORM UMAX system. Similar to HI-STORM FW FSAR [5.0.3], representative shielding analyses are performed in this chapter by only utilizing BPRAs in every PWR fuel location in the basket.

5.2.3.1 BPRAs

Burnable poison rod assemblies (BPRA) (including wet annular burnable absorbers) are an integral, yet removable, part of a large portion of PWR fuel. BPRAs are made of stainless steel in the region above the active fuel zone and may contain a small amount of inconel in this region. Within the active fuel zone the BPRAs may contain 2-24 rodlets which are burnable absorbers clad in either zircaloy or stainless steel. The stainless steel clad BPRAs create a significant radiation source (Co-60) while the zircaloy clad BPRAs create a negligible radiation source. Therefore, the stainless steel clad BPRAs are bounding.

The masses of this devise are listed in Table 5.2.6, while Table 5.2.7 presents the curies of Co-60 that were calculated for BPRAs in each region of the fuel assembly (e.g. incore, plenum, top). For specific site boundary evaluations, these levels/values can be used if they are bounding. Alternatively, more realistic values can be used.

5.2.4 Choice of Design Basis Assembly

The Westinghouse 17x17 assembly was selected as design basis assembly since it is been widely used throughout the industry. Site specific shielding evaluations should verify that those assemblies and assembly parameters are appropriate for the site-specific analyses.

5.3 MODEL SPECIFICATIONS

The shielding analyses of the HI-STORM UMAX module are performed with MCNP5 [5.0.4], which is a QA-validated code under Holtec International's quality program. A sample input file for MCNP is provided in Appendix 5.A.

Section 1.5 provides the drawings that describe the HI-STORM UMAX System. The nominal dimensions in these drawings were used to create the MCNP models used in the radiation transport calculations. Modeling deviations from these drawings are discussed below. Figure 5.3.1 shows cross sectional views of the HI-STORM UMAX module as it was modeled in MCNP for accident condition. Note that the inlet and outlet vents were modeled explicitly; therefore, streaming through these components is accounted for in the dose calculations. Figure 5.3.2 depicts the inlet plenum, part of the outlet and additionally the dose locations used to obtain a dose profile across the HI-STORM UMAX lid and surrounding ISFSI pad.

Since the HI-STORM UMAX models analyzed in this chapter use principally the same MPC models from the References [5.0.2][5.0.3], all figures, conservative modeling approximations, and modeling differences for the MPCs reported in the corresponding FSARs are applicable to the evaluations in this chapter. The differences between models and drawings for the module are listed and discussed here.

1. Minor penetrations in the body of the module (e.g. lift locations) are not modeled as these are small localized effects which will not affect the off-site dose rates.

2. The MPC supports and guides were conservatively neglected. The bottom pedestal was also neglected in the MCNP model.

3. The inlet plenum support plates and inlet plenum corner gussets were not included in the model.

4. The insulation installed on the divider shell was conservatively modeled as a void.

5. The cavities representing the optional ICCPS tube and the empty VVM are modeled as empty volumes surrounded by soil, i.e. any steel liner or other material in these areas, or any covers that would be located on top of those cavities, are conservatively neglected

6. The air inlets at the bottom of the divider shell were not modeled. This has negligible effect as most of the radiation is emanating from the top and side of the MPC.

7. The radius of the Closure Lid Upper Shield and the thickness of the Closure Lid Outer Shell are modeled as 53.625" and 1", while the actual dimensions are 54.125" and 0.5", respectively. The effect of the deviation on the dose rates is minimal since streaming through the inlet and outlet vents is the dominating

contributor to the dose rates. Also, the total thickness of the shielding materials is not changed. The actual dimensions will be considered for the site specific calculations.

8. The concrete density of the SFP used in the model is 2.3 g/cm^3, which is more than the actual concrete density; however, the impact on the dose rate is insignificant. The concrete density of 2.4 g/cm^3 is used in the shielding analysis for part of the ISFSI Pad (the soil density of 1.7 g/cm^3 (106 lb/ft^3) is used for the remainder of the ISFSI Pad). This concrete density may be more than the actual density of the soil/concrete of the ISFSI Pad. The actual density will be considered for the site specific calculations.

5.3.1 Fuel Configuration

The active fuel region is modeled as a homogenous zone. Calculations were performed for the HI-STORM 100 [5.0.2] to determine the acceptability of homogenizing the fuel assembly versus explicit modeling. Based on these calculations it was concluded that it is acceptable to homogenize the fuel assembly without loss of accuracy. The width of the PWR homogenized fuel assembly is equal to 17 times the pitch. The end fittings and the plenum regions are also modeled as homogenous regions of steel. The masses of steel used in these regions are shown in Table 5.2.1. The axial description of the design basis fuel assemblies is provided in Table 5.3.1.

5.3.2 Regional Densities

Composition and densities of the various materials used in the HI-STORM UMAX system for shielding analyses are given in Table 5.3.2. All of the materials and their actual geometries are represented in the MCNP model.

5.3.3 HI-STORM UMAX Optional Features

The HI-STORM UMAX system utilizes some items with optional specifications, based on site specific projects. Table 5.3.3 provides material and thickness of these items, as used in the shielding analyses. As stated in Subsection 5.1.1, site specific chosen options will be considered in performing site specific shielding calculations to show the compliance with the regulatory limits.

Also, to further reduce the occupational and site boundary dose rates, an optional divider shell shield ring (attached to the divider shell) can be implemented. The drawings provided in Chapter 1 give more information about this shield ring specification. The results presented in this chapter are for the cases without this shield ring. However, in site specific dose evaluations, this shield ring may be credited if it is used.

Table 5.3.1

DESCRIPTION OF THE AXIAL MCNP MODEL OF THE FUEL ASSEMBLIES†

Region	Start (in.)	Finish (in.)	Length (in.)	Actual Material	Modeled Material
PWR					
Lower End Fitting	0.0	2.738	2.738	SS304	SS304
Space	2.738	3.738	1.0	zircaloy	void
Fuel	3.738	147.738	144.0	fuel & zircaloy	fuel & zircaloy
Gas Plenum Springs	147.738	151.916	4.178	SS304 & inconel	SS304
Gas Plenum Spacer	151.916	156.095	4.179	SS304 & inconel	SS304
Upper End Fitting	156.095	159.765	3.670	SS304 & inconel	SS304

† All dimensions start at the bottom of the fuel assembly. The length of the fuel shims must be added to the distances to determine the distance from the top of the MPC baseplate.

5.4 SHIELDING EVALUATION

Shielding analyses methodology applied to HI-STORM UMAX is identical with all the previous Holtec International's licensing applications. The MCNP5 code was used for all of the shielding analyses [5.0.4]. MCNP is a continuous energy, three-dimensional, coupled neutron-photon-electron Monte Carlo transport code. Continuous energy cross section data are represented with sufficient energy points to permit linear-linear interpolation between points. The individual cross section libraries used for each nuclide are those recommended by the MCNP manual. Cross section libraries are based on ENDF/B-V and ENDF/B-VI, except for Sn isotopes where the ENDL92 library is used, and uranium isotopes where LANL/T16 libraries are used. These are the default libraries for the MCNP code version used here [5.0.4]. MCNP has been extensively benchmarked against experimental data by the large user community. References [5.4.1], [5.4.2], and [5.4.3] are three examples of the benchmarking that has been performed.

The energy distribution of the source term, as described earlier, is used explicitly in the MCNP model. A different MCNP calculation is performed for each of the three source terms (neutron, decay gamma, and ^{60}Co). The axial distribution of the fuel source term is described in Table 2.1.5 and Figures 2.1.3 and 2.1.4 of the HI-STORM FW FSAR [5.0.3]. The PWR and BWR axial burn-up distributions were obtained from References [5.4.4] and [5.4.5], respectively, and have previously been utilized in the HI-STORM FSAR [5.0.2]. These axial distributions were obtained from operating plants and are representative of PWR and BWR fuel with burnups greater than 30,000 MWD/MTU. The ^{60}Co source in the hardware was assumed to be uniformly distributed over the appropriate regions.

It has been shown that the neutron source strength varies as the burnup level raised by the power of 4.2. Since this relationship is non-linear and since the burnup in the axial center of a fuel assembly is greater than the average burnup, the neutron source strength in the axial center of the assembly is greater than the relative burnup times the average neutron source strength. In order to account for this effect, the neutron source strength in each of the 10 axial nodes listed in Table 2.1.5 in [5.0.3] was determined by multiplying the average source strength by the relative burnup level raised to the power of 4.2. The peak relative burnups listed in Table 2.1.5, loc. cit., for the PWR fuel is 1.105. By employing the power of 4.2 relationship, the neutron source strength in the peak nodes for the PWR fuel increases by 37.6% ($1.105^{4.2}/1.105$). The total neutron source strength increases by 15.6%.

MCNP was used to calculate doses at the various desired locations. MCNP calculates neutron or photon flux and these values can be converted into dose by the use of dose response functions. This is done internally in MCNP and the dose response functions are listed in the input file in Appendix 5.A. The response functions used in these calculations are listed in Table 5.4.1 and were taken from ANSI/ANS 6.1.1, 1977 [5.4.6].

The dose rates at the various locations were calculated with MCNP using a two-step process. The first step was to calculate the dose rate for each dose location per starting particle for each neutron and gamma group in each basket region for each axial and azimuthal dose location. The

second step is to multiply the dose rate per starting particle for each energy group and basket location (i.e., tally output/quantity) by the source strength (i.e., particles/sec) in that group and sum the resulting dose rates for all groups and basket locations in each dose location. The normalization of these results and calculation of the total dose rate from neutrons, fuel gammas or Co-60 gammas is performed with the following equation.

$$T_{final} = \sum_{j=1}^{M}\left[\sum_{i=1}^{N}\frac{T_{i,j}}{Fm_i} * F_{i,j}\right] \quad \text{(Equation 5.4.1)}$$

where,

T_{final} = Final dose rate (rem/h) from neutrons, fuel gammas, or Co-60
N = Number of groups (neutrons, fuel gammas) or Number of axial sections (Co-60 gammas)
M = Number of regions in the basket
$T_{i,j}$ = Tally quantity from particles originating in MCNP in group/section i and region j (rem/h)(particles/sec)
$F_{i,j}$ = Fuel Assembly source strength in group i and region j (particles/sec)
Fm_i = Source fraction used in MCNP for group i

Note that dividing by Fm_i (normalization) is necessary to account for the number of MCNP particles that actually start in group i. Also note that T_i is already multiplied by a dose conversion factor in MCNP.

The standard deviations of the various results were statistically combined to determine the standard deviation of the total dose in each dose location. The estimated variance of the total dose rate, S^2_{total}, is the sum of the estimated variances of the individual dose rates S^2_i. The estimated total dose rate, estimated variance, and relative error [5.0.4] are derived according to Equations 5.4.2 through 5.4.5.

$$R_i = \frac{\sqrt{S_i^2}}{T_i} \quad \text{(Equation 5.4.2)}$$

$$S_{Total}^2 = \sum_{i=1}^{n} S_i^2 \quad \text{(Equation 5.4.3)}$$

$$T_{Total} = \sum_{i=1}^{n} T_i \quad \text{(Equation 5.4.4)}$$

$$R_{Total} = \frac{\sqrt{S_{Total}^2}}{T_{Total}} = \frac{\sqrt{\sum_{i=1}^{n} S_i^2}}{T_{Total}} = \frac{\sqrt{\sum_{i=1}^{n} (R_i \times T_i)^2}}{T_{Total}} \quad \text{(Equation 5.4.5)}$$

where,

i	=	tally component index
n	=	total number of components
T_{Total}	=	total estimated tally
T_i	=	tally *i* component
S^2_{Total}	=	total estimated variance
S^2_i	=	variance of the *i* component
R_i	=	relative error of the *i* component
R_{Total}	=	total estimated relative error

Note that the two-step approach outlined above allows the accurate consideration of the neutron and gamma source spectrum, and the location of the individual assemblies, since the tallies are calculated in MCNP as a function of the starting energy group and the assembly location, and then in the second step multiplied with the source strength in each group in each location. It is therefore equivalent to a one-step calculation where source terms are directly specified in the MCNP input files, except for the following approximations:

- Fuel is modeled as fresh UO_2 fuel (rather than spent fuel) in MCNP, with an upper bound (5%) enrichment.
- The axial burnup profile is modeled by assigning a source probability to each of the 10 axial sections of the active region, based on a representative axial burnup profile [5.0.2]. For fuel gammas, the probability is proportional to the burnup, since the gamma source strength changes essentially linearly with burnup. For neutrons, the probability is proportional to the burnup raised to the power of 4.2, since the neutron source strength is proportional to the burnup raised to about that power [5.4.7]. This is a standard approach that has been previously used in the licensing calculations for the HI-STAR cask models [5.4.8] and [5.4.9] and HI-STORM overpack models [5.0.2] and [5.0.3].

Tables 5.1.1 and 5.1.2 provide dose rates adjacent to and at 1 meter distance from the HI-STORM UMAX module during normal conditions for the MPC-32 and MPC-37, respectively. Table 5.1.3 provides the annual dose at 100 meters from a HI-STORM UMAX module for the MPC-32 and MPC-37 including the contribution from BPRAs. These results clearly demonstrate that the off-site dose from a HI-STORM UMAX is a small fraction of the off-site dose from the aboveground HI-STORM systems. In addition, Table 5.1.4 presents the dose for the accident condition caused by an impact of tornado borne missile on the radiation protection space boundary.

Soil is used to represent Self-hardening Engineering Subgrade in the models between the modules, with a composition and density shown in Table 5.3.2, representing typical soil conditions [5.4.10]. This is conservative, since the areas between and around the modules would contain engineered fill with a typical density higher than soil. Furthermore, the dose rates around the VVM are dominated by the streaming through the inlet and outlet vents, and not by direct radiation through the soil and concrete. To substantiate this, a complete dose rate profile across the lid and the ISFSI pad was determined. For the ISFSI pad, two conditions were evaluated, the normal condition and a condition where the streaming from the inlets and outlets were artificially blocked. For this second condition, dose rates were also calculated at a distance of 100 m from the VVM. This would indicate what portion of the dose rate results from direct radiation through the concrete and soil of the ISFSI pad as opposed to radiation from the streaming from the air inlet and outlet. The dose locations for the profile are shown in Figure 5.3.2, and are labeled alphabetically (A through X). The calculated dose rates are listed in Tables 5.4.2 and 5.4.3 for MPC-32 and MPC-37, respectively. The following conclusions can be drawn from the results:

- The profile did not reveal any locations with dose rates higher than those shown in Figure 5.1.1 and Tables 5.1.1 and 5.1.2.
- On the ISFSI pad, the dose rates are fairly low compared to other areas.
- At a distance of 100 m, the dose rate from the ISFSI pad surface contributes about 20% of the total dose rate.

It is to be noted that site specific analyses to demonstrate compliance with regulatory requirements should use appropriate site specific soil properties if these are substantially different from the properties used in this chapter.

The highest dose rate is observed for the side of the closure lid just above the inlet plenum zone. To investigate the effect of any streaming from the inlet plenum region, additional calculations were performed for dose locations above the plenum at various radial locations, on the level of dose point 2. Table 5.4.5 presents the calculated dose rates for those locations, as a function of the radial distance from dose location 2, for the MPC-37. The results show that the maximum dose rate occurs at a distance of about 4 feet from the surface point 2. This information should be used by the radiation protection team to ensure operational activities around the lid following ALARA principles.

5.4.1 Excavation Dose Analysis

ISFSIs with HI-STORM UMAX VVMs might be built in one stage or in several stages. If the ISFSI is built in several stages, then excavation work will be necessary in the vicinity of the section of the ISFSI that is already in operation and contains loaded modules. To protect workers from radiation from the loaded modules, a radiation protection space (RPS) boundary is defined around the ISFSI in the drawing in Section 1.5. The RPS boundary is placed so that in a radial direction, a minimum of 10.75 ft of engineered fill remains between the construction site and the closest loaded module. For a loaded module on the periphery of the ISFSI, this places the boundary at least 15 ft from the center of the module. For a loaded module not on the periphery

of the ISFSI, this places the boundary at least 22 feet from the center of the module. Calculations were conservatively performed with the 6.5 ft remaining fill (soil is used in the model) around a loaded VVM instead of the 10.75 ft required by the RPS. The dose rates at the surface of the excavation are presented in table 5.4.4 for both MPC-32 and MPC-37. This dose rate is very low, specifically lower than the dose rates at 1 m from the inlet/outlet vents of the modules. The dose rates at a construction site might therefore be dominated by the dose rates from the inlet/outlet vents, and depending on the loading condition of the operating part of the ISFSI, temporary shielding might be used to reduce dose rates to the construction site. It is to be noted that 6.5 feet of soil is considered for this purpose without any concrete enclosure wall.

[§§§] Photon dose rates include dose rates from fuel gammas, n-gamma reactions and Co-60 sources. In addition, BPRAs are included in the photon dose rate.

5.5 REGULATORY COMPLIANCE

Chapters 1, 2 and this chapter of this FSAR describe in detail the shielding structures, systems, and components (SSCs) important-to-safety.

The shielding-significant SSCs important-to-safety have been evaluated in this chapter and their impact on personnel and public health and safety resulting from operation of an independent spent fuel storage installation (ISFSI) utilizing the HI-STORM UMAX System has also been evaluated.

In summary it can be concluded that the shielding of the HI-STORM UMAX System is in compliance with 10CFR72 and satisfies the applicable design and acceptance criteria including 10CFR20. Thus, this shielding evaluation provides reasonable assurance that the HI-STORM UMAX system will allow safe storage of spent fuel in full conformance with 10CFR72.

CHAPTER 6: CRITICALITY EVALUATION

6.0 INTRODUCTION

This chapter discusses the criticality safety of the HI-STORM UMAX system. Criticality safety depends foremost on the MPC and fuel basket, and the MPC content. Those are identical between the HI-STORM UMAX and the HI-STORM FW. Criticality safety of the HI-STORM UMAX is therefore demonstrated in this chapter by reference to criticality evaluations documented in Chapter 6 of the HI-STORM FW FSAR [2.0.1], with appropriate recognition of the differences in the overpack configuration. As noted in other chapters, Revision 3 of the HI-STORM FW FSAR has been added to this docket to eliminate the need to consult the HI-STORM FW FSAR in another docket.

6.1 ACCEPTANCE CRITERIA

The acceptance criteria for criticality evaluations for the HI-STORM UMAX system are presented in Subsection 2.0 of this FSAR.

6.2 EVALUATION

During storage conditions in the HI-STORM UMAX system, the maximum k_{eff} will be significantly below the limiting maximum k_{eff} since the MPC is internally dry. Under this condition, the configuration is very similar in all HI-STORM models, which consists of an internally dry MPC, an air gap between the MPC and the overpack, a steel shell or shells and concrete (above-ground) or soil (underground). Results for the HI-STORM UMAX VVM would therefore be practically identical to the results listed for storage conditions in Chapter 6 of the HI-STORM FW FSAR [2.0.1]. Any small differences in results would not affect the principal conclusions, since the maximum k_{eff} under storage conditions (dry inert environment) is substantially below the regulatory limit. Note that the analysis for the MPCs in the HI-STORM documented in Chapter 6 of the HI-STORM FW FSAR [2.0.1] conservatively assume that the gap between the MPC and the HI-STORM is flooded with water, thus increasing the neutron reflection compared to a dry cavity [2.0.1, Section 6.1]. Flooding under accident conditions of the UMAX is therefore also covered by the calculations for the HI-STORM FW. All other normal, off-normal and accident conditions in the HI-STORM UMAX system are identical to those in the HI-STORM FW, since the MPCs, including content, and HI-TRAC are identical between the two systems.

In summary, the limiting condition for storage of MPCs in HI-STORM UMAX is identical to the limiting conditions for the HI-STORM FW from a criticality perspective, and all other normal, off-normal and accident conditions are identical or equivalent between the systems from a criticality perspective. All results and conclusions for criticality safety of the MPCs previously analyzed in Chapter 6 of the HI-STORM FW FSAR [2.0.1] remain applicable to the HI-STORM UMAX system, and no additional calculations to demonstrate criticality safety are required for the HI-STORM UMAX system.

CHAPTER 7: CONFINEMENT EVALUATION

7.0 INTRODUCTION

This chapter discusses the confinement safety of the HI-STORM UMAX System. Confinement of all radioactive materials in the HI-STORM UMAX system is provided by the MPC. MPCs are identical between the HI-STORM UMAX and the HI-STORM FW. All normal, off-normal and accident conditions relevant for confinement are identical between the HI-STORM UMAX and the HI-STORM FW, and there are no new conditions for the HI-STORM UMAX system that would require additional confinement analyses. Confinement safety of the HI-STORM UMAX is therefore demonstrated in this chapter by reference to confinement evaluations documented in Chapter 7 of the HI-STORM FW [2.0.1], with appropriate recognition of the differences in the overpack configuration. For ease of reference, the entire body of Revision 3 of the HI-STORM FW FSAR has been placed in this docket.

7.1 ACCEPTANCE CRITERIA

The acceptance criteria for confinement evaluations for the HI-STORM UMAX system are presented in Chapter 2 of this FSAR.

7.2 EVALUATION

The MPCs will be stored in the HI-STORM UMAX VVM in a passive state just as they are stored in the above ground overpacks described in the HI-STORM FW FSAR. Furthermore, as shown in Chapter 4, the temperature field in the MPC is engineered to be bounded by that determined in the HI-STORM FW FSAR. Therefore, the stress levels in the MPC pressure retaining boundary will be bounded by that in its certification basis value in the HI-STORM FW FSAR which leads to the axiomatic conclusion that the confinement integrity determinations reached in the HI-STORM FW MPC's also apply to storage in HI-STORM UMAX.

In summary, the storage configuration of MPCs in HI-STORM UMAX is identical to the storage configuration in the HI-STORM FW from a confinement perspective. Therefore, all descriptions and conclusions for the confinement system presented in Chapter 7 of the HI-STORM FW [2.0.1] remain applicable to the HI-STORM UMAX system, and no additional confinement evaluations are required for the HI-STORM UMAX system.

CHAPTER 8: MATERIAL EVALUATION

8.1 INTRODUCTION

This chapter presents an assessment of the materials selected for use in the HI-STORM UMAX system components identified in the licensing drawings in Section 1.5. The assessment of the materials selected for use in the MPC and HI-TRAC (i.e., components common to HI-STORM UMAX system and the previously licensed HI-STORM FW system) is provided in Chapter 8 of the HI-STORM FW FSAR. Material considerations pertaining to the components common to the "FW" and the "UMAX" systems, are referenced in this FSAR, as appropriate, to the HI-STORM FW FSAR. To facilitate convenient access to the referenced material, the latest edition of the HI-STORM FW FSAR has been placed in this docket and a list of “FW” FSAR sections germane to this chapter is provided in the (unnumbered) table below.

APPLICABLE SECTIONS OF HI-STORM FW FSAR		
Location of UMAX FSAR	**Subject of the Reference**	**Location in HI-STORM FW FSAR, Revision 3***
Section 8.1	Material evaluation for use in the MPCs and HI-TRAC	Paragraph 8.2.1.2, 8.2.1.2.i and 8.2.1.2.iii
Table 8.1.1	Performance of materials used in the MPC and HI-TRAC for short term operations	Table 8.1.1 and 8.1.3
Table 8.1.4	Failure and degradation mechanisms related to the performance of materials used in the MPCs and HI-TRAC for short term and storage operations	Table 8.1.4
Paragraph 8.2.1.2.iv	Material selection evaluation of austenitic stainless steel	Paragraph 8.2.1.2.i
Section 8.4	Material Properties for MPCs and HI-TRAC	Paragraph 8.4.4.1
Section 8.5	Welding material and welding specification for MPC and HI-TRAC	Section 8.5
Section 8.7	Coatings and corrosion mitigation techniques for MPC and HI-TRAC	Sub-Section 8.7.2 and 8.7.3
Section 8.8	Gamma and neutron shielding materials used in HI-TRAC	Section 8.8
Section 8.9	Neutron Absorbing Materials	Section 8.9
Section 8.10	Seals for the HI-TRAC bottom lid	Section 8.11

* For convenience of reference, the specific revision of the HI-STORM FW FSAR that is referenced in the safety analysis herein is placed in this docket. Updated versions of the HI-STORM FW FSAR shall be placed in this docket as necessary so as to ensure that the safety analyses on the "UMAX" docket (72-1040) remain aligned with the material referenced in the HI-STORM FW FSAR.

Section 8.11	Chemical and galvanic reactions related to the MPC and HI-TRAC	Section 8.12
Section 8.12	Fuel cladding integrity during short term operations	Section 8.13
Section 8.13	Examination and testing requirements for the MPC and HI-TRAC	Section 8.14.1

In this chapter and in Chapters 2 and 3 of this FSAR, the significant mechanical, thermal, radiological, and metallurgical properties of materials identified for use in the components of the HI-STORM UMAX System VVM and ISFSI are presented.

The HI-STORM UMAX components must withstand the environmental conditions experienced during normal operation, off-normal conditions, and accident conditions for the entire service life. The major structural materials used in HI-STORM UMAX System are discussed in this chapter.

Chapter 1 provides a general description of the HI-STORM UMAX System including information on materials of construction. The ITS categories of the principal materials of construction in the HI-STORM UMAX VVM and ISFSI system are identified in the drawing package provided in Section 1.5.

The Materials selected for the HI-STORM UMAX VVM are the same as those used in its anatomically similar predecessor, HI-STORM 100U VVM, licensed in Docket number 72-1014, except the subgrade between the ISFSI pad and the Support Foundation Pad (SFP) which is labeled as Space A in Figure 2.4.4 is restricted to CLSM or lean concrete. Therefore, the material considerations for HI-STORM UMAX are substantially parallel to those for HI-STORM 100U.

Nevertheless, for completeness, it is necessary that the material considerations applicable to HI-STORM UMAX be independently evaluated for compliance with the ISG-15 [8.1.1] which contains the latest NRC position in this matter. The principal purpose of ISG-15 is to evaluate the dry cask storage system to ensure adequate material performance of components deemed to be important-to-safety at an independent spent fuel storage installation (ISFSI) under normal, off-normal, and accident conditions. Guidance on performing the safety evaluation of the materials is adopted directly from ISG-15.

ISG-15 sets down the following general acceptance criteria for material evaluation:

- The safety analysis report should describe all materials used for dry spent fuel storage components important-to-safety, and should consider the suitability of those materials for their intended functions in sufficient detail to evaluate their effectiveness in relation to all safety functions.

- The dry spent fuel storage system should employ materials that are compatible with wet and dry spent fuel loading and unloading operations and facilities. These materials should not degrade to the extent that a safety concern is created.

The information compiled in this chapter seeks to address the above acceptance criteria in full measure for the HI-STORM UMAX VVM and ISFSI. To perform the material suitability evaluation, it is necessary to characterize the following for each component: (i) the applicable environment, (ii) potential degradation modes and (iii) potential hazards to continued effectiveness of the selected material.

This FSAR seeks to qualify previously licensed MPCs (Table 1.2.1) in the HI-STORM FW docket for long-term storage in the HI-STORM UMAX modules The information required to address the short-term operations for the MPC and HI-TRAC are contained in Chapter 10 of the HI-STORM FW FSAR. The material evaluation effort, therefore, is directed towards the long-term storage and its consequences to the system's continued safety. Tables 8.1.1 and 8.1.2 provide a summary of the environmental states, potential degradation modes, and hazards applicable to the HI-STORM UMAX modules. Table 2.6.2 provides a listing of permissible materials used in the HI-STORM UMAX system. Table 8.1.3 provides the listing of material types that are important to safety and are subject to the ambient environmental of an ISFSI.

To provide a proper context for the subsequent evaluations, the potential degradation mechanisms applicable to the ventilated systems are summarized in Table 8.1.4. The degradation mechanisms listed in Table 8.1.4 are considered in the suitability evaluation presented in this chapter.

The material evaluation presented in this chapter is intended to be complete, even though *a' priori* conclusion of the adequacy of the materials can be made on the basis of the following facts:

i. The materials used in HI-STORM UMAX VVM are identical to those used in the widely deployed HI-STORM 100 System (Docket No. 72-1014) [8.1.2] including its underground VVM denoted as HI-STORM 100U and the HI-STORM FW system (Docket number 72-1032) [8.1.3].

ii. The thermal environment in the HI-STORM UMAX system emulates other HI-STORM models in all respects.

iii. The MPC transfer operations, described in Chapter 9 herein, are identical to those that have been practiced in the HI-STORM 100 system throughout the industry.

The organization of technical information in this chapter mirrors the format and content of Chapter 8 in the HI-STORM FW FSAR and complies with the guidance in NUREG-1536 [8.1.4]

Table 8.1.1

CONSIDERATIONS GERMANE TO PERFORMANCE OF MATERIALS USED IN THE MPCs IN LONG TERM STORAGE IN HI-STORM UMAX

Consideration	**Environment**
Environment	MPC's internal environment is hot (≤ 752°F), inertized and dry. Temperature of the MPC internals cycles vary gradually due to changes in the environmental temperature.
Potential degradation modes	Corrosion of the external surfaces of the MPC (stress, corrosion, cracking, pitting, etc.).
Potential hazards to effective performance	Blockage of ventilation ducts under an extreme environmental phenomenon leading to a rapid heat-up of the MPC internals.

Note that the considerations germane to the performance of materials used in the MPC and HI-TRAC for short term operations are addressed in Section 8.1 of the HI-STORM FW FSAR.

Table 8.1.2

CONSIDERATIONS GERMANE TO THE HI-STORM UMAX VVM MATERIAL PERFORMANCE

Consideration	**Performance Data**
Environment	Cool ambient air is progressively (but marginally) heated as it flows up the annulus between the Divider Shell and the MPC heating the inside surface of the cask and cooling the outside surface of the MPC. The heated air has reduced relative humidity the warmer it gets. As a result, the bottom external surface of the Closure Lid is heated and the top external surfaces are in contact with ambient air, rain, and snow, as applicable. The exterior surfaces of the CEC are in contact with either engineered fill or concrete (concrete encasement or "free-flow "concrete) and may be subjected to cathodic protection, as applicable.
Potential degradation modes	Peeling or perforation of surface preservatives on steel surfaces and corrosion of exposed steel surfaces.
Potential hazards to effective performance	Blockage of ducts by debris leading to overheating of the concrete in the overpack, scorching of the cask by proximate fire, lightning.

Table 8.1.3
MATERIAL TYPES IN THE HI-STORM UMAX SYSTEM COMPONENTS EXPOSED TO THE LONG-TERM AMBIENT ENVIRONMENT

	Material Type	**Components and Their Surfaces Exposed to Ambient Environment**
1.	Low carbon steel	• All surfaces of the closure lid • Internal surfaces of the CEC (expose to air) • External surfaces of the CEC (exposed to buffer concrete) or subgrade • Internal and External surfaces of the Divider shell
2.	Shielding concrete	• The outside surface of the ISFSI pad
3.	Alloy X Austenitic Stainless Steel	• External surfaces of the stored MPC • MPC Guides and MPC support surfaces inside the CEC. • Surfaces of the closure lid (optional per Section 1.5) • Internal surfaces of the CEC (optional per Section 1.5) • External surfaces of the CEC (optional per Section 1.5) • Internal External surfaces of the Divider shell (optional per Section 1.5)
4.	Elastomeric Gasket	• Closure Lid Seal • Divider Shell Seal

Table 8.1.4

FAILURE AND DEGRADATION MECHANISMS*

	Mechanism	Area of Performance Affected	Vulnerable Parts
1.	General Corrosion	Structural capacity	All carbon steel parts
2.	Stress Corrosion Cracking	Structural	Austenitic Stainless Steel
3.	Galling	Equipment handling and deployment	Threaded Fasteners
4.	Fatigue	Structural Integrity	Fuel Cladding & Bolting
5.	Brittle Fracture	Structural Capacity	Thick Steel Parts
6.	Boron Depletion	Criticality Control	Neutron Absorber

Note that the failure and degradation mechanisms related to the performance of materials used in the MPC and HI-TRAC for short term and storage operations are addressed in Section 8.1 of the HI-STORM FW FSAR.

* This table lists all potential (generic) mechanisms, whether they are credible for the HI-STORM UMAX System or not. The viability of each failure mechanism is discussed later in this chapter.

8.2 MATERIAL SELECTION

The acceptance criteria for the materials subject to long-term storage conditions in HI-STORM UMAX are extracted from ISG-15[8.1.1] as follows:

a. The material properties of a dry spent fuel storage component should meet its service requirements in the proposed cask system for the duration of the licensing period.

b. The materials that comprise the dry spent fuel storage should maintain their physical and mechanical properties during all conditions of operations. The spent fuel should be readily retrievable without posing operational safety problems.

c. Over the range of temperatures expected prior to and during the storage period, any ductile-to-brittle transition of the dry spent fuel storage materials, used for structural and nonstructural components, should be evaluated for its effects on safety.

d. Dry spent fuel storage gamma shielding materials should not experience slumping or loss of shielding effectiveness to an extent that compromises safety. The shield should perform its intended function throughout the licensed service period.

e. Dry spent fuel storage materials used for neutron absorption should be designed to perform their safety function.

f. Dry spent fuel storage protective coatings should remain intact and adherent during all loading and unloading operations within wet or dry spent fuel facilities, and during long-term storage.

It is recognized that the qualification of the materials used in the MPC types and the HI-TRAC transfer cask is documented in Section 8.2 of the HI-STORM FW FSAR. The material selection opportunities for the HI-STORM UMAX system, therefore, are limited to the VVM module assembly components and the reinforced concrete structures that support or surround them.

However, to obviate any new material qualification effort, the materials permitted for the HI-STORM UMAX system *are limited to those certified in other HI-STORM 100 and HI-STORM FW dockets*. The material qualification information presented in this chapter is accordingly adopted from Docket Number 72-1032.

8.2.1 Structural Materials

8.2.1.1 Cask Components and Their Constituent Materials

The major structural material that is used in the HI-STORM UMAX VVM is steel. The concrete in the VVM Closure Lid does not play a major structural role but is present in large quantity for the main purpose of shielding. The major structural materials in the ISFSI structures are the concrete and rebars in the Support Foundation Pad, the ISFSI Pad, and the Self-hardening Engineered Subgrade (SES).

8.2.1.2 Synopsis of Structural Materials

i. Carbon Steel, Low-Alloy Steel

Materials for the HI-STORM UMAX VVM are selected to preclude brittle fracture. Details of discussions are provided in Section 3.1 and Section 8.4, as applicable. The fracture toughness test requirements specified in Table 3.1.9 apply to the HI-STORM UMAX Closure Lid ferritic structural steels including any "significant-to-handling" (STH) parts of the Closure Lid.

ii. Reinforced Concrete

All reinforced concrete load bearing structures (concrete and rebar) in the HI-STORM UMAX ISFSI will conform to stress criteria of ACI-318(2005) [8.2.1]. Section 3.3 provides properties for reinforced concrete to be used for the HI-STORM UMAX interfacing ISFSI structures. The service life of the ISFSI structures is specified to be the same as that of the HI-STORM UMAX VVM.

iii. Self-hardening Engineered Subgrade

The SES material (i.e., lean concrete or CLSM) used in the HI-STORM UMAX ISFSI will conform to the stress criteria of ACI-318(2005) or ACI-229(1999). Tables 2.3.2 and 3.3.4 provide the critical properties for the SES material used for HI-STORM UMAX ISFSI safety analyses. In the interest of a reliably robust design and long service life, additional performance properties of CLSM are listed in table below. The service life for the SES is the same as that of the VVM and ISFSI reinforced concrete.

iv. Austenitic Stainless Steel

Austenitic stainless steel may be used for certain components of the HI-STORM UMAX VVM. Chapter 3 provides the structural evaluation for the HI-STORM UMAX VVM using the governing structural materials. Since stainless steel materials do not undergo a ductile-to-brittle transition in the minimum permissible service temperature range of the HI-STORM UMAX System, brittle fracture is not a concern for stainless steel components. It is

recognized that austenitic stainless steels are qualified for use with other HI-STORM UMAX System components (namely Alloy X for the MPC) by the HI-STORM FW FSAR.

Additional CLSM Performance Properties*		
Performance Property	**Test Property**	**Nominal Value**
Corrosive Resistance	pH Resistivity Permeability	7.5 – 11.5 > 279000 ohm-cm < 10^{-5} cm/sec
Flowability	Flow	6” – 8” (ASTM D 6103)
Excavatability	Unconfined Compressive Strength	Not excavatable since compressive strength is greater than 300 psi
Permeability	Water Permeability	< 10^{-5} cm/sec
Strength	Penetration Resistance	> 650
Acidity/Alkalinity	pH	7.5 – 11.5
Note: * These properties are not used in HI-STORM UMAX safety analyses; nominal values obtained from References [8.2.3], [8.2.4], and [8.2.5] are tabulated for information only.		

Chapter 3 discusses the structural evaluations of the HI-STORM UMAX System components and ISFSI structures. It is demonstrated that the structural steel components of the HI-STORM UMAX VVM and the SFP concrete meet the allowable stress limits for normal, off-normal, and accident loading conditions as applicable. The analyses documented in Chapter 3 also demonstrate that the SES remains stable under the Design Basis Earthquake condition and provides sufficient protection to the stored MPC even if any side of the self hardening sub-grade (SES) is fully exposed during excavation for ISFSI expansion.

8.2.2 Non-Structural Materials

i. Plain Concrete

Plain concrete is specified for the VVM Closure Lid for its shielding properties and also as an encasement around the exterior of the VVM CEC shell, if required, for its corrosion mitigation properties. Lean concrete (plain concrete with a lower cement ratio and hence lower compressive strength) is also specified as a suitable material for the structural subgrade below the ISFSI pad. The requirements on the shielding concrete are specified in Table 2.3.2 in Chapter 2.

The shielding performance of the plain concrete is maintained by ensuring that the minimum concrete density is met during construction and the allowable concrete temperature limits are not exceeded. The thermal analyses for normal and off-normal conditions are carried out in this FSAR to insure that the plain concrete does not exceed the allowable long term temperature limit provided in Table 2.3.7.

ii. Insulation

The Divider Shell is lined with insulation on its outer surface to prevent excessive heating of the ISFSI pad. The insulation selected shall be suitable for high temperature and high humidity operation and shall be foil faced, jacketed, or otherwise made water-resistant to ensure the required thermal resistance is maintained in accordance with Chapter 4. The high zinc content present in the coating of the Divider Shell provides protection for the jacketing or foil from the potential of galvanic corrosion. To ensure adequate radiation resistance, the insulation blanket does not contain any organic binders. The damage threshold for ceramics is known to be approximately $1x10^{10}$ Rads. Chloride corrosion is not a concern since chloride leachables are limited and sufficiently low. Stress corrosion cracking of the foil or jacketing, whether made from stainless steel or other material, is not an applicable corrosion mechanism due to minimal stresses derived from self-weight. The foil or jacketing and attachment hardware shall either have sufficient corrosion resistance (e.g., stainless steel, aluminum, or galvanized steel) or shall be protected with a suitable surface preservative. The insulation is adequately secured to prevent blockage of the ventilation passages in case of failure of a single attachment (strap, clamp, bolt or other attachment hardware). The following table provides the acceptance criteria for the selection of insulation material for the VVM assembly and ranks them in order of importance.

Acceptance Criteria for the Selection of the Insulation Material	
Rank	**Criteria**
1	Adequate thermal resistance (See Table 4.1.1)
2	Adequate high temperature resistance (See Table 2.3.7)
3	Adequate humidity resistance
4	Adequate radiation resistance
5	Adequate resistance to the ambient environment
6	Sufficiently low chloride leachables
7	Adequate integrity and resistance to degradation and corrosion during long-term storage

Kaowool® ceramic fiber insulation [8.2.2] is selected as one that satisfies the acceptance criteria to the maximum degree. The Kaowool® insulation material provides excellent resistance to chemical attack and is not degraded by oil or water. Alternatively, a Holtec-approved equivalent that meets the above acceptance criteria may be used.

8.2.3 Critical Characteristics and Equivalent Materials*

As defined in the Glossary, the *critical characteristics* of a material are the properties that the material must possess to enable the part in which it is used to render its intended design function. However, material designations adopted by the International Standards Organization (ISO) also affect the type of steels and steel alloys available from suppliers around the world. Therefore, it is necessary to provide for the ability in this FSAR to substitute materials with equivalent materials in the manufacture of the equipment governed by this FSAR.

As defined in this FSAR, the term “Equivalent Material” has a specific meaning: Equivalent materials are those that can be substituted for each other without adversely affecting the safety function of the SSC (system, structure, and component) in which the substitution is made. Substitution by an equivalent material can be made after the equivalence in accordance with the provisions of this FSAR has been established.

The concept of equivalent materials explained above has been previously used in the HI-STORM 100 FSAR [8.1.2] to qualify four different austenitic stainless steel alloys (ASME SA240 Types 304, 304LN, 316, and 316LN) to serve as candidate MPC materials.

The equivalence of materials is directly tied to the notion of *critical characteristics*. A critical characteristic of a material is a material property whose value must be specified and controlled to ensure an SSC will render its intended function. The numerical value of the critical characteristic invariably enters in the safety evaluation of an SSC and therefore its range must be guaranteed. To ensure that the safety calculation is not adversely affected, properties such as Yield Strength, Ultimate Strength, and Elongation must be specified as minimum guaranteed values. However, there are certain properties where both minimum and maximum acceptable values are required (in this category lies specific gravity and thermal expansion coefficients).

Table 8.2.1 lists the array of properties typically required in safety evaluation of an SSC in dry storage and transport applications. The required value of each applicable property, guided by the safety evaluation needs, defines the critical characteristics of the material. The subset of applicable properties for a material depends on the role played by the material. The role of a material in the SSC is divided into three categories:

* Materials in this section have been adapted from HI-STORM FW FSAR and therefore in Arial font [8.1.3]

Type	Technical Area of Applicability
S	Those needed to ensure structural compliance
T	Those needed to ensure thermal compliance (temperature limits)
R	Those needed to ensure radiation compliance (criticality and shielding)

The properties listed in Table 8.2.1 are the ones that may apply in a dry storage or transport application.

The following procedure shall be used to establish acceptable equivalent materials for a particular application:

Criterion i: Functional Adequacy:
Evaluate the guaranteed critical characteristics of the equivalent material against the values required to be used in safety evaluations. The required values of each critical characteristic must be met by the minimum (or maximum) guaranteed values (MGVs of the selected material).

Criterion ii: Chemical and Environmental Compliance:
Perform the necessary evaluations and analyes to ensure the candidate material will not excessively corrode or otherwise degrade in the operating environment.

A material from another designation regime that meets Criteria (i) and (ii) above is deemed to be an acceptable material, and hence, equivalent to the candidate material. For ITS materials used with the HI-STORM UMAX VVM, recourse to equivalent materials shall be made only if the designated material in this FSAR is not readily available or the use of another equivalent material is deemed to produce a desirable outcome such as improvement in fabricability, absence of lamination, tolerance adherence, etc. An example of an acceptable substitution is replacing carbon steel plate stock (A515 Gr. 70 or 516 Gr. 70) with forging (A105 or A350 LF-2).

As can be ascertained from its definition in the glossary, the *critical characteristics* of the material used in a subcomponent depend on its function. The Closure Lid, for example, serves as a shielding device and as a physical barrier to protect the MPC against loadings under all service conditions, including the Extreme Environmental phenomena. Therefore, the critical characteristics of steel used in the lid are its strength (yield and ultimate), ductility, and fracture resistance.

The appropriate critical characteristics for structural components of the HI-STORM UMAX System, therefore, are:

- Material yield strength, σ_y
- Material ultimate strength, σ_u
- Elongation, ε

- Charpy impact strength at the lowest service temperature for the part, C_i (Unless exempted by other provisions in the governing code)

Thus, the carbon steel specified in the drawing package can be substituted with different steel so long as each of the four above properties in the replacement material is equal to or greater than their minimum values used in the qualifying analyses used in this FSAR.

In the event that one or more of the critical characteristics of the replacement material is slightly lower than the original material, then the use of the §72.48 process shall be necessary to ensure that all regulaory predicates for the material substitution are fully satisfied.

Table 8.2.1

TYPICAL CRITICAL CHARACTERISTICS OF MATERIALS REQUIRED FOR SAFETY EVALUATION OF STORAGE AND TRANSPORT SYSTEMS

	Property	**Type**	**Purpose**	**Bounding Acceptable Value**
1.	Minimum Yield Strength	S	To ensure adequate elastic strength for normal service conditions	Min.
2.	Minimum Tensile Strength	S	To ensure material integrity under accident conditions	Min.
3.	Young's Modulus	S	For input in structural analysis model	Min.
4.	Minimum elongation of δ_{min}, %	S	To ensure adequate material ductility	Min.
5.	Impact Resistance at Ambient Conditions	S	To ensure protection against crack propagation	Min.
6.	Maximum Allowable Creep Rate	S	To prevent excessive deformation under steady state loading at elevated temperatures	Max.
7.	Thermal conductivity (minimum averaged value in the range of ambient to maximum service temperature, t_{max})	T	To ensure that the basket will conduct heat at the rate assumed in its thermal model	Min.
8.	Minimim Emmissivity	T	To ensure that the thermal calculations are performed conservatively.	Min.
9.	Specific Gravity	S (and R)	To compute weight of the component (and shielding effectiveness)	Max. (and Min.)
10.	Thermal Expansion Coefficient	T (and S)	To compute the change in basket dimension due to temperature (and thermal stresses)	Min. (and Max.)
11.	Boron-10 Content	R	To control reactivity	Min.

8.3 APPLICABLE CODES AND STANDARDS

The principle codes and standards applied to the HI-STORM UMAX System components are the ASME Code Section II [8.3.1], the ACI code [8.2.1], the ASTM Standards, and the ANSI standards. Chapter 1 provides details of the specific applications of these codes and standards along with the other codes and standards that are applicable. The principle codes and standards applied to the MPC and HI-TRAC are described in Section 8.3 of the HI-STORM FW FSAR and are not repeated here.

Chapter 2 discusses factored load combinations for ISFSI pad design per NUREG-1536 [8.1.4]. Codes ACI 360R-92, "Design of Slabs on Grade"; ACI 302.1R, "Guide for Concrete Floor and Slab Construction"; and ACI 224R-90, "Control of Cracking in Concrete Structures" are also used in the design and construction of the concrete pad, as appropriate. Section 2.2 elaborates on the specific applications of the ASME Boiler and Pressure Vessel code for the HI-STORM UMAX System.

Chapter 3 provides allowable stresses and stress intensities for various materials extracted from applicable ASME code sections for various service conditions. This chapter also provides discussions on fracture toughness test requirements per ASME code sections. Mechanical properties of materials are extracted from applicable ASME sections [8.3.1], [8.3.2] and are tabulated for various materials used in HI-STORM UMAX System. Concrete properties are from ACI 318-2005 code.

In order to meet the requirements of the codes and standards the materials must conform to the minimum acceptable physical strengths and chemical compositions and the fabrication procedures must satisfy the prescribed requirements of the applicable codes.

Additional codes and standards applicable to welding are discussed in Section 8.5 and those for the bolts and fasteners are discussed in Section 8.6.

Review of the above shows that the identified codes and standards are appropriate for the material control of major components. Additional material control is identified in material specifications. Material selections are appropriate for environmental conditions to be encountered during loading, unloading, transfer, and storage operations. The materials and fabrication of major components are suitable based on the applicable codes of record.

8.4 MATERIAL PROPERTIES

This section provides discussions on material properties that mainly include mechanical and thermal properties. Additional discussions related to materials used in the MPC and HI-TRAC are presented in Section 8.4 of the HI-STORM FW FSAR. The material properties used in the design and analysis of the HI-STORM UMAX System are obtained from established industry sources such as the ASME Boiler and Pressure Vessel Code [8.3.1], ASTM publications, handbooks, textbooks, other NRC-reviewed SARs, and government publications, as appropriate.

8.4.1 Mechanical Properties

Section 3.3 presents mechanical properties of all ITS materials used in the HI-STORM UMAX System. The structural materials include Alloy X, carbon steel, low-alloy and nickel-alloy steel, bolting materials, and weld materials. The properties include yield stress, mean coefficient of thermal expansion, ultimate stress, and Young's modulus of these materials and their variations with temperature. Certain mechanical properties are also provided for nonstructural materials such as concrete used for shielding.

The discussion on mechanical properties of materials in Chapter 3 provides reasonable assurance that the class and grade of the structural materials are acceptable under the applicable construction code of record. Selected parameters such as the temperature dependent values of stress allowables, modulus of elasticity, Poisson's ratio, density, thermal conductivity, and thermal expansion have been appropriately defined in conjunction with other disciplines. The material properties of all code materials are guaranteed by procuring materials from Holtec-approved vendors through the so-called "material dedication" process*, if necessary.

8.4.2 Thermal Properties

Section 4.2 presents thermal properties of materials used in the MPC such as Alloy X, Metamic-HT, aluminum shims and helium gas; materials present in HI-STORM UMAX such as carbon steel, stainless steel and concrete; and materials present in HI-TRAC transfer cask that include carbon steel, lead and demineralized water. The properties include density, thermal conductivity, heat capacity, viscosity, and surface emissivity/absorptivity. Variations of these properties with temperature are also provided in tabular forms.

The thermal properties of fuel (UO_2) and fuel cladding are also reported in Section 4.2. Thermal properties are obtained from standard handbooks or established text books (see Table 4.2.1).

* Dedication is a term of art in nuclear quality assurance.

8.4.3 Low Temperature Ductility of Ferritic Steels*

The risk of brittle fracture in the HI-STORM UMAX components is eliminated by utilizing materials that maintain high fracture toughness under "cold" conditions (temperatures < -40 degrees F)

The MPC canister is constructed from a menu of stainless steels termed Alloy X. These stainless steel materials do not undergo a ductile-to-brittle transition in the minimum service temperature range of the HI-STORM UMAX system. Therefore, brittle fracture is not a concern for the MPC components. Such an assertion cannot be made *a' priori* for the HI-STORM storage overpack and HI-TRAC transfer cask that contain ferritic steel parts. In general, the impact testing requirement for the HI-STORM overpack and the HI-TRAC transfer cask is a function of two parameters: the Lowest Service Temperature (LST)† and the normal stress level. The significance of these two parameters, as they relate to impact testing of the VVM is discussed below.

In normal storage mode, the LST of the HI-STORM storage overpack structural members may reach -40°F in the limiting condition wherein the spent nuclear fuel (SNF) in the contained MPCs emits no (or negligible) heat and the ambient temperature is at -40°F (design minimum per Chapter 2: Principal Design Criteria). During the heavy load handling operations at an ISFSI, the applicable lowest service temperature in the MPC's in FW docket is limited to a threshold ambient temperature below which lifting and handling of the HI-TRAC transfer cask is not permitted by the Technical Specification. Therefore, two distinct LSTs are applicable to load bearing metal parts within the HI-STORM UMAX overpack and the HI-TRAC transfer cask; namely,

LST = 0°F for the HI-STORM overpack during handling operations and for the HI-TRAC transfer cask during all normal operating conditions.

LST = -40°F for the HI-STORM overpack during all non-handling operations (i.e., normal and off-normal storage mode).

Parts used to lift the overpack or the transfer cask, which include the top flange in HI-TRAC, are referred to as "significant-to-handling" (STH) parts. All other parts of the overpack and the transfer cask will be referred to as "NF" components. It is important to ensure that all materials designated as "NF" or "STH" parts possess sufficient fracture toughness to preclude brittle fracture. For the STH parts, the necessary level of protection against brittle fracture is deemed to exist if the NDT (nil ductility transition) temperature of the part is at least 40°F below the LST.

It is well known that the NDT temperature of steel is a strong function of its composition, manufacturing process (viz., fine grain vs. coarse grain practice), thickness, and heat treatment.

* This subsection has been copied from the HI-STORM 100 FSAR (Section 3.1) without any substantive change.
† LST (Lowest Service Temperature) is defined as the daily average for the host ISFSI site when the outdoors portions of the "short-term operations" are carried out.

For example, it is well known that increasing the carbon content in carbon steels from 0.1% to 0.8% leads to the change in NDT from -50°F to approximately 120°F. Likewise, lowering of the normalizing temperature in the ferritic steels from 1200°C to 900°C may lower the NDT from 10°C to -50°C. It therefore follows that the fracture toughness of steels can be varied significantly within the confines of the ASME Code material specification set forth in Section II of the Code. For example, SA516 Gr. 70 can have a maximum carbon content of up to 0.3% in plates up to four inches thick. Section II further permits normalizing or quenching followed by tempering to enhance fracture toughness. Manufacturing processes that have a profound effect on fracture toughness, but little effect on tensile or yield strength of the material, are also not specified with the degree of specificity in the ASME Code to guarantee a well-defined fracture toughness. In fact, the Code relies on actual coupon testing of the part to ensure the desired level of protection against brittle fracture. For Section III, Subsection NF Class 3 parts, the desired level of protection is considered to exist if the lowest service temperature is equal to or greater than the NDT temperature (per NF 2311(b)(10)). Accordingly, the required NDT temperature for all load bearing metal parts in the HI-STORM UMAX overpack (NF and STH) is set at -40°F below the LST.

The STH components (Closure Lid strong backs) have thicknesses less than or equal to 1". The strong backs are fabricated from normalized SA516 Gr.70 material which is exempted from impact testing at lowest service temperatures above -30°F per ASME Section III, Subsection NF. Because the HI-TRAC Transfer Cask operations are limited to a minimum service temperature of 0°F for handling, the lid will also not be handled at temperatures below 0°F and the strong back material is thereby exempt from testing.

All other steel structural materials in the HI-STORM UMAX are made of SA516 Gr. 70, SA515 Gr. 70, SA36 or austenitic stainless steel. The SA516 Gr. 70 material used to fabricate the HI-STORM UMAX is exempt from impact testing per NF-2311(b), because:

i. The LST for handling operations is above the Minimum Design Temperature of SA516 Gr. 70 (for thickness less than 2-1/2") per Figure NF-2311(b)-1, and;

ii. During non-handling operations (i.e., <u>normal</u> storage mode), the maximum tensile stress in the HI-STORM overpack is less than the threshold limit of 6,000 psi specified in NF-2311(b)(7).

If the SA516 Gr. 70 plate is as-rolled (i.e., not normalized), then impact testing is required except when the maximum stress under normal conditions, including handling operations, does not exceed 6,000 psi tension (see NF-2311(b)(7)) or is non-tensile (compressive).

Table 3.1.9 provides a summary of impact testing requirements to ensure prevention of brittle fracture.

8.4.4 Creep Properties of Materials

Creep, a visco-elastic and visco-plastic effect in metals, manifests itself as a monotonically increasing deformation if the metal part is subjected to stress under elevated temperature. Since certain parts of the HI-STORM UMAX system, notably the fuel basket, operate at relatively high temperatures, creep resistance of the fuel basket is an important property. Creep resistance of the MPC internals is discussed in the HI-STORM FW FSAR. Creep is not a concern in the Enclosure Vessel, the HI-STORM UMAX, or the HI-TRAC steel weldment because of the operating metal temperatures, stress levels and material properties. Steels used in ASME Code pressure vessels have a high threshold temperature at which creep becomes a factor in the equipment design. The ASME Code Section II material properties provide the acceptable upper temperature limit for metals and alloys acceptable for pressure vessel service. In the selection of steels for the HI-STORM UMAX system, a critical criterion is to ensure that the sustained (normal) metal temperature of the part made of the particular steel type shall be less than the Code permissible temperature for pressure vessel service. This criterion guarantees that excessive creep deformation will not occur in the steels used in the HI-STORM UMAX system.

8.5 WELDING MATERIAL AND WELDING SPECIFICATION

Welds in the HI-STORM UMAX system are divided into two broad categories:

i. Structural welds
ii. Non-structural welds

Structural welds are those that are essential to withstand mechanical and inertial loads exerted on the component under normal storage and handling.

Non-structural welds are those that are subject to minor stress levels and are not critical to the safety function of the part. Non-structural welds are typically located in the redundant parts of the structure. The guidance in the ASME Code Section NF-1215 for secondary members may be used to determine whether the stress level in a weld qualifies it to be categorized as non-structural.

Both structural and non-structural welds must satisfy the material considerations listed in Tables 8.1.1 and 8.1.2 for the MPC and the HI-STORM UMAX VVM, respectively. In addition, the welds must not be susceptible to any of the applicable failure modes listed in Table 8.1.4
The welding material and welding specification considerations for the MPC and HI-TRAC are discussed in Section 8.5 of the HI-STORM FW FSAR.

To ensure that all structural welds in the HI-STORM UMAX system shall render their intended function, the following requirements are observed:

i. The welding procedure specifications comply with ASME Section IX for every Code material used in the system.

ii. The quality assurance requirements applied to the welding process correspond to the highest ITS classification of the parts being joined.

iii. The non-destructive examination of every weld is carried out using quality procedures that comply with ASME Section V.

The welding operations are performed in accordance with the requirements of codes and standards depending on the design and functional requirements of the components.

The selection of the weld wire, welding process, range of essential and non-essential variables,* and the configuration of the weld geometry has been carried out to ensure that each weld will have:

i. Greater mechanical strength than the parent metal.

* Please refer to Section IX of the ASME Code for the definition and delineation of essential and non-essential variables.

ii. Acceptable ductility, toughness, and fracture resistance.
iii. Corrosion resistance properties comparable to the parent metal.
iv. No risk of crack propagation under the applicable stress levels.

The welding procedures implemented in the manufacturing of HI-STORM UMAX components are intended to fulfill the above performance expectations.

The inspection and testing requirements of the HI-STORM UMAX System component welds are provided in Section 10.1.

The weld filler material shall comply with requirements set forth in the applicable Welding Procedure Specifications qualified to ASME Section IX at the manufacturer's facility. Only those Welding Procedures that have been qualified to the Code are permitted in the manufacturing of HI-STORM UMAX components.

The weld procedure qualification record specifies the requirements for fracture control (e.g., post weld heat treatment). The HI-STORM UMAX module assembly does not require any post weld heat treatment due to the material combinations and provisions in the applicable codes and standards.

Non-structural welds shall meet the following requirements:

1. The welding procedure shall comply with Section IX of the ASME Code or AWS D1.1.

2. The welder shall be qualified, at minimum, to the commercial code such as ASME Section VIII, Div.1, or AWS D1.1.

3. The weld shall be visually examined by the weld operator or a Q.C. inspector qualified to Level 1 (or above) per ASNT designation.

8.6 BOLTS AND FASTENERS

The HI-STORM UMAX VVM assembly does not employ any ITS bolts or fasteners. However, during the MPC transfer into the HI-STORM UMAX, the HI-TRAC and mating device may be attached to the VVM assembly to prevent tip-over during a seismic event. If bolts are used to secure the HI-TRAC against tip-over, the bolts and anchor location material would be considered ITS and would be procured in accordance with the Holtec QA program. Bolt and anchor location material would be selected from the list of materials identified in ASME Section II. The bolting materials used for the HI-TRAC are evaluated in section 8.6 of the HI-STORM FW FSAR.

The only bolts employed in the HI-STORM UMAX VVM system are those used to secure the vent flue to the inlet and outlet plenums. All bolts and fasteners are made of alloy materials which are not expected to experience any significant corrosion in the operating environment. The ISFSI operation and maintenance program shall call for coating of bolts and fasteners if the ambient environment is aggressive.

All threaded surfaces are treated with a preservative to prevent corrosion. The O&M program for the storage system calls for all bolts to be monitored for corrosion damage and replaced, as necessary.

8.7 COATINGS AND CORROSION MITIGATION

In order to provide reasonable assurance that the VVM will meet its intended Design Life of 60 years and perform its intended safety function(s), chemical and galvanic reactions and other potentially degrading mechanisms must be accounted for in its design and construction. Coatings and corrosion mitigation techniques related to the MPC and HI-TRAC are discussed in Section 8.7 of the HI-STORM FW FSAR.

It should be noted that, although the CEC is a buried steel structure it is substantially sequestered from the native soil through two engineered features:

a. A thick reinforced concrete Enclosure Wall surrounds the VVM array and, along with the Support Foundation pad, provides a physical separation (water intrusion protection) to the CECs.

b. The subgrade in contact with the CECs is either a "free flow" concrete or an engineered fill selected to provide a non-aggressive environment around the CECs.

The above engineered features provide an environmentally benign condition for the CECs. The above said, although the CEC is not a part of the MPC confinement boundary, it should not corrode to the extent where localized in-leakage of water occurs or where gross general corrosion prevents the component from performing its primary safety function. In the following, considerations in the VVM's design and construction consistent with the applicable guidance provided in ISG-15 [8.1.1] are summarized.

All VVM components are protected from galvanic corrosion by appropriate designs. Except for the CEC exterior surfaces (exterior CEC surface coating requirements discussed separately), all carbon steel surfaces of the VVM are lined and coated with the same or equivalent surface preservative that is used in the aboveground HI-STORM FW and HI-STORM 100 overpacks. The pre-approved surface preservative is a proven zinc-rich inorganic/metallic (may also be an organic zinc rich coating) material that protects galvanically and has self-healing characteristics for added protection. All exposed surfaces interior to the VVM are accessible for the reapplication of surface preservative, if necessary.

Additional preemptive measures to prevent corrosion are essential, if the substrate is of aggressive chemistry. A description of corrosion mitigation measures proposed to protect the HI-STORM UMAX systems and which are also approved for use in HI-STORM 100U VVM in Docket Number 72-1014, are presented in the following.

The native soil excavated at the ISFSI site shall preferably not be used as subgrade unless it has the requisite density and low corrosivity. To evaluate soil corrosivity, a "10 point" soil-test evaluation procedure, in accordance with the guidelines of Appendix A of ANSI/AWWA C105/A21 [8.7.1] will be utilized. The classical soil evaluation criteria in the aforementioned standard focuses on parameters such as: (1) resistivity, (2) pH, (3) redox (oxidation-reduction) potential, (4) sulfides, (5) moisture content, (6) potential for stray current, and (7) experience

with existing installations in the area. Using the procedure outlined in ref.[8.7.1] , the ISFSI soil environment corrosivity is categorized as either "mild" for a soil test evaluation resulting in 9 points or less or "aggressive" for a soil test evaluation resulting in 10 points or greater. The following table details the corrosion mitigation measures that shall be necessary if the native soil is used as the subgrade:

Implementation of Corrosion Mitigation Measures

Soil Environment Corrosivity	**Corrosion Mitigation Measures**		
	Coating (see note (i))	Concrete Encasement (see note (ii))	Cathodic Protection (see note (iii))
Mild	Required	Choice of either concrete encasement or cathodic protection; or both	
Aggressive	Required	Optional	Required

Notes:
i. An acceptable exterior surface preservative (coating) applied on the CEC carbon steel surface.
ii. Concrete encasement of the CEC external surfaces to establish a high pH buffer around the metal mass.
iii. A suitably engineered impressed current cathodic protection system (ICCPS).

The corrosion mitigation measures tabulated above are further detailed in the following subsections:

i. Exterior Coating

The CEC exterior shall be coated with a radiation resistant surface preservative designed for below-grade and/or immersion service. Inorganic and/or metallic coatings are sufficiently radiation-resistant for this application; therefore, radiation testing is not required. Organic coatings such as epoxy, however, must have proven radiation resistance or must be tested without failure to at least 10^7 Rad. Radiation resistance to lower radiation levels is acceptable on a site-specific basis. Radiation testing shall be performed in accordance with ASTM D 4082 [8.7.6] or equivalent. The coating should be conservatively treated as a Service Level II coating as described in Reg. Guide 1.54 [8.7.3]. As such, the coating shall be subjected to appropriate quality assurance in accordance with the applicable guidance provided by ASTM D 3843-00 [8.7.4]. The coating should preferably be shop-applied in accordance with manufacturer's instructions and, if appropriate, applicable guidance from ANSI C 210-03 [8.7.5]. The following table provides the acceptance criteria for the selection of coatings for the exterior surfaces of the CEC and ranks them in order of importance.

Acceptance Criteria for the Selection of Coatings	
Rank	**Criteria**
1	suitable for immersion and/or below grade service
2a	compatible with the ICCPS (if used) • adequate dielectric strength • adequate resistance to cathodic disbondment
2b	compatible with concrete encasement (if used) • adequate resistance to high alkalinity
3	adequate radiation resistance
4	adequate adhesion to steel
5	adequate bendability/ductility/cracking resistance/abrasion resistance
6	adequate strength to resist handling abuse and substrate stress

The Keeler & Long polyamide-epoxy coating is selected as one that satisfies the acceptance criteria to the maximum degree. Alternatively, a Holtec-approved equivalent that meets the acceptance criteria set forth in the table above may be used.

ii. Concrete Encasement

The CEC concrete encasement shall provide a minimum of 5 inches of cover to provide a pH buffering effect for additional corrosion mitigation. The required 5-inch minimum thickness is more conservative than that recommended in ACI Codes, such as ACI 318, which call for up to 3 inches of concrete cover over steel reinforcement in aggressive environments. Considering that the concrete encasement is restricted to mild soil environments (unless used in conjunction with cathodic protection) and has a non-structural role, an approximately 5-inch thick concrete encasement is considered more than sufficient to provide reasonable assurance that the design basis service life can be achieved. The lowest part of the CEC sits on the Support Foundation Pad.

Regardless of reinforcement method, the material selected shall be corrosion-resistant or otherwise appropriately coated (e.g., epoxy coated steel wire) for corrosion resistance.

The concrete encasement shall be installed in accordance with Holtec-approved procedures that utilize applicable guidance from the ACI codes (e.g., ACI 318 for commercial concrete). Installation procedures shall address mix designs (incorporating Portland cement), testing, mixing, placement, and reinforcement, with the aim to enhance concrete durability and minimize voids and micro-cracks.

iii. Impressed Current Cathodic Protection System (ICCPS)

If the aggressiveness of the subgrade around the CEC is highly aggressive and warrants an ICCPS then the user may choose to either extend an existing ICCPS to protect the installed ISFSI, or to establish an autonomous system. The initial startup of the ICCPS must occur within one year after installation of the VVM to ensure timely corrosion mitigation. In addition, the ICCPS should be maintained operable at all times after initial startup except for system shutdowns due to power outages, repair or preventive maintenance and testing, or system modifications. Because there are a multitude of ISFSI variables that will bear upon the design of the ICCPS for a particular site, the essential criteria for its performance and operational characteristics are set down in this FSAR, which the detailed design work for each ISFSI site must follow.

Design Criteria for the Impressed Current Cathodic Protection System
a. The cathodic protection system shall be capable of maintaining the CEC at a minimum (cathodic) potential as required by NACE Standard RP0285-2002 [8.7.7].   b. The ICCPS shall include provisions to infer its proper operation and effectiveness on a periodic basis.   c. The system shall be designed to mitigate corrosion of the CEC for its design life. Alternatively, the system shall be designed to mitigate corrosion of the CEC for its License Life with due consideration to provisions that would allow system upgrades or maintenance for extended service as required for potential future license extensions.   d. The cathodic protection system design, installation, operation, testing, and maintenance shall follow the applicable guidelines of: - 49CFR195 Subpart H “Corrosion Control”, Oct. 1, 2004 edition [8.7.8]   - NACE Standard RP0285-2002 “Corrosion Control of Underground Storage Tank Systems by Cathodic Protection” [8.7.7]

The following standards and/or publications may also be utilized for additional guidance in the design, installation, operation, testing, and maintenance of the ICCPS as needed (in case of conflict, the guidelines of item d above shall prevail):

- API RP1632, “Cathodic Protection of Underground Petroleum Storage Tanks and Piping Systems”
- NACE RP0169-96, “Control of External Corrosion on Underground or Submerged Piping Systems”
- 49CFR192 Subpart I “Requirements for Corrosion Control”, Oct. 1, 2004 edition
- Other standards or publications referenced by any of the above three standards and publications.

Records of system operating data necessary to adequately track the operable status of the ICCPS shall be maintained in accordance with the user's quality assurance program.

Finally, the surface preservative used to coat the CEC must meet the requirements described in (i) above but must also be compatible with cathodic protection and resistant to the alkaline conditions created by cathodic protection and/or concrete encasement.

8.8 GAMMA AND NEUTRON SHIELDING MATERIALS

Gamma and neutron shield materials in the HI-STORM UMAX VVM system are discussed in Section 1.2. The gamma and neutron shielding materials used in the MPC and HI-TRAC are discussed in Sections 8.8 and 8.9 of the HI-STORM FW FSAR. The primary shielding materials used in the HI-STORM UMAX VVM system, as listed in Table 8.1.3, are plain concrete, reinforced concrete, and steel.

The plain concrete provides the main shielding function in the HI-STORM UMAX lids to minimize sky shine.

8.8.1 Plain Concrete

Unlike the above ground HI-STORM models, the use of plain concrete for shielding purposes in the underground VVMs is limited to the VVM Closure Lid. The *critical characteristics* of concrete used in the Closure Lid are its density and compressive strength. Table 2.3.2 provides reference properties of plain concrete used in the Closure Lid. The temperature limits in Table 2.3.7 are adopted from the HI-STORM 100 FSAR where the bases for the thermal limits are documented.

The density of plain concrete within the HI-STORM UMAX overpack is subject to a minor decrease due to long-term exposure to elevated temperatures. The reduction in density occurs primarily due to liberation of unbonded water by evaporation.

The shielding analysis in Section 5.3 considers the density of concrete in the Closure Lid as an explicit input item in the computation of dose above the HI-STORM UMAX ISFSI structure.

As stated in sub-section 1.2.2, lean concrete may also be used as the material of construction for the subgrade (space A in Figure 2.4.4). The required structural properties of the subgrade concrete, if used, are provided in Tables 2.3.2 and 3.3.5. Because the subgrade material is completely protected from the ambient environment, the environmental demands on it are not very severe. At sites with high water tables, an Enclosure Wall may be incorporated in the ISFSI design to protect the subgrade from long term erosion and degradation.

8.8.2 Steel

Section 5.3 provides a discussion on steel as a shielding material and its composition used in the evaluation of its shielding characteristics.

8.9 NEUTRON ABSORBING MATERIALS

The discussion related to the selection and use of neutron absorbing materials used in the MPC and HI-TRAC are discussed in Section 8.9 of the HI-STORM FW FSAR and are not repeated here.

8.10 SEALS

The HI-STORM UMAX VVM assembly does not utilize any gaskets that seal against a large pressure differential.

The only external gasket used in the system is the soft gasket at the Closure lid-CEC Flange interface that helps prevent the ingress of moisture and insects (through the small crack that may exist due to weld distortion in the fabrication of interfacing fabricated steel weldment surfaces) into the module cavity space.

The Divider shell is sealed against the Closure lid using a pliable, non-organic seal material that is suitable for long-term ambient air application up to 300 deg. F.

The seals used with the HI-TRAC bottom lid are discussed in Section 8.11 of the HI-STORM FW FSAR.

8.11 CHEMICAL AND GALVANIC REACTIONS

The materials used in the HI-STORM UMAX System are examined to establish that these materials do not participate in any chemical or galvanic reactions when exposed to the various environments during all normal operating conditions and off-normal and accident events. Chemical and galvanic reactions related to the MPC and HI-TRAC are discussed in Section 8.12 of the HI-STORM FW FSAR.

The following acceptance criteria for chemical and galvanic reactions are extracted from ISG-15 [8.1.1] for use in HI-STORM UMAX VVM components.

a. The DCSS should prevent the spread of radioactive material and maintain safety control functions using, as appropriate, noncombustible and heat resistant materials.

b. A review of the DCSS, its components, and operating environments (wet or dry) should confirm that no operation (e.g., short-term loading/unloading or long-term storage) will produce adverse chemical and/or galvanic reactions, which could impact the safe use of the storage cask.

c. Components of the DCSS should not react with one another, or with the cover gas or spent fuel, in a manner that may adversely affect safety. Additionally, corrosion of components inside the containment vessel should be effectively prevented.

d. Potential problems from general corrosion, pitting, stress corrosion cracking, or other types of corrosion, should be evaluated for the environmental conditions and dynamic loading effects that are specific to the component.

The materials and their ITS pedigree are listed in the drawing package provided in Section 1.5. The compatibility of the selected materials with the operating environment and to each other for potential galvanic reactions is discussed in this section.

- External atmosphere – During long-term storage the casks are exposed to outside atmosphere, air with temperature variations, solar radiation, rain, snow, ice, etc.

As discussed herein, the components of the HI-STORM UMAX System have been engineered to ensure that the environmental conditions expected to exist at nuclear power plant installations do not prevent the cask components from rendering their respective intended functions.

The principal operational considerations that bear on the adequacy of the storage overpack for the service life are addressed as follows:

Exposure to Environmental Effects

All exposed surfaces of the HI-STORM UMAX VVM components are made from stainless steels or ferritic steels that are readily painted. Concrete, which serves strictly as a shielding

material in the VVM Closure Lid, is encased in steel. Therefore, the potential of environmental vagaries such as spalling of concrete are ruled out for HI-STORM UMAX VVM. Under normal storage conditions, the bulk temperature of the HI-STORM UMAX storage overpack will change very gradually with time because of its large thermal inertia. Therefore, material degradation from rapid thermal ramping conditions is not credible for the HI-STORM UMAX VVM. Similarly, corrosion of structural steel embedded in the concrete structures due to salinity in the environment at coastal sites is not a concern for HI-STORM UMAX VVM because it does not rely on rebars (indeed, it contains no rebars). The configuration of the storage VVM assures resistance to freeze-thaw degradation. In addition, the storage system is specifically designed for a full range of enveloping design basis natural phenomena that could occur over the service life of the storage system as catalogued in Section 2.2 and evaluated in Chapter 11.

The ISFSI pad, which is exposed to the elements, shall be subject to a surveillance program to monitor its potential degradation, as discussed in Chapter 10.

Material Degradation

The relatively low neutron flux to which the storage overpack is subjected cannot produce measurable degradation of the cask's material properties and impair its intended safety function. Exposed carbon steel components are coated to prevent corrosion. The ambient environment of the ISFSI storage pad mitigates damage due to exposure to corrosive and aggressive chemicals that may be produced at other industrial plants in the surrounding area.

Maintenance and Inspection Provisions

The requirements for periodic inspection and maintenance of the storage overpack throughout its service life are defined in Section 10.4. These requirements include provisions for routine inspection of the storage overpack exterior and periodic visual verification that the ventilation flow paths of the storage overpack are free and clear of debris. ISFSIs located in areas subject to atmospheric conditions that may degrade the storage cask or canister should be evaluated by the licensee on a site-specific basis to determine the frequency for such inspections to assure long-term performance. In addition, the HI-STORM UMAX system is designed for easy retrieval of the MPC from the storage overpack should it become necessary to perform more detailed inspections and repairs on the storage system.

The above findings are consistent with those of the NRC's Waste Confidence Decision Review [8.11.1], which concluded that dry storage systems designed, fabricated, inspected, and operated in accordance with such requirements are adequate for a 60-year Design and a 100-year service life while satisfying the requirements of 10CFR72.

8.12 FUEL CLADDING INTEGRITY

The discussion related to the fuel cladding integrity during short term operations is presented in Section 8.13 of the HI-STORM FW FSAR and are not repeated here.

8.13 EXAMINATION AND TESTING

Examination and testing are integral parts of manufacturing of the HI-STORM UMAX System components. Examination and testing requirements for the MPC and HI-TRAC are described in Section 8.14 of the HI-STORM FW FSAR. A comprehensive discussion on the examinations and testing that are conducted during the manufacturing process for the HI-STORM UMAX VVM is provided in Chapter 10 wherein the applicable codes and standards are also cited along with the acceptance criteria derived from them.

Post-fabrication inspections are discussed in Section 10.4 as part of the HI-STORM UMAX VVM System maintenance program. Inspections are conducted prior to fuel loading or prior to each fuel handling campaign. Other periodic inspections are conducted during storage.

The HI-STORM UMAX VVM is a passive device with no moving parts. Overpack vent screens are inspected on scheduled intervals for damage, holes, etc. The VVM's external surface, including identification markings, is visually examined on a periodic basis in accordance with the ISFSI's surveillance plan. The temperature monitoring system, if used, is inspected per the licensee's QA program and manufacturer's recommendations.

8.14 REGULATORY COMPLIANCE

The preceding sections describe the materials used in important-to-safety SSCs and the suitability of those materials for their intended functions in the HI-STORM UMAX System.

The requirements of 10CFR72.122(a) are met: The material properties of SSCs important to safety conform to quality standards commensurate with their safety functions.

The requirements of 10CFR72.104(a), 106(b), 124, and 128(a)(2) are met: Materials used for shielding are adequately designed and specified to perform their intended function.

The requirements of 10CFR72.122(h)(1) and 236(h) are met: The design of the DCSS and the selection of materials adequately protect the spent fuel cladding against degradation that might otherwise lead to gross rupture of the cladding by ensuring that the cladding temperature remains below the ISG-11 Rev 3 limits..

The requirements of 10CFR72.236(h) and 236(m) are met: The material properties of SSCs important-to-safety will be maintained during normal, off-normal, and accident conditions of operation as well as short-term operations so the spent fuel can be readily retrieved without posing operational safety problems.

The requirements of 10CFR72.236(g) are met: The material properties of SSCs important-to-safety will be maintained during all conditions of operation so the spent fuel can be safely stored for the specified service life and maintenance can be conducted as required.

The requirements of 10CFR72.236(h) are met: The HI-STORM UMAX System employs materials that are not vulnerable to degradation over time or react with one another during long-term storage.

CHAPTER 9: OPERATING PROCEDURES

9.0 INTRODUCTION

The operations associated with the use of the HI-STORM UMAX System are quite similar to the operations for the HI-STORM 100U system certified in Docket Number 72-1014. Because the HI-STORM UMAX System's scope of certification is limited to loading pre-certified MPCs (Table 1.2.1) using pre-certified transfer cask (Table 1.2.2), the operations culminating in the arrival of the MPC-bearing HI-TRAC VW transfer cask at the ISFSI are governed by the HI-STORM FW System FSAR [9.6.1]. The description of the operations governed by this FSAR pertains to staging the HI-TRAC transfer cask on the VVM cavity and ends with the removal of the empty transfer cask and replacement of the Closure Lid and installation of other appurtenances to place the storage system in a long-term storage configuration. The necessary information for executing the reverse set of steps to retrieve an MPC from a storage cavity is likewise provided. The guidance provided in this chapter shall be used as an aid to develop the short-term operations procedure specific to a host site that elects to deploy the HI-STORM UMAX system. The procedures provided in this chapter are prescriptive to the extent that they provide the basis and general guidance for plant personnel in preparing detailed written, site-specific, loading, handling, storage, and unloading procedures. Users may add, modify the sequence of, perform in parallel, or delete steps as necessary provided that the intent of this guidance is met and the requirements of the Certificate of Compliance (CoC) are complied within a *literal manner*. The information provided in this chapter complies with the provisions of NUREG-1536.

The information presented in this chapter along with the technical basis of the system design described in this SAR will be used to develop detailed operating procedures. In preparing the site-specific procedures, the user must consult the conditions of the CoC, equipment-specific operating instructions, and the plant's working procedures as well as the information in this chapter to ensure that the short-term operations shall be carried out with utmost safety and ALARA.

The following generic criteria shall be used to determine whether the site-specific operating procedures developed pursuant to the guidance in this chapter are acceptable for use:

- All heavy load handling instructions are in keeping with the guidance in industry standards and Holtec-provided instructions.
- The procedures are in conformance with this FSAR and its CoC.
- The procedures are in conformance with the HI-STORM FW System FSAR [9.6.1].
- The operational steps are ALARA.
- The procedures contain provisions for documenting successful execution of all safety significant steps for archival reference.

- Procedures contain provisions for classroom and hands-on training and for a Holtec-approved personnel qualification process to ensure that all operations personnel are adequately trained.
- The procedures are sufficiently detailed and articulated to enable craft labor to execute them in *literal compliance* with their content.

ISFSI owners are required to develop or modify existing programs and procedures to account for the implementation of the HI-STORM UMAX system. Written procedures are required to be developed or modified to account for such items as handling and storage of systems, structures and components (SSCs) identified as *important-to-safety*, heavy load handling, specialized instrument calibration, special nuclear material accountability, fuel handling procedures, training, equipment, and process qualifications. Users shall implement controls to ensure that all critical set points (e.g., Lift Weights) do not exceed the design limit of the specific equipment.

Control of the operation shall be performed in accordance with the user's Quality Assurance (QA) program to ensure critical steps are not overlooked and that the cask has been confirmed to meet all requirements of the CoC before being released for on-site storage under 10 CFR Part 72.

ALARA warnings highlighted in this chapter are included to alert users to radiological issues. Actions identified with these items are of an advisory nature and shall be implemented based on site-specific determination by the plant's radiation protection personnel.

Section 9.1 provides the technical basis for loading and unloading procedures. Section 9.2 provides the guidance for loading the HI-STORM UMAX system. Section 9.3 provides the procedures for ISFSI operations and general guidance for performing maintenance and for responding to abnormal events that may occur during normal loading operations. Section 9.4 provides the procedure for unloading the HI-STORM UMAX System. The loading steps and the illustrations, are illustrative (rather than definitive) because the architecture of a particular plant and its ISFSI may require significant adaptations for a safe and ALARA loading program.

Because the MPCs and transfer casks utilized in the HI-STORM UMAX system are originally certified in the HI-STORM FW docket, there is a close informational nexus between the two dockets with respect to the components common to both systems. Table 9.0.1 provides a matrix of the information in this FSAR that is supplemented by the corresponding material from the HI-STORM FSAR.the latest QA validated version of which (Rev 1) is placed in this docket for reference purposes.

TABLE 9.0.1: APPLICABLE SECTIONS OF HI-STORM FW FSAR*

Location of UMAX FSAR	**Subject of the reference**	**Location in HI-STORM FW FSAR, Revision 3**
Section 9.0	The operations culminating in the arrival of the MPC-bearing HI-TRAC at the ISFSI	Sections 9.1 and 9.2
Sub-Section 9.2.3	Loading of MPC	Sub-Sections 9.2.1 and 9.2.3
Sub-Section 9.4.1	Direction on further action such as return MPC to the fuel pool or loading in a transport cask for off-site shipment	Section 9.4
Sub-Section 9.4.2	HI-TRAC receipt inspection and cleanliness inspection	Table 9.2.5
Section 9.5	Steps to remove an MPC from a loaded VVM	Sub-Sections 9.4.3 and 9.4.4

* For convenience of reference, the specific revision of the HI-STORM FW FSAR that is referenced in the safety analysis herein is placed in this docket. Updated versions of the HI-STORM FW FSAR shall be placed in this docket as necessary so as to ensure that the safety analyses on the "UMAX" docket (72-1040) remain aligned with the material referenced in the HI-STORM FW FSAR.

9.1 TECHNICAL AND SAFETY BASIS FOR LOADING AND UNLOADING PROCEDURES

The procedures herein are developed for the loading, storing, and unloading of a loaded MPC in the HI-STORM UMAX System. The design of the HI-STORM UMAX System, along with the implementation procedures, the ancillary equipment, and the Technical Specifications, collectively serve to achieve ALARA, minimize risks to the operational staff, and mitigate consequences of potential adverse events.

The primary objective of the information presented in this chapter is to identify and describe the sequence of significant operations and actions that are important-to-safety for canister loading, canister handling, storage operations, and canister unloading to adequately protect crew health and to eliminate any conceivable danger to life or property, to protect the MPC's contents from dispersal, and to provide for the safe execution of tasks and operations.

In the event of an extreme environmental condition, the appropriate procedural guidance to respond to the situation must be available and ready for implementation at the nuclear plant. As a minimum, the procedures shall address establishing emergency action levels, implementation of emergency action program, establishment of personnel exclusions zones, monitoring of radiological conditions, actions to mitigate or prevent the release of radioactive materials, recovery planning and execution, and reporting to the appropriate regulatory agencies, as required.

9.2 PROCEDURE FOR PLACING THE LOADED MPC IN THE HI-STORM UMAX VVM

9.2.1 Overview of Loading Operations

The HI-STORM UMAX System differs from the HI-STORM FW System in that the vertical ventilated module (VVM) is an integral part of the ISFSI and is therefore immovable (cannot be transported on-site). Therefore, the transfer of the MPC from the transfer cask to the storage module cannot occur within the plant's Part 50 structure. Like the HI-STORM 100U the underground module (in Docket Number 72-1014), the transfer of the MPC occurs by staging the HI-TRAC transfer cask over the CEC cavity. The loaded HI-TRAC transfer cask is transported between the ISFSI and the Part 50 facility where the MPC is loaded using a heavy haul vertical cask transporter, heavy haul transfer trailer, a rail car, air pads and the like that have been previously used for such applications. In what follows, the acronym VCT (for vertical cask transporter) is used to denote the hauling machinery. The operational steps required to prepare, load the MPC, and transport it to the ISFSI using the HI-TRAC transfer cask are governed by the HI-STORM FW System FSAR [9.6.1]. The detailed operational steps presented in this chapter, therefore, start with the preparation to stage the loaded HI-TRAC over the recipient storage cavity.

Prior to the start of MPC transfer at the ISFSI, the VVM lid is removed and the storage cavity is inspected for absence of foreign matter. The Mating Device is positioned on top of the VVM. The outlet flue installed on other VVMs on the path to the recipient CEC cavity may need removal for short term operational reasons, such as to enable the VCT to reach the target cavity. It is recommended that an outlet flue be re-installed within approximately 6 hours to minimize thermal impacts to the system. If used, the Supplemental Cooling System (SCS) is disconnected from the HI-TRAC, the HI-TRAC annulus is drained, and the HI-TRAC is placed on top of the Mating Device (Figure 9.2.1). The MPC may be downloaded using the vertical cask crawler, the MPC downloader attached to the transfer cask, or other suitable lifting device. The MPC lifting device is attached to the MPC. The bottom lid is removed and the Mating Device drawer is opened. Optional temporary shielding may be installed, as guided by the licensee's Radiation Protection program, on or around the Mating Device. The MPC is lowered into the VVM (Figure 9.2.2). Following verification that the MPC is fully lowered, the MPC slings are disconnected from the lifting device and lowered onto or removed from the MPC lid. Alternately, the MPC lifting device may be removed. Any temporary shielding is removed, if necessary. The HI-TRAC and bottom lid may be reattached while on the VVM or may be removed and then reattached. HI-TRAC is removed from on top of the VVM. The MPC lift device is removed as necessary. The Mating Device is removed and the VVM lid is installed. Finally, the temperature monitoring elements and their instrument connections, if used at the ISFSI, are installed, and post-loading performance verification specified in the site loading procedures is performed.

Because the HI-STORM UMAX VVM is an integral part of the ISFSI itself, there is no handling

of the VVM. For an example of the rigging required to handle the HI-STORM UMAX VVM Closure Lid, see Figure 9.2.3.

9.2.2 Preparation for MPC Transfer

The required equipment/devices that participate in the transferring of the MPC into dry storage are, as a minimum:

1. Equipment to remove and install the VVM Closure Lid;
2. The vertical cask transporter (VCT) or equivalent load handling devices with redundant drop protection features;
3. The loaded transfer cask containing the MPC;
4. The Mating Device; and
5. MPC lifting and handling devices.

Prior to staging the Mating Device and the transfer cask on the recipient VVM cavity, the storage cavity shall be inspected for absence of debris, water, animals or insect nests, and the like. A general checklist for performing the pre-staging inspection of the VVM cavities is provided below:

1. The painted surfaces shall be inspected for corrosion and chipped, cracked, or blistered paint.
2. All lid surfaces shall be relatively free of dents, scratches, gouges, or other damage.
3. Lid lifting points shall be inspected for dirt, debris, and general condition.
4. Vent openings shall be free from obstructions.
5. Vent screens shall be available, intact, and free of holes and tears.
6. Temperature monitoring elements, if used, shall be inspected for availability, function, calibration, and provisions for mounting to the VVM outlet air passage.

<u>HI-STORM UMAX VVM Main Body</u>

1. Cooling passages shall be free from obstructions.
2. The interior cavity shall be free of debris, litter, tools, and equipment.
3. Painted surfaces shall be inspected for corrosion, and chipped, cracked or blistered paint.

<u>VERTICAL CASK TRANSPORTER (VCT)</u>

The VCT shall be serviced before the beginning of a dry storage campaign and all VCT checks are performed in accordance with its manufacturer's O&M manual. The quantity of fuel and other combustibles in the VCT shall be confirmed to be within the limits specified in the site's 72.212 safety evaluation report. The VCT shall be operated only if the ambient temperature is within the specified limit in the VCT's O&M manual. The VCT operator must have received training in the use of the VCT as specified in its O&M manual.

Finally, the Mating Device shall be inspected for any loose paint, scale, or other adherent debris and cleaned appropriately to eliminate the risk of foreign materials adhering to it that fall into the VVM cavity. The smooth operation of the lid drawer traction system shall be confirmed and moving surfaces lubricated, as specified in the applicable Holtec International Purchasing Specification.

The MPC transfer shall not occur if the meteorological forecast indicates a credible chance of adverse weather activity such as lightning, snow fall, rain, or heavy winds at the ISFSI during the planned transfer operation.

All slings and fasteners shall be inspected for general condition and indication of wear and degradation (such as a cut or nick in the sling) before accepting them for use.

9.2.3 Placement of the MPC into Storage

The operational steps presented in the following are intended to provide guidance to the user in preparing site-specific loading procedures that must be prepared with due consideration of the particular site's physical characteristics, its rigging plan, and its safety/ALARA practices. Figure 9.2.4 provides a pictorial overview of the loading steps.

Loading Steps

1. Load the MPC in accordance with Chapter 9 of the HI-STORM FW System FSAR [9.6.1]
2. Remove the Closure Lid using a crane or other equivalent lifting device.
3. Install the Mating Device on the VVM.
4. Place the loaded HI-TRAC transfer cask recipient on the Mating Device using the vertical cask crawler (or other suitable transportation device).
5. Rig the MPC to the lift components of the cask transporter or other suitable downloading device. Raise the MPC slightly to remove the weight of the MPC from the HI-TRAC Bottom lid (also called the Pool lid).
6. Unbolt the Bottom lid from the HI-TRAC body and lower the lid into the Mating Device.
7. Open the Mating Device drawer.

ALARA Warning:
Temporary shielding may be used to reduce personnel dose during transfer operations. If ALARA considerations dictate that temporary shielding not be used, personnel must remain clear of the immediate area around the Mating Device drawer during MPC downloading.

8. At the user's discretion, install temporary shielding to cover the potential streaming paths around the Mating Device drawer.
9. Lower the MPC into the VVM.
10. Verify that the MPC is fully seated in the VVM.

Caution:
Operations steps that occur with the MPC in the VVM with the Mating Device installed and the drawer closed must be performed in an expeditious manner to avoid excessive heating of the MPC and fuel. The Mating Device must be removed or the drawer opened to establish air cooling within the time limits described in Section 4.5. In the event of equipment malfunction that results in the blockage of air flow, corrective actions must occur within the time limits of the 100% blocked duct accident condition.

11. Disconnect the MPC rigging from the downloading device and lower them onto the MPC lid or remove them from the MPC.
12. Remove any temporary shielding and close the Mating Device drawer.
13. Reinstall the HI-TRAC Bottom lid.

ALARA Warning:
Personnel should remain clear (to the maximum extent practicable) of the VVM annulus when HI-TRAC is being removed to comply with ALARA requirements.

14. Remove the HI-TRAC transfer cask from the top of the VVM.
15. Partially open the Mating Device drawer and remove any MPC rigging.
16. DELETED
17. Close the Mating Device drawer and remove the Mating Device from on top of the VVM.

Guidance:
The lid shall be preferably kept less than 2 feet above the top surface of the VVM while over the MPC. This lift limit action is purely a defense-in-depth measure because the Closure Lid cannot fall and impact the MPC because of geometric constraints.

18. Install the VVM lid. Check that the rigging (in its specific configuration) is rated to lift the load (rated to lift two times the load per NUREG 0612).
19. Remove the VVM lid rigging equipment and re-install the outlet vent cover (if previously removed).
20. Install the VVM temperature monitoring elements (if used).
21. Install the flue extensions (that were removed to avoid interference with the VCT).
22. Perform shielding effectiveness testing, if required by the Technical Specification..

9.3 ACTIVITIES PERTAINING TO ISFSI OPERATIONS

The HI-STORM UMAX System heat removal is by totally passive means. As discussed in Chapter 10, surveillance of the HI-STORM VVM assembly to ensure its continued effectiveness involves the following principal activities:

1. Check for intrusion of foreign objects that may impair the system's thermal performance during normal operations and in the wake of an extreme environmental phenomenon including severe flood.
2. Check for corrosion damage to the steel parts, namely the CECs (oldest or most vulnerable VVM shall be inspected).
3. Check for structural damage to the ISFSI after an earthquake.
4. Perform the heat removal operability surveillance as specified the CoC.
5. Perform ISFSI Security Operations in accordance with the host site's security plan.

Routine maintenance on the HI-STORM UMAX System will typically be limited to cleaning and touch-up painting of the exposed steel surfaces, repair, and replacement of damaged vent screens, and removal of vent blockages (e.g., leaves, debris), if any (See Table 10.4.1 and 10.4.2 for specific requirements). The heat removal system operability surveillance should be performed after any event that may have an impact on the safe functioning of the HI-STORM UMAX system. These include, but are not limited to, wind storms, heavy snow storms, fire inside the ISFSI, seismic activity, flooding of the ISFSI, and/or observed animal, bird, or insect infestations. The responses to these conditions involve first assessing the dose impact to perform the corrective action (inspect the HI-STORM VVM cavity, clear the debris, check for any structural damage of the ISFSI pad, and/or replace damaged vent screens); perform the corrective action; and verify that the system is operable (check ventilation flow paths and radiation blockage capability). In the unlikely event of significant damage to the ISFSI, possibly from a Beyond-the-Design Basis earthquake, the situation may warrant removal of the MPC, and repair or replacement of the damaged ISFSI areas. Section 9.4 may be used as guidance for unloading the MPC from the HI-STORM UMAX.

9.4 PROCEDURE FOR REMOVING THE MPC FROM THE HI-STORM UMAX VVM CAVITY

9.4.1 Overview of HI-STORM UMAX System Unloading Operations

The MPC is recovered from the HI-STORM UMAX VVM at the ISFSI using the same set of steps as described in Section 9.2, except that the order is basically reversed. The VVM temperature monitoring elements (if used) and lid are removed. The flue extensions are removed as necessary to allow the VCT to access the target cavity. The Mating Device is installed and the Mating Device drawer is partially opened. The MPC lift rigging is attached to the MPC. The MPC rigging is attached to the MPC lift device and positioned on the MPC lid. The Mating Device drawer is closed and the HI-TRAC is positioned on top of the Mating Device and VVM. The HI-TRAC's Bottom lid is unbolted from the HI-TRAC and the Mating Device drawer is opened. The MPC slings are brought through the HI-TRAC and connected to the lift device. The MPC is raised into HI-TRAC and the Mating Device drawer is closed. The bottom lid is bolted to the HI-TRAC. The HI-TRAC is removed from on top of the VVM and transported out of the ISFSI area for further processing. The scope of this FSAR ends with the loaded HI-TRAC suspended from the VCT for further processing. Chapter 9 of the HI-STORM FW System FSAR [9.6.1] for the host MPC provides the direction on further action such as return to the fuel pool or loading in a transport cask for off-site shipment.

9.4.2 MPC Recovery from the HI-STORM UMAX VVM

PRINCIPAL OPERATING STEPS

1. If necessary, perform a transport route walkdown to ensure that the cask transport conditions are met for transporting the loaded HI-TRAC transfer cask. Remove all physical obstructions (e.g., flue extensions) that may interfere with the movement of the VCT.

2. Perform a HI-TRAC receipt inspection and cleanliness inspection in accordance with a written inspection checklist in accordance with the HI-STORM FW System FSAR [9.6.1]. Transport the HI-TRAC to the ISFSI using the cask transporter or other suitable device.

3. Remove the VVM temperature monitoring equipment (if used) from the (MPC donor) VVM cavity.

4. Remove the VVM Closure lid from the donor VVM cavity, preferably keeping its height above the top of the CEC Flange to under 2 feet. See Figure 9.2.3 for a rigging illustration.

Caution:
Operations steps that occur with the MPC in the VVM with the Mating Device installed and the drawer closed must be performed in an expeditious manner to avoid excessive heating of the MPC and fuel. The Mating Device must be removed or the drawer opened to establish air cooling within the time limits described in Section 4.5. In the event of equipment malfunction that results in the blockage of air flow, corrective actions must occur within the time limits of the 100% blocked duct accident condition.

5. Install the Mating Device on the VVM.
6. Partially open the Mating Device drawer.
7. Install the MPC rigging on the MPC lid..
8. Close the Mating Device drawer.
9. If previously drained, fill the neutron shield jacket with plant demineralized water or an approved antifreeze solution as necessary. Ensure that the fill and drain plugs are installed.
10. Align HI-TRAC over the Mating Device and VVM and mate the casks.
11. Unbolt the bottom lid from the HI-TRAC and lower into the Mating Device.
12. Open the Mating Device drawer.
13. At the user's discretion, install temporary shielding to cover the gap above and below the Mating Device drawer.
14. Raise the MPC rigging up through the HI-TRAC and attach them to the lifting device.
15. Raise the MPC into HI-TRAC.
16. Verify the MPC is in the full-up position.
17. Close the Mating Device drawer.
18. Reinstall the bottom lid to the HI-TRAC.
19. Lower the MPC onto the bottom lid.
20. Disconnect the slings from the lifting device and the MPC lift cleats.
21. Remove HI-TRAC from the top of the VVM.

22. Transport the HI-TRAC to the designated location using the cask transporter or other suitable device.

23. Remove the Mating Device from the VVM.

24. Install the VVM lid and vent flue assemblies on all storage cavities, where they were removed, to prevent entry of foreign objects into the VVM.

9.5 REGULATORY COMPLIANCE:

The operational steps required to place a loaded MPC into a HI-STORM UMAX VVM cavity have been described in this chapter. The steps to remove an MPC from a loaded VVM, which are essentially reverse of the steps in the loading sequence, have been provided in Chapter 9 of the HI-STORM FW System FSAR [9.6.1]. These loading steps are, of necessity, generic in their description and may require adaptation to a specific ISFSI. The implementation steps are nevertheless sufficiently detailed to lead to the conclusion that the guidelines of safety and ALARA set down in NUREG-1536 are fully satisfied. In particular, it can be concluded that:

i. There are no radiation streaming paths from the MPC during its transfer operation.
ii. The Mating Device handling operations occur near grade level thus eliminating the need for ladders/platforms and improving the human factors aspects.
iii. There are no freestanding structures in the MPC transfer operations and thus there is no risk of uncontrolled load movement under a (hypothetical) extreme environmental event such as tornado or high winds.
iv. The ventilation paths to passively cool the canister using ambient air during the transfer operation is maintained at all times (except during brief operations as mentioned above) thus protecting the fuel cladding from overheating and eliminating any thermally guided time limit on the duration for implementing the transfer steps.
v. All heavy load handling is carried out by handling devices that are equipped with redundant load drop protection features.
vi. Each storage cavity is independently accessible. Installation or removal of any MPC does not have to contend with other stored MPCs.
vii. Because the MPC insertion (and withdrawal) occurs in the vertical configuration with ample lateral clearances, there is no risk of scratching or gouging of the MPC's external surface (Confinement Boundary). Thus the ASME Section III Class 1 prohibition against damage to the pressure retaining boundary is maintained.

It is thus concluded that the HI-STORM UMAX ISFSI is engineered to meet the safety and ALARA imperatives contemplated in 10CFR 72 in full measures.

CHAPTER 10: ACCEPTANCE CRITERIA AND MAINTENANCE PROGRAM

10.0 INTRODUCTION

This chapter addresses the fabrication, inspection, test, and maintenance programs for the HI-STORM UMAX VVM assemblies. In particular, this chapter identifies the fabrication, inspection, test, and maintenance programs to be conducted on the HI-STORM UMAX VVM to verify that the structures, systems, and components (SSCs) classified as important-to-safety have been fabricated, assembled, inspected, tested, accepted, and maintained in accordance with the requirements set forth in this FSAR, the applicable regulatory requirements, and the Certificate of Compliance (CoC). The acceptance criteria and maintenance program requirements specified in this chapter apply to each HI-STORM UMAX system fabricated, assembled, inspected, tested, and accepted for use under the purview of the system's CoC. The assessment of the fabrication, inspection, test, and maintenance programs for the MPC and HI-TRAC used with the HI-STORM UMAX is described in Chapter 10 of the HI-STORM FW FSAR, a QA validated copy of which is placed in this docket for reference. The material in the HI-STORM FW FSAR which is relied upon to articulate the acceptance criteria and maintenance program of components that the "UMAX" system shares with "FW" is provided in a matrix form in Table 10.0.1 for ease of reference.

The controls, inspections, and tests set forth in this chapter, in conjunction with the design requirements described in previous chapters, ensure that the HI-STORM UMAX system will reject the decay heat of the stored radioactive materials in the MPCs to the environment by passive means and maintain radiation doses within regulatory limits. The controls, inspections, and tests set forth in Chapter 10 of the HI-STORM FW along with the MPC and HI-TRAC design requirements described in the HI-STORM FW, ensure that the system will maintain confinement of radioactive material and will maintain subcriticality control under normal, off-normal, and hypothetical accident conditions, including short term operations. The aforementioned design, controls, inspections, and tests described in the HI-STORM FW also ensure that the MPC and HI-TRAC will reject the decay heat of the stored radioactive materials to the environment by passive means and maintain radiation doses within regulatory limits.

Both pre-operational and operational tests and inspections are performed throughout HI-STORM UMAX system operations to assure that the system is functioning within its design parameters. These include receipt inspections, nondestructive weld examinations, thermal performance tests, and others. "Pre-operation", as referred to in this chapter, defines that period of time from acceptance inspection of a HI-STORM UMAX system until the loaded MPC is placed in the CEC cavity.

The HI-STORM UMAX system is classified as important-to-safety. Therefore, the individual structures, systems, and components (SSCs) that make up the HI-STORM UMAX system shall be designed, fabricated, assembled, inspected, tested, accepted, and maintained in accordance

with a quality program commensurate with the particular SSC's graded quality category. The licensing drawings identify all important-to-safety subcomponents of the HI-STORM UMAX system.

The acceptance test requirements on the manufactured welds in the HI-STORM UMAX system are contained in the component licensing drawings in Section 1.5. Additional details on the requirements in the drawings are provided in this chapter or in Chapter 10 of the HI-STORM FW FSAR for MPC and HI-TRAC, which will be incorporated in the shop manufacturing documents (viz., weld procedures, shop travelers, inspection procedures, and fabrication procedures) to ensure full compliance with this FSAR.

The VVM consists of a shop-fabricated CEC (Cavity Enclosure Container) installed below grade and a removable Closure Lid. The CEC is a welded shell-type structure made of steel plate and bar (or forging) stock. Likewise, the Closure Lid is made of welded and formed steel plates and bar (or forging) stock. However, unlike the CEC, the Closure Lid also contains shielding concrete.

By virtue of its underground configuration, the CEC is interfaced by the subgrade along its lateral surface, by the ISFSI pad near its flanged upper region and by the Support Foundation Pad (SFP) along its bottom surface. The requirements on these interfacing bodies, to the extent they are needed to enable the CEC to render its intended function, are provided in Chapter 2. All requirements pertaining to the manufacturing, inspection, testing, and maintenance of the VVM SSCs are presented in this chapter to comply with the provisions of 10CFR72.24(p).

The user of the HI-STORM UMAX system should consult this chapter and the Technical Specification to ensure that the site's acceptance criteria and maintenance program are consistent with the representations made herein. The user's maintenance program should also utilize the information that will be gathered and disseminated by Holtec International through the Company's "lessons learned" data base and other means that are intended to help ensure maximum shielding effectiveness and a long service life of the ISFSI .

Subsection 10.1.5	Requirements for component tests of valves, pressure relief device and fluid transport devices associated with the MPC and HI-TRAC	Sub-Section 10.1.5
Sub-Section 10.1.6	The shielding integrity testing requirements for the MPC and HI-TRAC	Sub-Section 10.1.6
Sub-Section 10.1.7	The thermal test requirement for the first manufactured MPC, either MPC-37 or MPC-89	Sub-Section 10.1.7

[1] For convenience of reference, the specific revision of the HI-STORM FW FSAR that is referenced in the safety analysis herein is placed in this docket. Updated versions of the HI-STORM FW FSAR shall be placed in this docket as necessary so as to ensure that the safety analyses on the “UMAX” docket (72-1040) remain aligned with the material referenced in the HI-STORM FW FSAR.

10.1 ACCEPTANCE CRITERIA

This section provides the workmanship inspections and acceptance tests to be performed on the HI-STORM UMAX ISFSI and VVM prior to and during loading of the system. Information on the workmanship inspections and acceptance tests to be performed on the MPC and HI-TRAC components are provided in Section 10.1 of the HI-STORM FW FSAR. These inspections and tests provide the assurance that all components of the HI-STORM UMAX system are fabricated, assembled, inspected, tested, and accepted for use under the conditions specified in this FSAR and the Certificate of Compliance issued by the NRC in accordance with the provisions of 10CFR72.

The testing and inspection acceptance criteria applicable to HI-STORM UMAX VVM are listed in Table 10.1.1 and discussed in more detail in the sections that follow. The testing and inspection acceptance criteria applicable to the MPC, including the MPC Lid-to-Shell weld, and the HI-TRAC are listed in Table 10.1.1 and 10.1.3 of the HI-STORM FW FSAR and are discussed in more detail in the HI-STORM FW FSAR. Chapter 9 from both this FSAR and the HI-STORM FW FSAR provide operating guidance. Chapter 13 of this FSAR provides the bases for the Technical Specifications. These inspections and tests are intended to demonstrate that the HI-STORM UMAX system has been fabricated, assembled, and examined in accordance with the design criteria contained in Chapter 2 of the HI-STORM UMAX FSAR. Identification and resolution of manufacturing non-compliances, if any, shall be performed in accordance with the Holtec International Quality Assurance Program approved by the USNRC (Docket Number 71-0784).

The material on testing and maintenance of system components in this FSAR governs the content of the daughter documents such as the Manufacturing Manual and the O&M Manual for the system components used in the manufacturing and long-term maintenance of the system components.

10.1.1 Fabrication and Nondestructive Examination (NDE)

This subsection summarizes the test program required for the HI-STORM UMAX system.

10.1.1.1 Fabrication Requirements

The manufacturing of UMAX VVM components shall be carried out in accordance with the CoC holder's NRC-approved QA program. All elements of the manufacturing cycle will be established to accord with the Important-to-Safety (ITS) designation of the specific part (indicated in the Licensing drawings) and the applicable provisions of the referenced codes and standards. The acceptance criteria for the manufactured components apply to each step of the manufacturing evolution, namely (a) supplier selection, (b) preparation of material procurement specifications, (c) preparation of the shop traveler and fabrication procedures, (d) fabrication activities such as forming, bending, plasma cutting, and welding, (e) in-process inspections, (f)

final inspection, (g) packaging for shipment, and (h) assembling of the documentation package to serve as the archival evidence of adherence to the quality requirements.

In order to receive the Certificate-of-Compliance under the CoC holder's QA program, the manufacturing of the HI-STORM UMAX VVM components must meet all of the technical, quality control, procedural (quality assurance) and administrative requirements set forth in the manufacturing program.

Similarly, the steel plates, bars, and forgings, as applicable, used in the construction of the HI-STORM UMAX VVM shall be dimensionally inspected to assure compliance with the requirements on the drawings. Test results shall be documented and become part of the quality documentation package. Dimensional inspections of the Closure Lid and its weight measurement after placement of the shielding concrete shall assure that the required amount of shielding material has been incorporated in the lid.

The fabrication controls and required inspections detailed in Section 10.1 of the HI-STORM FW FSAR shall be performed on the MPCs and HI-TRAC transfer casks, in order to assure compliance with the HI-STORM FW FSAR, the HI-STORM UMAX FSAR and the Certificate of Compliance. Specifically, the following fabrication controls and required inspections shall be performed on the HI-STORM UMAX system in order to assure compliance with this FSAR and the Certificate of Compliance.

i. Materials of construction specified for the HI-STORM UMAX system are identified in the drawings in Chapter 1. Materials for ITS Components shall be procured with certification and supporting documentation as required by the ASME Code, Section II, where applicable [10.1.1], Holtec procurement specifications, and 10CFR72, Subpart G. ITS materials and components shall be receipt inspected for visual and dimensional acceptability, material conformance to specification requirements, and traceability markings, as applicable. Controls shall be in place to ensure that material traceability is maintained throughout fabrication.

ii. Structural welds shall be performed using welders and weld procedures that have been qualified in accordance with ASME Code Section IX and ASME Section III, Subsection NF. Non-structural welds shall be performed using welders and weld procedures that have been qualified in accordance with ASME Code Section IX or AWS D1.1.

iii. Structural welds shall be visually examined in accordance with ASME Code, Section V, Article 9. NDE inspections of structural welds shall be performed in accordance with written and approved procedures by personnel qualified in accordance with SNT-TC-1A [10.1.2] or other site-specific, NRC-approved program for personnel qualification. Non-structural welds shall be visually examined by qualified welders or weld inspectors for cracks and other linear indications which must be repaired when identified.

iv. Single pass welds identified on the HI-STORM UMAX VVM drawing shall be made using a prequalified weld procedure. In addition to the normal procedure qualifications required by ASME Section IX or AWS D1.1, the weld procedure shall define limits on essential variables such that the weld produced will be guaranteed to have a minimum fillet size of 1/8”. Upon qualification of the weld procedure, the single pass welds identified on the licensing drawing can be fabricated and verification of use of proper essential variables for welding can be substituted for examination for proper weld size. Single pass welds shall be visually examined by qualified welders or weld inspectors for cracks and other linear indications which must be repaired when identified.

v. The HI-STORM UMAX system shall be inspected for cleanliness and proper packaging for shipping in accordance with written and approved procedures.

vi. Each VVM shall be durably marked with the appropriate model number, a unique identification number, and its empty weight per 10CFR72.236(k) at the completion of the acceptance test program.

vii. A documentation package shall be prepared and maintained during fabrication of each HI-STORM UMAX system to include detailed records and evidence that the required inspections and tests have been performed. The completed documentation package shall be reviewed to verify that the HI-STORM UMAX system components have been properly fabricated and inspected in accordance with the design and Code construction requirements. The documentation package shall include, as applicable, but not be limited to:

- Completed Shop Weld Records
- Inspection Records
- Nonconformance Reports
- Material Test Reports
- NDE Reports
- Dimensional Inspection Report

10.1.1.2 Visual Inspections and Measurements

The HI-STORM UMAX system components shall be assembled in accordance with the licensing drawing package in Section 1.5. The drawings provide dimensional tolerances that define the limits on the dimensions used in licensing basis analysis. Fabrication drawings provide additional dimensional tolerances necessary to ensure fit-up of parts. Visual inspections and measurements shall be made and controls shall be exercised to ensure that the cask components conform to the dimensions and tolerances specified on the licensing and fabrication drawings. These dimensions are subject to independent confirmation and documentation in accordance with the Holtec QA program approved in NRC Docket Number 71-0784.

The HI-STORM UMAX VVM, except for its Closure Lid, does not require unique marking other than that required for fuel ISFSI configuration management because it is not a transportable structure. The module is essentially an integral portion of the ISFSI, not a separate cask structure that can be moved by the user. As such, the markings provided on the MPC alone are sufficient to meet the requirements of 10CFR72.236(k). Nevertheless, it is required that each VVM cavity be labeled with an identifier that is unique for the specific site. Further, because the Closure Lid will be subject to handling, consistent with defense-in-depth guidelines for handling heavy loads at nuclear plants, its unique identifier and its bounding weight shall be permanently marked on a readily visible location.

The following shall be verified as part of visual inspections and measurements:

- Visual inspections and measurements shall be made to ensure that the systems' effectiveness is not significantly reduced as a result of manufacturing deviations. Any *important-to-safety* component found to be under the specified minimum thickness shall be justified under the rules of 10CFR72.48 or repaired or replaced, as appropriate.

- The HI-STORM UMAX CEC and Closure Lid shall be inspected to confirm that the labeling is complete and legible.

- The system components shall be inspected for cleanliness and prepared for shipment in accordance with written and approved procedures.

- Visual inspections shall be made to verify that neutron absorber panels and basket shims are present as required by the MPC basket design.

The visual inspection and measurement results for the HI-STORM UMAX system shall become part of the final quality documentation package.

10.1.1.3 Weld Examination

The examination of the HI-STORM UMAX system welds shall be performed in accordance with the drawing package in Section 1.5 and the applicable codes and standards.

Weld examination requirements for the MPC and HI-TRAC are described in Section 10.1 of the HI-STORM FW FSAR. All structural weld inspections shall be performed in accordance with written and approved procedures by personnel qualified in accordance with SNT-TC-1A. Structural welds for the VVM shall meet the acceptance criteria of ASME Section III, Subsection NF. All required inspections, examinations, and tests shall become part of the final quality documentation package. Non-structural weld inspections shall be performed by welders or weld inspectors qualified in accordance with written procedures. Non-structural welds shall be free of cracks and other linear indications.

10.1.2 Structural and Pressure Tests

The structural and pressure test requirements for the MPC and HI-TRAC are described in Section 10.1 of the HI-STORM FW FSAR. The following subparagraphs provide the structural and pressure test requirements for the HI-STORM UMAX VVM.

10.1.2.1 Lifting Locations

Because the HI-STORM UMAX system is immovable, it does not utilize any lifting appurtenances.

The only removable component in the HI-STORM UMAX system is the Closure Lid which features four lift lugs (see drawing in Section 1.5). Because the lugs are integral to the component, they possess high ductility and, as shown in Chapter 3, meet the factor of safety of 6 to yield and 10 to ultimate, as required by ANSI N14.6 [10.1.3]. The requirements for testing and inspection of the load handling equipment related to the HI-TRAC and MPC are covered in the governing license document for the respective component and are not repeated here.

Section 5 of NUREG-0612 [10.1.4] calls for measures to "provide an adequate defense-in-depth for handling of heavy loads...". The NUREG-0612 guidelines cite four major causes of load handling accidents, of which rigging failure is one:

i. operator errors
ii. rigging failure
iii. lack of adequate inspection
iv. inadequate procedures

The cask loading and handling operations program shall ensure maximum emphasis to mitigate the potential load drop accidents by implementing measures to eliminate shortcomings in all aspects of the operation including the four aforementioned areas.

Each lifting lug will be subjected to a dimensional test in the shop to ensure that it meet the dimensional requirements. The lift lugs will be load tested per ANSI 14.6 -1993 prior to the shipping of the Closure Lid to the ISFSI site.

10.1.3 Materials Testing

The materials testing requirements for the MPC and HI-TRAC are described in Section 10.1 of the HI-STORM FW FSAR. The following paragraphs provide the materials testing requirements for the HI-STORM UMAX VVM.

The steel materials used in the HI-STORM VVM will be tested in accordance with the requirements of the applicable material code.

The concrete utilized in the construction of the HI-STORM UMAX ISFSI shall be mixed, poured, and tested in accordance with the applicable code using written and approved procedures. Testing shall verify the material properties meet design requirements. Tests required shall be performed at a frequency as defined in the applicable ACI code.

10.1.4 Leakage Testing

Leakage testing shall be performed in accordance with the requirements of ANSI N14.5 [10.1.5]. Testing shall be performed in accordance with written and approved procedures with acceptance criteria being "leak tight" as defined in ANSI N14.5.

Helium leakage testing of the MPC base metals (shell, baseplate, and MPC lid) and MPC shell to baseplate and shell to shell welds is performed on the unloaded MPC. The helium leakage test of the vent and drain port cover plates and cover plate to MPC lid welds (field welds) shall be performed using procedures meeting the requirements of ANSI N14.5.

If a leakage rate exceeding the acceptance criterion is detected, then the cause of the leakage shall be determined and the area repaired per the requirements of ASME Code Section III, Subsection NB, Article NB-4450. Re-testing shall be performed until the leakage rate acceptance criteria is met.

Leak testing results for the MPC shall be documented and shall become part of the quality record documentation package.

There is no leakage testing required for the HI-STORM UMAX VVM.

10.1.5 Component Tests

10.1.5.1 Valves, Pressure Relief Devices, and Fluid Transport Devices

There are no valves, pressure relief device and fluid transport devices associated with the HI-STORM UMAX VVM. The requirements for component tests of valves, pressure relief device and fluid transport devices associated with the MPC and HI-TRAC are described in Section 10.1 of the HI-STORM FW FSAR.

10.1.5.2 Seals and Gaskets

There are no confinement seals or gaskets included in the HI-STORM UMAX system.

10.1.6 Shielding Integrity

The shielding integrity testing requirements for the MPC and HI-TRAC are described in Section 10.1 of the HI-STORM FW FSAR. There is no criticality control testing required for the HI-STORM UMAX VVM. The shielding integrity testing for the HI-STORM UMAX VVM is limited to dimensional checks of the steel components and concrete forming and to confirmation of the correct density for the concrete used in the Closure Lid and ISFSI pad.

10.1.7 Thermal Acceptance Tests

The thermal performance of the HI-STORM UMAX system, including the MPCs and HI-TRAC transfer cask, is demonstrated through analysis in Chapter 4 of this FSAR and the HI-STORM FW FSAR. Dimensional inspections to verify the item has been fabricated to the dimensions provided in the drawings shall be performed prior to system loading.

The thermal test requirement for the first manufactured MPC, either MPC-37 or MPC-89 is described in Section 10.1 of the HI-STORM FW FSAR.

Table 10.1.1

HI-STORM UMAX VVM ASSEMBLY INSPECTION AND TEST ACCEPTANCE CRITERIA

Function	**Fabrication**	**Pre-operation**	**Maintenance and Operations**
Visual Inspection and Nondestructive Examination (NDE)	Structural Steel Components: a) All structural welds shall be visually examined per ASME Section V, Article 9 with acceptance criteria per ASME Section III, Subsection NF, NF-5360. b) All structural welds requiring MT examination as shown on the drawings shall be MT examined per ASME Section V, Article 7 with acceptance criteria per ASME Section III, Subsection NF, NF-5340. c) NDE of weldments shall be defined on design drawings using ANSI NDE symbols and/or notations.	a) The VVM shall be visually inspected for general condition of coatings and insulation and for presence of FME prior to placement in service. b) VVM Assembly protection at the licensee's facility shall be verified. c) Exclusion of foreign material shall be verified prior to placing the VVM Assembly in service at the licensee's facility.	a) Indications identified during visual inspection shall be corrected, reconciled, or otherwise dispositioned. b) Exposed surfaces shall be monitored for coating deterioration and repair/recoat as necessary.

Table 10.1.1 (continued)

HI-STORM UMAX VVM ASSEMBLY INSPECTION AND TEST ACCEPTANCE CRITERIA

Function	**Fabrication**	**Pre-operation**	**Maintenance and Operations**
Visual Inspection and Nondestructive Examination (NDE) (continued)	General: a) Cleanliness of the VVM Assembly shall be verified upon completion of fabrication. b) Packaging of the VVM Assembly at the completion of shop fabrication shall be verified prior to shipment. c) Labeling of the CEC and the Closure Lid	General: a) Labeling of the CEC and the Closure Lid	
Structural	a) Verification of structural materials shall be performed through receipt inspection and review of certified material test reports (CMTRs) obtained in accordance with the item's quality category. b) Load testing of Closure Lid lift points	a) No structural or pressure tests are required for the VVM during pre-operation.	a) No structural or pressure tests are required for the VVM during operation.
Leak Tests	a) None.	a) None.	a) None.
Shielding Integrity	a) Concrete density shall be verified per Appendix 1.D of [10.1.4], at time of placement. b) Shell thicknesses and dimensions between inner and outer shells shall be verified as conforming to design drawings prior to concrete placement in the Closure Lid.	a) None	a) None.

Table 10.1.1 (continued)

HI-STORM UMAX VVM ASSEMBLY INSPECTION AND TEST ACCEPTANCE CRITERIA

Function	**Fabrication**	**Pre-operation**	**Maintenance and Operations**
Thermal Acceptance	a) Inner shell I.D. and vent size, configuration and placement shall be verified.	a) Visual examination of the insulation and coatings will be performed to verify that they are in good condition b) Air flow paths will be visually inspected to ensure they are clear and free of FME.	a) MPC lid temperature test shall be performed as discussed in Section 10.3 b) Periodic surveillance shall be performed by either (1) or (2) below, at the licensee's option. (1) Inspection of VVM inlet and outlet air vent openings for debris and other obstructions. (2) Temperature monitoring.
Cask Identification	a) Verification that the VVM identification is present in accordance with the drawings shall be performed upon completion of assembly.	a) The VVM identification shall be checked prior to loading.	a) The VVM identification shall be periodically inspected per licensee procedures and repaired or replaced if damaged.
Fit-up Tests	a) Where closely toleranced alignment between mating components is required, a component-to-component fit-up shall be performed directly whenever practical or using templates or other means.	a) Lid fit-up with the VVM shall be verified following placement of concrete around the VVM.	a) None.

10.2 SITE CONSTRUCTION

Like the aboveground HI-STORM overpacks, the site construction activities on the HI-STORM UMAX VVM components and ISFSI structures (namely, the Support Foundation Pad, the ISFSI Pad Subgrade, the ISFSI Pad, and the Enclosure Wall) shall be carried out to demonstrate compliance with the technical criteria set forth in this FSAR. The specific requirements, to ensure that the required *critical characteristics** of the VVM and the interfacing SSCs are realized, are summarized below.

a. All site construction processes shall be controlled by procedures, work instructions, or similar processes. These shall be reviewed and approved in accordance with the CoC holder or the site-licensee's NRC approved QA program.

b. All HI-STORM UMAX VVM components and structures designated as ITS shall be subject to the necessary quality assurance regimen established in accordance with the Company's QA program. The major NITS components in the ISFSI are the inlet and outlet flue extensions including the chimney cover and the concrete casement around the CEC shell, and the cathodic protection system (if used).

c. Compliance with the requirements in this FSAR shall be demonstrated by appropriate testing and the results documented for archival reference. For example, the strength properties of the subgrade can be established using the classical "plate test" or an equivalent method endorsed by a national consensus standard.

d. The density and compressive strength of the ISFSI concrete and the yield strength of the re-bars used in the ISFSI structures shall be confirmed to comply with the Purchasing Specification prepared by the cask designer for the particular site.

e. The insulation installed on the Divider shell shall be subject to visual examination to ensure that it is undamaged and properly secured.

f. The coating on the exterior surface, if used, of the CEC shall be inspected for absence of gross damage before the surface becomes inaccessible.

g. The concrete encasement, if used, shall be installed in accordance with the provisions of Chapter 8.

h. The dimensional compliance of the CEC, including its verticality, shall be inspected to establish compliance with the governing construction documents.

i. The installation of the corrosion barriers shall be in accordance with written procedures.

* See Glossary for definition.

j. All VVM surfaces that become inaccessible shall be photographed with sufficient resolution to provide a clear archive of their in-situ state at installation.

10.3 INSPECTIONS AND TESTING

i. Post-Construction Inspection:

Each as-built HI-STORM UMAX VVM shall be inspected for final acceptance before it is loaded with fuel. The following inspections define minimum acceptance requirements:

a. The as-installed CEC shall be inspected to ensure that it will not hinder installation of the Closure Lid.

b. The CEC Flange Shell gasket/seal bearing surfaces shall be inspected for its horizontal alignment (within specified tolerance). The seals shall be inspected for general condition (lack of cuts, tears, or degradation that could lead to poor sealing).

c. The Closure Lid skirt shall be checked for fit-up with the CEC Flange.

d. The outlet air passage in the Closure Lid shall be inspected for absence of obstruction such as debris and extensive weld spatter.

e. The results of the post-construction inspection shall be incorporated in the VVM's Documentation Package.

f. The impressed current cathodic protection system (ICCPS), if used, shall be tested for operability using Holtec provided procedures.

ii. Shielding Integrity and Effectiveness Test:

Operational neutron and gamma shielding effectiveness tests shall be performed after the first fuel loading at the host plant site using written and approved procedures. Calibrated neutron and gamma dose rate meters shall be used to measure the actual neutron and gamma dose rates at the accessible surface of the HI-STORM UMAX VVM. Measurements shall be taken at the locations specified in the Radiation Protection Program for comparison against the prescribed limits. The test is performed to identify the expected dose levels around the VVM in order to plan for appropriate radiation protection measures for future cask loadings. Dose rate measurements shall be documented and shall become part of the quality record of the loaded cask.

iii. Thermal Acceptance Test

The thermal performance of the HI-STORM UMAX system is demonstrated through analysis in Chapter 4 of this FSAR.

However, a thermal acceptance test shall be performed on the first fully loaded VVM assembly whose aggregate MPC heat load is at least 50% of the Design Basis maximum heat load per the system CoC. (Because of its in-ground installation, a thermal test at a lower heat load is apt to be too inaccurate to provide meaningful information.)

After the system has been in storage for at least one week (to reach steady state) and when the ambient is relatively quiescent and the solar heat deposition rate is minimal, the surface temperature of the top of the MPC lid shall be measured at the center and 4 orthogonally disposed peripheral locations.

The measured lid temperature data (at designated measurement points) shall be compared with the results predicted by the FLUENT analysis.

The measured temperatures (in Deg. F) must be no greater than 5% over the corresponding analytically predicted temperatures to be acceptable. Otherwise, the Design Basis heat load capacity of the VVM assembly will be downgraded by incorporating a penalty factor in the FLUENT model and the USNRC so informed. The reduced heat load values will become the *de facto* limits for all VVMs at the site until a root cause evaluation indicates extenuating circumstances unique to the site.

The heat load anomaly must be resolved by additional testing: until then, the reduced heat load limit will apply to all HI-STORM UMAX sites.

The technical specifications require periodic surveillance of the system air inlet and outlet vents or, optionally, implementation of a HI-STORM UMAX VVM air temperature monitoring program to provide continued assurance of the operability of the HI-STORM UMAX heat removal system.

iv. Storm Water Control Test

The HI-STORM UMAX VVM is designed to direct storm water and snow/ice melt-off away from the CEC Flange and the Closure Lid where the air passages are located. The engineered rain caps installed on the inlet and outlet serve to keep rain and snow away from the VVM cavity. Moreover, any minor amount of moisture that may intrude into the MPC storage cavity due to wind-driven rain will evaporate in a short period of time due to the continuous movement of heated air in the MPC storage cavity. To verify the effectiveness of the storm water drainage design, a one-time test shall be performed after construction of the first VVM to ensure that the design is effective in directing storm water away from the VVM to the ISFSI's drainage system. The VVM shall be subjected to a water spray that simulates exposure to rainfall of at least 2

inches per hour for at least one hour. At the conclusion of the water spray, the depth of the water (if any) in the bottom of the module cavity shall be measured. Any amount of water accumulation beyond wetting of the Bottom Plate indicates an inadequacy in rain diversion features of the VVM and shall be appropriately corrected. It should be noted that accumulation of water is not injurious to the thermal performance of the system. The only deleterious effect of prolonged exposure to water is the potential for reducing the service life of the preservative on the wetted surface of the Bottom Plate, CEC shell, and other interfacing components.

10.4 MAINTENANCE PROGRAM

An ongoing maintenance program shall be defined and incorporated into the HI-STORM UMAX system Operations and Maintenance Manual, which shall be prepared and issued prior to the first use of the system by a user. This document shall delineate the detailed inspections, testing, and parts replacement necessary to ensure continued structural, thermal performance, and radiological safety in accordance with 10CFR72 regulations, the conditions in the Certificate of Compliance, and the design requirements and criteria contained in this FSAR.

This section addresses the maintenance program for the HI-STORM UMAX VVM. The HI-STORM UMAX system does not require any changes to the maintenance requirements for the MPC described in its governing FSARs.

The HI-STORM UMAX system is totally passive by design and requires minimal preventive maintenance to ensure that it will render its intended design functions satisfactorily. Periodic surveillance (via temperature monitoring or visual or camera-aided inspection of air passages) is required to ensure that the air passage in the VVM is not blocked. Preventive or remedial painting of the exposed steel surfaces as part of the user's preventive maintenance program is recommended to mitigate corrosion. Such preventive maintenance activities are typical in scope and complexity to other standard maintenance activities at nuclear power plants.

In-service inspection for long-term interior and below-grade degradation shall be performed on a site-specific basis in accordance with Holtec specified long-term maintenance guidelines and the licensee's preventive maintenance program. At most potential ISFSI sites, visual inspection of accessible areas of the HI-STORM UMAX VVM is expected to be sufficient to detect in-service degradation. The frequency of this visual in-service inspection should be in performed in accordance with Table 10.4.1

Additional in-service inspection activities may include more thorough inspections for foreign material accumulation, corrosion (CEC wall thinning) and insulation degradation as warranted by site-specific conditions. In-service inspections for evaluating foreign material accumulation, corrosion (CEC wall thinning) and/or insulation degradation are not required if it is determined that the applicable degradation actuating mechanisms do not exist. A VVM with a loaded MPC may be inspected using remote devices such as a boroscope. The oldest VVM or VVM considered to be most vulnerable to corrosion degradation shall be selected for inspection.

As is true for all components certified pursuant to this FSAR, the maintenance activities on the HI-STORM UMAX VVM shall be performed in accordance with a written program that fulfills the requirements of the CoC holder's 10CFR72 Subpart G compliant QA program; the owner site's Safety Plan and corrective action program; and the system's Technical Specification.

Among the QA commitments are performance of maintenance by trained personnel by written procedures and written documentation of the maintenance work performed and of the results

obtained. Table 10.4.2 provides a listing of the minimum maintenance activities on the HI-STORM UMAX VVM.

In summary, the HI-STORM UMAX System is totally passive by design: There are no active components or monitoring systems required to assure the performance of its safety functions. As a result, only minimal maintenance will be required over its lifetime, and this maintenance would primarily result from the effects of weather. Typical of such maintenance would be the reapplication of corrosion inhibiting materials on accessible external surfaces. Visual inspection of the vent screens is required to ensure the air flow passages are free from obstruction. Such maintenance requires methods and procedures that are far less demanding than those currently in use at power plants.

Maintenance activities shall be performed under the licensee's NRC-approved quality assurance program. Maintenance activities shall be administratively controlled and the results documented.

10.4.1 Structural and Pressure Parts

Prior to each MPC loading, a visual examination in accordance with a written procedure shall be required of the Closure Lid lift lugs and the HI-TRAC Tapped Anchor Locations (TALs), bottom lid bolts, and bolt holes. The examination shall inspect for indications of overstress such as cracks, deformation, wear marks, corrosion, etc. Repairs in accordance with written and approved procedures shall be required if an unacceptable condition is identified.
As described in Chapters 7 and 12 of this FSAR, there are no credible normal, off-normal, or accident events which can cause the structural failure of the MPC. Therefore, periodic structural or pressure tests on the MPCs following the initial acceptance tests are not required as part of the storage maintenance program.

10.4.2 Leakage Tests

There are no seals or gaskets used on the fully-welded MPC confinement system. As described in Chapters 7 and 12, there are no credible normal, off-normal, or accident events which can cause the failure of the MPC Confinement Boundary welds. Therefore, leakage tests are not required as part of the storage maintenance program.

10.4.3 Subsystem Maintenance

The HI-STORM UMAX System does not include any active subsystems that provide auxiliary cooling. If the cask user chooses to use an air temperature monitoring system in lieu of visual inspection of the air inlet and outlet vents, the thermocouples and associated temperature monitoring instrumentation shall be maintained and calibrated in accordance with the user’s QA program commensurate with the equipment’s safety classification and designated QA category.

10.4.4 Pressure Relief Devices

The pressure relief devices used on the water jackets for the HI-TRAC transfer cask shall be confirmed to have been calibrated as specified in the licensing basis FSAR for the HI-TRAC to ensure pressure relief settings are accurate prior to the cask's use at a HI-STORM UMAX ISFSI.

10.4.5 Shielding

The gamma and neutron shielding materials in the HI-TRAC and MPC are not subject to measurable degradation over time or as a result of usage. The radiation shielding capacity of the HI-STORM UMAX System is expected to remain undiminished over time. Therefore, unless the VVM is subjected to an extreme environmental event that imparts stresses or temperatures beyond-the-design-basis limits for the system (i.e., prolonged fire or impact from a beyond-the-design basis large energetic projectile) with the plausible potential to degrade the shielding effectiveness of the VVM, no shielding effectiveness tests beyond that required by the plant's Radiation Protection Program are required over the life of the HI-STORM UMAX System.

Radiation monitoring of the ISFSI by the licensee in accordance with 10CFR72.104(c) provides ongoing evidence and confirmation of shielding integrity and performance. If increased radiation doses are indicated by the facility monitoring program, additional surveys of the ISFSI shall be performed to determine the cause of the increased dose rates.

The water level in the HI-TRAC water jacket shall be verified during each loading campaign in accordance with the licensee's approved operations procedures.

The neutron absorber panels installed in the MPC baskets are not expected to degrade under normal long-term storage conditions. Therefore, no periodic verification testing of neutron poison material is required on the HI-STORM UMAX System.

10.4.6 Thermal

In order to assure that the HI-STORM UMAX System continues to provide effective thermal performance during storage operations, surveillance of the air vents (or alternatively, by temperature monitoring) shall be performed in accordance with written procedures.

For those licensees choosing to implement temperature monitoring as the means to verify VVM Assembly heat transfer system operability, a maintenance and calibration program shall be established in accordance with the plant-specific Quality Assurance Program, the equipment's quality category, and manufacturer's recommendations.

Table 10.4.1

HI-STORM SYSTEM MAINTENANCE PROGRAM SCHEDULE

Task	Frequency
VVM cavity visual inspection	Prior to MPC loading
Divider shell visual inspection	Prior to MPC loading
Closure Lid visual inspection	Prior to MPC loading
VVM external surface (accessible) visual examination	Annually, during storage operation
VVM inlet and outlet vent screen visual inspection for damage, holes, etc.	Monthly
VVM inlet and outlet vent inspection for blockage	Daily unless monitoring is performed using temperature monitoring equipment
HI-TRAC cavity visual inspection	Prior to each handling campaign
HI-TRAC TAL visual inspection	Prior to each handling campaign
HI-TRAC bottom lid bolts and bolt holes	Prior to each handling campaign
HI-TRAC pressure relief device calibration	Per the device manufacturer's recommendation.
HI-TRAC water jacket water level visual examination	During each handling campaign in accordance with licensee approved operations procedures
VVM visual inspection of identification markings	Annually
VVM Air Temperature Monitoring System	Per licensee's QA program and manufacturer's recommendations
VVM inlet plenum inspection for accumulation of FME.	Every five years or following a severe weather event that may introduce significant FME material.

Table 10.4.2

MAINTENANCE ACTIVITIES FOR THE HI-STORM UMAX VVM

	Activity	Frequency	Comment
1.	CEC cavity is visually inspected	Prior to MPC installation	To ensure that VVM internal components are properly aligned, the surface preservatives on all exposed surfaces are undamaged, the insulation on the Divider Shell is undamaged and the cavity is free of visible foreign material.
2.	Lid Examination	Prior to MPC installation	Ensure that the preservatives on the external surfaces are in good condition and the lid is free of dents and rust stains.
3.	Screen Inspection	Prior to installation of the flanged screen assembly and monthly when in use	Ensure that the screen is undamaged.
4.	ISFSI pad	Annually	Ensure that the ISFSI Pad (raised areas near the VVM) is free of visible cracks or repaired as appropriate, the interface between the ISFSI Pad and the CEC Flange is grouted (or caulked) if necessary, the ISFSI drain system is functional, the ground water collection and removal system (if used) is in working order. Ensure that the subgrade settlement is minimal and unsightly surface cracks in the ISFSI pad have not developed. Implement counter measures to prevent the opening of surface cracks and excessive pad settlement, if observed. The cathodic protection system shall be routinely verified as operable in accordance with the guidance set forth in this FSAR and the CoC.
5.	Shielding Effectiveness Test	As required by the Radiation Protection Program	—

Table 10.4.2 (continued)

MAINTENANCE ACTIVITIES FOR THE HI-STORM UMAX VVM

	Activity	Frequency	Comment
6.	ISFSI Settlement	Every five years	Confirm that the VVM settlement is within the range of the Plant's "best estimate". Implement countermeasures if the settlement is determined to be excessive by the CoC holder.
7.	VVM Air Temperature Monitoring System (if used)	Per Licensee's QA Program and manufacturer's recommendations	—
8.	VVM In-Service Inspection	Annually	Ensure that the vent screen assembly fasteners or weldments remain coated with preservative, the screen is undamaged, all visible external surfaces are free from significant corrosion, and the air passages are not degraded.
10.	Additional VVM In-Service Inspection for Long-Term Interior and Below-grade Degradation: a) Visual inspection of accessible areas for long-term degradation. b) Additional in-service inspection activities include inspection for foreign material accumulation, corrosion (CEC thinning) and insulation degradation	a) Monthly visual inspection of accessible areas. b) Frequencies for additional in-service inspections are determined on a site-specific basis.	Inspection activities shall be commensurate with site-specific conditions. Under site conditions existing at most ISFSI sites, visual inspection of accessible areas is sufficient to determine the general condition of the system.

10.5 CASK IDENTIFICATION

The HI-STORM UMAX VVM and Closure Lids shall be marked with a durable unique identifier to comply with the provisions of 10CFR72.236(k). Each MPC and HI-TRAC transfer cask shall be marked with a model number, identification number (to provide traceability back to documentation), and the empty weight of the item in accordance with the marking requirements specified in 10 CFR 72.236(k).

10.6 REGULATORY COMPLIANCE

The information presented in this chapter fulfills the regulatory requirements pertaining to the testing and maintenance of the HI-STORM UMAX System, resolution of issues concerning adequacy and reliability, and cask identification. This section demonstrates the corresponding compliance information on the HI-STORM UMAX VVM.

a. The program for pre-operational testing and initial operations, as required by 10CFR72.24(p) for the HI-STORM UMAX VVM, is provided in Section 10.3 herein.

b. The maintenance protocol for the HI-STORM UMAX VVM, as specified in §72.236(g), is provided in Section 10.4 herein.

c. The quality assurance requirements on the design, fabrication, and on-site construction of the HI-STORM UMAX VVM commensurate with its ITS designation (as defined in Section 1.5) are invoked through Chapter 14 of this FSAR and summarized in Sections 10.1, 10.2, and 10.3 herein as called for in §72.24(c), §72.122(a), §72.122(f), §72.128(a)(1) and §72.236(l).

d. The provisions of §72.82(d) and §72.162 with respect to acceptance criteria and the appropriate test program to ensure compliance with the acceptance criterion are fulfilled by Section 10.1, et seq., herein.

e. The quality requirements with respect to inspection, testing, and documentation, as set down in §72.212(b)(8), are provided in Section 10.1 herein.

f. The provisions of §72.236(k) with respect to labeling is met as provided in Section 10.1 here-in.

g. The quality requirements with respect to design and testing for methods of criticality control and confinement effectiveness as set down in §72.124(b), §72.236(c), and §72.236(j) are provided in the governing licensing documents applicable to the MPC type to be stored in the UMAX and are not part of the scope of this application.

CHAPTER 11: RADIATION PROTECTION

11.0 INTRODUCTION

This chapter contains the design considerations and operational features that are incorporated in the HI-STORM UMAX system to protect plant personnel and the public from exposure to radioactive contamination and ionizing radiation during handling of the loaded MPCs at the ISFSI. Occupational exposure estimate for typical canister handling operations described in Chapter 9 is discussed in this chapter. Chapter 5 presents dose evaluations at 100 m from a single HI-STORM UMAX system. This 100 m dose information from Chapter 5 can be used for ISFSI planning purposes. The information provided in this chapter meets the requirements of NUREG-1536 [11.0.1].

The HI-STORM UMAX is an underground vertical ventilated module (VVM) designed to accommodate all MPC models listed in Table 1.2.1 for storage at an ISFSI. However, this chapter only supports the certification of the MPC-37 and MPC-89. Because of its underground disposition, the radiological dose to plant personnel as well as members of the general public from an operating ISFSI with HI-STORM UMAX VVM assembly is well below those of its aboveground counterpart. Since the determination of off-site doses is necessarily site-specific, similar dose assessment shall be prepared by the licensee as part of implementing the HI-STORM UMAX System in accordance with 10CFR72.212 [11.0.2].

11.1 ENSURING THAT OCCUPATIONAL RADIATION EXPOSURES ARE AS-LOW-AS-REASONABLY-ACHIEVABLE (ALARA)

11.1.1 Policy Considerations

The HI-STORM UMAX has been designed in accordance with 10CFR72 [11.0.2] and maintains radiation exposures ALARA-consistent with 10CFR20 [11.1.1] and the guidance provided in Regulatory Guides 8.8 [11.1.2] and 8.10 [11.1.3]. Licensees using the HI-STORM UMAX system are permitted to utilize and apply their existing site ALARA policies, procedures, and practices for ISFSI activities to ensure that personnel exposure requirements of 10CFR20 [11.1.1] are met. Personnel performing ISFSI operations shall be trained on the operation of the HI-STORM UMAX system, and shall be familiarized with the expected dose rates around the MPC, HI-STORM VVM, and HI-TRAC transfer cask during all phases of loading, storage, and unloading operations. Pre-job ALARA briefings will be held with workers and radiological protection personnel prior to work on or around the HI-STORM UMAX system. Worker dose rate monitoring, in conjunction with trained personnel and well-planned activities, will significantly reduce the overall dose received by the workers. When preparing or making changes to site-specific procedures for ISFSI activities, users shall ensure that ALARA practices are implemented and the 10CFR20 [11.1.1] standards for radiation protection are met in accordance with the site's written commitments.

11.1.2 Radiation Exposure Criteria

The radiological protection criteria that limit exposure to radioactive effluents and direct radiation from an ISFSI using the HI-STORM UMAX system are as follows:

1. 10CFR72.104 [11.0.2] requires that for normal operation and anticipated occurrences, the annual dose equivalent to any real individual located beyond the owner-controlled area boundary must not exceed 25 mrem to the whole body, 75 mrem to the thyroid, and 25 mrem to any other critical organ. This dose would be a result of planned discharges, direct radiation from the ISFSI, and any other radiation from uranium fuel cycle operations in the area. The licensee is responsible for demonstrating site-specific compliance with these requirements. As discussed below, the design features of the HI-STORM UMAX system components are configured to meeting this and other criteria cited below without undue burden to the user.

2. 10CFR72.106 [11.0.2] requires that any individual located on or beyond the nearest owner-controlled area boundary may not receive from any design basis accident the more limiting of a total effective dose equivalent of 5 rem, or the sum of the deep dose equivalent and the committed dose equivalent to any individual organ or tissue (other than the lens of the eye) of 50 rem. The lens dose equivalent shall not exceed 15 rem and the shallow dose equivalent to skin or to any extremity shall not exceed 50 rem. The licensee is responsible for demonstrating site-specific compliance with this requirement.

3. 10CFR20 [11.1.1], Subparts C and D, limit occupational exposure and exposure to individual members of the public. The licensee is responsible for demonstrating site-specific compliance with this requirement.

4. Regulatory Position 2 of Regulatory Guide 8.8 [11.1.2] provides guidance regarding facility and equipment design features. This guidance has been followed in the design of the HI-STORM UMAX storage system as described below:

    - Regulatory Position 2a, regarding access control, is met by locating the ISFSI in a Protected Area in accordance with 10CFR72.212(b)(5)(ii) [11.0.2] Depending on the site-specific ISFSI design, other equivalent measures may be used. Unauthorized access is prevented once a HI-STORM UMAX VVM is loaded in an ISFSI. Due to the passive nature of the system, only limited monitoring is required, thus reducing occupational exposure and supporting ALARA considerations. The licensee is responsible for site-specific compliance with these criteria.

    - Regulatory Position 2b, regarding radiation shielding, is met by the storage cask and transfer cask biological shielding that minimizes personnel exposure, as described in Chapter 5 and in this chapter. Fundamental design considerations that most directly influence occupational exposures with dry storage systems in general and which have been incorporated into the HI-STORM UMAX system design include:

        – system designs that reduce or minimize the number of handling and transfer operations for each spent fuel assembly;

        – system designs that reduce or minimize the number of handling and transfer operations for each MPC loading;

- system designs that maximize fuel capacity, thereby taking advantage of the self-shielding characteristics of the fuel and the reduction in the number of MPCs that must be loaded and handled;

- system designs that minimize planned maintenance requirements;

- system designs that minimize decontamination requirements at ISFSI decommissioning;

- system designs that optimize the placement of shielding with respect to anticipated worker locations and fuel placement;

- thick ISFSI pad and Self-hardening Engineered Subgrade (SES) provide gamma and neutron shielding;

- streaming paths in the HI-STORM UMAX VVM minimized and limited to the air vent passages; and

- low-maintenance design to reduce occupational dose during long-term storage.

- Regulatory Position 2c, regarding process instrumentation and controls, is met since there are no radioactive systems at an ISFSI.
- Regulatory Position 2d, regarding control of airborne contaminants, is met since the HI-STORM UMAX storage system is designed to withstand all design basis conditions to protect the MPC from losing its confinement integrity. As a result, it is reasonable to postulate that no gaseous releases are anticipated. No surface contamination is expected since the exterior of the MPC is delivered in a clean condition when the transfer cask arrives at the ISFSI.
- Regulatory Position 2e, regarding crud control, is not applicable to a HI-STORM UMAX system ISFSI since there are no radioactive systems at an ISFSI that could contain crud.
- Regulatory Position 2f, regarding decontamination, is met since the exterior of the loaded transfer cask is decontaminated prior to being removed from the plant's fuel building.
- Regulatory Position 2g, regarding monitoring of airborne radioactivity, is met since the MPC provides confinement for all design basis conditions. There is no need for monitoring since no airborne radioactivity is anticipated to be released from the casks at an ISFSI.

- Regulatory Position 2h, regarding resin treatment systems, is not applicable to an ISFSI since there are no treatment systems containing radioactive resins at the ISFSI.
- Regulatory Position 2i, regarding other miscellaneous ALARA items, is met since stainless steel is used in the MPC Enclosure Vessel. This material is resistant to the damaging effects of radiation and is well proven in the used fuel cask service. Use of this material quantitatively reduces or eliminates the need to perform maintenance (or replacement) on the primary confinement system.

11.1.3 Operational Considerations

Operational considerations that most directly influence occupational exposures with dry storage systems in general and that have been incorporated into the design of the HI-STORM UMAX system include:

- totally-passive design requiring minimal maintenance and monitoring (other than security monitoring) during storage;
- remotely operated lift yoke and mating device to reduce time operators spend in the vicinity of the loaded MPC;
- descriptive operating procedures that provide guidance to minimize dose and alert workers to possible changing radiological conditions;
- preparation and inspection of the HI-STORM UMAX VVM and the HI-TRAC transfer cask in low-dose areas;
- HI-STORM UMAX VVM temperature monitoring equipment allows remote monitoring of the vent operability surveillance;
- a sequence of short-term operations based on ALARA considerations; and
- use of mock-ups and dry run training to prepare personnel for actual work situations

11.1.4 Auxiliary/Temporary Shielding

In addition to the design and operational features built into the HI-STORM UMAX system components, a number of ancillary shielding devices can be deployed to mitigate occupational dose. Ancillaries are developed on a site-specific basis that further reduce radiation at key work locations and/or allow for a rapid execution of operations to reduce the time personnel spend in the radiation field. Licensees are encouraged to use such ALARA-friendly ancillaries and practices.

To further reduce the occupational and site boundary dose rates, an optional divider shell shield ring (attached to the divider shell) can be implemented. The drawings provided in

Chapter 1 give more information about this shield ring specification. The results presented in this chapter are for the cases without this shield ring. However, in site specific dose evaluations, this shield ring may be credited if it is used.

11.2 RADIATION PROTECTION FEATURES IN THE SYSTEM DESIGN

As shown in Chapter 5, the HI-STORM UMAX system has excellent radiation blockage characteristics. The long-term shielding effectiveness in the HI-STORM UMAX system is assured to an extremely high level of confidence by virtue of its physical configuration, choice of materials, and design embodiment, as summarized below:

a. Absence of penetrations in the VVM body: The CEC has no penetrations and thus has no path that can serve as a conduit for radiation streaming. All penetrations are in the lid and are configured to maximize scattering of photons and neutrons.

b. Axisymmetric penetrations in the lid: As shown in the drawings, the only penetration in the lid – the exit vent – is axisymmetric that precludes a direct "line-of-sight" from the fuel to the outside. Because the air passage in the lid is formed by welded steel shapes, they will remain invariant over time, making their shielding performance reliably constant over years of use.

c. Aging of foundation, subgrade: Even though a very stiff support foundation is specified, some settlement of the foundation is expected. However, any settlement of the foundation would have no deleterious effect on the extent of shielding to the environment.

   Furthermore, because the subgrade is unloaded, except when a transporter is passing over it, the settlement of the ISFSI pad is expected to be minimal over the ISFSI's service life. Any subgrade settlement, however, will result in a corresponding compaction of its material, which will improve the subgrade's shielding capability. The settlement of the subgrade will not result in any new loading on the CEC structure (which is autonomously supported on the foundation) or the Closure Lid, which is autonomously supported on the CEC structure. As required by the system's maintenance program, any visible gap or crevice between the Container Flange and the surface pad shall be filled with grout or caulking for both aesthetic purposes and enhancement of degradation and corrosion mitigation.

d. Effect of Corrosion: It can be readily deduced from the VVM's design that the only surfaces that are not accessible for corrosion monitoring are the bottom face and outer cylindrical surface of the CEC. As discussed in Chapter 8, corrosion mitigation measures for these surfaces are prescribed and expected to provide adequate corrosion mitigation beyond the Design Life of the VVM. Additionally, any CEC or bottom plate corrosion would have a negligible effect on the off-site dose as the majority of the off-site dose contribution is from the inlets, the inlet plenum region and the outlet.

Thus, the potential for reduction in the shielding effectiveness of the HI-STORM UMAX system due to corrosion is not a concern.

e. Water Intrusion: The HI-STORM UMAX system has three barriers against water intrusion in the fuel space, each of which is engineered to independently prevent incursion of water:

i. The Support Foundation pad and the Enclosure shell (see the Drawing package in Section 1.5) provide a robust barrier against seepage of groundwater in the subgrade surrounding the CECs.

ii. The CEC is a thick-walled welded container that has no penetrations in its body through which water may leak in the MPC storage cavities.

iii. The MPC is a stainless steel weldment designed with fully volumetrically examined Section III class 1 butt welds.

f. Materials of Construction: The materials of construction in the underground portion of the CEC are carbon steel and stainless steel, both of which are proven materials of long-term shielding endurance under neutron and gamma fluence levels that are orders of magnitude greater than those present in the CEC. The Closure Lid is comprised of carbon or stainless steel that encases plain concrete. Concrete, like steel, is a proven durable material in a radiation environment that suffers negligible change in its shielding capability over long periods of use in a radiation environment. Therefore, material-degradation-induced reduction in the shielding effectiveness of the VVM is not a credible concern.

In summary, The design features of the HI-STORM UMAX components ensure that the occupational dose as well as off-site dose from the ISFSI will be ALARA.

11.3 ESTIMATED ON-SITE CUMULATIVE DOSE ASSESSMENT

11.3.1 Estimated Exposures for Loading and Unloading Operations

This section discusses the cumulative exposure to personnel performing loading, unloading, and transfer operations using the HI-STORM UMAX system. Additionally, this section provides measured operational dose values from the actual loading campaigns of an above ground system. As the operational aspects of both underground and aboveground systems are quite similar, as discussed below, the realistic campaign dose of the aboveground system would also be applicable to the HI-STORM UMAX.

The operations associated with the use of the HI-STORM UMAX, described in Chapter 9, are quite similar to the operations for all other variations of the HI-STORM 100 and HI-STORM FW systems. In both the aboveground and underground overpack, the MPC is transferred between the HI-TRAC and the overpack and in both cases the lid of the overpack is placed atop the overpack once the HI-TRAC is removed from the overpack. The only significant difference between the aboveground and underground overpack is the position of the HI-TRAC relative to ground level. For the aboveground overpack, the bottom of the HI-TRAC is approximately 18 feet above the ground and for the underground overpack, the bottom of the HI-TRAC is essentially at ground level. From an operations perspective, it will be easier to access the mating device and the pool lid bolts when the HI-TRAC is positioned atop the underground overpack rather than the aboveground overpack. In both cases, the same bolting and unbolting operations around the base of the HI-TRAC must be performed. Therefore, the estimated occupational dose for these scenarios is the same. The fact that the body of the HI-TRAC is closer to the ground when the underground overpack is being loaded will not affect the occupational dose rate since it is assumed that the workers not performing a task are positioned far enough away as to receive minimal dose. Once the MPC transfer is complete and the HI-TRAC has been removed, the lid is placed on the overpack. For the underground overpack, this is a relatively simple operation of lifting the lid and placing it in the correct location. Unlike the aboveground overpack, the lid is not bolted to the body of the overpack. However, the outlet vent cover is installed on the overpack lid after the lid is placed upon the HI-STORM UMAX, an installation that requires bolting. Installation of the outlet vent cover places workers over the lid and adds some time to the operation. As the dose rates on the side of the outlet vent (dose location 2 in Chapter 5) and top of the VVM lid (dose location 3 in Chapter 5) are small (see Tables 5.1.1 and 5.1.2), the operational dose for this operation would be very small compared to the entire MPC transfer into the VVM. Nevertheless, it is recommended that the operators do not spend any unnecessary time on top of the lid to ensure/meet the ALARA principle.

As for the above-ground systems, exposure estimates for loading operations are expected to bound those for unloading operations for the HI-STORM UMAX. This assessment is based on the similarity of many loadings versus operations with the elimination of several of the more dose-intensive operations (such as weld inspections and leakage testing).

In summary, the estimates of occupational exposure for the entire MPC transfer operations from Reference [11.3.2] are directly applicable to the HI-STORM UMAX, and no further evaluations are performed here.

Additionally, experience has shown that the occupational doses are in general significantly lower than those estimated in [11.3.1] and [11.3.2]. To highlight this, typical total occupational doses for 5 cask loadings are listed in Table 11.3.1, while Table 11.3.2 presents the dose of each operational step for Casks 4 and 5 from Table 11.3.1. These are for aboveground systems using a 100 t HI-TRAC. As discussed above, since the operational sequence for loading the HI-STORM UMAX is essentially the same as for the above ground systems, similar values would be expected for the HI-STORM UMAX.

11.3.2 Excavation Activities

In the event it is desired to expand an ISFSI utilizing the HI-STORM UMAX design, excavation of material (i.e., soil) is required. Radiation protection of the excavation activities is achieved by prescribing a minimum proximity of any excavation to an existing HI-STORM UMAX array. Site specific radiation protection measures for excavation activities need to include confirmation of the minimum SES properties along with the minimum distances between the excavation area and the loaded VVMs, as well as radiological monitoring of the excavation area.

Site specific evaluations also need to be performed to ensure that the radiation protection space boundary is maintained. Site specific accident scenarios (e.g., seismic conditions) will need to be accounted for in these evaluations. Table 5.4.4 presents a representative dose rate at the surface of the radiation protection space. Additionally, a general accident scenario evaluation has been performed for the HI-STORM UMAX design. The impact of a tornado missile penetrating the SES creating a horizontal hole extending 5.5 feet from the external surface of the radiation protection boundary was considered. This evaluation, presented in Table 5.1.4, demonstrates that the dose at the site boundary is below the limit specified in 10 CFR 72.

11.3.3 Normal Operation of Storage

During normal operation of storage, radiation will predominantly emanate from the inlet and outlet vents and the top of the lid. However, there are also some additional radiations streaming paths and scenarios that may have to be considered in the radiation protection program. The following two scenarios have been evaluated for the HI-STORM UMAX design.

The first scenario evaluated address radiation streaming from a loaded VVM through an adjacent empty VVM. An empty VVM adjacent to a loaded VVM could potentially constitute a radiation streaming path since the SES providing shielding is limited between adjacent VVMs. Therefore, radiation passing through the SES to the unloaded VVM will have a path of less shielding and could contribute to occupational dose. This evaluation is presented in Chapter 5, and concluded that there are no concerns about the dose rates

contributing to occupational dose across the top of the empty VVM due to radiation streaming from the loaded neighboring VVM.

The second scenario concerns the SES access tube, or test station, that is part of the ICCPS design and could represent a potential streaming path. Therefore, radiation passing through the SES access tube could contribute to occupational dose. This evaluation is presented in Chapter 5, and assumes a tube located about 5.5 feet from the center of the VVM with a diameter of 4 inches, that reaches down to the support foundation. With these dimensions, it is shown that there are no concerns about the dose rates contributing to occupational dose on the top of the SES access tube due to radiation streaming from a loaded VVM. However, if the tube is larger or located closer to the VVM, then the actual dimensions should be considered in the site specific dose rate calculations, and the result of the calculations should be considered in the site specific radiation protection program.

11.3.4 Estimated Exposures for Surveillance and Maintenance

Because of its low profile, the surveillance at a HI-STORM UMAX ISFSI can be performed without physically walking between the VVMs and therefore, occupational exposure required for security surveillance and maintenance will be bounded by above ground systems [11.3.2]. Typical estimates of the occupational exposure required for security surveillance and maintenance of an ISFSI can be found in References [11.3.1][11.3.2]. Security surveillance time is based on a daily security patrol around the perimeter of the ISFSI security fence. Users may opt to utilize electronic temperature monitoring of the HI-STORM UMAX modules or remote viewing methods instead of performing direct visual observation of the modules. Although the HI-STORM UMAX system requires only minimal maintenance during storage (e.g., touch-up paint), maintenance will be required around the ISFSI for items such as security equipment maintenance, grass cutting, snow removal, vent system surveillance, drainage system maintenance, and lighting, telephone, and intercom repair. Such infrequent activities are not included in the site boundary dose assessment.

Table 11.3.1

MEASURED TOTAL OPERATIONAL DOSE FOR A LOADING CAMPAIGN USING HI-STORM SYSTEMS

Cask Number	Total Heat Load (kW)	Total Campaign Dose (mrem)
1	23.79	370
2	24.96	208
3	25.70	183
4	25.75	164
5	26.36	187

Table 11.3.2 MEASURED OPERATIONAL DOSE FOR DIFFERENT TASKS FOR CASKS 4 AND 5 IN TABLE 11.3.1		
Task Description	Cask 4 (mrem)	Cask 5 (mrem)
	25.75 kW	26.36 kW
Preparations and placement of HI-TRAC in spent fuel pool	2	3
Fuel loading and verification	13	8
Placement of HI-TRAC in the decontamination pit and decontamination	35	34
Welding of MPC lid	14	18
Drying operation	20	19
Welding of the closure plates	33	34
Stackup operation	43	60
Move HI-STORM to ISFSI	4	11
Total dose	**164**	**187**

CHAPTER 12: ACCIDENT EVALUATION

12.0 INTRODUCTION

This chapter is focused on the safety evaluation of all off-normal and accident events germane to the HI-STORM UMAX vertical ventilated module (VVM) containing a loaded Multi-purpose Canister (MPC). For each postulated event, the event cause, means of detection, consequences, and corrective actions, as applicable, are discussed and evaluated. For other miscellaneous events (i.e., those not categorized as either design basis off-normal or accident condition events), a similar outline for safety analysis is followed. As applicable, the evaluation of consequences includes the impact on the structural, thermal, shielding, criticality, confinement, and radiation protection performance of the system due to each postulated event.

The analyses summarized in this chapter focus on the governing canisters out of the population of MPCs listed in Table 1.2.1. This chapter, however, supports the certification of only MPC-37 and MPC-89 at this time. The analyses reported for smaller canisters are for reference purposes only.

The structural, thermal, shielding, criticality, and confinement features and performance of the HI-STORM UMAX system under the short-term operations and various conditions of storage are discussed in Chapters 3, 4, 5, 6, and 7. The evaluations provided in this chapter are based on the design features and analyses reported therein. The accidents considered in this chapter follow the guidance in NUREG-1536.

Technical descriptions and safety analyses pertaining to the components common to the "FW" and the "UMAX" systems are referenced in this FSAR, as appropriate, to the HI-STORM FW FSAR. To facilitate convenient access to the referenced material, the latest edition of the HI-STORM FW FSAR has been placed in this docket and a list of "FW" FSAR sections germane to this chapter is provided in Table 12.0.1 herein.

TABLE 12.0.1

APPLICABLE SECTIONS OF HI-STORM FW FSAR*

Location of UMAX FSAR	**Subject of the Reference**	**Location in HI-STORM FW FSAR, Revision 3**
Sub-Section 12.1.1	Structural evaluation of the MPC enclosure vessel for off-normal internal pressure conditions	Sub-Section 3.4.4
Sub-Section 12.1.2	Limitations on the use of the HI-TRAC VW cask for loading MPCs under off-normal thermal conditions	Sub-Section 12.1.2
Sub-Section 12.1.3	Leakage of one MPC seal weld	Sub-Section 12.1.3
Sub-Section 12.1.6	FHD malfunction evaluations	Sub-Section 12.1.5
Sub-Section 12.2.1	Fire accident evaluation	Sub-Section 12.2.4
Sub-Section 12.2.2	Partial blockage of MPC basket vent holes	Sub-Section 12.2.5
Sub-section 12.2.3	Tornado analysis for HI-TRAC VW	Sub-Section 12.2.6
Sub-Section 12.2.7	Confinement Boundary Leakage	Section 7.1
Sub-Section 12.2.13	HI-TRAC VW handling accidents	Sub-Section 12.2.1
Sub-Section 12.3.2	MPC reflood evaluation	Sub-Section 12.3.1

* For convenience of reference, the specific revision of the HI-STORM FW FSAR that is referenced in the safety analysis herein is placed in this docket. Updated versions of the HI-STORM FW FSAR shall be placed in this docket as necessary so as to ensure that the safety analyses on the "UMAX" docket (72-1040) remain aligned with the material referenced in the HI-STORM FW FSAR.

12.1 OFF-NORMAL CONDITIONS

Off-normal conditions, as defined in accordance with ANSI/ANS-57.9, are those conditions which, although not occurring regularly, are expected to occur no more than once a year. In this section, design events pertaining to off-normal operation for expected operational occurrences are considered. The off-normal conditions are described in Section 2.3.

The following off-normal events are applicable to the HI-STORM UMAX system:

- Off-Normal Pressure
- Off-Normal Environmental Temperature
- Leakage of One Seal
- Partial Blockage of the Air Inlet Plenum
- Hypothetical Non-Quiescent Wind
- FHD Malfunction

The results of the evaluations presented herein demonstrate that the HI-STORM UMAX System can withstand the effects of off-normal events and remain in compliance with the applicable acceptance criteria.

12.1.1 Off-Normal Pressure

The sole pressure boundary in the HI-STORM UMAX storage System is the MPC enclosure vessel. The off-normal pressure condition is specified in Section 2.3. The off-normal pressure for the MPC internal cavity is a function of the initial helium fill pressure and the steady state temperature reached within the MPC cavity under normal ambient temperature. The MPC internal pressure under the off-normal condition is evaluated with 10% of the fuel rods ruptured and with 100% of ruptured rods fill gas and 30% of ruptured rods fission gases released to the cavity.

12.1.1.1 Postulated Cause of Off-Normal Pressure

After fuel assembly loading, the MPC is drained, dried, and backfilled with an inert gas (helium) to assure long-term fuel cladding integrity during dry storage. Therefore, the probability of failure of intact fuel rods in dry storage is extremely low. Nonetheless, the event is postulated and evaluated.

12.1.1.2 Detection of Off-Normal Pressure

The HI-STORM UMAX system is designed to withstand the MPC off-normal internal pressure without any effects on its ability to meet its safety requirements. There is no requirement or safety imperative for detection of off-normal pressure and, therefore, no monitoring is required.

12.1.1.3 Analysis of Effects and Consequences of Off-Normal Pressure

The MPC off-normal internal pressure is reported in Section 4.6.1.4 for the limiting fuel storage scenario wherein the canister pressurized to the technical specification maximum helium backfill pressure sustains a 10% rod rupture that causes a 100% of the ruptured rod fill gas and 30% of the ruptured rod gaseous fission products released into the MPC cavity.

The analysis of the above scenario shows that the MPC pressure remains below the design MPC internal pressure (given in Table 2.3.5).

i. Structural

The structural evaluation of the MPC enclosure vessel for off-normal internal pressure conditions is discussed in the HI-STORM FW FSAR [4.1.2]. The stresses resulting from the off-normal pressure are confirmed to be bounded by the applicable pressure boundary stress limits.

ii. Thermal

The MPC internal pressure for off-normal conditions is reported in Table 4.4.7. The design basis internal pressure used in the structural evaluation (Table 2.3.5) bounds the computed off-normal condition pressure.

iii. Shielding

There is no effect on the shielding performance of the system as a result of this off-normal event.

iv. Criticality

There is no effect on the criticality control features of the system as a result of this off-normal event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this off-normal event. As discussed in the structural evaluation above, all pressure boundary stresses remain within allowable ASME Code values, assuring Confinement Boundary integrity.

vi. Radiation Protection

Since there is no degradation in shielding or confinement capabilities as discussed above, there is no effect on occupational or public exposures as a result of this off-normal event.

12.1.1.4 Corrective Action for Off-Normal Pressure

The HI-STORM UMAX system is designed to withstand the off-normal pressure without any effects on its ability to maintain safe storage conditions. Therefore, there is no corrective action requirement for off-normal pressure.

12.1.1.5 Radiological Impact of Off-Normal Pressure

The event of off-normal pressure has no radiological impact because the confinement barrier and shielding integrity are not affected.

12.1.1.6 Conclusion

Based on this evaluation, it is concluded that the off-normal pressure does not affect the safe operation of the HI-STORM UMAX system.

12.1.2 Off-Normal Environmental Temperatures

The HI-STORM UMAX System is designed for use at any site in the United States. Off-normal environmental temperatures have been conservatively selected to bound the environmental temperatures at all candidate sites in the United States (See Subsection 2.3.3 for definition of the term off-normal environmental temperature). The off-normal temperature limits are reported in Table 2.3.6.

12.1.2.1 Postulated Cause of Off-Normal Environmental Temperatures

The off-normal environmental temperature is postulated as a constant ambient temperature caused by extreme weather conditions. To determine the effects of the off-normal temperatures, it is conservatively assumed that these temperatures persist for a sufficient duration to allow the HI-STORM UMAX System to achieve thermal equilibrium. Because of the large mass of the HI-STORM UMAX System with its corresponding large thermal inertia and the limited duration for the off-normal temperatures, this assumption is conservative.

12.1.2.2 Detection of Off-Normal Environmental Temperatures

The HI-STORM UMAX System is designed to withstand the off-normal environmental temperatures without any effects on its ability to maintain safe storage conditions. There is no requirement for detection of off-normal environmental temperatures for the HI-STORM UMAX overpack and MPC. The limitations on the use of the transfer cask for loading canisters in the HI-STORM UMAX system under off-normal thermal conditions are contained in Section 12.1.2 of the HI-STORM FW FSAR which must be observed.

12.1.2.3 Analysis of Effects and Consequences of Off-Normal Environmental Temperatures

The off-normal event is considered to be characterized by an off-normal environmental temperature with insolation for sufficient duration to reach thermal equilibrium. The evaluation is performed for a limiting fuel storage configuration. The off-Normal ambient temperature condition is evaluated in Subsection 4.6.1.1. The results are in compliance with off-normal pressure and temperature limits in Tables 2.3.5 and 2.3.7 in Chapter 2.

The off-normal event considering an environmental temperature of -40°F and no solar insolation for a sufficient duration to reach thermal equilibrium is evaluated with respect to material design temperatures of the HI-STORM UMAX VVM. The HI-STORM UMAX VVM structure is conservatively assumed to reach the extreme cold condition (-40°F) throughout its body. The qualification of the VVM structure under the extreme cold condition is provided in Chapter 8.

i. Structural

The effect on the MPC for the upper off-normal thermal conditions is an increase in the internal pressure. As shown in Section 4.6.1.1, the resultant pressure is below the off-normal design pressure (Table 2.3.5). The stresses resulting from the off-normal pressure are confirmed to be bounded by the applicable pressure boundary stress limits. The effect of the lower off-normal thermal conditions (i.e., -40°F) requires an evaluation of the potential for brittle fracture. Such an evaluation is presented in Chapter 8.

ii. Thermal

The resulting off-normal system and fuel assembly cladding temperatures for the hot conditions are provided in Table 4.6.1. This evaluation indicates that all temperatures for the off-normal environmental temperatures event are within the allowable values for off-normal conditions listed in Table 2.3.7. Additionally, the increased temperatures generate an elevated MPC internal pressure, reported in Table 4.6.5, which is less than the off-normal design pressure limit specified in Table 2.3.5. The temperatures and pressures resulting from the off-normal ambient temperature event are confirmed to be bounded by

the applicable system temperature and pressure limits; therefore, there is no adverse effect on the system's thermal function.

iii. Shielding

There is no effect on the shielding performance of the system as a result of this off-normal event.

iv. Criticality

There is no effect on the criticality control features of the system as a result of this off-normal event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this off-normal event. As discussed in the structural evaluation above, all pressure boundary stresses in the canister remain within allowable ASME Code values, assuring Confinement Boundary integrity.

vi. Radiation Protection

Since there is no degradation in shielding or confinement capabilities as discussed above, there is no effect on occupational or public exposures as a result of this off-normal event.

12.1.2.4 Corrective Action for Off-Normal Environmental Temperatures

The HI-STORM UMAX System is designed to withstand the off-normal environmental temperatures without any effects on its ability to maintain safe storage conditions. As required by the HI-STORM FW FSAR [4.1.2], for ambient temperatures from 0° to 32°F, ethylene glycol fortified water must be used in the water jacket of the HI-TRAC VW transfer cask to prevent freezing. There are no corrective actions required for off-normal environmental temperatures.

12.1.2.5 Radiological Impact of Off-Normal Environmental Temperatures

Off-normal environmental temperatures have no radiological impact, as the confinement barrier and shielding integrity are not affected.

12.1.2.6 Conclusion

Based on the above evaluation, it is concluded that the specified off-normal environmental temperatures do not affect the safe operation of the HI-STORM UMAX System.

12.1.3 Leakage of One MPC Seal Weld

Leakage of one MPC seal weld evaluated in the HI-STORM FW FSAR Section 12.1.3 [4.1.2] is incorporated by reference.

12.1.4 Partial Blockage of Air Inlet Plenum

Partial blockage (50%) of the air intake system has been postulated as an off-normal event in Section 2.5.

The HI-STORM UMAX intake ducts are designed with debris screens, as is the outlet vent flue located in the Closure Lid. These screens protect the openings from the incursion of foreign objects. However, as required by the design criteria presented in Chapter 2, it is conservatively assumed that 50% of the air inlet opening is completely blocked. The scenario of the partial blockage of air inlets is evaluated with a normal ambient temperature (Table 2.3.6), full solar insolation, and Design Basis SNF decay heat value case. This condition is analyzed in Chapter 4 to demonstrate the acceptability of the system thermal performance during this event.

12.1.4.1 Postulated Cause of Partial Blockage of Air Inlets

The presence of screens prevents foreign objects from entering the openings and the screens are either inspected periodically or the system temperature field is monitored per the technical specifications. It is, however, possible that blowing debris may partially block the inlet openings for a short time until the openings are cleared of debris.

12.1.4.2 Detection of Partial Blockage of Air Inlet

The detection of the partial blockage of air inlet openings will occur during the routine visual inspection of the screens or temperature monitoring of the outlet air required by the technical specifications. The frequency of inspection is based on an assumed complete blockage of all air inlet openings. There is no inspection requirement as a result of the postulated partial inlet blockage because the complete blockage of all air inlet openings is bounding.

12.1.4.3 Analysis of Effects and Consequences of Partial Blockage of Air Inlets

i. Structural

The effect of partial blockage of the air inlet plenum on the MPC is an increase in component and fuel cladding temperatures and internal pressure and thus an increase in pressure boundary stresses. However, the resultant temperatures and pressures are below the off-normal design limits as discussed in the thermal effects evaluation below. The MPC stresses resulting from the partial blockage of air inlets are confirmed to be bounded by the applicable pressure boundary stress limits; therefore, there is no effect on structural function.

In summary, there are no structural consequences as a result of this off-normal event since the HI-STORM UMAX components do not exceed the off-normal temperature limits (Table 2.3.7).

ii. Thermal

The thermal evaluation of partial blockage of air inlet is discussed in Subsection 4.6.1.2. The calculated bounding temperatures conservatively evaluated as a 50% blockage of sufficient duration to reach the asymptotic maximum (steady-state) temperature field are reported in Table 4.6.1 and below the MPC and VVM off-normal design temperature limits specified in Table 2.3.7, as applicable. Additionally, the increased temperatures generate an elevated MPC internal pressure, reported in Table 4.6.5, which is less than the off-normal design pressure limit specified in Table 2.3.5. The temperatures and pressures resulting from the partial blockage of air inlet event are confirmed to be bounded by the applicable system temperature and pressure limits; therefore, there is no adverse effect on the system's thermal function.

iii. Shielding

There is no adverse effect on the function of shielding features of storage the system as a result of this off-normal event.

iv. Criticality

There is no effect on the criticality control features of the system as a result of this off-normal event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this off-normal event.

vi. Radiation Protection

Since there is no degradation in shielding or confinement capabilities as discussed above, there is no predicted adverse effect on occupational or public exposures as a result of this off-normal event.

12.1.4.4 Corrective Action for Partial Blockage of Air Inlets

The corrective action for the partial blockage of air inlet openings is the removal, cleaning, and replacement of the affected mesh screens. After clearing of the blockage, the storage module

temperatures will return to the normal temperatures reported in Chapter 4. Partial blockage of air inlet openings does not affect the safe operation of the HI-STORM UMAX System.

Periodic inspection of the HI-STORM UMAX air opening screens is required per the technical specifications. Alternatively, per the technical specifications, the outlet air temperature is monitored. The frequency of inspection is based on an assumed blockage of all air inlet openings analyzed in Section 12.2.

12.1.4.5 Radiological Impact of Partial Blockage of Air Inlets

The off-normal event of partial blockage of the air inlet opening has no radiological impact because the confinement barrier is not breached and the system's shielding effectiveness is not diminished.

12.1.4.6 Conclusion

Based on the above evaluation, it is concluded that the off-normal partial blockage of air inlet ducts event does not affect the safe operation of the HI-STORM UMAX VVM.

12.1.5 Hypothetical Non-Quiescent Wind

12.1.5.1 Cause of Event

Wind is a meteorological event that occurs in every area in the world. The normal condition of storage of the canisters assumes quiescent ambient conditions with an annular average temperature that bounds the historical data for all sites in the United States. The hypothetical non-quiescent wind condition is intended to simulate the thermal response of a site subject to a persistent wind event that tends to disrupt the heat rejection performance of the system.

12.1.5.2 Simulation of the Event

The HI-STORM UMAX storage system is designed to store the canisters listed in Table 1.2.1 at any ISFSI site in the United States in compliance with this FSAR. Chapter 4 evaluates the effects of low speed wind postulated as a constant horizontal wind caused by hypothetical weather conditions (see Section 4.6.1.3). To determine the effects of this hypothetical wind event, it is conservatively assumed that the wind persists in a fixed direction for a sufficient duration to allow the HI-STORM UMAX system to reach thermal equilibrium. Temperature results are compared with off-normal temperature limits. Because of the large mass of the HI-STORM UMAX System with its corresponding large thermal inertia and the unlikely condition of a unidirectional wind existing for a long period of time, this assumption is extremely conservative.

12.1.5.3 Safety Analysis

The following is an evaluation of effects on structural, thermal, criticality, confinement, and radiation protection performance on the HI-STORM UMAX storage system:

i. Structural

The effect on the MPC for the hypothetical non-quiescent wind condition is an increase in component and fuel cladding temperatures and internal pressure and thus an increase in pressure boundary stresses. However, the resultant temperatures and pressures are below the off-normal design limits as discussed in the thermal effects evaluation below. The MPC stresses resulting from the off-normal temperature event are confirmed to be bounded by the applicable pressure boundary stress limits; therefore, there is no effect on structural function.

ii. Thermal

Chapter 4 calculates peak fuel cladding temperatures as a function of the horizontal wind speed. The calculated maximum peak cladding temperatures reported in Table 4.6.4 are below the off-normal limits specified in Table 2.3.7 for both moderate burnup and high burnup fuel. Additionally, the elevated MPC internal pressure is reported in Table 4.6.5, which is less than the off-normal design pressure limit specified in Table 2.3.5. By this evaluation, temperatures and pressures resulting from the hypothetical non-quiescent wind event are confirmed to be bounded by the applicable system off-normal temperature and pressure limits; therefore, there is no effect on thermal function.

iii. Shielding

There is no effect on the function of shielding features of the system as a result of this event.

iv. Criticality

There is no effect on the function criticality control features of the MPC as a result of this event.

v. Confinement

There is no effect on the function of confinement features of the MPC as a result of this event.

vi. Radiation Protection and Consequences

Since there is no effect on shielding or confinement functions as discussed above, there is no radiological consequence (from effluents and direct radiation) and no expected increase to occupational exposures as a result of this event.

12.1.5.4 Corrective Action and Counter-measures

Because the HI-STORM UMAX System is designed to withstand the hypothetical non-quiescent wind event without any effect on its ability to maintain safe storage conditions, there is no requirement for detection and counter-measures.

12.1.5.5 Conclusion

Based on this evaluation, it is concluded that the hypothetical non-quiescent wind event does not affect the safe operation of the HI-STORM UMAX VVMs.

12.1.6 FHD Malfunction

FHD malfunction evaluated in the HI-STORM FW FSAR Section 12.1.5 [4.1.2] is incorporated by reference.

12.2 ACCIDENT EVENTS

Accidents, in accordance with ANSI/ANS-57.9, are either infrequent events that could reasonably be expected to occur during the lifetime of the HI-STORM UMAX system or events postulated because their consequences may affect the public health and safety. Sections 2.4 and 2.5, respectively, define the structurally and thermally significant loadings that are classified design basis accidents. These design basis accident events have been evaluated in this FSAR to quantify the safety margins in the storage system.

The load combinations evaluated for postulated accident conditions are defined in Chapter 2. The structural qualification of accidents is provided in Chapter 3.

The following accident events germane to the safety evaluation of HI-STORM UMAX system are identified by reference to Sections 2.4 and 2.5:

- Fire Accident
- Partial Blockage of MPC Basket Vent Holes in long- term storage
- Tornado
- Flood
- Earthquake
- 100% Fuel Rod Rupture
- Confinement Boundary Leakage
- Explosion
- Lightning
- 100% Blockage of Air Inlets
- Burial Under Debris
- Extreme Environmental Temperature
- HI-TRAC VW Transfer Cask Handling Accident

The results of the evaluations performed in this FSAR demonstrate that the HI-STORM UMAX storage system can withstand the effects of all credible and hypothetical accident conditions and natural phenomena without affecting its safety function, In the following, the evaluation of the design basis postulated accident conditions and natural phenomena is presented which demonstrates that the requirements of 10CFR72.122 and of 10 CFR72.106(b) and 10CFR20 are met.

12.2.1 Design Basis Fire Event (Load Case 5 in Section 2.4)

12.2.1.1 Cause of Fire

The potential of a fire accident near an ISFSI pad is considered to be rendered extremely remote by ensuring that there are no significant combustible materials in the area. The only credible concern is related to a transport vehicle fuel tank fire engulfing a loaded HI-STORM UMAX

VVM or a HI-TRAC VW transfer cask. HI-TRAC VW transfer cask fire evaluated in the HI-STORM FW FSAR Section 12.2.4 [4.1.2] is incorporated by reference. HI-STORM UMAX fire is evaluated in the following.

12.2.1.2 Fire Analysis

The HI-STORM UMAX System must withstand elevated temperatures under the Design Basis Fire event defined in Table 2.3.1. The acceptance criteria for the fire accident are provided in Section 2.3 and the thermal analysis is contained in Section 4.6.2.1.

i. Structural

The effect of the fire accident on the HI-STORM UMAX system is an increase in fuel cladding and system component temperatures and MPC internal pressure and thus an increase in MPC pressure boundary stresses. However, the resultant temperatures and pressures are below the accident design limits as discussed below. The MPC stresses resulting from the fire accident event are confirmed to be bounded by the applicable pressure boundary stress limits; therefore, there is no effect on structural function.

ii. Thermal

As discussed in Chapter 4, the effect of the fire does not cause any system component or the contained fuel to exceed any limit set in this FSAR. The Design Basis Fire has a negligible impact on MPC pressure. The temperatures and pressures resulting from the fire accident event are confirmed to be bounded by the applicable system temperature and pressure limits; therefore, there is no deleterious effect on the system's thermal function.

iii. Shielding

The loss of shielding, if any, has been determined by scoping calculations to be of insignificant consequence in Chapter 4. With respect to concrete damage from a fire, NUREG-1536 (4.0,V,5.b) states: "the loss of a small amount of shielding material is not expected to cause a storage system to exceed the regulatory requirements in 10 CFR 72.106 and, therefore, need not be estimated or evaluated in the FSAR.

Less than 5% of the Closure Lid concrete thickness is computed to exceed the short-term temperature limit therefore the effect of this small amount of degraded (not lost) shielding material is not estimated or evaluated in this FSAR.

iv Criticality

There is no effect on the criticality control features of the system as a result of this event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this event since the structural integrity of the confinement boundary is unaffected.

vi. Radiation Protection

Since there is minimal reduction, if any, in shielding and no effect on the confinement capabilities as discussed above, there is no effect on occupational or public exposures as a result of this accident event.

12.2.1.3 Fire Accident Corrective Actions

Upon detection of a fire adjacent to a loaded HI-STORM UMAX VVM, the ISFSI owner shall take the appropriate immediate actions necessary to extinguish the fire. Following the termination of the fire, a visual and radiological inspection of the equipment shall be performed.

If damage to the HI-STORM UMAX VVM as the result of a fire event is widespread, and/or as radiological conditions require (based on dose rate measurements), the MPC shall be removed from the HI-STORM UMAX VVM in accordance with the procedure set down in Chapter 9. However, the thermal analysis described herein demonstrates that only a limited amount of lid concrete which is behind the steel enclosure exceeds its design temperature. The HI-STORM UMAX VVM may be returned to service after appropriate restoration (reapplication of coatings, etc.) if there is no significant increase in the measured dose rates (i.e., the shielding effectiveness of the overpack is confirmed) and if the visual inspection is satisfactory.

There is no effect on the function of criticality control features of the MPC as a result of this accident event.

Based on the foregoing evaluation, it is concluded that the overpack fire accident does not affect the safe operation of the HI-STORM UMAX VVMs.

12.2.1.4 Conclusion

Based on the above evaluation, it is concluded that the Design Basis Fire accident does not affect the safe operation of the HI-STORM UMAX System.

12.2.2 Partial Blockage of MPC Basket Vent Holes

Partial blockage of MPC basket vent holes evaluated in the HI-STORM FW FSAR Section 12.2.5 [4.1.2] is incorporated by reference.

12.2.3 Tornado (Load Case 02 in Section 2.4)

12.2.3.1 Causal Factors

Tornado and high winds are principally caused by the uneven heating of the earth's atmosphere, coupled with gravitational forces and the rotation of the earth. The HI-STORM UMAX System will be deployed in an open area environment and thus will be subject to ambient environmental conditions throughout the storage period. Additionally, the transfer of the MPC between the HI-TRAC VW transfer cask and the storage overpack may be performed at the unsheltered ISFSI concrete pad. It is therefore possible that the HI-STORM UMAX storage system may experience the extreme environmental conditions resulting in the impact from a tornado-borne projectile.

12.2.3.2 Tornado Analysis

A tornado event is characterized by high wind velocities and tornado-generated missiles. The reference missiles considered in this FSAR (see Table 2.3.3) are of three sizes: small, medium, and large. A small projectile, upon collision with a cask, would tend to penetrate it. A large projectile, such as an automobile, on the other hand, would tend to cause deformation.

Because of its underground construction, the HI-STORM UMAX is not subject to overturning action by the tornado wind. The effect of tornado missiles propelled by high velocity winds that attempt to penetrate the exposed portions of the HI-STORM UMAX must, however, be considered.

The tornado analysis for a HI-TRAC VW transfer cask evaluated in the HI-STORM FW FSAR Section 12.2.6 [4.1.2] is incorporated by reference.

The evaluation of effects on structural, thermal, criticality, confinement, and radiation protection performance on the HI-STORM UMAX system is summarized below.

i. Structural

Analyses presented in Chapter 3 show that the impact of large and intermediate tornado missiles (see Table 2.3.3) on the HI-STORM UMAX closure lid does not result in the perforation of the lid or result in a structural collapse of the lid. The sole effect of the tornado missile impact on the HI-STORM UMAX VVM is some minor global deformation of the VVM Closure Lid under the large missile and some localized deformation of the VVM Closure Lid under the intermediate missile. All Design Basis missiles are found to be stopped by the VVM assembly before reaching the MPC stored inside. Therefore, MPC damage by impact from a Design Basis Missile is ruled out.

ii. Thermal

There is no effect on the function of HI-STORM UMAX VVM heat transfer features as a result of this accident event. The deformations in the VVM Closure Lid due to missile impact are minor relative to the available area of the flow opening.

iii. Shielding

Certain tornado missile scenarios may result in shielding degradation of the HI-STORM UMAX Closure Lid; however, the overall shielding effect will be negligible due to the sheer size and mass of the Closure Lid. (The HI-STORM UMAX VVM is heavily shielded (a thick MPC lid protected by the monolithic steel-concrete-steel VVM Closure Lid weighing in excess of 30,000 lbs; see Section 3.2.)

iv. Criticality

There is no effect on the criticality control features of the MPC as a result of this accident event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this accident event.

12.2.3.3 Radiation Protection and Consequences

There is no effect on shielding or confinement functions of the MPC. The effect on shielding function of the VVM Closure Lid is negligible and therefore the radiological impact on the site boundary dose will be negligible. Thus, a negligible increase in radiological consequence (from effluents and direct radiation) is expected as a result of this accident. A minor increase to occupational exposures for the performance of corrective actions is also expected.

12.2.3.4 Tornado Accident Corrective Action

Following exposure of the HI-STORM UMAX System to a tornado, the ISFSI owner shall perform a visual and radiological inspection of the facility.

Damage sustained by the VVMs or vent screens shall be inspected and may be repaired, if required, while in-service. The system may continue in service after appropriate restoration (reapplication of coatings, etc.) if there is no significant increase in the measured dose rates (i.e., the system's shielding effectiveness is confirmed) and if the final visual inspection is satisfactory.

12.2.3.5 Conclusion

Based on the above evaluation, it is concluded that the Design Basis tornado accident will not affect the safe operation of the HI-STORM UMAX System.

12.2.4 Flood (Load Case 7 in Table 2.4.1)

12.2.4.1 Cause of Flood

Many ISFSIs are located in flood plains susceptible to floods. Therefore, it is necessary for such ISFSIs to define a Design Basis Flood (DBF). The potential sources for the floodwater may be swelling rivers or streams from heavy rains or rapid melting of upstream snow, tsunami, dam break, earthquake, hurricane, etc.

12.2.4.2 Analysis

Because of its underground construction, the HI-STORM UMAX is not subject to overturning action by moving floodwater. The permissible height of floodwater for storing an MPC is governed by the design basis flood defined in Table 2.4.1. An MPC not qualified to withstand the external pressure from a site's Design Basis Flood event shall not deployed in the HI-STORM UMAX system.

The following is an evaluation of effects on structural, thermal, criticality, confinement, and radiation protection performance on the HI-STORM UMAX system.

i. Structural

Unlike free standing casks, moving flood water is not an event of safety consequence to the HI-STORM UMAX: The buried configuration of the HI-STORM UMAX system renders it immune from sliding (that is germane to above ground freestanding casks) under the action of a design basis flood. Since the CEC shell is directly in contact with the Self-hardening Engineered Subgrade, there is no risk of a global deformation of the CEC under the DBF event.

ii. Thermal

The flooded HI-STORM UMAX ISFSI will reject heat to the floodwater. Because the heat transfer coefficient in water is considerably greater than that under the ventilation air, the temperature of the contents will be lowered. Furthermore, the heat dissipated from MPC and MPC pedestal flood tends to boil the flood water entering "UMAX" cavity and lower water level to restore sufficient air ventilation flow. Thus, the thermal effect of flood is actually salutary for the system's performance.

Partial blockage of the bottom cutout is evaluated in Section 4.6.2.5. The resulting maximum temperatures are provided in Table 4.6.9, and confirmed to maintain below the accident temperature limits specified in Table 2.3.7. In the case when flood water/soil is just high enough to completely block the divider shell cutout, it is bounded by the 100% inlet duct blockage accident discussed in Section 12.2.10.

iii. Shielding

There is no adverse effect on the function of shielding features of the system as a result of this accident event. The floodwater provides additional shielding that would further reduce radiation dose.

iv. Criticality

There is no adverse effect on the criticality control features of the stored MPC as a result of this accident event. The criticality analysis is unaffected because under the flooding condition water cannot enter the MPC contents space and therefore the reactivity would be less than that under the loading condition in the spent fuel pool (when the MPC is flooded).

v. Confinement

Because, as shown in Chapter 3, the external pressure on the MPC from the DBF is well below its design basis pressure bearing capacity, there is no risk of degradation of the confinement function of the MPC as a result of this accident event. As discussed in the structural evaluation above, all stresses remain within allowable values, assuring confinement boundary integrity.

vi. Radiation Protection and Consequences

Since there is no effect on shielding or confinement functions as discussed above, there is no radiological consequence (from effluents and direct radiation) as a result of this accident event. A minor increase to occupational exposures for the performance of corrective actions is expected.

12.2.4.3 Flood Accident Corrective Action

The configuration of the HI-STORM UMAX VVMs makes them uniquely suited to withstand a flooding event. Indeed, introducing water in the CEC is an effective method to lower the MPC contents' temperature. However, accumulation of debris in the intake plenum or the storage cavities is undesirable as is the risk of corrosion from long-term exposure to floodwaters. Thus, while the short-term effect of flood on the loaded HI-STORM UMAX VVM is essentially benign, corrective actions after such an event are necessary. Visual examination using a boroscope or a camera or temperature monitoring of the exiting air to identify blockage of the

cooling passages following flooding or other site specific natural events is necessary to ensure adequate cooling.

If a state of vent blockage is discovered, then corrective actions to alleviate such condition will be required. To restore the system to a normal configuration, all floodwater and any debris deposited by the receding water must be removed. The specific methods to be used shall be addressed in the site emergency action plan. Examples of acceptable cleaning approaches include:

1. The MPC is removed from the VVM using the HI-TRAC VW transfer cask, allowing direct access to the interior of the VVM through both the inlet vents and the top of the module cavity. Water sprays and vacuuming are used to directly clean the VVM passages and surfaces.

2. Appropriate vacuuming equipment is inserted through the inlet plenum and down to the transverse shells. Water is sprayed in through the outlet vents. Remote cameras are used to inspect the VVM cooling passages to identify and remove debris.

The adequacy of the cooling passages clearance operation is verified by visual inspection or, if the optional temperature monitoring is used, the return of the control temperatures to within allowable limits.

12.2.4.4 Conclusion

Based on the above evaluation, it is concluded that the flood accident does not affect the safe operation of the loaded HI-STORM UMAX VVMs.

12.2.5 Earthquake (Load Case 03 in Section 2.4)
12.2.5.1 Cause of Event

Earthquake is a terrestrial instability event cause by relative movements in the mantle of the earth. The extent of seismic motion at an ISFSI location is established by geotechnical analyses. The intensity of the earthquake is substantially affected by the time span within which its probability is prognosticated.

12.2.5.2 Analysis of the Effect of Design Basis Earthquake (DBE)

The HI-STORM UMAX storage system has been qualified to a fully articulated DBE event set down in Section 2.4. The specified seismic event for the candidate ISFSI must satisfy the acceptance criteria defined in Chapters 2 and 3 to permit the HI-STORM UMAX ISFSI to be established at the site.

i. Structural

The most significant structural effect of the earthquake on the HI-STORM UMAX system are those corresponding to interface forces arising from the MPC rattling action, which acts to apply stresses on the MPC shell and MPC fuel basket panels. The MPC primary stresses resulting from the earthquake event are confirmed to be bounded by the applicable stress limits, and MPC shell secondary stresses local to the area of MPC lid are limited to small plastic deformation without risk of breaching the MPC shell; therefore, there is no effect on structural function.

All other effects correspond to ability of the VVM CEC, ISFSI Pad, and Support Foundation Pad to resist the earthquake loadings. Because the VVM is buried in the substrate, tip-over of the VVM is not credible. The entire VVM can move laterally with the surrounding and supporting substrate. Because of its underground construction, the HI-STORM UMAX VVM is inherently safe under seismic events. Analyses presented in Chapter 3 show that the VVM will continue to render its intended function under a seismic event whose severity is bounded by the Design Basis Earthquake set forth in Chapter 2. Therefore, there is no adverse effect on the structural function of the system.

ii. Thermal

There is no effect on the function of HI-STORM UMAX VVM heat transfer features as a result of this accident event because no constriction of the air flow passages within the system is predicted to occur. Concentricity between the MPC within the CEC shell is maintained by design features and therefore the effect of MPC movement within the storage cavity has a negligible impact on air flow distribution. Thus, the cooling effectiveness of the HI-STORM UMAX VVMs is expected to remain essentially undiminished in the wake of a DBE event.

iii. Shielding

There is no adverse effect on the function of shielding features of the system as a result of this accident event.

iv. Criticality

There is no effect on the criticality control features of the MPC as a result of this accident event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this accident event. Structural evaluation shows all stresses and strains do not exceed design criteria, assuring confinement boundary integrity.

vi. Radiation Protection and Consequences

Since there is no effect on shielding or confinement functions as discussed above, there is no radiological consequence (from effluents and direct radiation) as a result of this accident event. A minor increase to occupational exposures for the performance of corrective actions is expected.

12.2.5.3 Earthquake Accident Corrective Action

Under a seismic event at an ISFSI, any damage to the HI-STORM UMAX system is expected to be localized and limited to the MPC guides and the MPC shell. A visual inspection in the wake of a seismic event shall be performed as follows:

- Visual inspection to confirm the extent of damage (if any) to the MPC shell is negligible.
- Visual inspection to verity the extent of damage (if any) to other VVM components important-to-safety is negligible.
- Visual inspection to confirm that the insulation attached to the Divider shell remains securely attached and undamaged
- Visual inspection to confirm all air flow passages are clear of obstructions.

Inspections requirements may be modified depending on the severity of the earthquake and other site-specific conditions. Corrective actions shall be implemented based on the results of the inspection.

12.2.5.4 Conclusion

Based on the above evaluation, it is concluded that the Design Basis Earthquake will not affect the safe operation of the HI-STORM UMAX system. Corrective actions, however, may be necessary to restore the system to the pre-seismic condition.

12.2.6 100% Fuel Rod Rupture

This accident event postulates the non-mechanistic condition that all the fuel rods rupture and that the quantities of fission product gases and fill gas are released from the fuel rods into the MPC cavity consistent with ISG-5, Revision 1.

CERTIFICATE OF SERVICE

I hereby certify that on July 20, 2020, I electronically filed the foregoing with the Clerk of the Court for the United States Court of Appeals for the Ninth Circuit by using the appellate CM/ECF system.

Participants in the case who are registered CM/ECF users will be served by the appellate CM/ECF system.

Dated: July 20, 2020

12.2.6.1 Cause of 100% Fuel Rod Rupture

Through all credible accident conditions, the HI-STORM UMAX system maintains the spent nuclear fuel in an inert environment while maintaining the peak fuel cladding temperature below the required short-term temperature limits, thereby providing assurance of fuel cladding integrity. Therefore, there is no credible cause for 100% fuel rod rupture. This accident is postulated in NUREG-1536 to evaluate the MPC confinement barrier for the maximum possible internal pressure based on the *non-mechanistic* failure of 100% of the fuel rods.

12.2.6.2 Analysis

The following is an evaluation of effects on structural, thermal, criticality, confinement, and radiation protection performance on the HI-STORM UMAX storage system.

i. Structural

The effect of 100% rod rupture on the MPC is an increase in pressure boundary stresses. Calculations in Chapter 4 show that the accident internal pressure limit bounds the pressure from the 100% fuel rod rupture event; therefore, there is no effect on the MPC's structural function.

ii. Thermal

A bounding MPC internal pressure for the 100% fuel rod rupture condition is presented in Table 4.4.7. The design basis accident condition MPC internal pressure set in Table 2.3.5 and used in the structural evaluation bounds the calculated value. The increased pressure due to the 100% rod rupture has the concomitant (beneficial) effect of enhanced heat transfer through the gases in the MPC cavity. It is concluded that temperatures and pressures resulting from the accident event are bounded by the applicable system temperature and pressure limits; therefore, there is no adverse effect on thermal function.

v. Shielding

There is no adverse effect on function of the shielding features of the system as a result of this accident event.

vi. Criticality

There is no effect on the function of criticality control features of the MPC as a result of this accident event.

vii. Confinement

There is no effect on the function of confinement features of the MPC as a result of this accident event. Structural evaluation shows all stresses remain within allowable values, assuring confinement boundary integrity.

viii. Radiation Protection and Consequences

Since there is no effect on shielding or confinement functions as discussed above, there is no radiological consequence (from effluents and direct radiation) and no expected increase to occupational exposures as a result of this accident event.

Based on the above, it is concluded that the non-mechanistic 100% fuel rod rupture accident event does not affect the safe operation of the HI-STORM UMAX system.

12.2.6.3 100% Fuel Rod Rupture Dose Calculations

The breach of fuel cladding postulated in this accident event does not result in any physical change to the storage system other than some release of gases and a limited quantity of solids (particulates) into the gaseous helium space. The amount of the radiation source remains unaffected. Hence, the radiation dose at the site boundary will not change perceptibly, i.e., there are no consequences to the site boundary dose.

12.2.6.4 100% Fuel Rod Rupture Accident Corrective Action

As shown in the analysis of the 100% fuel rod rupture accident, the MPC Confinement Boundary is not damaged. The HI-STORM UMAX storage System is designed to withstand this accident and continue performing the safe storage of spent nuclear fuel under normal storage conditions. No corrective actions are required.

12.2.6.5 Conclusion

The above evaluation shows that this accident event will not adversely affect the continued safety of the storage system

12.2.7 Confinement Boundary Leakage

None of the postulated environmental phenomenon or accident conditions identified in Chapter 2 has been determined to precipitate failure of the confinement boundary. The MPC uses redundant confinement closures to assure that there is no release of radioactive materials. The analyses presented in the HI-STORM FW FSAR and in Chapter 3 herein demonstrate that the MPC remains intact during all postulated accident conditions. The information contained in Chapter 7 of the HI-STORM FW FSAR demonstrates that the MPC is designed, fabricated, tested, and inspected to meet the guidance of ISG-18 such that unacceptable leakage from the Confinement Boundary is non-credible.

12.2.8 Explosion (Load Case 01 in Section 2.4)

12.2.8.1 Cause of Explosion

An explosion within the protected area of an ISFSI is improbable since there are no explosive materials permitted within the site boundary. However, an explosion as a result of combustion of the fuel contained in a cask transport vehicle is possible. As the fuel available for the explosion is limited in quantity, the effects of an explosion on a reinforced structure are minimal. Explosions that are credible for a specific ISFSI would require a site hazards evaluation under the provisions of 10CFR72.212 regulations by the ISFSI owner using the methodology set forth in Chapter 3.

12.2.8.2 Explosion Analysis

Any credible explosion accident for the MPC is bounded by the accident external design pressure (Table 2.3.5). Because explosive materials are not stored within close proximity to the casks, the design basis pressure wave from explosion is limited to a small value (Table 2.3.1). The bounding analysis in Chapter 3 shows that the MPC and the CEC can withstand the effects of substantial accident external pressures without collapse or rupture.

i. Structural

The effect of explosion at the HI-STORM UMAX ISFSI is a near instantaneous increase of external pressure over the top exterior surface of the VVM closure lid and in the air passages and cavity space of the VVM due to the explosion-induced pressure wave. Chapter 3 includes an evaluation of the effect of the design-basis pressure wave set in Table 2.3.1 and applied as a static pressure on the exterior surfaces of the closure lid producing a downward force. Since the pressure wave entering the VVM through the closure lid vents will have slightly less energy, there is no need to consider uplift of the closure lid. Thus, the evaluation shows that the overpressure wave does not result in lid separation and that all lid stresses are a fraction of the allowable limits. Therefore, the continued structural integrity of the Closure Lid is assured.

Site-specific explosion scenarios that are not evidently bounded by the design basis explosion load considered in this FSAR shall be evaluated under the provisions of 10CFR72.212.

ii. Thermal

There is no effect on the function of HI-STORM UMAX VVM heat transfer features as a result of this accident event occurring at the ISFSI. No deformation of the HI-STORM UMAX VVM components that would result in the constriction of the air flow passages within the VVM is indicated.

iii. Shielding

There is no effect on the function of shielding features of the system as a result of this accident event.

v. Criticality

There is no effect on the function of criticality control features of the MPC as a result of this accident event.

vi. Confinement

There is no effect on the confinement function of the MPC as a result of this accident event. As the above mentioned structural evaluation shows, all stresses remain within allowable values, assuring confinement boundary integrity.

vii. Radiation Protection and Consequences

Since there is no effect on shielding or confinement functions as discussed above, there is no radiological consequence (from effluents and direct radiation) as a result of this accident event. A negligible-to-minor increase to occupational exposures for the performance of corrective actions is expected.

12.2.8.3 Corrective Action

As there is no permanent damage indicated by this accident event, there is no need for a corrective action.

12.2.8.4 Conclusion

Based on the above evaluation, it is concluded that the design basis explosion accident event does not affect the safe operation of the loaded HI-STORM UMAX storage system.

12.2.9 Lightning

12.2.9.1 Cause of Lightning

Lightning is a meteorological event that occurs in all parts of the world.

12.2.9.2 Lightning Analysis

Because of its underground construction, the subterranean portion of the HI-STORM UMAX System is unlikely to be subjected to a direct lightning strike. The HI-STORM UMAX closure lid is, however, aboveground (albeit a low profile structure) and could be subjected to a direct strike.

When the HI-STORM UMAX VVM is struck with lightning, the lightning will discharge through the steel shell of the lid and the CEC structure to the ground. Lightning strikes have high currents, but their duration is short (i.e., less than a second). The VVM shell and lid are composed of conductive steel and, as such, provides a direct path to the ground into the substrate with which it has a large interface.

Because the VVMs are buried in substrate, they are self-grounding. The lightning current will discharge into the VVM steel structure and directly into the ground. Therefore, the MPC (made of relatively non-conductive austenitic stainless steel) will be unaffected.

i. Structural

There is no structural consequence as a result of this event.

ii. Thermal

There is no effect on the thermal performance of the system as a result of this event.

iii. Shielding

There is no effect on the shielding performance of the system as a result of this event.

iv. Criticality

There is no effect on the criticality control features of the system as a result of this event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this event.

vi. Radiation Protection

Since there is no degradation in shielding or confinement capabilities as discussed above, there is no effect on occupational or public exposures as a result of this event.

12.2.9.3 Lightning Dose Calculations

As lightning strike has no effect on the Confinement Boundary or shielding materials, no dose analysis is necessary.

12.2.9.4 Lightning Accident Corrective Action

The HI-STORM UMAX System will not sustain any damage from the lightning accident that might adversely affect its performance. Therefore, no surveillance or corrective action is required subsequent to a lightning action at the HI-STORM UMAX ISFSI.

12.2.9.5 Conclusion

Based on this evaluation, it is concluded that a lightning event will not affect the safe operation of the HI-STORM UMAX System.

12.2.10 100% Blockage of Air Inlet

12.2.10.1 Cause of 100% Blockage of Air Inlet

This event is defined as a complete blockage of all VVM inlets. A complete blockage of all VVM inlets cannot be realistically postulated to occur at most sites. However, a flood, blizzard snow accumulation, tornado debris, or volcanic activity, where applicable, can cause a significant blockage.

12.2.10.2 100% Blockage of Air Inlet Analysis

The immediate consequence of a complete blockage of the air inlet openings is that the normal circulation of air for cooling the MPC is stopped. An amount of heat will continue to be removed by localized air circulation patterns in the outlet opening, and the MPC will continue to radiate heat to the relatively cooler soil. As the temperatures of the MPC and its contents rise, the rate of heat rejection will increase correspondingly. Under this condition, the temperatures of the HI-STORM UMAX overpack, the MPC and the stored fuel assemblies will rise as a function of time.

As a result of the large mass and correspondingly large thermal capacity of the HI-STORM UMAX overpack, it is expected that a significant temperature rise is only possible if the blocked condition is allowed to persist for an extended duration. This accident condition is, however, a short duration event that will be identified by the ISFSI staff, at worst, during scheduled periodic surveillance at the ISFSI site and corrected using the site's emergency response process.

i. Structural

There are no structural consequences as a result of this event

`

ii. Thermal

A thermal analysis is performed in Subsection 4.6.2.3 to determine the effect of a complete blockage of all inlets for an extended duration. For this event, both the fuel cladding and

component temperatures (see Table 4.6.7) remain below their accident temperature limits (see Table 2.3.7). The MPC internal pressure for this event is evaluated and reported in Table 4.6.10 and is bounded by the design basis internal pressure for accident conditions (see Table 2.3.5).

iii. Shielding

The above thermal results indicate insignificant loss of material and, therefore, the effect of this event on the shielding capacity is expected to be negligible.

iv. Criticality

There is no effect on the function of criticality control features of the MPC as a result of this accident event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this accident event.

vi. Radiation Protection and Consequences

Since there is no effect on shielding or confinement functions as discussed above, there is no radiological consequence (from effluents and direct radiation) as a result of this event. A negligible-to-minor increase to occupational exposures for the performance of corrective actions is expected.

12.2.10.3 Corrective Action

Analysis of the 100% blockage of air inlet accident shows that the temperatures for system components and fuel cladding are within the accident temperature limits if the blockage is cleared within the maximum elapsed period between scheduled surveillance inspections. Upon detection of the complete blockage of the air inlet openings, the ISFSI owner shall activate its emergency response procedure to remove the blockage with mechanical and manual means as necessary. After clearing the overpack openings, the system shall be visually and radiologically inspected for any damage. If exit air temperature monitoring is performed in lieu of direct visual inspections, the difference between the ambient air temperature and the exit air temperature will be the basis for the assurance that the temperature limits are not exceeded.

For an accident event that completely blocks the inlet or outlet air openings for greater than the analyzed duration, a site-specific evaluation or analysis may be performed to whether adequate heat removal for the duration of the event would occur. Adequate heat removal is defined as the minimum rate of heat dissipation that ensures cladding temperatures limits are met and structural integrity of the MPC and overpack is not compromised. For those events where an evaluation or analysis is not performed or is not successful in showing that cladding temperatures remain

below their short term temperature limits, the site's emergency plan shall include provisions to address removal of the material blocking the air inlet openings and to provide alternate means of cooling prior to exceeding the time when the fuel cladding temperature reaches its short-term temperature limit. Alternate means of cooling could include, for example, spraying water into the air outlet opening using pumps or fire-hoses or blowing air into the air outlet opening, to directly cool the MPC.

12.2.10.4 Conclusion

Based on the above evaluation, it is concluded that the 100% blockage of air inlet accident event does not affect the safe operation of the HI-STORM UMAX System, if the blockage is removed in the specified time period.

12.2.11 Burial Under Debris

12.2.11.1 Cause of Burial Under Debris

Complete burial of the entire HI-STORM UMAX VVM assembly is not a credible accident because it is a large structure (see the drawing package in Section 1.5) and during storage at the ISFSI, there are no large structures above the casks that may collapse and bury the VVM. The minimum regulatory distance(s) from the ISFSI to the nearest site boundary and the controlled area around the ISFSI concrete pad precludes the close proximity of substantial amounts of vegetation. However, for purposes of safety evaluation, complete burial of the VVM including blockage of all inlet and outlet flow passages is assumed.

12.2.11.2 Burial Under Debris Analysis

Burial of the inlet plenum under debris will adversely affect thermal performance because the debris will block the inflow of air. This will cause the fuel cladding temperatures to increase. A thermal analysis has been performed to determine the time for the fuel cladding temperatures to reach the *accident condition temperature limit* due to a burial of the inlet plenum under debris accident, assuming that the debris causes complete cut-off of cool air through the inlet passages. This computed time, T-max, is specified in the Technical Specification as an LCO.

i. Structural

The effect of 100% blockage of air inlet on the MPC is an increase in component and fuel cladding temperatures and internal pressure and thus an increase in pressure boundary stresses. However, the resultant temperatures and pressures, for a burial duration equal to T-max, are below the accident condition design limits as discussed in the thermal effects evaluation below. The MPC stresses resulting from the blockage of air inlet are confirmed to be bounded by the applicable ASME code limits; therefore, there is no effect on structural function.

ii. Thermal

The fuel cladding and MPC integrity is evaluated in Subsection 4.6.2.4. The evaluation demonstrates that the fuel cladding and confinement function of the MPC are not compromised even if the burial event lasts for a substantial duration.

iii. Shielding

The above thermal results indicate that there will be no material loss in the shielding capacity of the system.

iv. Criticality

There is no effect on the function of criticality control features of the MPC as a result of this accident event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this accident event.

vi. Radiation Protection and Consequences

Since there is no effect on shielding or confinement functions as discussed above, there is no radiological consequence (from effluents and direct radiation) as a result of this event. A negligible-to-minor increase to occupational exposures for the performance of corrective actions is expected.

12.2.11.3 Corrective Action

Analysis of the burial-under-debris accident shows that the fuel cladding peak temperatures are not exceeded for the duration of the accident equal to T-max. Upon detection of the burial-under-debris accident, the ISFSI operator shall assign personnel to remove the debris from around and inside the VVM cavity with mechanical and manual means as necessary. After removing the debris, the storage cavities shall be visually inspected for any damage. The loaded MPC may have to be removed from the VVM cavities to allow complete inspection of the VVM cavities. Removal of obstructions to the air flow path shall be performed prior to the re-insertion of the MPC. The site's emergency action plan shall include provisions for the implementation of this corrective action.

12.2.11.4 Conclusion

Based on the above evaluation, it is concluded that the burial-under-debris accident event does not affect the safe operation of the HI-STORM UMAX System, if the blockage is removed in the specified time period.

12.2.12 Extreme Environmental Temperature

12.2.12.1 Cause of Extreme Environmental Temperature

The extreme environmental temperature is postulated (see Table 2.3.6) as a 3-day average temperature caused by extreme weather conditions.

12.2.12.2 Extreme Environmental Temperature Analysis

To determine the effects of the extreme temperature, it is conservatively assumed that the temperature persists for a sufficient duration (3 days) to allow the HI-STORM storage system to achieve thermal equilibrium.

The accident condition considering an extreme environmental temperature (Table 2.3.6) for a duration sufficient to reach thermal equilibrium is evaluated with respect to accident condition design temperatures listed in Table 2.3.7.

i. Structural

The effect on the MPC for the extreme environmental temperature conditions is an increase in component and fuel cladding temperatures and internal pressure and thus an increase in pressure boundary stresses. However, the resultant temperatures and pressures are below the accident design limits as discussed in the thermal effects evaluation below. The MPC stresses resulting from the extreme environmental temperatures event are confirmed to be bounded by the applicable pressure boundary stress limits; therefore, there is no effect on structural function.

ii. Thermal

The thermal evaluation of extreme environmental temperature is discussed in Section 4.6.2.2. The calculated bounding temperatures and pressures are conservatively evaluated assuming the asymptotic maximum (steady-state) condition to have been reached. Temperature results reported in Table 4.6.6 indicate that all thermal criteria are met. Additionally, the increased temperatures generate an elevated MPC internal pressure, reported in Table 4.6.10, which is less than the accident design pressure limit specified in Table 2.3.5. The temperatures and pressures resulting from the increased pressure event are confirmed to be bounded by the applicable system temperature and pressure limits; therefore, there is no effect on thermal function.

iii. Shielding

There is no effect on the function of shielding features of the system as a result of this accident event. Concrete temperatures in the lid are confirmed to remain below its accident temperature limit.

iv. Criticality

There is no effect on the function of criticality control features of the MPC as a result of this accident event.

v. Confinement

There is no effect on the confinement function of the MPC as a result of this accident event. Structural evaluation shows all stresses remain within allowable values, assuring confinement boundary integrity.

vi. Radiation Protection and Consequences

Since there is no effect on shielding or confinement functions as discussed above, there is no radiological consequence (from effluents and direct radiation) and no increase to occupational or public exposures as a result of this accident event.

12.2.12.3 Corrective Action

The extreme environmental temperature is a self-correcting event. No corrective action is required.

12.2.12.4 Conclusion

Based on this evaluation, it is concluded that the extreme environment temperature accident event does not affect the safe operation of the HI-STORM UMAX System.

12.2.13 HI-TRAC VW Transfer Cask Handling Accident

HI-TRAC VW transfer cask handling accident evaluated in the HI-STORM FW FSAR Section 12.2.1 [4.1.2] is incorporated by reference.

12.3 OTHER EVENTS

This section addresses miscellaneous events, which are placed in the category of "other events" since they cannot be categorized as off-normal or accident events. The following "other events" are discussed in this chapter:

- Hazards during Construction Proximate to the ISFSI
- MPC Reflood

The results of the evaluations performed herein demonstrate that the loaded HI-STORM UMAX VVMs can withstand the effects of "other events" without affecting safety function.

12.3.1 Construction Proximate to an Operating ISFSI

12.3.1.1 Cause of the Event

This situation will arise if the facility owner decides to expand the existing storage capacity by adding VVM assemblies adjacent to an operating ISFSI. As demonstrated in Chapter 3, the Self-hardening Engineered Subgrade (SES), in the absence of the optional Enclosure Wall, can remain intact under the Design Basis Earthquake condition and can effectively protect loaded VVMs against tornado missile impacts. This FSAR permits excavation adjacent to one side of the HI-STORM UMAX ISFSI at any given time. However, the excavation depth shall be limited to the bottom surface of the Support Foundation Pad (SFP).

12.3.1.2 Safety Analysis

i. Structural

The soil-structure interaction analysis of the ISFSI assuming that the subgrade has been excavated down to the SFP elevation for (a theoretically) infinite distance next to one side of the ISFSI has been performed. The analyses show that the storage system is kinematically stable and the stresses in the reinforced concrete structures meet the applicable ACI limits and that the canister retrievability in the wake of an earthquake is assured. In the absence the optional Enclosure Wall, the tensile stress developed in the SES under the Design Basis Earthquake condition is well below the tensile capacity of the SES material. Moreover, the local strains in the stored canisters from internal impact are well within the limit specified in this FSAR.

Furthermore, the scenario of a tornado missile striking the exposed SES has also been considered in Chapter 3. Analyses summarized in Section 3.4 show that the design basis projectiles (large, medium, or small), specified in Chapter 2 of this FSAR, applied in the most vulnerable location of the construction cavity, will fail to reach any stored MPC.

ii. Thermal

There is no effect on the thermal performance of the system as a result of this event.

vii. Shielding

There is no effect on the function of shielding features of the system as a result of this event.

viii. Criticality

There is no effect on the function criticality control features of the MPC as a result of this event.

ix. Confinement

There is no effect on the function of confinement features of the MPC as a result of this event.

x. Radiation Protection

To protect an installed ISFSI from any site construction activity in its proximity, a certain minimum ground buffer distance beyond the edge of the perimeter of the VVM arrays is prescribed in the licensing drawings. This radiation protection space (RPS) defines the no-construction zone around the installed and loaded VVMs (see Chapter 1).

A generic evaluation of the shielding consequences of digging a cavity adjacent to the RPS has been considered in Chapter 5 of this FSAR. The analyses show that the dose at the edge of the cavity is well below 0.2 mrem/hr, which is well below the customary limit that requires radiation posting at nuclear power plants. Therefore, the excavation activities shall be ALARA.

Nevertheless, the owner will implement appropriate measures and provide appropriate safety training to the construction crew in keeping with the plant's radiation protection plan. Analysis of the consequences of any credible site-specific loads or events during site construction work shall be performed with due consideration of the duration and nature of the site construction activity. As is required for deploying casks certified under 10CFR72, Subpart L, every site modification that may potentially impact the continued operability of the ISFSI must be evaluated for acceptability under 10CFR72.212.

Because the actual projectiles for a specific ISFSI site are often different from the tornado-borne missiles analyzed in Chapters 3 and 5 herein, a site-specific analysis of the effect of all credible missiles shall be performed assuming that the largest construction cavity adjacent to the ISFSI

exists. PRA considerations shall not be used to rule out any missile that has been determined to be credible in the plant's FSAR.

To summarize, the RPS provides sufficient margin (buffer) against design basis projectiles analyzed in Chapter 3. In addition to the generic analyses documented in this FSAR, a site-specific evaluation pursuant to §72.212 shall be performed for all other credible hazards that can be postulated during site construction. Administrative controls to guard against accidental human error in excavations (such as encroachment of the RPS) shall be addressed through written procedures consistent with the required controls needed for a safety significant activity within a Part 50 controlled area.

Furthermore, the ISFSI owner shall implement ameliorative measures to prevent unacceptable damage to the ISFSI from any other credible adverse scenarios unique to a site that has not been considered in this FSAR. An example of such a measure is the installation of a berm to protect against environmental events such as soil erosion and mud slides. Such site-specific design initiatives at any "UMAX" ISFSI, like its aboveground counterpart, are within the purview of the plant's §72.212 process.

12.3.1.3 Corrective Action

As the excavation work is a planned activity, no corrective action is required.

12.3.1.4 Conclusion

An excavation activity adjacent to an operating ISFSI is permitted provided all safety and radiation protection requirements of the host plant are followed.

12.3.2 MPC Reflood

MPC reflood evaluated in the HI-STORM FW FSAR Section 12.3.1 [4.1.2] is incorporated by reference.

CHAPTER 13: OPERATING CONTROLS AND LIMITS

13.0 INTRODUCTION

This chapter defines the operating controls and limits (i.e., Technical Specifications) including their supporting bases for deployment and storage of an approved MPC type (see Table 1.2.1) in a HI-STORM UMAX VVM at an ISFSI. Table 1.2.1 provides the CoC amendment numbers for the MPCs that have been considered in the safety analysis documented in this report. Thus while the safety analyses have been carried out in this FSAR for all MPCs presently certified in Docket # 72-1014 (HI-STORM 100) and Docket # 1032 (HI-STORM UMAX), the Certificate-of- Compliance sought pursuant to this licensing submittal is limited to qualifying only MPC-37 and MPC-89 which have been previously certified in the HI-STORM FW docket.

13.1 PROPOSED OPERATING CONTROLS AND LIMITS

13.1.1 NUREG-1536 (Standard Review Plan) Acceptance Criteria

This portion of the FSAR establishes the commitments regarding the HI-STORM UMAX system and its use. Other 10CFR72 [13.1.1] and 10CFR20 [13.1.2] requirements in addition to the Technical Specifications may apply. The conditions for a general license holder found in 10CFR72.212 [13.1.1] shall be met by the licensee prior to loading spent fuel into the HI-STORM UMAX system. The general license conditions governed by 10CFR72 [13.1.1] are not repeated within these Technical Specifications. Licensees are required to comply with all commitments and requirements.

The Technical Specifications provided in Appendix A to the CoC and the authorized contents and design features provided in Appendix B to the CoC are primarily established to maintain subcriticality, the confinement boundary, shielding and radiological protection, heat removal capability, and structural integrity under normal, off-normal and accident conditions.

Table 13.1.1 addresses each of these conditions applicable to HI-STORM UMAX and identifies the appropriate Technical Specification(s) designed to control the condition Table 13.1.2 provides the list of Technical Specifications for the loading operations and long term fuel storage in the HI-STORM UMAX system.

Table 13.1.1

13.2 DEVELOPMENT OF OPERATING CONTROLS AND LIMITS

This section provides a discussion of the operating controls and limits, and training requirements for the HI-STORM UMAX system to assure long-term performance consistent with the conditions analyzed in this FSAR.

13.2.1 Training Modules

Training modules are to be developed under the licensee's training program to require a comprehensive, site-specific training, assessment, and qualification (including periodic re-qualification) program for the operation and maintenance of the HI-STORM UMAX Spent Fuel Storage Cask (SFSC) System and the Independent Spent Fuel Storage Installation (ISFSI). The training modules shall include the following elements, at a minimum:

1. HI-STORM UMAX System Design (overview);

2. ISFSI Facility Design (overview);

3. Systems, Structures, and Components Important-to-Safety (overview);

4. HI-STORM UMAX System Safety Analysis Report (overview);

5. NRC Safety Evaluation Report (overview);

6. Certificate of Compliance conditions;

7. HI-STORM UMAX Technical Specifications, Approved Contents, Design Features and other Conditions for Use;

8. HI-STORM UMAX Regulatory Requirements (e.g., 10CFR72.48, 10CFR72, Subpart K, 10CFR20, 10CFR73);

9. Required instrumentation and use;

10. Operating Experience Reviews

11. HI-STORM UMAX System and ISFSI Procedures, including
    - Procedural overview
    - Fuel qualification and loading
    - MPC /HI-TRAC/VVM Closure Lid rigging and handling, including safe load pathways
    - MPC welding operations

- HI-TRAC/VVM staging operation
- Auxiliary equipment operation and maintenance (e.g., draining, moisture removal, helium backfilling and cooldown)
- MPC/HI-TRAC/VVM pre-operational and in-service inspections and tests
- Transfer and securing of the loaded HI-TRAC onto the transport vehicle
- Movement of HI-TRAC to ISFSI.
- Transfer of MPC to VVM
- Preparation of MPC/HI-TRAC VVM for fuel unloading
- Retrieval of MPC from VVM
- Surveillance
- Radiation protection
- Maintenance
- Security
- Off-normal and accident conditions, responses, and corrective actions

13.2.2 Dry Run Training

A dry run training exercise of the loading, closure, handling, and transfer of the HI-STORM UMAX system shall be conducted by the licensee prior to the first use of the system to load spent fuel assemblies. Dry run training already performed successfully for the HI-STORM 100 System can be substituted for dry run steps applicable to HI-STORM UMAX. The dry run shall include, but is not limited to the following:

1. Inspection of the HI-STORM UMAX System components.

2. Moving the MPC/HI-TRAC into the spent fuel pool.

3. Preparation of the MPC/HI-TRAC for fuel loading.

4. Selection and verification of specific fuel assemblies to ensure conformance.

5. Locating specific assemblies and placing assemblies into the MPC/HI-TRAC (using a dummy fuel assembly), including appropriate independent verification.

6. Remote installation of the MPC lid and removal of the MPC/HI-TRAC from the spent fuel pool.

7. MPC welding, NDE inspections, pressure testing, draining, moisture removal, and helium backfilling (for which a mockup MPC may be used).

8 Movement of the loaded HI-TRAC to the ISFSI.

9. Transfer of the MPC from the HI-TRAC into the HI-STORM UMAX VVM at the ISFSI.

13.2.3 Functional and Operating Limits, Monitoring Instruments, and Limiting Control Settings

The controls and limits apply to operating parameters and conditions which are observable, detectable, and/or measurable. The HI-STORM UMAX system is completely passive during storage and requires no monitoring instruments. The user may choose to implement a temperature monitoring system or visually inspect the vent screens to verify operability of the VVM heat removal system in accordance with Technical Specification Limiting Condition for Operation (LCO) 3.1.2.

13.2.4 Limiting Conditions for Operation (LCO)

Limiting Conditions for Operation (LCO) specify the minimum capability or level of performance that is required to assure that the HI-STORM UMAX system can fulfill its safety functions.

13.2.5 Equipment

The HI-STORM UMAX system and its components have been analyzed for specified normal, off-normal, and accident conditions, including extreme environmental conditions. Analysis has shown that no credible condition or event prevents the HI-STORM UMAX system from meeting its safety function. As a result, there is no threat to public health and safety from any postulated accident condition or analyzed event. When all equipment is loaded, tested, and placed into storage in accordance with procedures developed for the ISFSI, no failure of the system to perform its safety function is expected to occur.

13.2.6 Surveillance Requirements

The analyses show that the HI-STORM UMAX system fulfills its safety functions, provided that the Technical Specifications and the Authorized Contents described in Subsection 2.1.8 are met. Surveillance requirements during loading, unloading, and storage operations are provided in the Technical Specifications.

13.2.7 Design Features

This subsection describes HI-STORM UMAX system design features that are Important to Safety. These features require design controls and fabrication controls. The design features, detailed in this FSAR and in Appendix B to the CoC, are established in specifications and drawings which are controlled through the quality assurance program. Fabrication controls and inspections are in place to ensure that the HI-STORM UMAX system is fabricated in accordance with the licensing drawings in Section 1.5.

13.2.8 MPC

a. Basket material composition, properties, dimensions, and tolerances for criticality control.
b. Canister material mechanical properties for structural integrity of the confinement boundary.
c. Canister and basket material thermal properties and dimensions for heat transfer control.
d. Canister and basket material composition and dimensions for dose rate control.

13.2.9 HI-STORM UMAX VVM

a. HI-STORM UMAX VVM material mechanical properties and dimensions for structural integrity to provide protection of the MPC and shielding of the spent nuclear fuel assemblies during handling and storage operations.
b. HI-STORM UMAX VVM material thermal properties and dimensions for heat transfer control.
c. HI-STORM UMAX VVM material composition and dimensions for dose rate control.

13.2.10 HI-TRAC Transfer Cask

a. HI-TRAC transfer cask material mechanical properties and dimensions for structural integrity to provide protection of the MPC and shielding of the spent nuclear fuel assemblies during loading, unloading and handling operations.
b. HI-TRAC transfer cask material thermal properties and dimensions for heat transfer control.
c. HI-TRAC transfer cask material composition and dimensions for dose rate control.

13.2.11 Verifying Compliance with Fuel Assembly Decay Heat, Burnup, and Cooling Time Limits

The examples below demonstrate how the user of the system can determine if fuel assemblies, including NFH, are acceptable for loading in either the MPC-37 or the MPC-89 in accordance with the allowable decay heat, burnup, and cooling time for the approved contents.

Example 1

In this example, it will be assumed that the MPC-37 is being loaded with array/class 17x17A fuel as shown in Figure 2.1.7 with heat loads from Table 2.1.8. Note that sub-design heat load patterns are excluded in this example.

Table 13.2.1 provides four hypothetical fuel assemblies in the 17x17A array/class that will be evaluated for acceptability for loading in the MPC-37. The decay heat values and the fuel classification in Table 13.2.1 are determined by the user. The other information is taken from the fuel assembly and reactor operating records.

Fuel Assembly Number 1 is acceptable for storage in the cells identified in Table 13.2.3 for MPC-37 (Figure 2.1.7) Heat Load Charts 1 and 3 for "Short", "Standard" and "Long" fuel assemblies (depending on the assembly length) displayed in Figures 2.1.12, 2.1.13, 2.1.16, 2.1.17 and 2.1.18. Fuel Assembly Number 1 is not acceptable for storage in the cells identified in Table 13.2.3 for MPC-37 (Figure 2.1.7) Heat Load Charts 1 and 3, and is not acceptable for storage in MPC-37 (Figure 2.1.7) Heat Load Chart 2 for "Short", "Standard" and "Long" fuel assemblies in Figures 2.1.14 and 2.1.15 because the total heat load of the fuel assembly and the non-fuel hardware exceeds the per storage cell decay heat limit. "Short", "Standard" and "Long" fuel assemblies are defined in Table 2.1.7.

Fuel Assembly Number 2 is not acceptable for loading. Fuel Assembly 2 is limited to the cell locations for DFCs in the MPC-37 (Figure 2.1.1). These cells have a decay heat limits lower than the decay heat of the assembly. This assembly will need additional cooling time (reduction in decay heat) to be acceptable for loading in the MPC-37.

Fuel Assembly Number 3 is acceptable for loading in the cells identified in Table 13.2.4 for MPC-37 Heat Load Charts 1 and 2 for "Short", "Standard" and "Long" fuel assemblies (depending on the fuel assembly height) displayed in Figures 2.1.12, 2.1.13, 2.1.14 and 2.1.15. Fuel Assembly Number 3 is also acceptable for loading in the cells identified in Table 13.2.5 for MPC-37 Heat Load Chart 3 for "Short", "Standard" and "Long" fuel displayed in Figures 16, 17 and 18. The fuel assembly is limited to these locations due to the non-fuel hardware (Figure 2.1.5) and the total heat load of the fuel assembly and non-fuel hardware is less than the decay heat limits for these cells.

Fuel Assembly Number 4 is not acceptable for loading in the MPC-37 because its cooling time is less than the minimum of 3 years. When the fuel assembly attains three years cooling time it can be reevaluated based on the decay heat.

Example 2

In this example, it will be assumed that the MPC-89 is being loaded with array/class 10x10A fuel as shown in Figure 2.1.8 with heat loads from Table 2.1.9. Sub-design heat loads are excluded in this example.

Table 13.2.2 provides four hypothetical fuel assemblies in the 10x10A array/class that will be evaluated for acceptability for loading in the MPC-89. The decay heat values and the fuel classification in Table 13.2.2 are determined by the user. The other information is taken from the fuel assembly and reactor operating records.

Fuel Assembly Number 1 is acceptable for loading in the MPC-89 as Moderate Burnup Fuel (MBF) for long-term storage (Figure 2.1.22). Fuel Assembly 1 is limited to the cell locations for DFCs in the MPC-89 (Figure 2.1.2). These cells have a decay heat limit higher than the decay heat of the assembly, therefore the assembly is acceptable for loading in the MPC-89 as MBF for long-term storage, but it is limited to the cells depicted in Figure 2.1.2.

Fuel Assembly Number 2 is not acceptable for loading in the MPC-89 as MBF (Figure 2.1.22). Fuel Assembly 2 is limited to the cell locations for DFCs in the MPC-89 (Figure 2.1.2). These cells have a decay heat limit lower than the decay heat of the assembly. This assembly will need additional cooling time (reduction in decay heat) to be acceptable for loading in the MPC-89.

Fuel Assembly Number 3 is acceptable for loading in all cell locations of the MPC-89 (Figure 2.1.8) as MBF for long-term storage.

Fuel Assembly Number 4 is not acceptable for loading in the MPC-89 (Figure 2.1.22). The decay heat limit of the cells is lower than the decay heat limit of the assembly.

13.3 TECHNICAL SPECIFICATIONS

Technical Specifications for the HI-STORM UMAX system are provided in Appendix A to the Certificate of Compliance. Authorized Contents (i.e., fuel specifications) and Design Features are provided in Appendix B to the CoC. Bases applicable to the Technical Specifications are provided in the FSAR Appendix 13.A. The format and content of the HI-STORM UMAX system Technical Specifications and Bases are that of the Improved Standard Technical Specifications for power reactors, to the extent they apply to a dry spent fuel storage cask system. NUMARC Document 93-03, "Writer's Guide for the Restructured Technical Specifications" [13.3.1] was used as a guide in the development of the Technical Specifications and Bases.

13.4 REGULATORY EVALUATION

Table 13.1.2 lists the Technical Specifications for the HI-STORM UMAX system. The Technical Specifications are detailed in Appendix A to the Certificate of Compliance. Authorized Contents (i.e., fuel specifications) and Design Features are provided in Appendix B to the CoC.

The conditions for use of the HI-STORM UMAX system identify necessary Technical Specifications, limits on authorized contents (i.e., fuel), and design features to satisfy 10 CFR Part 72, and the applicable acceptance criteria have been satisfied. Compliance with these Technical Specifications and other conditions of the Certificate of Compliance provides reasonable assurance that the HI-STORM UMAX system will provide safe storage of spent fuel and is in compliance with 10 CFR Part 72, the regulatory guides, applicable codes and standards, and accepted practices.

HI-STORM UMAX SYSTEM FSAR

APPENDIX 13.A

TECHNICAL SPECIFICATION BASES

FOR THE HOLTEC HI-STORM UMAX CANISTER STORAGE SYSTEM

BASES TABLE OF CONTENTS

Note: The text matter in the “arial” font is excerpted from the HI-STORM FW FSAR.

B 3.0 LIMITING CONDITION FOR OPERATION (LCO) APPLICABILITY

BASES

LCOs	LCO 3.0.1, 3.0.2, 3.0.4, and 3.0.5 establish the general requirements applicable to all Specifications and apply at all times, unless otherwise stated.
LCO 3.0.1	LCO 3.0.1 establishes the Applicability statement within each individual Specification as the requirement for when the LCO is required to be met (i.e., when the facility is in the specified conditions of the Applicability statement of each Specification).
LCO 3.0.2	LCO 3.0.2 establishes that upon discovery of a failure to meet an LCO, the associated ACTIONS shall be met. The Completion Time of each Required Action for an ACTIONS Condition is applicable from the point in time that an ACTIONS Condition is entered. The Required Actions establish those remedial measures that must be taken within specified Completion Times when the requirements of an LCO are not met. This Specification establishes that: a. Completion of the Required Actions within the specified Completion Times constitutes compliance with a Specification; and b. Completion of the Required Actions is not required when an LCO is met within the specified Completion Time, unless otherwise specified. There are two basic types of Required Actions. The first type of Required Action specifies a time limit in which the LCO must be met. This time limit is the Completion Time to restore a system or component or to restore variables to within specified limits. Whether stated as a Required Action or not, correction of the entered Condition is an action that may always be considered upon entering ACTIONS. The second type of Required Action specifies the remedial measures that permit continued operation that is not further restricted by the Completion Time. In this case, compliance with the Required Actions provides an acceptable level of safety for continued operation.

(continued)

BASES

LCO 3.0.2 (continued)	Completing the Required Actions is not required when an LCO is met or is no longer applicable, unless otherwise stated in the individual Specifications. The Completion Times of the Required Actions are also applicable when a system or component is removed from service intentionally. The reasons for intentionally relying on the ACTIONS include, but are not limited to, performance of Surveillances, preventive maintenance, corrective maintenance, or investigation of operational problems. Entering ACTIONS for these reasons must be done in a manner that does not compromise safety. Intentional entry into ACTIONS should not be made for operational convenience.
LCO 3.0.3	This specification is not applicable to a dry storage cask system because it describes conditions under which a power reactor must be shut down when an LCO is not met and an associated ACTION is not met or provided. The placeholder is retained for consistency with the power reactor technical specifications.
LCO 3.0.4	LCO 3.0.4 establishes limitations on changes in specified conditions in the Applicability when an LCO is not met. It precludes placing the HI-STORM UMAX System in a specified condition stated in that Applicability (e.g., Applicability desired to be entered) when the following exist: a. Facility conditions are such that the requirements of the LCO would not be met in the Applicability desired to be entered; and b. Continued noncompliance with the LCO requirements, if the Applicability were entered, would result in being required to exit the Applicability desired to be entered to comply with the Required Actions. Compliance with Required Actions that permit continuing with dry fuel storage activities for an unlimited period of time in a specified condition provides an acceptable level of safety for continued operation. This is without regard to the status of the dry storage system. Therefore, in such cases, entry into a specified condition in the Applicability may be made in accordance with the provisions of the Required Actions. The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or components before entering an associated specified condition in the Applicability.

(continued)

BASES	
LCO 3.0.4 (continued)	The provisions of LCO 3.0.4 shall not prevent changes in specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of LCO 3.0.4 shall not prevent changes in specified conditions in the Applicability that are related to the unloading of an SFSC. Exceptions to LCO 3.0.4 are stated in the individual Specifications. Exceptions may apply to all the ACTIONS or to a specific Required Action of a Specification.
LCO 3.0.5	LCO 3.0.5 establishes the allowance for restoring equipment to service under administrative controls when it has been removed from service or determined to not meet the LCO to comply with the ACTIONS. The sole purpose of this Specification is to provide an exception to LCO 3.0.2 (e.g., to not comply with the applicable Required Action(s)) to allow the performance of testing to demonstrate: a. The equipment being returned to service meets the LCO; or b. Other equipment meets the applicable LCOs. The administrative controls ensure the time the equipment is returned to service in conflict with the requirements of the ACTIONS is limited to the time absolutely necessary to perform the allowed testing. This Specification does not provide time to perform any other preventive or corrective maintenance.

B 3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY

BASES

SRs	SR 3.0.1 through SR 3.0.4 establish the general requirements applicable to all Specifications and apply at all times, unless otherwise stated.
SR 3.0.1	SR 3.0.1 establishes the requirement that SRs must be met during the specified conditions in the Applicability for which the requirements of the LCO apply, unless otherwise specified in the individual SRs. This Specification is to ensure that Surveillances are performed to verify that systems and components meet the LCO and variables are within specified limits. Failure to meet a Surveillance within the specified Frequency, in accordance with SR 3.0.2, constitutes a failure to meet an LCO.

Systems and components are assumed to meet the LCO when the associated SRs have been met. Nothing in this Specification, however, is to be construed as implying that systems or components meet the associated LCO when:

a. The systems or components are known to not meet the LCO, although still meeting the SRs; or

b. The requirements of the Surveillance(s) are known to be not met between required Surveillance performances.

Surveillances do not have to be performed when the HI-STORM UMAX System is in a specified condition for which the requirements of the associated LCO are not applicable, unless otherwise specified.

Surveillances, including Surveillances invoked by Required Actions, do not have to be performed on equipment that has been determined to not meet the LCO because the ACTIONS define the remedial measures that apply. Surveillances have to be met and performed in accordance with SR 3.0.2, prior to returning equipment to service. Upon completion of maintenance, appropriate post-maintenance testing is required. This includes ensuring applicable Surveillances are not failed and their most recent performance is in accordance with SR 3.0.2. Post maintenance testing may not be possible in the current specified conditions in the Applicability due to the necessary dry storage cask system parameters not having been established. In these situations, the equipment may be considered to meet the LCO provided testing has been satisfactorily completed to the extent possible and the equipment is not otherwise believed to be incapable of performing its function. This will allow dry fuel storage activities to proceed to a specified condition where other necessary post maintenance tests can be completed.

(continued)

BASES

SR 3.0.2

SR 3.0.2 establishes the requirements for meeting the specified Frequency for Surveillances and any Required Action with a Completion Time that requires the periodic performance of the Required Action on a "once per..." interval.

SR 3.0.2 permits a 25% extension of the interval specified in the Frequency. This extension facilitates Surveillance scheduling and considers facility conditions that may not be suitable for conducting the Surveillance (e.g., transient conditions or other ongoing Surveillance or maintenance activities).

The 25% extension does not significantly degrade the reliability that results from performing the Surveillance at its specified Frequency. This is based on the recognition that the most probable result of any particular Surveillance being performed is the verification of conformance with the SRs. The exceptions to SR 3.0.2 are those Surveillances for which the 25% extension of the interval specified in the Frequency does not apply. These exceptions are stated in the individual Specifications as a Note in the Frequency stating, "SR 3.0.2 is not applicable."

As stated in SR 3.0.2, the 25% extension also does not apply to the initial portion of a periodic Completion Time that requires performance on a "once per..." basis. The 25% extension applies to each performance after the initial performance. The initial performance of the Required Action, whether it is a particular Surveillance or some other remedial action, is considered a single action with a single Completion Time. One reason for not allowing the 25% extension to this Completion Time is that such an action usually verifies that no loss of function has occurred by checking the status of redundant or diverse components or accomplishes the function of the affected equipment in an alternative manner.
The provisions of SR 3.0.2 are not intended to be used repeatedly merely as an operational convenience to extend Surveillance intervals or periodic Completion Time intervals beyond those specified.

(continued)

BASES

SR 3.0.3 SR 3.0.3 establishes the flexibility to defer declaring affected equipment as not meeting the LCO or an affected variable outside the specified limits when a Surveillance has not been completed within the specified Frequency. A delay period of up to 24 hours or up to the limit of the specified Frequency, whichever is less, applies from the point in time that it is discovered that the Surveillance has not been performed in accordance with SR 3.0.2, and not at the time that the specified Frequency was not met.

This delay period provides adequate time to complete Surveillances that have been missed. This delay period permits the completion of a Surveillance before complying with Required Actions or other remedial measures that might preclude completion of the Surveillance.

The basis for this delay period includes consideration of HI-STORM UMAX System conditions, adequate planning, availability of personnel, the time required to perform the Surveillance, the safety significance of the delay in completing the required Surveillance, and the recognition that the most probable result of any particular Surveillance being performed is the verification of conformance with the requirements. When a Surveillance with a Frequency based not on time intervals, but upon specified facility conditions, is discovered not to have been performed when specified, SR 3.0.3 allows the full delay period of 24 hours to perform the Surveillance.

SR 3.0.3 also provides a time limit for completion of Surveillances that become applicable as a consequence of changes in the specified conditions in the Applicability imposed by the Required Actions.

Failure to comply with specified Frequencies for SRs is expected to be an infrequent occurrence. Use of the delay period established by SR 3.0.3 is a flexibility which is not intended to be used as an operational convenience to extend Surveillance intervals.

(continued)

BASES

SR 3.0.3 (continued)	If a Surveillance is not completed within the allowed delay period, then the equipment is considered to not meet the LCO or the variable is considered outside the specified limits and the Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon expiration of the delay period. If a Surveillance is failed within the delay period, then the equipment does not meet the LCO, or the variable is outside the specified limits and the Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon the failure of the Surveillance. Completion of the Surveillance within the delay period allowed by this Specification, or within the Completion Time of the ACTIONS, restores compliance with SR 3.0.1.
SR 3.0.4	SR 3.0.4 establishes the requirement that all applicable SRs must be met before entry into a specified condition in the Applicability. This Specification ensures that system and component requirements and variable limits are met before entry into specified conditions in the Applicability for which these systems and components ensure safe conduct of dry fuel storage activities. The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or components before entering an associated specified condition in the Applicability. However, in certain circumstances, failing to meet an SR will not result in SR 3.0.4 restricting a change in specified condition. When a system, subsystem, division, component, device, or variable is outside its specified limits, the associated SR(s) are not required to be performed per SR 3.0.1, which states that Surveillances do not have to be performed on equipment that has been determined to not meet the LCO. When equipment does not meet the LCO, SR 3.0.4 does not apply to the associated SR(s) since the requirement for the SR(s) to be performed is removed. Therefore, failing to perform the Surveillance(s) within the specified Frequency does not result in an SR 3.0.4 restriction to changing specified conditions of the Applicability. However, since the LCO is not met in this instance, LCO 3.0.4 will govern any restrictions that may (or may not) apply to specified condition changes.

(continued)

BASES	
SR 3.0.4 (continued)	The provisions of SR 3.0.4 shall not prevent changes in specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of LCO 3.0.4 shall not prevent changes in specified conditions in the Applicability that are related to the unloading of an SFSC. The precise requirements for performance of SRs are specified such that exceptions to SR 3.0.4 are not necessary. The specific time frames and conditions necessary for meeting the SRs are specified in the Frequency, in the Surveillance, or both. This allows performance of Surveillances when the prerequisite condition(s) specified in a Surveillance procedure require entry into the specified condition in the Applicability of the associated LCO prior to the performance or completion of a Surveillance. A Surveillance that could not be performed until after entering the LCO Applicability would have its Frequency specified such that it is not "due" until the specific conditions needed are met. Alternately, the Surveillance may be stated in the form of a Note as not required (to be met or performed) until a particular event, condition, or time has been reached. Further discussion of the specific formats of SRs' annotation is found in Section 1.4, Frequency.

B 3.1 SFSC Integrity

B 3.1.1 Multi-Purpose Canister (MPC)

BASES

BACKGROUND

A TRANSFER CASK with an empty MPC is placed in the spent fuel pool and loaded with fuel assemblies meeting the requirements of the CoC. A lid is then placed on the MPC. The TRANSFER CASK and MPC are raised to the top of the spent fuel pool surface. The TRANSFER CASK and MPC are then moved into the preparation area where the MPC lid is welded to the MPC shell and the welds are inspected and tested. The water is drained from the MPC cavity and drying is performed. The MPC cavity is backfilled with helium. Then, the MPC vent and drain port cover plates and closure ring are installed and welded. Inspections are performed on the welds.

MPC cavity moisture removal using vacuum drying or forced helium dehydration is performed to remove residual moisture from the MPC cavity space after the MPC has been drained of water. If vacuum drying is used, any water that has not drained from the fuel cavity evaporates from the fuel cavity due to the vacuum. This is aided by the temperature increase due to the decay heat of the fuel.

If forced helium dehydration is used, the dry gas introduced to the MPC cavity through the vent or drain port absorbs the residual moisture in the MPC. This humidified gas exits the MPC via the other port and the absorbed water is removed through condensation and/or mechanical drying. The dried helium is then forced back to the MPC until the temperature acceptance limit is met.

After the completion of drying, the MPC cavity is backfilled with helium meeting the requirements of the CoC.

Backfilling of the MPC fuel cavity with helium promotes gaseous heat dissipation and the inert atmosphere protects the fuel cladding. Backfilling the MPC with helium in the required quantity eliminates air in-leakage over the life of the MPC because the cavity pressure rises due to heat up of the confined gas by the fuel decay heat during storage.

(continued)

BASES	
APPLICABLE SAFETY ANALYSIS	The confinement of radioactivity during the storage of spent fuel in the MPC is ensured by the confinement boundary of the MPC in which the fuel assemblies are stored. Long-term integrity of the fuel and cladding depend on storage in an inert atmosphere. This is accomplished by removing water from the MPC and backfilling the cavity with an inert gas. The thermal analyses of the MPC assume that the MPC cavity is filled with dry helium of a minimum quantity to ensure the assumptions used for convection heat transfer are preserved. Keeping the backfill pressure below the maximum value preserves the initial condition assumptions made in the MPC over-pressurization evaluation.
LCO	A dry, helium filled, and sealed MPC establishes an inert heat removal environment necessary to ensure the integrity of the fuel cladding. Moreover, it also ensures that there will be no air in-leakage into the MPC cavity that could damage the fuel cladding over the storage period.
APPLICABILITY	The dry, sealed, and inert atmosphere is required to be in place prior to TRANSPORT OPERATIONS to ensure both the confinement and heat removal mechanisms are in place during these operating periods. These conditions are not required during LOADING OPERATIONS or UNLOADING OPERATIONS as these conditions are being established or removed, respectively, during these periods in support of other activities being performed with the stored fuel.

(continued)

BASES

ACTIONS

A note has been added to the ACTIONS which states that, for this LCO, separate Condition entry is allowed for each MPC. This is acceptable since the Required Actions for each Condition provide appropriate compensatory measures for each MPC not meeting the LCO. Subsequent MPCs that do not meet the LCO are governed by subsequent Condition entry and application of associated Required Actions.

A.1

If the cavity vacuum drying pressure or demoisturizer exit gas temperature limit has been determined not to be met prior to TRANSPORT OPERATIONS, an engineering evaluation is necessary to determine the potential quantity of moisture left within the MPC cavity. Since moisture remaining in the cavity during these modes of operation represent a long-term degradation concern, immediate action is not necessary. The Completion Time is sufficient to complete the engineering evaluation commensurate with the safety significance of the CONDITION.

A.2

Once the quantity of moisture potentially left in the MPC cavity is determined, a corrective action plan shall be developed and actions initiated to the extent necessary to return the MPC to an analyzed condition. Since the quantity of moisture estimated under Required Action A.1 can range over a broad scale, different recovery strategies may be necessary. Since moisture remaining in the cavity during these modes of operation represent a long-term degradation concern, immediate action is not necessary. The Completion Time is sufficient to develop and initiate the corrective actions commensurate with the safety significance of the CONDITION.

(continued)

BASES	
ACTIONS (continued)	B.1 If the helium backfill quantity limit has been determined not to be met prior to TRANSPORT OPERATIONS, an engineering evaluation is necessary to determine the quantity of helium within the MPC cavity. Since too much or too little helium in the MPC during these modes represents a potential overpressure or heat removal degradation concern, an engineering evaluation shall be performed in a timely manner. The Completion Time is sufficient to complete the engineering evaluation commensurate with the safety significance of the CONDITION. B.2 Once the quantity of helium in the MPC cavity is determined, a corrective action plan shall be developed and initiated to the extent necessary to return the MPC to an analyzed condition either by adding or removing helium or by demonstrating through analysis that all system limits will continue to be met. Since the quantity of helium estimated under Required Action B.1 can range over a broad scale, different recovery strategies may be necessary. Since elevated or reduced helium quantities existing in the MPC cavity represent a potential overpressure or heat removal degradation concern, corrective actions should be developed and implemented in a timely manner. The Completion Time is sufficient to develop and initiate the corrective actions commensurate with the safety significance of the CONDITION. C.1 If the helium leak rate limit has been determined not to be met prior to TRANSPORT OPERATIONS, an engineering evaluation is necessary to determine the impact of increased helium leak rate on heat removal and off-site dose. Since the HI-STORM UMAX VVM is a ventilated system, any leakage from the MPC is transported directly to the environment. Since an increased helium leak rate represents a potential challenge to MPC heat removal and the off-site doses, reasonably rapid action is warranted. The Completion Time is sufficient to complete the engineering evaluation commensurate with the safety significance of the CONDITION.

(continued)

BASES	
ACTIONS (continued)	C.2 Once the consequences of the elevated leak rate from the MPC are determined, a corrective action plan shall be developed and initiated to the extent necessary to return the MPC to an analyzed condition. Since the recovery mechanisms can range over a broad scale based on the evaluation performed under Required Action C.1, different recovery strategies may be necessary. Since an elevated helium leak rate represents a challenge to heat removal rates and offsite doses, reasonably rapid action is required. The Completion Time is sufficient to develop and initiate the corrective actions commensurate with the safety significance of the CONDITION. D.1 If the MPC fuel cavity cannot be successfully returned to a safe, analyzed condition, the fuel must be placed in a safe condition in the spent fuel pool. The Completion Time is reasonable based on the time required to re-flood the MPC, cut the MPC lid welds, move the TRANSFER CASK into the spent fuel pool, remove the MPC lid, and remove the spent fuel assemblies in an orderly manner and without challenging personnel.
SURVEILLANCE REQUIREMENTS	SR 3.1.1.1 , SR 3.1.1.2, and SR 3.1.1.3 The long-term integrity of the stored fuel is dependent on storage in a dry, inert environment. Under certain conditions, cavity dryness may be demonstrated either by evacuating the cavity to a very low absolute pressure and verifying that the pressure is held over a specified period of time or by recirculating dry helium through the MPC cavity to absorb moisture until the gas temperature or dew point at the specified location reaches and remains below the acceptance limit for the specified time period. A low vacuum pressure or a demoisturizer exit temperature meeting the acceptance limit is an indication that the cavity is dry. Other conditions require the forced helium dehydration method of moisture removal to be used to provide necessary cooling of the fuel during drying operations.

(continued)

BASES	
SURVEILLANCE REQUIREMENTS (continued)	Cooling provided by normal operation of the forced helium dehydration system ensures that the fuel cladding temperature remains below the applicable limits since forced recirculation of helium provides more effective heat transfer than that which occurs during normal storage operations. The conditions and requirements for drying the MPC cavity based on the burnup class of the fuel (moderate or high), heat load, and the applicable short-term temperature limit are given in the CoC/TS Appendix A, Table 3-1. The temperature limits and associated cladding hoop stress calculation requirements are consistent with the guidance in NRC Interim Staff Guidance (ISG) Document 11. Having the proper quantity of helium in the MPC ensures adequate heat transfer from the fuel to the fuel basket and surrounding structure of the MPC and precludes any overpressure event from challenging the normal, off-normal, or accident design pressure of the MPC. Meeting the helium leak rate limit prior to TRANSPORT OPERATIONS ensures there is adequate helium in the MPC for long term storage and that there is no credible effluent dose from the MPC. All of these surveillances must be successfully performed once, prior to TRANSPORT OPERATIONS to ensure that the conditions are established for SFSC storage which preserve the analysis basis supporting the MPC design.

B 3.1 SFSC Integrity

B 3.1.2 SFSC Heat Removal System

BASES	
BACKGROUND	The SFSC Heat Removal System is a passive, air-cooled, convective heat transfer system that ensures heat from the MPC canister is transferred to the environs by the chimney effect. Air is drawn into the inlet ducts and travels down the space between the Cavity Enclosure Container (CEC) and the Divider Shell, through the cut-outs at the bottom of the Divider Shell, up the space between the Divider Shell and the MPC, and out through the outlet duct. The MPC transfers its heat from its surface to the air via natural convection. The buoyancy created by the heating of the air creates a chimney effect.
APPLICABLE SAFETY ANALYSIS	The thermal analyses of the SFSC take credit for the decay heat from the spent fuel assemblies being ultimately transferred to the ambient environment surrounding the VVM. Transfer of heat away from the fuel assemblies ensures that the fuel cladding and other SFSC component temperatures do not exceed applicable limits. Under normal storage conditions, the inlet and outlet duct screens are unobstructed and full air flow occurs. Analyses have been performed for half and complete obstruction of the inlet duct screens. Blockage of half of the inlet ducts reduces air flow through the VVM and decreases heat transfer from the MPC. Under this off-normal condition, no SFSC components exceed the short term temperature limits. The complete blockage of all inlet air ducts stops normal air cooling of the MPC. The MPC will continue to radiate heat to the relatively cooler subgrade. With the loss of normal air cooling, the SFSC component temperatures will increase toward their respective short-term temperature limits. None of the components reach their temperature limits over the duration of the analyzed event.

(continued)

BASES	
LCO	The SFSC Heat Removal System must be verified to be operable to preserve the assumptions of the thermal analyses. Operability is defined as 50% or more of the inlet vent duct areas are unblocked and available for flow. Operability of the heat removal system ensures that the decay heat generated by the stored fuel assemblies is transferred to the environs at a sufficient rate to maintain fuel cladding and other SFSC component temperatures within design limits. The intent of this LCO is to address those occurrences of air duct screen blockage that can be reasonably anticipated to occur from time to time at the ISFSI (i.e., Design Event I and II class events per ANSI/ANS-57.9). These events are of the type where corrective actions can usually be accomplished within one 8-hour operating shift to restore the heat removal system to operable status (e.g., removal of loose debris). This LCO is not intended to address low frequency, unexpected Design Event III and IV class events (ANSI/ANS-57.9) such as design basis accidents and extreme environmental phenomena that could potentially block one or more of the air ducts for an extended period of time (i.e., longer than the total Completion Time of the LCO). This class of events is addressed site-specifically as required by Section 3.4.11 of Appendix B to the CoC.
APPLICABILITY	The LCO is applicable during STORAGE OPERATIONS. Once a VVM containing an MPC loaded with spent fuel has been placed in storage, the heat removal system must be operable to ensure adequate dissipation of the decay heat from the fuel assemblies.
ACTIONS	A note has been added to the ACTIONS which states that, for this LCO, separate Condition entry is allowed for each SFSC. This is acceptable since the Required Actions for each Condition provide appropriate compensatory measures for each SFSC not meeting the LCO. Subsequent SFSCs that don't meet the LCO are governed by subsequent Condition entry and application of associated Required Actions.

(continued)

BASES

ACTIONS (continued)

A.1

Although the heat removal system remains operable, the blockage should be cleared expeditiously.

B.1

If the heat removal system has been determined to be inoperable, it must be restored to operable status within eight hours. Eight hours is a reasonable period of time to take action to remove the obstructions in the air flow path.

C.1

If the heat removal system cannot be restored to operable status within eight hours, the VVM and the fuel may experience elevated temperatures. Therefore, dose rates are required to be measured to verify the effectiveness of the radiation shielding provided by the concrete. This Action must be performed immediately and repeated every twelve hours thereafter to provide timely and continued evaluation of the effectiveness of the concrete shielding. As necessary, the system user shall provide additional radiation protection measures such as temporary shielding. The Completion Time is reasonable considering the expected slow rate of deterioration, if any, of the concrete under elevated temperatures.

C.2.1

In addition to Required Action C.1, efforts must continue to restore cooling to the SFSC. Efforts must continue to restore the heat removal system to operable status by removing the air flow obstruction(s) unless optional Required Action C.2.2 is being implemented.

This Required Action must be complete in 24 hours. The Completion Time is consistent with the thermal analyses of this event, which show that all component temperatures remain below their short-term temperature limits up to 32 hours after event initiation.

(continued)

BASES

ACTIONS (continued)

C.2.1 (continued)

The Completion Time reflects the 8 hours to complete Required Action B.1 and the appropriate balance of time consistent with the applicable analysis results. The event is assumed to begin at the time the SFSC heat removal system is declared inoperable. This is reasonable considering the low probability of all inlet ducts becoming simultaneously blocked.

C.2.2

In lieu of implementing Required Action C.2.1, transfer of the MPC into a TRANSFER CASK will place the MPC in an analyzed condition and ensure adequate fuel cooling until actions to correct the heat removal system inoperability can be completed. Transfer of the MPC into a TRANSFER CASK removes the SFSC from the LCO Applicability since STORAGE OPERATIONS does not include times when the MPC resides in the TRANSFER CASK.

An engineering evaluation must be performed to determine if any deterioration which prevents the VVM from performing its design function. If the evaluation is successful and the air inlet duct screens have been cleared, the VVM heat removal system may be considered operable and the MPC transferred back into the VVM. Compliance with LCO 3.1.2 is then restored. If the evaluation is unsuccessful, the user must transfer the MPC into a different, fully qualified VVM to resume STORAGE OPERATIONS and restore compliance with LCO 3.1.2

In lieu of performing the engineering evaluation, the user may opt to proceed directly to transferring the MPC into a different, fully qualified VVM or place the TRANSFER CASK in the spent fuel pool and unload the MPC.

The Completion Time of 24 hours reflects the Completion Time from Required Action C.2.1 to ensure component temperatures remain below their short-term temperature limits for the respective decay heat loads.

(continued)

BASES

SURVEILLANCE REQUIREMENTS

SR 3.1.2

The long-term integrity of the stored fuel is dependent on the ability of the SFSC to reject heat from the MPC to the environment. There are two options for implementing SR 3.1.2, either of which is acceptable for demonstrating that the heat removal system is OPERABLE.

Visual observation that all air inlet duct screens are unobstructed ensures that the SFSC is operable. If greater than 50% of the air inlet duct screens are blocked the heat removal system is inoperable and this LCO is not met. While 50% or less blockage of the total air inlet duct screen area does not constitute inoperability of the heat removal system, corrective actions should be taken promptly to remove the obstruction and restore full flow.

Visual observation of air outlet duct screen blockage does not constitute inoperability of the heat removal system; however, corrective action should be taken to promptly remove the obstruction.

As an alternative, for VVMs with air temperature monitoring instrumentation installed in the air outlets, the temperature difference between the outlet air and the ambient air may be monitored to verify operability of the heat removal system. Blocked air inlet duct screens will reduce air flow and increase the outlet duct air temperature. Based on the analyses, if the temperature difference between the ambient air and the outlet duct air meets the criteria in the LCO, adequate air flow is occurring to provide assurance of long term fuel cladding integrity. The reference ambient temperature used to perform this Surveillance shall be measured at the ISFSI facility.

The Frequency of 24 hours is reasonable based on the time necessary for SFSC components to heat up to unacceptable temperatures assuming design basis heat loads, and allowing for corrective actions to take place upon discovery of blockage of air ducts.

B 3.1 SFSC INTEGRITY

B 3.1.3 MPC Cavity Reflooding

BASES	
BACKGROUND	In the event that an MPC must be unloaded, the TRANSFER CASK with its enclosed MPC is returned to the preparation area to begin the process of fuel unloading. The MPC closure ring, and vent and drain port cover plates are removed. The MPC gas is sampled to determine the integrity of the spent fuel cladding. The pressure in the MPC cavity is ensured to be less than the 100 psig design pressure. This is accomplished via direct measurement of the MPC gas pressure or via analysis. After ensuring the MPC cavity pressure meets the LCO limit, the MPC is then reflooded with water at a controlled rate and/or the pressure monitored to ensure that the pressure remains below 100 psig. Once the cavity is filled with water, the MPC lid weld is removed leaving the MPC lid in place. The TRANSFER CASK and MPC are placed in the spent fuel pool and the MPC lid is removed. The fuel assemblies are removed from the MPC and the MPC and TRANSFER CASK are removed from the spent fuel pool and decontaminated. Ensuring that the MPC cavity pressure is less than the LCO limit ensures that any steam produced within the cavity is safely vented to an appropriate location and eliminates the risk of high MPC pressure due to sudden generation of large steam quantities during re-flooding.
APPLICABLE SAFETY ANALYSIS	The confinement of radioactivity during the storage of spent fuel in the MPC is ensured by the MPC in which the fuel assemblies are stored. Standard practice in the dry storage industry has historically been to directly reflood the storage canister with water. This standard practice is known not to induce fuel cladding failures. The integrity of the MPC depends on maintaining the internal cavity pressures within design limits. This is accomplished by introducing water to the cavity in a controlled manner such that there is no sudden formation of large quantities of steam during MPC reflooding. (Ref. 1).

(continued)

BASES	
LCO	Determining the MPC cavity pressure prior to and during re-flooding ensures that there will be sufficient venting of any steam produced to avoid excessive MPC pressurization.
APPLICABILITY	The MPC cavity pressure is controlled during UNLOADING OPERATIONS after the TRANSFER CASK and integral MPC are back in the FUEL BUILDING and are no longer suspended from, or secured in, the transporter. Therefore, the MPC Reflood LCO does not apply during TRANSPORT OPERATIONS and STORAGE OPERATIONS. A note has been added to the APPLICABILITY for LCO 3.1.3 which states that the LCO is only applicable during wet UNLOADING OPERATIONS. This is acceptable since the intent of the LCO is to avoid uncontrolled MPC pressurization due to water flashing during re-flooding operations. This is not a concerning for dry UNLOADING OPERATIONS.
ACTIONS	A note has been added to the ACTIONS which states that, for this LCO, separate Condition entry is allowed for each MPC. This is acceptable since the Required Actions for each Condition provide appropriate compensatory measures for each MPC not meeting the LCO. Subsequent MPCs that do not meet the LCO are governed by subsequent Condition entry and application of associated Required Actions. A If the MPC cavity pressure limit is not met, actions must be taken to restore the parameters to within the limits before initiating or continuing re-flooding the MPC. Immediately is an appropriate Completion Time because it requires action to be initiated promptly and completed without delay, but does not establish any particular fixed time limit for completing the action. This offers the flexibility necessary for users to plan and implement any necessary work activities commensurate with the safety significance of the condition, which is governed by the MPC heat load.

(continued)

BASES	
SURVEILLANCE REQUIREMENTS	SR 3.1.3.1 The integrity of the MPC is dependent on controlling the internal MPC pressure. By controlling the MPC internal pressure prior to and during re-flooding the MPC, sufficient steam venting capacity exists during MPC re-flooding. The LCO must be met on each SFSC before the initiation of MPC re-flooding operations to ensure the design and analysis basis are preserved.

B 3.2 SFSC Radiation Protection

B 3.2.1 TRANSFER CASK Surface Contamination

BASES	
BACKGROUND	A TRANSFER CASK is immersed in the spent fuel pool in order to load the spent fuel assemblies. As a result, the surface of the TRANSFER CASK may become contaminated with the radioactive material from the spent fuel pool water. This contamination is removed prior to moving the TRANSFER CASK to the ISFSI, in order to minimize the radioactive contamination to personnel or the environment. This allows dry fuel storage activities to proceed without additional radiological controls to prevent the spread of contamination and reduces personnel dose due to the spread of loose contamination or airborne contamination. This is consistent with ALARA practices.
APPLICABLE SAFETY ANALYSIS	The radiation protection measures, implemented during MPC transfer and transportation using the TRANSFER CASK, are based on the assumption that the exterior surfaces of the TRANSFER CASK have been decontaminated. Failure to decontaminate the surfaces of the TRANSFER CASK could lead to higher-than-projected occupational doses.
LCO	Removable surface contamination on the TRANSFER CASK exterior surfaces and accessible surfaces of the MPC is limited to 1000 dpm/100 cm^2 from beta and gamma sources and 20 dpm/100 cm^2 from alpha sources. These limits are taken from the guidance in IE Circular 81-07 (Ref. 2) and are based on the minimum level of activity that can be routinely detected under a surface contamination control program using direct survey methods. Only loose contamination is controlled, as fixed contamination will not result from the TRANSFER CASK loading process.

(continued)

BASES

LCO (continued)

Experience has shown that these limits are low enough to prevent the spread of contamination to clean areas and are significantly less than the levels which would cause significant personnel skin dose. LCO 3.2.1 requires removable contamination to be within the specified limits for the exterior surfaces of the TRANSFER CASK and accessible portions of the MPC. The location and number of surface swipes used to determine compliance with this LCO are determined based on standard industry practice and the user's plant-specific contamination measurement program for objects of this size. Accessible portions of the MPC means the upper portion of the MPC external shell wall accessible after the inflatable annulus seal is removed and before the annulus shield ring is installed. The user shall determine a reasonable number and location of swipes for the accessible portion of the MPC. The objective is to determine a removable contamination value representative of the entire upper circumference of the MPC, while implementing sound ALARA practices.

APPLICABILITY

Verification that the surface contamination is less than the limit in the LCO is performed during LOADING OPERATIONS. This occurs before TRANSPORT OPERATIONS, when the LCO is applicable. Measurement of surface contamination is unnecessary during UNLOADING OPERATIONS as surface contamination would have been measured prior to moving the subject TRANSFER CASK to the ISFSI.

(continued)

BASES	
ACTIONS	A note has been added to the ACTIONS which states that, for this LCO, separate Condition entry is allowed for each TRANSFER CASK. This is acceptable since the Required Actions for each Condition provide appropriate compensatory measures for each TRANSFER CASK not meeting the LCO. A subsequent use of the TRANSFER CASK that does not meet the LCO are governed by subsequent Condition entry and application of associated Required Actions. <u>A.1</u> If the removable surface contamination of a TRANSFER CASK or MPC, as applicable, which has been loaded with spent fuel is not within the LCO limits, action must be initiated to decontaminate the TRANSFER CASK or MPC and bring the removable surface contamination to within limits. The Completion Time of 7 days is appropriate given that sufficient time is needed to prepare for, and complete the decontamination once the LCO is determined not to be met.
SURVEILLANCE REQUIREMENTS	SR 3.2.1.1 This SR verifies that the removable surface contamination on the TRANSFER CASK and/or accessible portions of the MPC is less than the limits in the LCO. The Surveillance is performed using smear surveys to detect removable surface contamination. The Frequency requires performing the verification during LOADING OPERATIONS in order to confirm that the TRANSFER CASK or VVM can be moved to the ISFSI without spreading loose contamination.

B 3.3 SFSC Criticality Control

B 3.3.1 Boron Concentration

BASES	
BACKGROUND	A TRANSFER CASK with an empty MPC is placed in the spent fuel pool and loaded with fuel assemblies meeting the requirements of the Certificate of Compliance. A lid is then placed on the MPC. The TRANSFER CASK and MPC are raised to the top of the spent fuel pool surface. The TRANSFER CASK and MPC are then moved into the preparation area where the MPC lid is welded to the MPC shell and the welds are inspected and tested. The water is drained from the MPC cavity and drying is performed. The MPC cavity is backfilled with helium. Then, the MPC vent and drain cover plates and MPC closure ring are installed and welded. Inspections are performed on the welds. For those MPCs containing PWR fuel assemblies credit is taken in the criticality analyses for boron in the water within the MPC. To preserve the analysis basis, users must verify that the boron concentration of the water in the MPC meets specified limits when there is fuel and water in the MPC. This may occur during LOADING OPERATIONS and UNLOADING OPERATIONS.
APPLICABLE SAFETY ANALYSIS	The spent nuclear fuel stored in the SFSC is required to remain subcritical ($k_{eff} \leq 0.95$) under all conditions of storage. The HI-STORM UMAX SFSC is analyzed to store a wide variety of spent nuclear fuel assembly types with differing initial enrichments. For all PWR fuel loaded in the MPC-37, credit was taken in the criticality analyses for neutron poison in the form of soluble boron in the water within the MPC. Compliance with this LCO preserves the assumptions made in the criticality analyses regarding credit for soluble boron.

(continued)

BASES	
LCO	Compliance with this LCO ensures that the stored fuel will remain subcritical with a $k_{eff} \leq 0.95$ while water is in the MPC. LCOs 3.3.1.a provides the minimum concentration of soluble boron required in the MPC water for the MPC-37. The amount of soluble boron is dependent on the initial enrichment of the fuel assemblies to be loaded in the MPC. Fuel assemblies with an initial enrichment less than or equal to 4.0 wt. % U-235 require less soluble boron than those with initial enrichments greater than 4.0 wt. % U-235. For initial enrichments greater than 4.0 wt. % U-235 and up to 5.0 wt. % U-225, interpolation is permitted to determine the required minimum amount of soluble boron. All fuel assemblies loaded into the MPC-37 are limited by analysis to maximum enrichments of 5.0 wt. % U-235. The LCO also requires that the minimum soluble boron concentration for the most limiting fuel assembly array/class and classification to be stored in the same MPC be used. This means that the highest minimum soluble boron concentration limit for all fuel assemblies in the MPC applies in cases where fuel assembly array/classes are mixed in the same MPC. This ensures the assumptions pertaining to soluble boron used in the criticality analyses are preserved.
APPLICABILITY	The boron concentration LCO is applicable whenever an MPC-37 has at least one PWR fuel assembly in a storage location and water in the MPC. During LOADING OPERATIONS, the LCO is applicable immediately upon the loading of the first fuel assembly in the MPC. It remains applicable until the MPC is drained of water. During UNLOADING OPERATIONS, the LCO is applicable when the MPC is reflooded with water. Note that compliance with SR 3.0.4 assures that the water to be used to flood the MPC is of the correct boron concentration to ensure the LCO is satisfied upon entering the Applicability.

(continued)

BASES

ACTIONS

A note has been added to the ACTIONS which states that, for this LCO, separate Condition entry is allowed for each MPC. This is acceptable since the Required Actions for each Condition provide appropriate compensatory measures for each MPC not meeting the LCO. Subsequent MPCs that do not meet the LCO are governed by subsequent Condition entry and application of associated Required Actions.

A.1 and A.2

Continuation of LOADING OPERATIONS, UNLOADING OPERATIONS or positive reactivity additions (including actions to reduce boron concentration) is contingent upon maintaining the SFSC in compliance with the LCO. If the boron concentration of water in the MPC is less than its limit, all LOADING OPERATIONS, UNLOADING OPERATIONS or positive reactivity additions must be suspended immediately.

A.3

In addition to immediately suspending LOADING OPERATIONS, UNLOADING OPERATIONS and positive reactivity additions, action to restore the concentration to within the limit specified in the LCO must be initiated immediately. One means of complying with this action is to initiate boration of the affected MPC. In determining the required combination of boration flow rate and concentration, there is no unique design basis event that must be satisfied; only that boration is initiated without delay. In order to raise the boron concentration as quickly as possible, the operator should begin boration with the best source available for existing plant conditions.

Once boration is initiated, it must be continued until the boron concentration is restored. The restoration time depends on the amount of boron that must be injected to reach the required concentration.

(continued)

BASES

SURVEILLANCE REQUIREMENTS

SR 3.3.1.1

The boron concentration in the MPC water must be verified to be within the applicable limit within four hours prior to entering the Applicability of the LCO. For LOADING OPERATIONS, this means within four hours of loading the first fuel assembly into the MPC using two independent measurements to ensure the requirements of 10 CFR 72.124(a) are met. These two independent measurements will be repeated every 48 hours while the MPC is submerged in water or if water is to be added to or recirculated through the MPC.

For UNLOADING OPERATIONS, this means verifying the boron concentration in the source of borated water to be used to reflood the MPC within four hours of commencing reflooding operations and every 48 hours after until all the fuel is removed from the MPC. Two independent measurements will be taken to ensure the requirements of 10 CFR 72.124(a) are met. This ensures that when the LCO is applicable (upon introducing water into the MPC), the LCO will be met.

Surveillance Requirement 3.3.1.1 is modified by a note which states that SR 3.3.1.1 is only required to be performed if the MPC is submerged in water or if water is to be added to, or recirculated through the MPC. This reflects the underlying premise of this SR which is to ensure, once the correct boron concentration is established, it need only be verified thereafter if the MPC is in a state where the concentration could be changed. After the completion of the surveillance methods, events which might change the soluble boron concentration will be administratively controlled per the LCO. If actions are taken that could result in a reduction in the boron concentration the surveillance will be performed again.

There is no need to re-verify the boron concentration of the water in the MPC after it is removed from the spent fuel pool unless water is to be added to, or recirculated through the MPC, because these are the only credible activities that could potentially change the boron concentration during this time. This note also prevents the interference of unnecessary sampling activities while lid closure welding and other MPC storage preparation activities are taking place in an elevated radiation area atop the MPC. Plant procedures should ensure

BASES	
SURVEILLANCE REQUIREMENTS	that any water to be added to, or recirculated through the MPC is at a boron concentration greater than or equal to the minimum boron concentration specified in the LCO.

CHAPTER 14†: QUALITY ASSURANCE PROGRAM

14.0 INTRODUCTION

14.0.1 Overview

This chapter provides a summary of the quality assurance program implemented by Holtec International for activities related to the design, qualification analyses, material procurement, fabrication, assembly, testing and use of structures, systems, and components of the Company's dry storage/transport systems including the HI-STORM UMAX System which includes the HI-TRAC transfer cask. This chapter is included in this FSAR to fulfill the requirements in 10 CFR 72.140 (c) (2) and 72.2(a)(1),(b).

Important-to-safety activities related to construction and deployment of the HI-STORM UMAX System are controlled under the NRC-approved Holtec Quality Assurance Program. The Holtec QA program manual [14.0.1] is approved by the NRC [14.0.2] under Docket 71-0784. The Holtec QA program satisfies the requirements of 10 CFR 72, Subpart G and 10 CFR 71, Subpart H. In accordance with 10 CFR 72.140(d), this approved 10 CFR 71 QA program will be applied to spent fuel storage cask activities under 10 CFR 72. The additional recordkeeping requirements of 10 CFR 72.174 are addressed in the Holtec QA program manual and must also be complied with.

The Holtec QA program is implemented through a hierarchy of procedures and documentation, listed below.

1. Holtec Quality Assurance Program Manual

2. Holtec Quality Assurance Procedures

3. a. Holtec Standard Procedures
   b. Holtec Project Procedures

Quality activities performed by others on behalf of Holtec are governed by the supplier's quality assurance program or Holtec's QA program extended to the supplier. The type and extent of Holtec QA control and oversight is specified in the procurement documents for the specific item or service being procured. The fundamental goal of the supplier oversight portion of Holtec's QA program is to provide the assurance that activities performed in support of the supply of safety-significant items and services are performed correctly and in compliance with the procurement documents.

† This chapter has been prepared in the format and section organization set forth in Regulatory Guide 3.61.

14.0.2 Graded Approach to Quality Assurance

Holtec International uses a graded approach to quality assurance on all safety-related or important-to-safety projects. This graded approach is controlled by Holtec Quality Assurance (QA) program documents as described in Subsection 14.0.1.

NUREG/CR-6407 [14.0.3] provides descriptions of quality categories A, B and C. Using the guidance in NUREG/CR-6407, Holtec International assigns a quality category to each individual, important-to-safety component of the HI-STORM UMAX System and HI-TRAC transfer cask. The ITS categories assigned to the HI-STORM UMAX cask components are identified in licensing drawing in Section 1.5. Quality categories for ancillary equipment are provided in Chapter 9 of this FSAR. Quality categories for other equipment needed to deploy the HI-STORM UMAX System at a licensee's ISFSI are defined on a case-specific basis considering the component's design function using the guidelines of NUREG/CR-6407 [14.0.3].

Activities affecting quality are defined by the purchaser's procurement contract for use of the HI-STORM UMAX System at an independent spent fuel storage installation (ISFSI) under the general license provisions of 10CFR72, Subpart K. These activities include any or all of the following: design, procurement, fabrication, handling, shipping, storing, cleaning, assembly, inspection, testing, operation, maintenance, repair and monitoring of HI-STORM UMAX structures, systems, and components (SSCs) that are important-to-safety.

The quality assurance program described in the QA Program Manual fully complies with the requirements of 10CFR72 Subpart G and the intent of NUREG-1536 [14.0.4]. However, NUREG-1536 does not explicitly address incorporation of a QA program manual by reference. Therefore, invoking the NRC-approved QA program in this FSAR constitutes a literal deviation from NUREG-1536. This deviation is acceptable since important-to-safety activities are implemented in accordance with the latest revision of the Holtec QA program manual and implementing procedures. Further, incorporating the QA Program Manual by reference in this FSAR avoids duplication of information between the implementing documents and the FSAR and any discrepancies that may arise from simultaneous maintenance to the two program descriptions governing the same activities.

ARLINGTON, TEXAS 76011-4511

December 19, 2018

EA-18-155

Mr. Doug Bauder
Vice President and Chief Nuclear Officer
Southern California Edison Company
San Onofre Nuclear Generating Station
P.O. Box 128
San Clemente, CA 92674-0128

SUBJECT: ERRATA: SAN ONOFRE NUCLEAR GENERATING STATION - NRC SPECIAL INSPECTION REPORT 050-00206/2018-005, 050-00361/2018-005, 050-00362/2018-005, 072-00041/2018-001 AND NOTICE OF VIOLATION

Mr. Bauder:

It was identified that the U.S. Nuclear Regulatory Commission (NRC) Special Inspection Report No. 050-00206/2018-005, 050-00361/2018-005, 050-00362/2018-005, 072-00041/2018-001, dated November 28, 2018 Agency Document and Management System (ADAMS) (ADAMS Accession No. ML18332A357) and Notice of Violation (Notice) incorrectly identified the cited violation against 10 CFR 72.192, regarding “Operator training and certification program,” in lieu of citing the violation against 10 CFR 72.190, “Operator requirements.” The corrected inspection report and Notice shall refer to “10 CFR 72.190” in all applicable areas. As specified in 10 CFR 72.13, the regulation identified under 10 CFR 72.190 is applicable to a general licensee, which is the type of license held by Southern California Edison Company. The inspection report and all its enclosures, including the Notice, is reissued in its entirety under the same inspection report number and is enclosed.

The change to the citation in the Notice involving training and certification of personnel does not change the content of the inspection report, or the two apparent violations. As such, the communications provided in the November 28, 2018, inspection report regarding your opportunity to request a predecisional enforcement conference (PEC) or alternative dispute resolution (ADR) remains in effect from the date of the original inspection report, November 28, 2018. On December 10, 2018, SONGS informed the NRC that it requested a PEC. My staff is working with your staff to schedule the PEC.

In accordance with 10 CFR 2.390 of the NRC's "Agency Rules of Practice and Procedure," a copy of this letter, its enclosures, and your response (if any), will be made available electronically for public inspection in the NRC Public Document Room and from the NRC's ADAMS, accessible from the NRC Web site at http://www.nrc.gov/reading-rm/adams.html.

If you have any questions concerning this matter, please contact Dr. Janine F. Katanic, CHP, of my staff at 817-200-1151.

Sincerely,

/RA/

Troy W. Pruett, Director
Division of Nuclear Materials Safety

SUBJECT: REVISED NRC SPECIAL INSPECTION REPORT 050-00206/2018-005, 050-00361/2018-005, 050-00362/2018-005, 072-00041/2018-001 AND REVISED NOTICE OF VIOLATION

Mr. Bauder:

This letter refers to the Special Inspection conducted on September 10-14, 2018, at your facility in San Clemente, California. The inspection was conducted in response to the misalignment of a loaded spent fuel storage canister as it was being downloaded into the storage vault at the San Onofre Nuclear Generating Station (SONGS). Based on the criteria specified in Management Directive 8.3, "NRC Incident Investigation Program," the Nuclear Regulatory Commission (NRC) initiated a Special Inspection in accordance with Inspection Procedure 93812, "Special Inspection." The basis for initiating the Special Inspection and the focus areas for review are detailed in the Special Inspection Charter (Enclosure 3), dated August 17, 2018 (Agencywide Document Access and Management System (ADAMS) Accession ML18229A203).

The enclosed report documents the results of the inspection. The inspectors discussed the preliminary inspection findings with Mr. Thomas Palmisano and members of your staff on September 14, 2018, at the conclusion of the onsite portion of the inspection. A final exit briefing was conducted telephonically with Mr. Palmisano and members of your staff on November 1, 2018.

Based on the results of the Special Inspection, two apparent violations were identified and are being considered for escalated enforcement action in accordance with the NRC Enforcement Policy. The current Enforcement Policy is included on the NRC Web site at http://www.nrc.gov/about-nrc/regulatory/enforcement/enforce-pol.html. The circumstances surrounding these apparent violations, the significance of the associated issues, and the need for corrective actions were discussed with Mr. Palmisano at the conclusion of the onsite inspection and during the final telephonic exit briefing. The apparent violations involved the failure to: (1) ensure important-to-safety equipment was available to provide redundant drop protection features for a spent fuel canister during downloading operations; and (2) make a timely notification to the NRC Headquarters Operations Center for the August 3, 2018, disabling of important-to-safety equipment.

The NRC is concerned about apparent weaknesses in management oversight of the dry cask storage operations. Your staff did not perform adequate direct observational oversight of downloading activities performed by your contractor, ensure adequate training of individuals responsible for performing downloading operations, provide adequate procedures for downloading operations, or ensure that conditions adverse to quality were entered into the corrective action program. The NRC identified that a causal factor for the misalignment incident involved management weakness in the oversight of dry cask storage operations.

Before the NRC makes its enforcement decision, we are providing you with an opportunity to: (1) request a predecisional enforcement conference (PEC) or (2) request alternative dispute resolution (ADR). If a PEC is held, it will be open for public observation and the NRC will issue a press release to announce the time and date of the conference.

If you choose to request a PEC, the conference will afford you the opportunity to provide your perspective on these matters and any other information that you believe the NRC should take into consideration before making an enforcement decision. The decision to hold a PEC does not mean that the NRC has determined that a violation has occurred or that enforcement action will be taken. This conference would be conducted to obtain information to assist the NRC in making an enforcement decision.

The topics discussed during the conference may include information to determine whether a violation occurred, information to determine the significance of a violation, information related to the identification of a violation, and information related to any corrective actions taken or planned. In presenting your corrective actions, you should be aware that the promptness and comprehensiveness of your actions will be considered in assessing any civil penalty for the apparent violations. The guidance in NRC Information Notice 96-28, “Suggested Guidance Relating to Development and Implementation of Corrective Action,” may be helpful and can be obtained at the NRC Web site at http://pbadupws.nrc.gov/docs/ML0612/ML061240509.pdf.

In lieu of a PEC, you may also request ADR with the NRC in an attempt to resolve this issue. Alternative dispute resolution is a general term encompassing various techniques for resolving conflicts using a neutral third party. The technique that the NRC has decided to employ is mediation. Mediation is a voluntary, informal process in which a trained neutral mediator works with parties to help them reach resolution. If the parties agree to use ADR, they select a mutually agreeable neutral mediator who has no stake in the outcome and no power to make decisions. Mediation gives parties an opportunity to discuss issues, clear up misunderstandings, be creative, find areas of agreement, and reach a final resolution of the issues.

Additional information concerning the NRC’s program can be obtained at http://www.nrc.gov/about-nrc/regulatory/enforcement/adr.html. The Institute on Conflict Resolution at Cornell University has agreed to facilitate the NRC’s program as a neutral third party. Please contact the Institute on Conflict Resolution at 877-733-9415 within 10 days of the date of this letter if you are interested in pursuing resolution of these issues through ADR. Alternative dispute resolution sessions are not conducted with public observation though the outcome of the ADR agreement is made public.

A PEC should be held within 30 days and an ADR session within 45 days of the date of this letter. Please contact Dr. Janine F. Katanic at 817-200-1151 within 10 days of the date of this letter to notify the NRC of your intended response.

In addition, please be advised that the number and characterization of apparent violations described in the enclosed inspection report may change as a result of further NRC review. You will be advised by separate correspondence of the results of our deliberations on this matter.

The NRC determined that three Severity Level IV violations of NRC requirements occurred. These violations were evaluated in accordance with Section 2.2.2 of the NRC Enforcement Policy. The NRC determined the issuance of a Notice of Violation (Notice) is appropriate because the actions to restore compliance have not been fully developed and implemented, and the actions must be effective prior to beginning fuel handling activities.

The three Severity Level IV violations are cited in the enclosed Notice and the circumstances surrounding them are described in detail in the subject inspection report. The violations involved failures to: (1) identify conditions potentially adverse to quality for placement into your corrective actions program; (2) assure that operations of important to safety equipment were limited to trained and certified personnel or under direct supervision; and (3) provide adequate procedures for dry cask storage operations involving downloading operations.

In accordance with 10 CFR 2.390 of the NRC's "Agency Rules of Practice and Procedure," a copy of this letter, its enclosures, and your response, will be made available electronically for public inspection in the NRC Public Document Room and from the NRC's ADAMS, accessible from the NRC Web site at http://www.nrc.gov/reading-rm/adams.html. To the extent possible, your response should not include any personal privacy or proprietary information so that it can be made available to the public without redaction.

If you have any questions concerning this matter, please contact Dr. Janine F. Katanic, CHP, of my staff at 817-200-1151.

Sincerely,

/RA/

Troy W. Pruett, Director
Division of Nuclear Materials Safety

Docket Nos.: 50-206; 50-361; 50-362; 72-041

3. Special Inspection Charter dated August 17, 2018 (ML18229A203)

NOTICE OF VIOLATION

Southern California Edison Company
San Clemente, CA

Docket Nos.: 050-00206, 050-00361, 050-00362, 072-00041
License Nos.: NPF-10; NPF-15; DPR-13
EA No: 18-155

During an NRC Special Inspection conducted September 10 through November 1, 2018, three violations of NRC requirements were identified. In accordance with the NRC Enforcement Policy, the violations are listed below:

A. 10 CFR 72.172 requires, in part, that, licensees establish measures to ensure that conditions adverse to quality, such as failures, malfunctions, deficiencies, and deviations, are promptly identified and corrected.

   Contrary to the above, from January 30 to August 3, 2018, the licensee failed to establish measures to ensure that conditions adverse to quality, such as failures, malfunctions, deficiencies, and deviations, were promptly identified and corrected. Specifically:

   1. On July 22, 2018, the loading crew experienced difficulty in aligning canister 28 for downloading into the independent spent fuel installation vault. However, the licensee failed to enter this deviation in downloading conditions into its corrective action program to determine the cause of the misalignment problem and develop corrective actions to preclude reoccurrence.

   2. From January 30 to August 3, 2018, during canister downloading, contact between the canister and vault components frequently occurred. However, the licensee failed to enter instances of contact into its corrective action program and perform an assessment to disposition the exterior conditions of the downloaded canisters and vault components.

This is a Severity Level IV violation (NRC Enforcement Policy Section 6.3).

B. 10 CFR 72.190 requires, in part, that the operation of equipment and controls that have been identified as important to safety in the Safety Analysis Report and in the license must be limited to trained and certified personnel or be under the direct supervision of an individual with training and certification in the operation. The HI-STORM UMAX SYSTEM Final Safety Analysis Report (FSAR), Revision 4, dated August 14, 2017, specifies, in part, that the operations at the independent spent fuel storage installation are governed by the HI-STORM FW SYSTEM FSAR, Revision 5, dated June 20, 2017, which specifies that the multipurpose canister lifting slings and multipurpose canister lift attachments are designated as important to safety equipment.

   Contrary to the above, from January 30 to August 3, 2018, the licensee failed to assure that operations of equipment and controls that had been identified as important to safety in the Safety Analysis Report were limited to trained and certified personnel or were under the direct supervision of an individual with training and certification in the operation. Specifically:

1. The training program failed to adequately train and certify the rigger/spotter position involved in the important to safety downloading operation.

2. The training program for the vertical cask transporter operator position failed to have adequate proficiency testing, on the controls related to the load indicating device and downloading operations.

This is a Severity Level IV violation (NRC Enforcement Policy Section 6.3).

C. 10 CFR 72.150, requires, in part, that the licensee prescribe activities affecting quality by documented instructions or procedures of a type appropriate to the circumstances and must include appropriate quantitative or qualitative acceptance criteria for determining that important activities have been satisfactorily accomplished.

Contrary to the above, from January 30 to August 3, 2018, the licensee failed to prescribe activities affecting quality by documented instructions or procedures of a type appropriate to the circumstances and include appropriate quantitative or qualitative acceptance criteria for determining that important activities have been satisfactorily accomplished. Specifically:

1. Procedure HPP-2464-400, "Multi-Purpose Canister Transfer at SONGS," Revision 15, step 7.6.23, failed to provide qualitative and quantitative directions for the vertical cask transporter operator to monitor control panel indications that would identify a canister had become misaligned during downloading operation.

2. Procedure HPP-2464-400, "Multi-Purpose Canister Transfer at SONGS," Revision 15, step 7.6.23, failed to include adequate instructions for the rigger/spotter to monitor the downloading slings for a slack condition.

This is a Severity Level IV violation (NRC Enforcement Policy Section 6.3).

Pursuant to the provisions of 10 CFR 2.201, Southern California Edison Company is hereby required to submit a written statement or explanation to the U.S. Nuclear Regulatory Commission, ATTN: Document Control Desk, Washington, DC 20555-0001, with a copy to the Regional Administrator, U.S. Nuclear Regulatory Commission, Region IV, 1600 E. Lamar Blvd., Arlington, TX 76011, within 30 days of the date of the letter transmitting this Notice of Violation (Notice).

This reply should be clearly marked as a "Reply to a Notice of Violation, EA-18-155" and should include, for each violation: (1) the reason for the violation, or, if contested, the basis for disputing the violation or severity level; (2) the corrective steps that have been taken and the results achieved; (3) the corrective steps that will be taken; and (4) the date when full compliance will be achieved. Your response may reference or include previous docketed correspondence, if the correspondence adequately addresses the required response. If an adequate reply is not received within the time specified in this Notice, an order or a Demand for Information may be issued requiring information as to why the license should not be modified, suspended, or revoked, or why such other action as may be proper should not be taken. Where good cause is shown, consideration will be given to extending the response time.

If you contest this enforcement action, you should also provide a copy of your response, with the basis for your denial, to the Director, Office of Enforcement, U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001.

Your response will be made available electronically for public inspection in the NRC Public Document Room or in the NRC's Agencywide Documents Access and Management System (ADAMS), accessible from the NRC Web site at http://www.nrc.gov/reading-rm/adams.html. To the extent possible, your response should not include any personal privacy or proprietary information so that it can be made available to the public without redaction.

If personal privacy or proprietary information is necessary to provide an acceptable response, then please provide a bracketed copy of your response that identifies the information that should be protected and a redacted copy of your response that deletes such information. If you request withholding of such material, you must specifically identify the portions of your response that you seek to have withheld and provide in detail the bases for your claim of withholding (e.g., explain why the disclosure of information will create an unwarranted invasion of personal privacy or provide the information required by 10 CFR 2.390(b) to support a request for withholding confidential commercial or financial information).

Dated this 19th day of December 2018

EXECUTIVE SUMMARY

NRC Special Inspection Report 050-00206/2018005; 050-00361/2018005; 050-00362/2018005; and 072-00041/2018-001

On September 10-14, 2018, the U.S. Nuclear Regulatory Commission performed an announced Special Inspection of the independent spent fuel storage installation at the decommissioning San Onofre Nuclear Generating Station in San Clemente, California. The inspection continued with an in-office review of training material, licensee analyses, procedures, and other materials gathered during the onsite inspection through November 1, 2018. The Southern California Edison Company, the licensee and owner of San Onofre Nuclear Generating Station, has an NRC General License for its independent spent fuel installation under Title 10 of the *Code of Federal Regulations* (10 CFR) Part 72. The scope of the inspection was to evaluate the facts and circumstances involved in the August 3, 2018, misalignment incident, and review the licensee's follow-up investigation, causal evaluation, and planned corrective actions.

<u>NRC Special Inspection of San Onofre Nuclear Generating Station Canister Misalignment Incident of August 3, 2018</u>

- The licensee's actions that led to disabling the important to safety downloading slings and removal of redundant drop protection features were identified as an apparent violation of Technical Specification 5.2.c.3 requirements. (Section 3.1.1)

- The NRC team identified missed opportunities where the licensee could have addressed the potential for a downloading misalignment. For example, on July 22, 2018, one of the crews experienced misalignment difficulty resulting in a prolonged downloading operation. The licensee did not enter the adverse condition into the corrective action program to determine the cause and develop appropriate corrective actions. This was identified as a Severity Level IV violation of 10 CFR 72.172 requirements. (Section 3.1.1)

- Personnel lacked the proper training, proficiency testing, and certifications to operate important to safety equipment identified in the HI-STORM UMAX SYSTEM Final Safety Analysis Report, Revision 4, dated August 14, 2017. This was identified as a Severity Level IV violation of 10 CFR 72.190 requirements. (Section 3.1.2)

- Dry cask storage procedures did not provide adequate directions for how to determine the downloader slings were slack. Slack in the slings was an indicator of a loss-of-load. Further, procedures did not include qualitative or quantitative means to determine when a canister had become misaligned. These procedure inadequacies were identified as a Severity Level IV violation of 10 CFR 72.150 requirements. (Section 3.1.3)

- No licensee or contractor oversight staff were in direct visual observation of important to safety activities during downloading operations on August 3, 2018. Licensee oversight was not a part of communications between the cask loading supervisor, the rigger/spotter, and vertical cask transporter operator during downloading operations. (Section 3.1.3)

- The licensee concluded and the NRC agreed that the minor removal of divider shell coating during downloading operations did not affect the design functions for shielding, structural, and thermal safety functions. The licensee's plan to address future inspection of the divider shells in their aging management program is acceptable. (Section 3.1.4)

- The licensee failed to make the required 24-hour NRC notification of the August 3, 2018, incident where important to safety equipment was disabled when required to mitigate the consequences of an accident and no redundant equipment was available to perform the safety function. This failure was identified as an apparent violation of 10 CFR 72.75(d) requirements. (Section 3.1.4)

- The causal evaluations performed by the licensee and its contractor identified apparent and root causes for the August 3, 2018, canister misalignment incident that included inadequate training, inadequate procedures, poor utilization of the corrective action program, and insufficient management oversight. (Section 3.1.5)

- The licensee's consequence analysis resulting from a hypothetical 25-foot canister drop determined that the canister integrity would be maintained. The NRC will continue to inspect the licensee's consequence analysis. (Section 3.1.5)

- The licensee provided an analysis to demonstrate that wear on canister 29 during the downloading incident would meet established acceptance criteria. The NRC determined that more analysis was required to accept that the canister meets design requirements. This charter item will be reviewed during a future NRC inspection. (Section 3.1.6)

- All associated corrective actions for the August 3, 2018, incident had not been fully developed and implemented by the licensee. The NRC will review the licensee's revised procedures, training plans, equipment modifications, and performance testing (dry runs) of its dry cask storage operations during a future inspection to determine the effectiveness of corrective actions for the incident. (Section 3.1.7)

REPORT DETAILS

1 Inspection Scope

On September 10-14, 2018, the NRC performed an announced Special Inspection at the San Onofre Nuclear Generating Station (SONGS) in San Clemente, California, which was followed by in-office reviews of additional information provided by the licensee through November 1, 2018. The scope of the inspection was to interview personnel associated with the August 3, 2018, misalignment incident to independently evaluate the circumstances of the canister misalignment; identify and review all pertinent records, documents, and procedures related to the licensee's downloading operations; evaluate procedure adequacy and adherence; evaluate the reportability requirements; and to evaluate the root cause analyses and corrective actions to prevent recurrence.

2 Background

2.1 General Description of Multi-purpose Canister Downloading Operations

On November 8, 2018, the NRC conducted a public meeting webinar (NRC's Agencywide Documents Access and Management System (ADAMS) Accession ML18319A139). The presentation provides a summary of a downloading operation.

A vertical cask transporter (VCT) is used for transporting the transfer cask and multi-purpose canister (MPC or canister) loaded with spent fuel onto the independent spent fuel storage installation (ISFSI) pad. Dry cask storage workers manipulate the VCT to align the transfer cask over the ISFSI vertical ventilated module (VVM or vault) in which the canister will be stored. Once alignment has been achieved and the transfer cask is securely bolted to a mating device, the transfer cask is disconnected from the VCT. Lifting slings are connected to the top of the canister and the VCT overhead lift beam. The VCT lift beam is raised until the load of the canister is supported and no longer resting on the bottom of the transfer cask.

While the canister is being supported by the lift beam and slings, a drawer on the mating device is opened. Once the drawer is open, the VCT operator lowers the lift beam, which lowers the canister into the storage vault. The VCT can be moved during the download to make fine adjustments for canister alignment within the vault. While the canister is being lowered, it passes through a divider shell assembly. The divider shell has a shield ring that the canister must pass through as it is being lowered into the vault. When fully downloaded, the canister will be seated on a pedestal in the cavity enclosure container in the vault.

2.2 August 3, 2018 Canister Misalignment

On August 3, 2018, as the loaded canister was being lowered into the vault, personnel failed to notice that the canister was misaligned. The licensee and its contractor continued to lower the VCT lift beam until staff believed that the canister had been fully lowered to the bottom of the vault. Staff involved in the download failed to recognize the lifting slings were slack. A radiation protection technician identified radiation readings that were not consistent with a fully lowered canister. The licensee then identified that the loaded spent fuel canister was resting on a shield ring near the top of the vault,

preventing it from being lowered, and that the rigging and lifting slings were slack and no longer bearing the load of the canister.

With the slings slack, the lifting equipment was no longer capable of performing it's important to safety function of holding and controlling the loaded canister. The canister could have experienced an approximately 17-18 foot drop into the storage vault if the canister had slipped off the shield ring. This load drop accident is not a condition analyzed in the dry fuel storage system's Final Safety Analysis Report (FSAR).

The licensee restored the control of the load to the slings and lifting devices. The estimated time the canister was in an unsupported position was approximately 45 minutes. The licensee repositioned and lowered the canister into the vault. The licensee subsequently halted all dry fuel storage movement operations in order to fully investigate the incident and develop corrective actions to prevent recurrence.

The licensee informed Region IV staff of the misalignment incident on August 6, 2018. Region IV discussed the licensee's plans for evaluation and follow-up for the incident and the status of fuel loading operations. The licensee agreed to suspend fuel loading operations until such time as their senior management was satisfied with their corrective actions, the NRC completed their inspection, and the NRC determines that corrective actions are sufficient to prevent a similar occurrence. Region IV chartered a Special Inspection Team to review the incident, any relevant background information, causal and risk assessments conducted by the licensee, and proposed and completed corrective actions.

3 Special Inspection Charter (IP 93812)

3.1 Inspection Scope

Following the notification to NRC Region IV of the August 3, 2018, misalignment incident, the NRC evaluated the information provided against the criteria for a reactive inspection. Based on the criteria in Management Directive 8.3, "NRC Incident Investigation Program," and Inspection Manual Chapter 0309, "Reactive Inspection Decision Basis for Reactors," a decision was made to perform a Special Inspection. The Special Inspection Charter is provided in Enclosure 3.

The Special Inspection was conducted onsite from September 10-14, 2018, and continued with in-office review until November 1, 2018. The Special Inspection focused on understanding the August 3, 2018, misalignment incident. The inspection included interviewing personnel involved in the incident, developing a timeline, and assessing the licensee's immediate corrective actions.

The sections below provide inspection details for each of the Special Inspection Charter items.

3.1.1 Charter Item 5

Inspection Scope

"Interview personnel associated with the August 3, 2018, misalignment incident to develop a timeline to ensure the licensee's investigation contained all necessary information to identify all contributing factors and develop adequate corrective actions."

The NRC team interviewed licensee and contractor staff involved or present during the August 3, 2018, misalignment incident. The NRC also reviewed records related to dry cask storage operations.

Observations and Findings

Based on interviews and records reviewed, the following timeline was developed:

Date/Time (± 30 minutes)	Activity
August 3, 2018	
12:40 p.m.	Downloading begins for canister 29: All dry cask storage supervision and licensee oversight, including radiation protection staff exited the ISFSI pad to stand in a low-dose area on the ISFSI pad ramp (approximately 150 feet away from the operations). Only the rigger/spotter in the motor-powered boom lift device man-basket (JLG) and the VCT operator remained on the ISFSI pad.
1:05 p.m.	VCT operator and rigger/spotter notify cask loading supervisor (CLS) that the canister has been fully lowered into the ISFSI vault.
1:12 p.m.	The radiation protection technician (RPT) determines radiation levels indicate that the canister was not fully lowered. Work activities were stopped to plan recovery actions with the radiation protection supervisor and CLS. The rigger in charge (RIC) began making preparations to enter the JLG.

1:15 p.m.	Notifications were made to Holtec management.
	The RIC was escorted to the JLG by an RPT.
	The RIC recognized the downloading slings were slack and bundled on the ground near the base of the VCT.
1:33 p.m.	The RIC observed the top of the canister was about 4 feet from the top of the transfer cask and not lowered into the vault.
	The RIC directed the VCT operator to lift the canister.
1:41 p.m.	The canister load was fully supported by the VCT and downloading slings.
1:50 p.m.	An alternate CLS arrived and began to direct operations for downloading to the VCT operator.
	The alternate CLS and RIC noted that during downloading operations the canister experienced interference twice and had to be re-aligned.
2:22 p.m.	Downloading operations completed.
6:00 p.m.	Licensee places hold on all lifting operations.
August 6, 2018	At approximately 4 pm (CDT), the licensee informally contacted NRC Region IV to discuss the August 3, 2018, misalignment incident.
August 7, 2018	NRC Region IV and licensee management agreed that ISFSI operations would cease until the NRC performed an inspection and reviewed the licensee’s corrective actions to resume work.
September 14, 2018	At 4 pm (ET) the licensee made a formal notification per 10 CFR 72.75(d)(1) to the NRC Headquarters Operations Center regarding the August 3, 2018, misalignment incident.

Violation of 10 CFR 72.172, Corrective Actions

Interviews with Williams Industrial Services Group and Sonic Systems (Holtec International subcontractors) employees indicated that of a loss-of-load condition or a canister misalignment issue was experienced during dry run evolutions and known to several dry cask storage workers. The Special Inspection team identified a prior canister misalignment issue that occurred on July 22, 2018, in which downloading operations lasted 90 minutes, instead of the expected 15 minutes for downloading canister 28. This incident was documented in a Production Traveler. A Production Traveler is a document that the licensee uses to track the performance of dry fuel storage operations by the

contractor, Holtec International. The Production Travelers were used to track how well the contractor was providing their contracted services to the licensee. The licensee did not enter this condition adverse to quality into its corrective action program.

Licensee oversight generally waited for Holtec staff to initiate a field condition report (FCR) before writing a corresponding condition report. In the Production Traveler for canister 28, the 90 minute delay was related to adjustments that were needed for the VCT towers as canister weight started to lower prematurely before the downloading was complete. This type of misalignment also occurred during the August 3, 2018, incident. On July 22, 2018, the downloading crew for canister 28, noted the reduction in the canister weight and corrected the alignment error. The canister was never unsupported by the slings. No condition report or FCR was generated by either the licensee or contractor.

Through interviews with licensee and contractor staff, the NRC determined that between January 30 and August 3, 2018, the downloading activity often involved contact between the canister and other vault components during downloading. The licensee and its contractor did not enter the misalignment and contact events into the corrective action program. Consequently, actions to assess and disposition the exterior conditions of the downloaded canisters and other components within the vault, such as the divider shell assembly, were not performed. The licensee is responsible to ensure the important to safety components continue to meet their original design criteria and address any aging management concerns the changes could impact. Any deviations, such as scratches or removal of coatings are required to be evaluated to ensure the deviations are not detrimental to the system.

Interviews with individuals involved in dry cask loading operations in August 2018, revealed that the difficulty in aligning the canister was not shared with others, nor was it incorporated into procedures or formal training programs. The VCT operator and the rigger/spotter in charge of downloading operations during the August 3, 2018, incident indicated that they did not know until afterwards that the condition they experienced was something that should have been anticipated.

Title 10 CFR 72.172 requires, in part, that, licensees establish measures to ensure that conditions adverse to quality, such as failures, malfunctions, deficiencies, and deviations are promptly identified and corrected. Contrary to the above, the licensee failed to establish measures to ensure that conditions adverse to quality, such as failures, malfunctions, deficiencies, and deviations were promptly identified and corrected. Specifically:

1. On July 22, 2018, the crew experienced difficulty in aligning canister 28 for downloading into the ISFSI vault. However, the licensee failed to enter this deviation in downloading conditions into its corrective action program to determine the cause of the misalignment problem and develop corrective actions to preclude reoccurrence.

2. From January 30 to August 3, 2018, during canister downloading, contact between the canister and the vault components frequently occurred. The licensee failed to enter instances of contact into its corrective action program and perform an assessment to disposition the exterior conditions of the downloaded canisters and vault components.

The team determined that this violation was more than minor because the failure to implement corrective actions contributed to the misalignment incident of August 3, 2018. Additionally, the failure to evaluate and disposition wear marks on a canister, if left uncorrected, could impact the adequacy of the aging management program. The Special Inspection team assessed and dispositioned this violation in accordance with Section 2.2.2 of the NRC Enforcement Policy. The team characterized the violation as a Severity Level IV violation. The NRC determined the issuance of a Notice is appropriate because the actions to restore compliance have not been fully developed and implemented, and the actions must be effective prior to beginning fuel handling activities. (VIO 07200041/2018-001-01, Failure to identify and correct conditions adverse to quality)

Apparent Violation of Technical Specification 5.2.c.3, Redundant Lifting Equipment

On August 3, 2018, the licensee performed operations involving movement of a loaded spent fuel storage canister into its ISFSI vault. As the loaded spent fuel canister was being lowered into the vault, licensee and contractor personnel failed to notice that the canister was misaligned and the weight of the canister was not being supported by the redundant important to safety slings (See Sections 2.1 and 2.2).

Title 10 CFR 72.212(b)(3) requires, in part, that each cask used by the general licensee conforms to the terms, conditions, and specifications of a Certificate of Compliance listed in 10 CFR 72.214. Title 10 CFR 72.214 includes a list of all the approved spent fuel storage casks that can be utilized under the conditions specified in a specific Certificate of Compliance, including Amendment 2 of Certificate of Compliance 072-01040. Certificate of Compliance 072-01040, Amendment 2, Condition 4, “HEAVY LOADS REQUIREMENTS,” requires that lifting operations outside of structures governed by 10 CFR Part 50 must be in accordance with Technical Specifications, Appendix A, Section 5.2.

Technical Specification, Appendix A, Section 5.2.c.3 requires that the transfer cask, when loaded with spent fuel, may be lifted and carried at any height during multi-purpose canister transfer operations provided the lifting equipment is designed with redundant drop protection features which prevent uncontrolled lowering of the load.

Contrary to the above, on August 3, 2018, the licensee failed to ensure that redundant drop protection features were available to prevent uncontrolled lowering of the load. Specifically, the licensee inadvertently disabled the redundant important to safety downloading slings while lowering canister 29 into the storage vault. During the approximately 45 minute time-frame, the canister rested on a shield ring unsupported by the redundant downloading slings at approximately 17-18 feet above the fully seated position. This failure to maintain redundant drop protection placed canister 29 in an unanalyzed condition because the postulated drop of a loaded spent fuel canister is not analyzed in the FSAR.

The licensee’s failure to ensure the system’s designed redundant drop protection features were available to prevent uncontrolled lowering of the loaded canister was identified as an apparent violation of Technical Specification 5.2.c.3.
(AV 07200041/2018-001-02, Failure to ensure redundant drop protection features are available)

Conclusions

The licensee failed to adequately implement the corrective action program for ISFSI operations. This failure resulted in missed opportunities to resolve misalignment errors during canister downloading operations between January 30 and August 3, 2018, and a violation of 10 CFR 72.172.

On August 3, 2018, the licensee failed to recognize that a misalignment of a canister during downloading operations caused redundant drop protection (slings) to be disabled and an apparent violation of Technical Specification 5.2.c.3.

3.1.2 Charter Item 1

Inspection Scope

"Identify and review all pertinent records, documents, and procedures related to the licensee's downloading operations at the ISFSI pad including but not limited to: worker training and qualifications; rigging equipment qualification, testing, and preventative maintenance; and lifting equipment qualification, testing, and preventative maintenance. Evaluate the adequacy of the above noted procedures, worker training, and equipment testing and preparation."

The Special Inspection team reviewed licensee rigging procedures and NUREG-0612 "Control of Heavy Loads at Nuclear Power Plants," training modules. The team reviewed the qualifications for the dry cask storage workers including the records for the workers involved in the August 3, 2018, misalignment incident. The team reviewed the inspection and maintenance records for special lifting devices used during dry fuel storage operations and the qualification records for rigging equipment. The team reviewed procedures used during canister downloading operations.

Observations and Findings

The equipment used for dry cask storage operations met applicable inspection requirements specified in the Holtec HI-STORM UMAX FSAR. The special lifting devices used to transport the transfer cask and to perform downloading operations were designed and tested according to American National Standards Institute (ANSI) N14.6, "American National Standard for Radioactive Materials – Special Lifting Devices for Shipping Containers Weighing 10,000 Pounds or More." The slings used during downloading had a sufficient load rating for the maximum credible load imposed by the canister. The slings were tested according to the safety requirements of American Society of Mechanical Engineers (ASME) B30.9, "Slings." The purchase specifications, qualifications, and maintenance records for the VCT, downloading slings, canister lift cleats, lift lugs, and lift links were satisfactory.

Violation of 10 CFR 72.190, Training and Certification Qualifications

The NRC team reviewed the qualifications of workers involved in the August 3, 2018, incident. Interviews with the individuals primarily responsible for verifying that the canister was properly downloaded into the ISFSI vault showed that the licensee's training program was inadequate for the positions that are designated as rigger/spotter and VCT operator. The VCT operator training program qualifications did not establish

adequate required proficiency training exercises for downloading operations. The VCT operator on August 3, 2018, had never been tested on or exercised with the canister simulator during a pre-operational testing, “dry run” downloading operation. The August 3, 2018, misalignment incident was the first time the VCT operator had actually completed downloading operations as the VCT operator.

Neither the rigger/spotter nor VCT operator was properly trained in determining a loss-of-load condition during downloading operations. The VCT operator stated that he was knowledgeable of the VCT human-machine interface (HMI) screens and that indications provided a digital reading that could allow the operator to determine if the canister was not supported by the slings. However, the VCT operator stated that he did not use the VCT HMI screen to monitor the load of the canister at any time during the August 3, 2018, downloading operations. The VCT operator indicated that he only utilized the HMI screen to determine how evenly the VCT lift beam was descending.

From his position on the VCT, the VCT operator could not see the canister downloader slings. The only indication of a loss-of-load would come from monitoring the VCT hydraulic beam pressure digital reading on the VCT HMI screen, which was not performed. Since the operator had not performed any proficiency training with the VCT during a dry run downloading operation, the individual was inexperienced with the use of the HMI screen to monitor load loss.

The licensee’s training program did not provide a formal process to be qualified for the rigger/spotter position during downloading operations. The rigger/spotter stated that he was not trained on and did not know his roles and responsibilities during the downloading evolution. The August 3, 2018, misalignment incident was the first time the rigger/spotter had attempted to perform downloading operations as the rigger/spotter in the JLG.

The NRC team’s interview with the foreman indicated that the rigger/spotter was selected primarily because of his low accumulated radiation dose. From interviews with licensee and contractor staff, an experienced RIC was usually the individual placed in the JLG and acted as the rigger/spotter for the downloading operations. On August 3, 2018, it was the RIC who eventually entered the JLG after the misalignment and directed the VCT operator to lift the canister with the VCT lift beam to regain the load on the slings. The RIC had immediately recognized that the canister was not downloaded into the ISFSI vault when he arrived and saw the condition of the downloader slings.

The failure to ensure operators are adequately qualified and proficiency tested when operating important to safety equipment and directing critical lift operations is a performance deficiency. The licensee’s training program that allowed the rigger/spotter and VCT operator to be placed into a situation where their lack of training rendered them incapable of meeting the requirements for the job represented a failure of the licensee’s training program.

Title 10 CFR 72.190 requires, in part, that the operation of equipment and controls that are identified as important to safety in the Safety Analysis Report must be limited to trained and certified personnel or be under the direct supervision of an individual with training and certification in the operation. The HI-STORM UMAX SYSTEM FSAR, Revision 4, dated August 14, 2017, specifies, in part, that the operations at the ISFSI are

governed by the HI-STORM FW SYSTEM FSAR, Revision 5, dated June 20, 2017, which specifies that the MPC lifting slings and MPC lift attachments are designated as important to safety equipment. Contrary to the above, from January 30 to August 3, 2018, the licensee failed to assure that operations of equipment and controls that had been identified as important to safety in the Safety Analysis Report were limited to trained and certified personnel or were under the direct supervision of an individual with training and certification in the operation. Specifically, the licensee's training program:

1. Failed to adequately train and certify the rigger/spotter position involved in the important to safety downloading operation.

2. Failed to have adequate proficiency testing on the controls related to the load indicating device and downloading operations for the VCT operator position.

The team determined that this violation was more than minor because the licensee's failure to establish an adequate training program contributed to the misalignment incident on August 3, 2018. The team assessed and dispositioned this violation in accordance with Section 2.2.2 of the NRC Enforcement Policy. The team characterized the violation as a Severity Level IV violation. The NRC determined the issuance of a Notice is appropriate because the actions to restore compliance have not been fully developed and implemented, and the actions must be effective prior to beginning fuel handling activities. (VIO 07200041/2018-001-03, Failure to establish adequate training program)

The team identified that the simulator canister used for training and dry run demonstrations had a specified outer diameter that was less than that of the actual spent fuel storage canisters being downloaded into the vault. The simulator canister provided approximately 0.75 inch more clearance than the actual canisters loaded with spent fuel. This difference may be acceptable for the dry run activities; however, the difference was not noted in any of the licensee's training materials for rigger/spotters or the VCT operators. This represents a situation of negative training that may have contributed to the August 3, 2018, misalignment incident.

Conclusions

The important to safety lifting equipment and special lifting devices being used for dry cask storage operations met applicable regulatory requirements.

Personnel lacked the proper training, proficiency testing, and certifications to operate important to safety equipment identified in the HI-STORM UMAX SYSTEM FSAR, Revision 4, dated August 14, 2017. This was identified as a violation of 10 CFR 72.190 requirements.

3.1.3 Charter Items 2 and 4

Inspection Scope

"Evaluate the adequacy of the loading procedure(s) with respect to verification of the movement, centering, lowering, and positioning the canister within the ISFSI vault and procedure adherence. Interviews with personnel involved in the ISFSI loading operations should be conducted to evaluate licensee and contractor communications between crane/VCT operators, rigging and spotting staff, cask loading supervisors, radiation protection staff, and licensee oversight personnel. Evaluate the adequacy of pre-job briefings that may have taken place prior to fuel loading operations."

"Based on the review of the procedures and interviews of personnel involved with loading operations, evaluate the adequacy of procedure adherence."

The Special Inspection team reviewed Holtec Procedure HPP-2464-400, "Multi-Purpose Canister Transfer Operations at SONGS," Revision 15; Holtec Procedure HPP-2464-600, "Responding to Abnormal Conditions," Revision 6; SONGS Procedure SO123-0-A7, "Notification and Reporting of Significant Events," Revision 46; and other applicable procedures related to the August 3, 2018, misalignment incident. The team reviewed the pre-job briefing in use by the CLSs. The team discussed ISFSI communications during downloading operations with the licensee and contractor staff.

Observations and Findings

Violation of 10 CFR 72.150, Procedures

The VCT is not equipped with a load-cell to provide the weight of the canister. A hydraulic pressure indication for the lift beam could be used to provide a qualitative means for determining if the slings are not supporting the canister's weight. This pressure indication is displayed on the VCT HMI control panel.

The team identified examples of a violation of 10 CFR 72.150, "Instructions, Procedures, and Drawings." Holtec Procedure HPP-2464-400 provided direction and guidance for verifying canister movement, canister centering operations, and for lowering the canister into the vault. Many steps in the procedure provided direction without quantitative or qualitative means to verify that important to safety steps had been achieved, including detection of a loss-of-load condition and final verification that the canister had been fully downloaded into the vault. For example, step 7.6.12 instructed the VCT operator to continue to raise the VCT lift beam slowly until the full weight of the canister is on the VCT.

However, there is no quantitative direct measurement for the VCT operator to determine when the "full weight" of the canister is indicated on the VCT HMI control panel. The procedure contained a note that the load on the VCT HMI screen may be used to determine if downloader slings had become slack. However the procedure did not direct the VCT operator to monitor the HMI control panel nor provide a qualitative or quantitative value that would notify the VCT operator that the canister had become misaligned and that the VCT was no longer bearing the load of the canister.

Holtec Procedure HPP-2464-400, step 7.6.23, states, if at any time the download slings become slack prior to the canister being in the full down position then immediately stop lowering the canister. During downloading operations there was only one position who could determine whether or not the slings had gone slack. That position was the rigger/spotter who is responsible to monitor the movement of the canister during downloading operations from the elevated JLG basket. The rigger/spotter was observing the slings during the August 3, 2018, downloading evolution. However, the rigger/spotter was only observing the slings for “slack” at the top of the transfer cask.

The procedure did not provide adequate direction to the rigger/spotter to observe the slings near the base of the VCT, which had become slack and were bundling up on the ground. Additionally, the procedure did not provide direction for the rigger/spotter to monitor the height of the canister in relation to the height of the lift beam.

Title 10 CFR 72.150, requires, in part, that the licensee prescribe activities affecting quality by documented instructions or procedures of a type appropriate to the circumstances and must include appropriate quantitative or qualitative acceptance criteria for determining that important activities have been satisfactorily accomplished.

Contrary to the above, from January 30 to August 3, 2018, the licensee failed to prescribe activities affecting quality by documented instructions or procedures of a type appropriate to the circumstances and include appropriate quantitative or qualitative acceptance criteria for determining that important activities have been satisfactorily accomplished. Specifically:

1. Procedure HPP-2464-400, “Multi-Purpose Canister Transfer at SONGS,” Revision 15, step 7.6.23, failed to provide qualitative and quantitative directions for the VCT operator to monitor control panel indications that would identify a canister had become misaligned during downloading operation.

2. Procedure HPP-2464-400, “Multi-Purpose Canister Transfer at SONGS,” Revision 15, step 7.6.23, failed to include adequate instructions for the rigger/spotter to monitor the downloading slings for a slack condition.

The team determined that this violation was more than minor because the licensee’s failure to prescribe adequate procedures contributed to the August 3, 2018, misalignment incident. The team assessed and dispositioned this violation in accordance with Section 2.2.2 of the NRC Enforcement Policy. The team characterized the violation as a Severity Level IV violation. The NRC determined the issuance of a Notice is appropriate because the actions to restore compliance have not been fully developed and implemented, and the actions must be effective prior to beginning fuel handling activities. (VIO 07200041/2018-001-04, Failure to provide adequate instructions of procedures)

Communications

During downloading on August 3, 2018, radiation protection staff directed the CLS and licensee oversight personnel to relocate to a low dose area off of the ISFSI pad. The low dose waiting area was located approximately 150 feet away from the ISFSI operations on the heavy haul path that is approximately 8 feet lower in elevation. From the low dose area, neither the contractor nor licensee oversight staff could observe the

downloading activities. The NRC determined that the removal of oversight staff in an effort to minimize radiation dose without other compensatory measures resulted in inadequate supervisory oversight of important to safety lifting operations.

The communication protocols used by the CLS, VCT operator, and the rigger/spotter was reviewed by the team. The CLS was in direct communications via radio and headsets with the VCT operator and rigger/spotter. The radios provided adequate communication in the noisy environment of the VCT. Communication between the CLS, VCT operator, and the rigger/spotter during the downloading operation was informal. The CLS did not request a reading of the HMI control panel to determine hydraulic pressure and repeat-backs of the location of canister during the downloading process were misunderstood.

Radiation Protection staff were not provided headsets for communications. Radiation Protection staff were able to communicate concerns directly with the CLS, who could communicate radiological concerns to workers, if necessary.

The licensee's oversight personnel were not provided headsets during downloading operations. The licensee did not provide direct oversight of downloading operations. During the August 3, 2018, misalignment incident, neither licensee oversight nor contractor supervision were in a position to directly monitor the downloading operations or the actual condition of the canister.

Conclusions

Dry cask storage procedures did not provide adequate directions for how to determine the downloader slings were slack. The downloading procedure did not include qualitative or quantitative means for determining when a canister had become misaligned. These procedure inadequacies were identified as examples of a violation of 10 CFR 72.150 requirements.

No licensee or contractor oversight personnel were in direct visual observations of the important to safety activities during downloading operations on August 3, 2018. All personnel except the rigger/spotter and VCT operator left the ISFSI pad during downloading operations. Licensee oversight was not a part of the communications between the CLS, the rigger/spotter, and VCT operator during canister downloading operations. Without adequate communications and visual observation, the licensee and the contractor were unable to verify that important to safety dry cask storage activities were adequately performed.

3.1.4 Charter Items 3 and 8

Inspection Scope

"Review and evaluate the licensee's immediate corrective actions taken after the incident for adequacy and notifications to the NRC and safety assessments performed immediately following the incident. Review the licensee's inspection documentation

and/or analysis to determine whether the vault's divider shell experienced any damage that would inhibit the component from performing its designed safety function."

"Investigate the licensee's procedures for reportability to the NRC and determine if the licensee made the correct decision regarding notifications made to the NRC for this incident."

The Special Inspection team reviewed the licensee's initial assessment of the incident through presentations and discussions provided by the licensee. The team reviewed all condition reports and entries made into the licensee's and dry cask storage vendor's corrective action programs regarding the canister misalignment incident, and the condition of the divider shell and canister 29. The team reviewed the notification requirements of 10 CFR 72.75 against the conditions experienced during the August 3, 2018, misalignment incident and reviewed licensee Procedure SO123-0-A7, "Notification and Reporting of Significant Events," Revision 46.

<u>Observations and Findings</u>

Divider Shell Assessment

The licensee immediately stopped all dry cask storage operations following the misalignment incident of August 3, 2018, pending a root cause evaluation to be performed by their dry cask storage vendor, Holtec International. The licensee initiated an apparent cause evaluation to determine if problems in its organization may have contributed to the misalignment incident.

The misalignment incident was entered into the corrective action program by Holtec as FCR 2464-1189. The Holtec FCR was initiated to investigate the August 3, 2018, incident as a human performance issue. This FCR prompted the licensee to initiate Action Request 0818-76588. This action request included an assessment of the condition of the divider shell and canister.

Action Request 0818-76588 described the removal of paint/coating from the divider shell. The action request concluded that the incidental transfer of divider shell coating to the canister shell did not affect the canister's design functions of confinement, shielding, structural, thermal, and criticality. Future actions to address coating presence will be included in the licensee's ISFSI aging management plan. The NRC team reviewed the licensee's assessment for the divider shell and concluded the component can perform its safety functions. Additionally, the licensee's plan to address future inspection of the divider shells in its aging management program was acceptable.

Apparent Violation 10 CFR 72.75, Reporting

The team identified an apparent violation of 10 CFR 72.75 for late notification of 24-hour reporting requirements involving important to safety equipment that was disabled or failed to function as designed when the equipment is required by license condition and no redundant equipment is available and operable to perform the required safety function.

On August 3, 2018, during downloading operations associated with canister 29 the licensee disabled the important to safety slings while downloading a canister (See

Section 2.1 and 2.2). The canister was placed in a potential load drop condition for approximately 45 minutes before the licensee was able to restore the load onto the important to safety slings, thereby restoring the redundant drop protection features.

After the incident, the licensee provided a courtesy notification to the NRC Region IV office at approximately 4 p.m. CDT on the afternoon of August 6, 2018.
Section 10 CFR 72.75(d)(1), would have allowed for notification to be made to the NRC Operations Center as late as 0800 EDT on Monday, August 6, 2018. The courtesy notification made to the regional office did not satisfy the reporting requirements of 10 CFR 72.75. During the August 6, 2018, call, the NRC informed the licensee that a formal report to the NRC was likely required.

Notification of the NRC Operations Center did not occur until the licensee was prompted by the NRC team on September 14, 2018. The condition was reported to the NRC Headquarters Operations Center on September 14, 2018, at 1600 EDT (Event Notification 53605).

Title 10 CFR 72.75(d)(1) requires, in part, that each licensee shall notify the NRC within 24 hours after the discovery of any of the following events involving spent fuel in which important to safety equipment is disabled or fails to function as designed when: (i) the equipment is required by regulation, license condition, or certification of compliance to be available and operable to mitigate the consequences of an accident; and (ii) no redundant equipment was available and operable to perform the required safety function.

Contrary to the above, from August 6 to September 14, 2018, the licensee failed to notify the NRC after discovery of important to safety equipment being disabled and failing to function as designed when required by the Certificate of Compliance to provide redundant drop protection features to prevent and mitigate the consequences of a drop accident and no redundant equipment was available and operable to perform the required safety function.

The licensee's failure to make the required 24-hour notification to the NRC within the required timeframe was identified as an apparent violation of 10 CFR 72.75(d).
(AV 07200041/2018-001-05, Failure to make 24-hour notification)

Conclusions

The licensee concluded that the incidental removal of divider shell coating during downloading operations did not affect the design functions for shielding, structural, and thermal safety functions. The NRC has reviewed the licensee's assessment for the divider shell and has concluded the component can perform its safety functions. Additionally, the licensee's plan to address future inspection of the divider shells in their aging management program is acceptable.

The licensee failed to make the required formal 24-hour NRC notification of the August 3, 2018, event where important to safety equipment was disabled when the equipment was required to mitigate the consequences of an accident and no redundant equipment was available to perform the safety function. This failure was identified as an apparent violation of 10 CFR 72.75(d) requirements.

3.1.5 Charter Item 6

Inspection Scope

"Review the licensee's root cause investigation results, to determine whether the review thoroughly identified all contributing factors and that final corrective actions will be adequate to prevent reoccurrence. Evaluate whether prior operational experience relating to complications or issues associated with canister downloading operations was identified and considered as part of the licensee's root cause investigation and corrective action development."

The Special Inspection team reviewed the causal evaluations that were performed for the August 3, 2018, misalignment incident. Specifically, the team reviewed Holtec International's Root Cause Analysis Report for the canister downloading incident and the licensee's Apparent Cause Evaluation to assess oversight effectiveness during the August 3, 2018, download of canister 29.

Observations and Findings:

Holtec International's Root Cause Evaluation

The licensee directed Holtec to perform a causal evaluation as a follow-up item in condition report action request 0818-76588 that the licensee initiated following the August 3, 2018, misalignment incident. The Holtec causal evaluation identified one root cause and five contributing causes:

- Root Cause: Holtec Management failed to implement appropriate program improvements or the necessary level of oversight commensurate with the complexity and risks associated with downloading operations.
- Contributing Cause 1: Inadequate content in procedures for recognizing special conditions.
- Contributing Cause 2: Design review process did not ensure that unintended consequences of design features were captured.
- Contributing Cause 3: Communication protocols with the chain of command established during canister movement were not well defined.
- Contributing Cause 4: Holtec had not established a continuous learning environment which promoted the use of internal and external operating experience.
- Contributing Cause 5: Holtec Training Program did not fully establish qualification or proficiency requirements for workers performing downloading operations.

Southern California Edison Company's Apparent Cause Evaluation

The licensee initiated an apparent cause evaluation (ACE) to determine how its organization may have contributed to allowing the August 3, 2018, loss-of-load incident to occur. The licensee's apparent causes were related to deficiencies in procedures, training, and in oversight of contractor activities.

- Apparent Cause 1: Management failed to establish a process to ensure that site dry cask storage procedures were technically accurate.
- Apparent Cause 2: Management failed to establish licensee and contractor training to support procedure implementation.
- Apparent Cause 3: Management failed to sufficiently detail contractor Oversight Specialist guidance.
- Contributing Cause 1: ISFSI project management was not routinely observing dry cask storage operations.
- Contributing Cause 2: ISFSI project management was not consistently initiating condition reports for dry cask storage operations that deviated from normal.

Both the licensee and Holtec causal evaluations reviewed many of the items identified by the NRC team. Those items being: procedure adequacy; training adequacy; adequacy of the corrective action program; oversight adequacy; and the inconsistent use of operational experience during routine dry cask storage operations.

The causal evaluations assessed the severity of the canister misalignment incident. The licensee determined that in the event of a canister drop accident from 25 feet into the vault, there was no risk of radioactive exposure to the public. A publicly available version of the licensee's drop analysis summary is available in ADAMS (ADAMS Accession No. ML18330A003). The NRC will continue to review the adequacy of the causal analyses, corrective actions, and potential consequences during a follow-up inspection which is planned to be performed before the resumption of fuel handling activities.

Conclusions

The apparent and root causes for the August 3, 2018, canister misalignment incident involved inadequate training, inadequate procedures, poor utilization of the corrective action program, and insufficient oversight.

3.1.6 Charter Item 7

Inspection Scope

"Review the licensee's planned actions that will address the point loading condition that was experienced by the affected canister. If applicable, review the licensee's analysis that demonstrated the canister will continue to perform as designed for continued storage OR review licensee's inspection plan to safely remove or lift the canister from

the vault to support inspection of the bottom of the canister to demonstrate the canister did not receive any damage that would inhibit the component from continuing to perform as designed."

Observations and Findings

The licensee performed an evaluation to demonstrate the canister continues to meet the design and performance requirements described in the FSAR. The Special Inspection team reviewed the licensee's initial assessment of the canister 29 condition after the misalignment incident.

The preliminary evaluation provided by the licensee stated that both the canister and vault were not expected to have any physical damage that would exceed the pre-defined limits used during receipt inspection and manufacturer acceptance testing. The NRC requested additional analysis to ensure that the canister meets design requirements. Additionally, the licensee is evaluating whether the canister will require increased surveillance frequency for the aging management program. The licensee had not completed the evaluation for NRC review prior to the NRC's inspection exit meeting. This charter item will be reviewed during a future NRC inspection.

Conclusions

The licensee has chosen to provide an analysis to demonstrate that the potential damage to canister 29 during the downloading would meet established acceptance criteria. The NRC determined that additional analysis was required for the NRC to ensure that the canister meets design requirements. This charter item will be reviewed during a future NRC inspection.

3.1.7 Charter Item 9

Inspection Scope

"As directed by regional management, observe resumption of fuel loading operations to verify that corrective actions were effective in addressing deficiencies that contributed to the incident. This should include evaluation of procedure and/or equipment enhancements; review or observation of training and briefings provided to riggers, crane operators, spotters and observers, supervisors and other personnel involved in fuel loading operations."

Observations and Findings

The licensee suspended all fuel handling activities following the August 3, 2018, misalignment incident. The NRC will review the licensee's revised procedures, training plans, equipment modifications, and performance testing (dry runs) of its dry cask storage operations in a future inspection to determine the effectiveness of corrective actions for the incident.

Conclusions

All associated corrective actions for the August 3, 2018, incident had not been completely finalized or implemented by the licensee. The NRC will review the licensee's

revised procedures, training plans, equipment modifications, and performance testing (dry runs) of its dry cask storage operations during a future inspection to determine the effectiveness of corrective actions for the incident.

3.1.8 Charter Item 10

Inspection Scope:

"Determine if the inspection should be elevated to an Augmented Inspection Team (AIT) inspection and promptly notify regional management of any recommendation to escalate the special inspection to an AIT."

As a daily action item, the NRC Special Inspection Team reviewed NRC Inspection Manual Chapter 0309, "Reactive Inspection Decision Basis for Reactors," Enclosure 2, to determine whether any of the facts or details uncovered during the course of the inspection met the deterministic criteria that would require the Special Inspection at SONGS to be elevated to an AIT.

Observations and Findings

The deterministic criteria for an event to be elevated to an AIT effort are delineated in Manual Chapter 0309. The Special Inspection Team did not identify any indication that the August 3, 2018, misalignment incident at SONGS led to a radiological release. Additionally, the incident did not involve the failure of the spent fuel canister, the release of radiological contamination, or external radiation levels that exceeded 10 rads/hr. Consequently, there was no need to elevate the inspection effort to an AIT. The team's daily re-evaluation was communicated to Regional management during the week of onsite inspection effort.

Conclusions

The NRC team did not identify any information that would have required the Special Inspection to be elevated to an AIT effort.

4 Exit Meeting Summary

On September 14, 2018, following the onsite portion of the inspection, the inspectors provided a debrief of the preliminary results to Mr. Tom Palmisano, former Vice President and Chief Nuclear Officer and other members of the licensee staff. The licensee acknowledged the issues presented by the NRC inspection team.

On November 1, 2018, the inspectors presented the final inspection results to Mr. Tom Palmisano, former Vice President and Chief Nuclear Officer and other members of the licensee staff. The licensee acknowledged the issues presented.

On November 8, 2018, the NRC performed a public webinar meeting to discuss the inspection team's preliminary results.

Division of Nuclear Materials Safety

SUBJECT: INSPECTION CHARTER TO EVALUATE THE NEAR-MISS LOAD DROP EVENT AT SAN ONOFRE NUCLEAR GENERATING STATION

A special inspection has been chartered to review the licensee's follow-up investigation, causal evaluation, and planned corrective actions regarding the near-miss drop event involving a loaded spent fuel storage canister at the San Onofre Nuclear Generating Station (SONGS) Independent Spent Fuel Storage Installation (ISFSI) on Friday, August 3, 2018. (License Nos. NPF-10 and NPF-15, Docket Nos. 50-361, 50-362 and 72-41).

CONTACT: Janine F. Katanic, PhD, CHP, FCDB/DNMS
(817) 200-1151

BACKGROUND AND BASIS

On Friday, August 3, 2018, at approximately 1:30 pm (PST), SONGS was engaged in operations involving movement of a loaded spent fuel storage canister into its underground ISFSI storage vault (HI-STORM UMAX storage system). As the loaded spent fuel canister was being lowered into the storage vault using lifting and rigging equipment, the licensee's personnel failed to notice that the canister was misaligned and was not being properly lowered. The licensee continued to lower the rigging and lifting equipment until it believed that the canister had been fully lowered to the bottom of the storage vault. However, a radiation protection technician identified elevated radiation readings that were not consistent with a fully lowered canister. The licensee then identified that the loaded spent fuel canister was hung up on a metal flange near the top of the storage vault, preventing it from being lowered, and that the rigging and lifting equipment was slack and no longer bearing the load of the canister.

In this circumstance, with the important to safety (ITS) rigging and lifting equipment completely down in the lowest position, the ITS equipment was disabled from performing its designed safety function of holding and controlling the loaded canister from a potential canister drop condition. The licensee reported that the canister was resting on a metal flange within the storage vault. It was estimated that the canister could have experienced an approximately 17-18 foot drop into the storage vault if the canister had slipped off the metal flange or if the metal flange failed. This load drop accident is not a condition analyzed in the dry fuel storage system's Final Safety Analysis Report (FSAR).

In response to the discovery that the canister was not fully lowered, the licensee took immediate actions to restore control of the load to the rigging and lifting devices. The estimated time the canister was in an unanalyzed credible drop condition was approximately 45 minutes to 1 hour in duration. The licensee regained control of the load, repositioned the canister, and lowered the canister into the storage vault. The licensee halted all dry fuel storage movement operations in order to fully investigate the incident and develop corrective actions to prevent a recurrence. In addition, the licensee has shared the operational experience with another site with a similar dry fuel storage system.

Region IV became aware of the SONGS "near-miss" incident on Monday, August 6, 2018, when the licensee provided a courtesy notification and described it as a "near-miss" or "near-hit" event. The reporting requirements of the incident are still being evaluated by the Region and discussed with the licensee.

On August 7 and 16, 2018, Region IV and NMSS representatives participated in conference calls with licensee representatives in order to gather additional facts regarding the circumstances of the incident and the licensee's investigation. Region IV is evaluating the information provided by the licensee and is coordinating with the Division of Spent Fuel Management, NMSS.

The NRC is chartering this special inspection pursuant to Management Directive 8.3, "NRC Incident Investigation Program," and NRC Inspection Manual Chapter 0309, "Reactive Inspection Decision Basis for Reactors."

The purpose of the inspection is to investigate the occurrence; interview personnel; observe equipment; and review relevant documentation, including the results of the licensee's investigation and causal analysis, and development and implementation of actions to prevent

recurrence. The licensee has committed to not resume fuel loading operations until after this special inspection and associated reviews are complete. Once the licensee has confirmed its plans to resume fuel loading operations, inspectors will also observe the loading operations to ensure that the corrective actions are adequate. These observations may be conducted as part of this special inspection or as an independent inspection activity, as directed by regional management.

SCOPE

The inspection should seek to address the following items at a minimum:

1. Identify and review all pertinent records, documents, and procedures related to the licensee's downloading operations at the ISFSI pad including but not limited to: worker training and qualifications; rigging equipment qualification, testing, and preventative maintenance; and lifting equipment qualification, testing, and preventative maintenance. Evaluate the adequacy of the above noted procedures, worker training and equipment testing and preparation.

2. Evaluate the adequacy of the loading procedure(s) with respect to verification of MPC movement, centering the MPC over the ISFSI vault, lowering the MPC, and positioning the MPC within the ISFSI vault. Interviews with personnel involved in the ISFSI loading operations should be conducted to evaluate licensee and contractor communications between crane/VCT operators, rigging and spotting staff, cask loading supervisors, radiation protection staff, and licensee oversight personnel. Evaluate the adequacy of pre-job briefings that may have taken place prior to fuel loading operations.

3. Review and evaluate the licensee's immediate corrective actions taken after the event for adequacy of notifications to the licensee and safety assessments performed immediately following the event. Review the licensee's inspection documentation and/or analysis to determine whether the vault's divider shell experienced any damage that would inhibit the component from performing its designed safety function.

4. Based on the review of procedures and interviews of personnel involved with loading operations, evaluate the adequacy of procedure adherence.

5. Interview personnel associated with the event to develop a timeline to ensure the licensee's investigation contained all necessary information to identify all contributing factors and develop adequate corrective actions.

6. Review the licensee's root cause investigation results, to determine whether the review thoroughly identified all contributing factors and that final corrective actions will be adequate to prevent reoccurrence. Evaluate whether prior operational experience relating to complications or issues associated with canister downloading operations was identified and considered as part of the licensee's root cause investigation and corrective action development.

7. Review the licensee's planned actions that will address the point loading condition that was experienced by the affected canister. If applicable, review the licensee's analysis that demonstrated the canister will continue to perform as designed for continued storage OR review licensee's inspection plan to safely remove or lift the canister from the vault to support inspection of the bottom of the canister to demonstrate the canister did not

receive any damage that would inhibit the component from continuing to perform as designed.

8. Investigate the licensee's procedures for reportability to the NRC and determine if the licensee made the correct decision regarding notifications made to the NRC for this event.

9. As directed by regional management, observe resumption of fuel loading operations to verify that corrective actions were effective in addressing deficiencies that contributed to the event. This should include evaluation of procedure and/or equipment enhancements; review or observation of training and briefings provided to riggers, crane operators, spotters and observers, supervisors and other personnel involved in fuel loading operations.

10. Determine if the inspection should be elevated to an AIT and promptly notify regional management of any recommendation to escalate the special inspection to an AIT.

GUIDANCE

The NRC is chartering this special inspection pursuant to Management Directive 8.3, "NRC Incident Investigation Program," and NRC Manual Chapter 0309, "Reactive Inspection Decision Basis for Reactors." The Manual Chapter and Management Directive identify Inspection Procedure 93812, "Special Inspection," for specific use in reviewing events. Planned Dates of Inspection are September 10-14, 2018.

This inspection should emphasize fact-finding in its review of the circumstances surrounding the near-miss canister drop event. Safety concerns identified that are not directly related to near-miss drop event should be reported to NRC management for appropriate action.

Daily briefings with NRC management should occur to discuss the team's progress and preliminary observations.

In accordance with Manual Chapter 0610, a report documenting the results of the inspection should be issued within 30-45 days of the completion of the inspection.

This Charter may be modified should NRC inspectors find significant new information that warrants review. Should you have any questions concerning this charter, please contact Janine F. Katanic at 817-200-1151.

UNITED STATES
NUCLEAR REGULATORY COMMISSION
REGION IV
1600 EAST LAMAR BOULEVARD
ARLINGTON, TEXAS 76011-4511

November 22, 2019

Mr. Doug Bauder
Vice President and Chief Nuclear Officer
Southern California Edison Company
San Onofre Nuclear Generating Station
P.O. Box 128
San Clemente, CA 92674-0128

SUBJECT: SAN ONOFRE NUCLEAR GENERATING STATION INDEPENDENT SPENT FUEL STORAGE INSTALLATION (ISFSI) INSPECTION REPORT 050-00206/2019-003, 050-00361/2019-005, 050-00362/2019-005, 072-00041/2019-001

Dear Mr. Bauder:

This letter refers to the U.S. Nuclear Regulatory Commission's (NRC's) unannounced inspections conducted from July 2019 through September 2019, of the dry cask storage activities associated with your Independent Spent Fuel Storage Installation (ISFSI). The NRC inspectors discussed the results of this inspection with you and other members of your staff during a final telephonic exit meeting conducted on October 21, 2019. The inspection results are documented in the enclosure to this letter.

The inspections examined activities conducted under your license as they relate to safety and compliance with the Commission's rules and regulations and with the conditions of your license. Within these areas, the inspection consisted of selected examination of procedures and representative records, observations of site meetings, performance of independent radiation measurements, and interviews with personnel. Specifically, the inspections reviewed compliance with the requirements specified in the Holtec International HI-STORM UMAX Certificate of Compliance No. 1040 and the associated Technical Specifications, the HI-STORM UMAX Final Safety Analysis Report (FSAR), and Title 10 of the *Code of Federal Regulations* (CFR) Part 72, Part 50, and Part 20.

During the on-site inspections, the NRC observed and confirmed that site personnel completed all required corrective actions identified through causal evaluations for the August 3, 2018, canister misalignment incident to return to fuel loading and transfer operations. Specifically, the NRC inspectors conducted unannounced on-site inspections to evaluate the classroom training, pre-operational training exercises, and a significant number of fuel loading, processing, and dry cask storage transfer evolutions. The NRC inspectors concluded the corrective actions were effectively implemented to ensure the safe transfer of spent fuel to the site's ISFSI.

Based on the results of these inspections, the NRC documented one violation of NRC requirements. The violation was determined to be a Severity Level IV violation of low safety significance under the NRC's traditional enforcement process. The NRC is treating this violation as a non-cited violation (NCV) consistent with Section 2.3.2.a of the NRC Enforcement Policy. If you contest the violation or significance of the NCV, you should provide a response within 30 days of the date of this inspection report, with the basis for your denial, to the U.S. Nuclear

Regulatory Commission, ATTN: Document Control Desk, Washington, DC 20555-0001, with copies to: (1) the Regional Administrator, Region IV, and (2) the Director, Office of Enforcement, U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001.

In accordance with 10 CFR 2.390 of the NRC's "Agency Rules of Practice and Procedure," a copy of this letter, its enclosure, and your response if you choose to provide one, will be made available electronically for public inspection in the NRC Public Document Room or from the NRC's Agencywide Documents Access and Management System (ADAMS). ADAMS is accessible from the NRC's Website at http://www.nrc.gov/reading-rm/adams.html. To the extent possible, your response should not include any personal privacy or proprietary information so that it can be made available to the Public without redaction.

If you have any questions regarding this inspection report, please contact Lee Brookhart at 817-200-1549, or the undersigned at 817-200-1249.

Sincerely,

/RA/

Greg Warnick, Chief
Reactor Inspection Branch
Division of Nuclear Materials Safety

EXECUTIVE SUMMARY

NRC Supplemental Inspection Report 050-00206/2019003; 050-00361/2019005; 050-00362/2019005; and 072-00041/2019001

On July 1-3, 8, 10-11, 15-18, and 22-28; August 12-14, 19-23, and 28; and September 24, 2019, the U.S. Nuclear Regulatory Commission (NRC) performed a series of unannounced on-site inspections of dry fuel storage activities of the Independent Spent Fuel Storage Installation (ISFSI) at the decommissioning San Onofre Nuclear Generating Station (SONGS) in San Clemente, California. The on-site inspections were augmented through in-office review of the licensee's condition reports, records, procedures, and other materials gathered and provided prior to and after the on-site portion of the inspections through October 21, 2019. The scope of the inspection was to evaluate and review the licensee's actions related to the resumption of fuel transfer operations from the Unit 2 and Unit 3 spent fuel pools to dry storage following an extended stoppage in loading due to the August 3, 2018, canister misalignment incident. For additional discussions and evaluations of the August 3, 2018, incident, see the NRC Special Inspection Report 050-00206/2018-005, 050-00361/2018-005, 050-00362/2018-005, and 072-00041/2018-001 and Notice of Violation and NRC Supplemental Inspection Report 050-00206/2018-006, 050-00361/2018-006, 050-00362/2018-006, and 072-00041/2018-002 (NRC's Agencywide Documents Access and Management System (ADAMS) Accession Nos. ML18341A172 and ML19190A217, respectively).

During the on-site inspections, the NRC observed and confirmed that the licensee completed all required corrective actions from the licensee's causal evaluations to return to fuel loading operations. Dry cask storage operations were performed in an atmosphere that was free from schedule pressures with an emphasis on procedure adherence. The NRC inspectors verified that the corrective actions implemented were effective to ensure the safe transfer of spent fuel to the site's ISFSI.

<u>Operation of an Independent Spent Fuel Storage Installation, IP 60855</u>

- Several on-site evaluations of the licensee's classroom training lessons and pre-operational dry run training exercises were completed by the inspectors during the inspection period. The inspectors confirmed the corrective actions from the licensee's causal evaluations were adequately implemented regarding licensee oversight, enhanced procedures, and use of new equipment and personnel. The completion of training and dry run exercises of personnel and the demonstration of the newly implemented oversight structure confirmed the licensee was effective in implementing all corrective actions to ensure the safe resumption of fuel loading operations. (Section 1.1)

- The inspectors completed numerous unannounced on-site inspections of the licensee's return to fuel loading operations. The inspections included near 24-hour coverage to evaluate and observe the critical tasks associated with the licensee's spent fuel loading, processing, and downloading operations. The inspectors confirmed the workers were qualified and trained under the licensee's new training program. The procedures utilized in the transfer operations contained the new quantitative and qualitative steps to ensure important tasks were adequately accomplished. During downloading evolutions, the licensee's operations contained the required new personnel, new equipment, and additional oversight to safely place a canister into the UMAX ISFSI. The inspectors determined the licensee was adequately implementing all required corrective actions from the causal

evaluations and the status of the canisters during downloading was constantly monitored and properly handled to avoid any possible misalignment issues. (Section 1.2)

- The inspectors determined that the licensee was placing all relevant identified issues into the Southern California Edison Corrective Action Program (CAP). A large detailed list of issues placed into the site's CAP was reviewed by inspectors and it was determined that the site had established a low threshold of identifying concerns/issues and placing them into the CAP for proper review and resolution. A few of the issues placed into the licensee's CAP, during the inspection period, are further discussed in this report. From all the condition reports reviewed, the inspectors determined the licensee was taking adequate corrective actions to resolve the issues and were appropriately performing reviews for extent of cause and extent of condition when required. (Section 1.3)

Follow-up of Events and Notices of Enforcement Discretion, IP 71153

- The inspectors documented one Severity Level IV, non-cited violation (NCV) related to Licensee Event Report (LER) 2018-002-0 (ADAMS Accession No. ML19050A170), which was previously reviewed and discussed in NRC Supplemental Inspection Report 072-00041/2018-002. Specifically, the violation related to the licensee's failure to conduct past low-profile transporter operations, from January 2018 through August 2018, in accordance with the station's site-specific seismic analysis. The NRC determined that the finding was of low safety significance since the licensee had performed an additional analysis for a revision to the LER 2018-002-1 (ADAMS Accession No. ML19221B590), which bounded any potential contact that could have occurred during a postulated seismic event. The inspectors concluded that the potential impact from adjacent structures (such as light posts) to the conveyance and the loaded transfer cask during a postulated seismic event would not have exceeded any design basis requirements. The licensee had restored compliance prior to resumption of fuel loading activities by revising the transportation procedure to ensure requirements from the site-specific seismic analysis were clearly followed and painted lines along the ISFSI haul path to provide visual boundaries during spent fuel transport operations. The original and revised LERs are closed. (Section 2.2)

Review of 10 CFR 72.48 Evaluations, IP 60857

- Safety screenings had been performed in accordance with the licensee's procedures and 10 CFR 72.48 requirements. All screenings and evaluations reviewed were determined to have been adequately evaluated. (Section 3.3)

REPORT DETAILS

Summary of Plant Activities

The San Onofre Nuclear Generating Station (SONGS) Independent Spent Fuel Storage Installation (ISFSI) consists of two ISFSI designs located adjacent to each other: the Orano Transnuclear (TN) Nuclear Horizontal Modular Storage (NUHOMS) system and the Holtec International Storage Module Underground Maximum Capacity (HI-STORM UMAX) system.

The TN ISFSI contains a total of 63 advanced horizontal storage modules (AHSMs) on the NUHOMS ISFSI pad. Fifty-one of the AHSMs are loaded with the stainless steel dry shielded canisters (DSCs). Spent fuel from all three reactors are stored in 50 of the AHSMs. Greater-than-Class-C (GTCC) waste from the Unit 1 reactor decommissioning project was stored in the 51st module. The twelve empty AHSMs will be available for storage of additional GTCC waste from the decommissioning Units 2 and 3 reactors. The 24PT1-DSCs (Unit 1 fuel) are loaded and maintained under Amendment 0 of Certificate of Compliance (CoC) No. 72-1029 and the 24PT4-DSCs (Units 2 and 3 fuel) are loaded and maintained under Amendment 1 of CoC No. 72-1029. Both CoC amendments were being maintained under NUHOMS Final Safety Analysis Report (FSAR), Revision 5.

The HI-STORM UMAX ISFSI portion was designed to hold 75 Holtec multi-purpose canisters (MPCs). The Holtec MPC-37 canister design can hold 37 pressurized water reactor fuel assemblies in accordance with UMAX CoC No. 72-1040, Amendment 2; HI-STORM UMAX FSAR, Revision 4; and the HI-STORM Flood and Wind (FW) FSAR, Revision 5. The licensee had 35 canisters stored at the UMAX ISFSI at the end of inspection period. Dry cask storage operations had resumed in July 2019, after an 11-month safety stand-down in operations following an August 3, 2018, canister misalignment incident at the UMAX ISFSI.

1 Operation of an Independent Spent Fuel Storage Installation (IP 60855)

1.1 Dry Run and Training Evolutions

a. Inspection Scope

The NRC performed numerous unannounced on-site inspections to evaluate, observe, and assess the licensee's corrective actions following the 11-month stop in fuel movement due to the August 3, 2018, canister misalignment incident.

On July 1-3, 8, and 10-11, 2019, the inspectors observed the licensee successfully complete specific pre-operational dry runs and training of crew personnel on the procedures that were revised based on corrective actions from the licensee's causal evaluations. These dry run demonstrations and training qualifications for crew personnel were targeted on specific evolutions from the revised Procedures HPP-2464-400, "MPC Transfer at SONGS," Revision 22 and HPP-2464-500, "MPC Unloading at SONGS," Revision 8.

The dry run operations observed by the NRC included MPC simulator travel inside the transfer cask on the low-profile transporter from the fuel building along the delineated haul path to the UMAX ISFSI pad, transfer of the transfer cask from the low-profile transporter to the vertical cask transporter (VCT), travel of the VCT up and onto the

ISFSI pad, alignment and securing of the transfer cask to the mating device, and downloading/uploading of the MPC simulator into and out of the UMAX ISFSI vault.

In addition, inspectors periodically observed classroom training while on-site and verified worker qualifications for crews performing dry run training and for workers that had previously completed the exercises.

b. Observations and Findings

The inspectors observed six classroom training lessons under the newly implemented training program. The classroom training was established to qualify the workers to perform fuel transfer operations. The classroom training contained detailed discussions and presentations to ensure all qualified workers understood and were knowledgeable of the changes made in the licensee's transport procedures. The training reviewed the licensee's new oversight structure in place, the new equipment that was required to be used, and the new personnel additions, including their roles and responsibilities. The classroom attendees were attentive, and the classroom environment was interactive with the students actively participating throughout the lessons.

During the observed dry run evolutions, the inspectors were able to observe implementation for several layers of corrective actions as described in the licensee's causal evaluations. Licensee oversight personnel were present at all times during MPC simulator transfer operations as required by the revised oversight task guides. Additional crew personnel and newly implemented canister monitoring equipment (camera, video monitors, and load monitoring devices) were successfully utilized during the training evolutions. The crew followed the new procedures to complete the dry runs. The downloading procedure was revised to include new quantitative and qualitative steps that ensured important tasks were adequately accomplished.

All licensee identified observations, concerns, and issues gathered during the dry run training exercises were captured and placed into the licensee's corrective action program (CAP). The collection of action reports (ARs) were reviewed by the inspectors and were confirmed to be adequately resolved. Resolution of items included additional procedural revisions to enhance the process and additional training on subjects for the crew. The inspectors confirmed the licensee's attention to placing issues into the site's CAP was appropriate and the licensee had established a low-threshold to properly identify, address, and correct issues of concern which could lead to conditions adverse to quality.

c. Conclusions

Several on-site evaluations of the licensee's classroom training lessons and pre-operational dry run training exercises were completed by the inspectors during the inspection period. The inspectors confirmed the corrective actions from the licensee's causal evaluations were adequately implemented regarding licensee oversight, enhanced procedures, use of new equipment and personnel, and placing issues into the licensee's CAP. The completion of training and dry run exercises of personnel and the demonstration of the newly implemented oversight structure confirmed the licensee was effective in implementing all corrective actions to ensure the safe resumption of fuel loading operations.

1.2 Spent Fuel Loading Operations

a. Inspection Scope

This ISFSI inspection included near 24-hour coverage of the loading operations for the critical tasks associated with the licensee's first few canister loading and transfer operations. Inspectors from NRC Region IV office and NRC's Headquarters' Division of Fuel Management observed operations to evaluate and confirm the licensee's corrective actions were being implemented and were effective to ensure safe processing and transport of spent fuel to the site's ISFSI. The inspectors reviewed selected procedures and records to verify ISFSI operations were compliant with Holtec CoC No. 72-1040 license Technical Specifications and the Holtec UMAX FSAR.

On July 15-18, 2019, inspectors observed the transport and downloading of MPC #30 into the SONGS UMAX ISFSI. This canister had been seismically restrained and stored in the Unit 3 fuel building since the August 3, 2018, canister misalignment incident. The NRC inspectors observed operations which included transport of the loaded transfer cask to the UMAX ISFSI and downloading of the canister into the UMAX ISFSI vault.

On July 22-28, 2019, inspectors observed the loading of MPC #31 in the SONGS Unit 2 fuel building. This was the first complete fuel loading operation conducted at SONGS since the August 3, 2018, canister misalignment event. The inspectors observed and evaluated critical evolutions which included 24-hour coverage on fuel movements and fuel verification, heavy lifts associated with the fuel building crane, welding and nondestructive testing of the canister lid-to-shell closure operations, hydrostatic pressure testing, forced helium dehydration, helium backfill, vent/drain port cover welding and nondestructive testing, helium leak testing, radiological surveys, transport of the loaded transfer cask, and downloading of the canister into the UMAX ISFSI vault.

On August 12-14, 19-23, and 28, 2019, inspectors followed-up on the status of site activities and observed the loading of MPC #32. The inspectors provided near 24-hour coverage of the loading operations which included fuel preparation activities, spent fuel movements, heavy lifts associated with the fuel building crane, welding and nondestructive testing of the canister lid-to-shell weld, hydrostatic pressure testing, forced helium dehydration, helium backfill, vent/drain port cover welding and nondestructive testing, helium leak testing, radiological surveys, transport of the loaded transfer cask, and downloading of the canister into the UMAX ISFSI vault.

On September 24, 2019, inspectors reviewed the status of condition reports that had been initiated for recent dry cask storage operations, observed activities related to the processing of MPC #35, and observed the preparations for transport of MPC #34 which was scheduled to be downloaded during the week.

b. Observations and Findings

Throughout the numerous unannounced on-site inspections, the inspectors confirmed that corrective actions associated with the causal evaluations from the August 3, 2018, canister misalignment incident were adequately implemented and effective during the site's return to fuel transfer operations. The inspectors reviewed selected training records to verify work personnel had completed the new training requirements prior to participating in the operations. Through interviews with the crew and loading operation

supervisors, the inspectors confirmed individuals were knowledgeable and competent in their designated roles and responsibilities. The inspectors verified that pre-job briefs and on-the-job-site drills were conducted and contained pertinent information to ensure the crews were prepared to perform and accomplish the critical tasks of each operation.

The inspectors confirmed that revised loading procedures contained the enhanced procedure requirements identified and corrected during the causal evaluation period. These procedure enhancements provided quantitative and qualitative steps to ensure important tasks were adequately accomplished. Additionally, the licensee had performed numerous procedure revisions to capture additional lessons learned from the dry run exercises to enhance the loading operations. The inspectors observed that the dry cask storage operations were performed in an atmosphere that was free from schedule pressures with an emphasis on procedure adherence. During all observed downloading operations, the site adequately implemented all previously identified corrective actions to ensure a misalignment during downloading was avoided or properly resolved.

The inspectors observed and evaluated that the licensee was implementing the new oversight strategies as described in the site's oversight program. The inspectors observed that the licensee implemented multiple layers of oversight participation and provided direct surveillances on all critical activities. The oversight program consisted of three layers of contractor surveillance. The initial layer of licensee oversight was comprised of a contractor technical representative (CTR) which worked alongside each of the vendor's Cask Loading Supervisors (CLS) to perform the work activities. The CTR served in a role of assisting the contractors to meet common goals, facilitate a look ahead perspective, assist with implementation of procedure and safety enhancements, provide coaching, steer evolutions to correct discovered gaps, help resolve issues, and identify areas of improvement.

The second layer of oversight consisted of an oversight specialist (OS). Each shift contained multiple OSs to provide surveillances and assessments on critical activities which were defined in the SCE Procedure G-XV93-PTP, "Pool to Pad Desktop Guide." The OS responsibility includes, evaluating vendor performance for adherence to procedures, capturing issues to place into the corrective action program, providing a holistic approach to ensure conditions different than normal would be recognized, documenting concerns and lessons learned, ensuring the resolution of issues placed in the licensee's CAP, and conducting paired observations and peer observations of other oversight personnel.

The third layer of oversight included personnel from SCE's nuclear quality oversight office which performed independent oversight surveillances and assessments on the vendor's, the CTRs', and the OSs' activities. The inspectors confirmed that each layer of oversight was participating, surveilling, and assessing, as required in the operations that the NRC observed. The inspectors observed that the licensee had established an oversight program that was highly effective in ensuring all activities followed the required procedures, addressed issues of concern and placed issues adverse to quality into the CAP, identified weaknesses and trends that could be improved, and thoroughly took responsibility to ensure operations were performed in a safe and controlled manner.

During the downloading operations, the inspectors confirmed that the operations included the additional trained personnel which were strategically placed in key locations

on man-lifts and on and around the VCT to ensure monitoring of the canister was accomplished as it was lowered into the UMAX vault. The downloading crews utilized the new load monitoring equipment (camera, video monitor, load sensing shackles, wireless headsets, and wireless weight monitoring) to ensure the weight of canister, the position of the canister, and the status of lowering was always known and properly communicated to the crew, supervisors, and oversight. The process to move the spent fuel canister into the UMAX ISFSI was performed in a safe manner over several hours while using the licensee's enhanced procedures and careful observations by the required licensee oversight individuals.

c. Conclusions

The inspectors completed numerous unannounced on-site inspections of the licensee's return to fuel loading operations. The inspections included near 24-hour coverage to evaluate and observe the critical tasks associated with the licensee's spent fuel loading, processing, and downloading operations. The inspectors confirmed the workers were qualified and trained under the licensee's new training program. The procedures utilized in the transfer operations contained the new quantitative and qualitative steps to ensure important tasks were adequately accomplished. During downloading evolutions, the licensee's operations contained the required new personnel, new equipment, and additional oversight to safely place a canister into the UMAX ISFSI. The inspectors determined the licensee was adequately implementing all required corrective actions from the causal evaluations and the status of the canister during downloading was constantly monitored and properly handled to avoid any possible misalignment issue.

1.3 Corrective Actions

a. Inspection Scope

The inspectors reviewed licensee and vendor corrective action reports that had been initiated since the NRC supplemental inspection that concluded in June of 2019. The inspectors reviewed the reports to ensure the issues were being properly addressed, resolved, and the extent of condition or the extent of cause were determined. Additionally, inspectors reviewed the reports to determine if the licensee had addressed causal evaluation corrective actions which included lowering the threshold to place issues into the CAP and that all ISFSI vendor issues on-site would be captured in the SCE CAP.

b. Observations and Findings

The licensee implemented corrective actions to ensure all ISFSI issues with the possibility of being averse to quality were placed into SCE's CAP. The inspectors reviewed a large list of ARs that had been initiated since the last NRC inspection. The detailed list of issues placed into the site's CAP demonstrated the site had established a low threshold of identifying concerns/issues and placing them into the CAP for proper review and resolution. During classroom training lessons, the inspectors verified the new training material included presentations to the crew, supervisors, and oversight to contain a heightened attention for identifying problems and placing them into the SCE CAP.

The inspectors selected ARs for additional review and observed that the conditions described in the ARs were properly addressed, the resolutions were identified to contain the proper corrective actions, and the resolutions addressed extent of condition and extent of cause, when required. Noteworthy condition reports selected by the inspectors for additional follow-up are described below.

Mating Device Closure

One condition report, AR 0719-60949, documented a procedural violation that occurred after the downloading of MPC #30 had been completed on July 18, 2019. During the evolution to remove the Transfer Cask from the stack up configuration, an individual from the cask loading crew inadvertently allowed a portion of their body to cross under the cone of influence of the suspended heavy load (empty transfer cask). The Cask Loading Supervisor (CLS) immediately suspended operations to make the required notifications, initiate condition reports, and discuss the worker's actions with licensee oversight and the crew. During a stand-down meeting to discuss the industrial safety issue with the crew, licensee senior oversight personnel and vendor senior supervisors questioned the CLS if the mating device drawer was in a fully open or partially open position.

Licensee Procedure HPP-2464-400 contained a conservative limit on the time frame that the mating device drawer could be closed. Steps 7.7.8 - 7.7.12 required that the "Mating Device must be removed, or the drawer [fully] opened to establish air cooling [for the MPC] within 4 hours," following downloading and after removing the transfer cask from the stack-up configuration. The CLS was aware of the 4-hour time limitation but had directed the crew to close the drawer approximately half way during the break period for foreign material intrusion concerns. Once it was identified that the drawer was only partially opened, and did not meet the procedure requirement to be fully open, the licensee took immediate corrective actions to fully open the drawer to comply with the procedure.

The licensee estimated that the drawer had been either closed or partially opened for a timeframe of 4 hours and 38 minutes which exceeded the 4-hour time limit in the procedure.

The licensee took immediate corrective actions to place the issue of failing to follow procedure requirements into their corrective action program. In addition, the licensee initiated an event investigation, requested a thermal evaluation from the vendor, and provided training to the cask loading crew and loading oversight staff.

The new thermal analysis from the vendor was initiated to verify the canister did not exceed any design basis limit and evaluate whether the 4-hour procedure time limit for the Mating Device drawer position was appropriate. The UMAX FSAR Section 4.4 and Table 4.1.2 stated the design basis canister (highest thermal canister) would have a peak cladding temperature of 693 °F under normal long-term operations inside the UMAX vault. The canisters loaded at SCE were well below that maximum kW limit (30 kW was the maximum canister loaded at SONGS verses the allowed maximum design basis of approximately 34 kW). The analysis provided by the vendor demonstrated that with the drawer fully closed for 8 hours, the peak cladding temperature, based on the site-specific heat loads, would only rise 27 °F from the steady-state condition. This analysis verified that an 8-hour time limit would still maintain

peak cladding temperatures well below NRC's dry canister peak cladding temperature limits of 752 °F. Additionally, the thermal evaluation confirmed that MPC #30 had never approached nor exceeded any design basis limit from the FSAR.

The inspectors reviewed results of the event investigation, the new thermal analysis, actions taken to train the crew, and the revisions to the procedure. The inspectors confirmed that the partial-closure of the drawer for 38 minutes beyond the conservative time-limit placed in the licensee's procedure, had no effect on the condition of spent fuel and did not cause the canister to exceed any normal operating temperature limit described in the FSAR. Additionally, the licensee's procedure change to extend the time-limit to 8 hours was acceptable and would still preclude a canister from exceeding any established design basis limit described in the FSAR.

The NRC determined this failure to follow a procedure requirement constitutes a minor violation that is not subject to enforcement action in accordance with the NRC's Enforcement Policy. This procedure violation was minor because the limit exceeded was a conservative limit. The FSAR normal operating temperature limits were never approached and the safety significance of exceeding the procedural limit was minor.

Multi-Purpose Canister Storage

During the inspection period, one issue the inspectors closely monitored involved the discovery of rainwater inside some of the unused MPC-37 canisters that were stored at the SONGS site. The two storage areas used at the site included a laydown area inside the owner controlled protected area (PA) and a staging area in Parking Lot #4, adjacent to the site. Both locations were outdoors and subject to ambient environmental conditions.

An SCE oversight individual, while performing routine surveillances of Holtec's activities, initiated AR 0119-19778 in January 2019 which detailed that water had been observed pooling and collecting on the covers of MPCs stored on-site at SONGS, at both storage locations. The licensee determined that the possibility of water intrusion into MPCs being stored at SONGS needed to be addressed and evaluated for impacts to MPC cleanliness and storage requirements.

The likelihood of rainwater intrusion into stored MPC canisters was considered to be low because the MPCs were wrapped in several layers of polymer vapor barrier, had a water tight cap installed, and included a water proof tarpaulin cover that was folded completely over the tops of the stored MPCs. This low likelihood was supported by an initial investigation of an MPC with pooling water on its cover that was inspected in the owner-controlled PA. The inspection showed that no water or corrosion products were present inside of that MPC. Based on those preliminary results, the licensee and Holtec determined that water intrusion was not a problem for any of the other MPCs stored at SONGS.

However, starting in April 2019, the licensee initiated several condition reports that identified that some of the protective barriers and coverings on the MPCs had failed. Specifically, the licensee discovered moisture behind the green vapor barrier sheeting during inspections performed by the licensee. Further inspection identified that the Velcro closures in the MPC tarpaulin covers had failed under the pressure of rainwater pooling on top. The pooling rainwater seeped past the Velcro closures and into the MPC

cavity. The licensee's investigation determined that the protective covers used for the on-site storage of the MPCs failed due to environmental conditions during their prolonged (eleven month) time outdoors. The water identified inside the MPCs had the potential to create adverse conditions, therefore, the condition reports required that an engineering evaluation be performed to determine the effects of moisture intrusion on all MPCs in long term storage and to determine a solution for the problem.

The canisters stored at SONGS were in the possession of Holtec International, the dry cask storage vendor performing pool to pad spent fuel services for the licensee. All unused staged canisters were required to be controlled in accordance with Holtec's Quality Assurance Program. The licensee, SCE, takes possession of the spent fuel canisters as they are placed into service to store the licensee's spent fuel. As such, the licensee performed its inspections of the MPC storage conditions through its contractor oversight role. The licensee worked with Holtec to address the identified issues.

Holtec Procedure HSP-315, "Packaging Shipping Storage of Fabricated and Finished Products," Revision 12, detailed the storage requirements for MPCs. The MPCs at SONGS were to be stored in accordance with the requirements of ANSI 45.2.2, "Packaging, Shipping, Receiving, Storage, and Handling of Items for Nuclear Power Plants," Level C requirements. For Level C storage, Holtec Procedure Step 6.4.3.7.a, stated that items stored in a marine environment shall be stored in a temperature and humidity-controlled building to prevent condensation. However, Step 6.4.3.7.b states that if indoor storage facilities are unavailable, items shall be thoroughly wrapped in a vapor barrier to prevent moisture intrusion.

Holtec issued a condition report (FCR 2464-1417) to address the discovery of degraded MPC protective coverings at SONGS. Holtec issued Response to Request for Technical Information (RRTI) 2464-072 which contained recovery actions that required MPC cleaning and flushing operations. Holtec directed the use of Holtec Procedures HSP-314, "Cleaning of Fabricated Component and Finished Products," Revision 14, and HPP-2464-622, "MPC Cleaning at SONGS," Revision 0, to return the canisters to a Class C cleanliness level as required by ANSI N45.2.1 criteria.

Holtec initiated an MPC flushing, cleaning, and inspection operation to return the MPC canisters to vendor delivered specifications. The canister cleaning operations took place in an open area near the turbine deck so that the turbine deck crane could be used to lift, upend, and manipulate the MPC canisters that required flushing and cleaning. The MPCs were strapped into an Up-Ender, a rig configured to allow the MPC to be fully supported during crane manipulations. The crane allowed the MPC to be positioned onto cribbing that tilted the MPC opening slightly downwards so that the water used in the flushing operations could freely flow into a catch basin. Flushing took place at SONGS using deionized water. The water collected in the catch basin was sampled after the flushing was complete. The water was chemically analyzed to ensure there was no unacceptable chemical contaminates left after the flushing operations.

The inspectors observed the condition of MPCs being stored at SONGS on August 12-14, 2019. At the time of the NRC inspection, Holtec had completed the inspection activities for 14 MPCs of approximately 42 MPCs stored in Parking Lot #4 and in the owner-controlled PA. Ten of the 14 MPCs had standing water at the bottom of the fuel basket. The standing water ranged from 0.5 to 24 inches. The inspectors observed some cleaning operations during its August 19-23, 2019, fuel loading inspection at

SONGS. During these inspections, NRC verified the rainwater and any possible particulates were removed during the flushing operations. The cleaned MPCs were being assessed using ANSI N45.2.1 standards prior to being returned to storage or used in fuel loading operations.

The inspectors concluded that the licensee was performing frequent and thorough surveillances of activities on-site. The licensee was capturing potential issues and adequately resolving those issues through the site's CAP. The actions to clean, flush, analyze, and disposition the canister to meet all applicable requirements prior to use were effective and adequate.

In response to the water intrusion issues, NRC identified a potential issue regarding Holtec's adherence to Holtec Procedure HSP-315, "Packaging, Shipping, and Storage of Fabricated and Finished Products," Revision 12, that occurred at the SONGS site. The inspectors determined that dry cask storage vendor, Holtec, was responsible for MPC storage activities at the site. As such, NRC Region IV has forwarded this issue of concern to the Inspection and Oversight Branch, Division of Fuel Management, for review.

c. Conclusions

The inspectors determined that the licensee was placing all relevant identified issues into the SCE CAP program. A large detailed list of issues placed into the site's CAP was reviewed by inspectors and it was determined that the site had established a low threshold for identifying concerns/issues and placing them into the CAP for proper review and resolution. The inspectors further determined the licensee was taking adequate corrective actions to resolve the issues including a review for extent of cause and extent of condition when required.

2 Follow-up of Events and Notices of Enforcement Discretion (IP 71153)

2.1 Inspection Scope

The inspectors evaluated licensee events to verify the licensee's response and corrective actions were adequate to restore compliance. The inspectors reviewed licensee event reports (LERs) to ensure the reports were timely, accurate, included the required information, and that the required corrective actions had been completed.

2.2 Observations and Findings

a. (Closed) Licensee Event Report 2018-002-0 and 2018-002-1, Spent Nuclear Fuel Transport Conveyance Vehicle Operated Outside Obstacle Clearance Limits

Licensee Event Report 2018-002-0, dated February 14, 2019 (ADAMS Accession No. ML19050A170) was previously discussed in the NRC Supplemental Inspection Report dated July 9, 2019 (ADAMS Accession No. ML19190A217). In the LER, the licensee identified that transporter's center of gravity was not maintained within limitations specified in the site's specific analysis and operations had been conducted too close to adjacent structures (light posts). These past operations were determined to be outside the calculated clearance limits specified in the site's seismic analysis. The licensee identified that the site procedures, at the time, did not provide sufficient detail to

comply with the seismic stability calculation. No actual seismic incidents or collisions with obstacles occurred during past fuel transfer operations and there was no impact to plant personnel or public health and safety. The LER 2018-002-0, at the time, described that an analysis was still in progress to determine if past operations were acceptable.

On August 6, 2019, SCE issued an updated LER 2018-002-1 (ADAMS Accession No. ML19221B590) in accordance with 10 CFR 72.75(d)(1) and (g) for past operations of the low-profile-transporter. The revised LER described that the licensee had performed additional seismic analysis and concluded that there were no safety consequences for traveling along the ISFSI haul route with reduced seismic clearances to adjacent structures and obstacles (light posts). The NRC reviewed the LER revision's additional analysis that bounded any potential contact that could have occurred to the transporter and transfer cask during a postulated seismic event and concluded that the potential impact would not exceed any design basis requirements.

Inspectors found that the updated LER contained adequate content to be closed out in this inspection report. No seismic events have occurred that resulted in damage to the low-profile-transporter or transfer cask during the fuel transfer campaign that began in January 2018. The licensee's failure to follow the site-specific seismic analysis, for past operations, was determined by inspectors to be a violation of NRC requirements (Section 2.2.b). These LERs are closed.

b. Finding Related to the Licensee's Event Report

The licensee's event notification EN #53798 documented that past low-profile transporter (HI-PORT) operations had not been conducted within the requirements of the original seismic evaluation HI-2167363, "Seismic Stability Analysis of HI-TRAC on HI-PORT at SONGS," Revision 4. At times the low-profile-transporter was operated outside of the 10-inch travel height restriction of the seismic analysis. Also, the proximity distance to adjacent structures was never formally outlined along the haul path from the fuel buildings to the ISFSI pad. Evaluation HI-2167363, Section 5.0, "Conclusions," stated that the loaded HI-PORT height should be setup to have a maximum clearance of 10 inches between the dropdeck and haul path and a minimum clearance of 32 inches should be maintained between the outer edges of the HI-PORT and adjacent safety related structures or structures that may adversely affect the HI-PORT along the haul path at all times.

Title 10 CFR 72.212(b)(3), requires, in part, that the general licensee shall ensure that each cask used conforms to the terms, conditions, and specifications of a Certificate of Compliance as listed in 10 CFR 72.214.

Title 10 CFR 72.214 states, in part, that Certificate Number 1040 [Docket Number 072-01040] Amendment Number 2, effective date January 9, 2017, is an approved cask for storage of spent fuel under the conditions specified in the Certificate of Compliance for the Holtec HI-STORM UMAX Storage System.

Certificate of Compliance 072-01040, Appendix B, Technical Specification 3.4.15 requires, in part, the loaded transfer cask and its conveyance shall be evaluated to ensure, under the site-specific Design Basis Earthquake (DBE), that the cask and its conveyance does not tip-over or slide off the haul route.

Contrary to the above, from January 30, 2018, to August 3, 2018, the licensee failed to ensure the cask and its conveyance was evaluated under the site-specific DBE. Specifically, the licensee identified that past HI-PORT transportation operations were not evaluated under the site-specific DBE, since operations were conducted outside the height and stand-off requirements in seismic evaluation HI-2167363.

This violation was dispositioned per the traditional enforcement process using Section 2.3 of the NRC's Enforcement Policy. The NRC determined that the finding was of low safety significance since the licensee had re-performed the evaluation, addressed the deviation that occurred, and demonstrated the canister and its conveyance would not have tipped over, slipped off, or experienced damage beyond design basis requirements along the haul route during those transportation operations due to being operated outside of the identified limits. This finding was determined by inspectors to be of more than minor safety significance, since if left uncorrected, the deficiency could lead to a more significant safety concern.

Consistent with the guidance in Section 1.2.6.D of the NRC Enforcement Manual, if a violation does not fit an example in the Enforcement Policy Violation Examples, it should be assigned a severity level: (1) commensurate with its safety significance; and (2) informed by similar violations addressed in the Violation Examples. The violation was evaluated to be similar to a Severity Level IV violation in Enforcement Policy Section 6.1.d.1.

The licensee entered the finding into its CAP as AR 1218-46759. The licensee restored compliance, before fuel loading resumption activities, by (1) changing the transportation procedure to ensure requirements from the site-specific seismic analysis were clearly outlined and followed, (2) painting lines along the ISFSI haul path to provide visual boundaries that the HI-PORT operator should not cross during spent fuel transport operations, and (3) revising the site-specific seismic analyses to bound transportation operations conducted at the site. Because the licensee entered the issue into its CAP, the safety significance of the issue was low, and the issue was not repetitive or willful, this Severity Level IV violation was treated as an NCV, consistent with Section 2.3.2.a of the Enforcement Policy (NCV 07200044/2019-001-01; "Failure to Ensure the Loaded Transfer Cask and its Conveyance was Evaluated Under the Site-Specific DBE" (10 CFR 72.212(b)(3)).

2.3 <u>Conclusions</u>

The inspectors documented one Severity Level IV, non-cited violation (NCV) related to the licensee's failure to conduct past transportation operations, utilizing the low-profile transporter, in accordance with the station's site-specific seismic analysis. The NRC determined that the finding was of low safety significance since the licensee had performed an additional analysis for a revision to the LER which bounded any potential contact that could have occurred during a postulated seismic event. The inspectors concluded that the potential impact to the transfer cask would not have exceeded any design basis requirements. The licensee restored compliance, prior to fuel loading resumption activities, by changing the transportation procedure to ensure requirements from the site-specific seismic analysis were clearly outlined and followed and revised the site-specific seismic analyses to bound transportation operations conducted at the site. The original and revised LERs are closed.

3 Review of 10 CFR 72.48 Evaluations (IP 60857)

3.1 Inspection Scope

The licensee's 10 CFR 72.48 screenings and evaluations performed since the NRC's last ISFSI inspection (ADAMS Accession No. ML19190A217) were reviewed to determine compliance with regulatory requirements.

3.2 Observations and Findings

The licensee's 10 CFR 72.48 screenings and evaluations for ISFSI program changes since June 2019 were reviewed to determine regulatory compliance. The licensee had performed a number of procedure revisions and some equipment or process changes under the 72.48 process since the last inspection. NRC inspectors reviewed the 72.48 screens for those procedure changes and design change packages made within the ISFSI program. None of the screens led to a full 10 CFR 72.48 safety evaluation. All screenings were determined to be adequately evaluated.

3.3 Conclusions

All required safety screenings and safety evaluations had been performed in accordance with procedures and requirements of 10 CFR 72.48. All screenings and safety evaluations reviewed were determined to have been adequately evaluated.

4 Exit Meeting Summary

On October 21, 2019, the NRC inspectors presented the final inspection results to Mr. Doug Bauder, Vice-president and Chief Nuclear Officer, Southern California Edison and other members of the licensee's staff. The licensee acknowledged the issues presented.

Division of Spent Fuel Storage and Transportation
Interim Staff Guidance - 1, Revision 2
Classifying the Condition of Spent Nuclear Fuel for Interim Storage and Transportation Based on Function[1]

Issue

This Interim Staff Guidance (ISG) provides guidance to the staff on classifying spent nuclear fuel as either (1) damaged, (2) undamaged, or (3) intact, before interim storage or transportation. This is not a regulation or requirement and can be modified or superseded by an applicant with supportable technical arguments.

Regulatory Basis

Fuel-Specific Regulations:

A fuel-specific regulation means a characteristic or performance requirement of the fuel specifically named in the applicable Code of Federal Regulations (CFR). These are regulations that specify capabilities that the spent nuclear fuel (SNF) must have. Examples include:

10 CFR 71.55(d) states, in part: "A package used for the shipment of fissile material must be so designed and constructed and its contents so limited that under the tests specified in 10 CFR 71.71 ('Normal conditions of transport')

(1) The contents would be subcritical.
(2) The geometric form of the package contents would not be substantially altered."

10 CFR 72.44(c) states, in part: "Technical specifications must include requirements in the following categories: (1) Functional and operating limits . . . (I) . . . for an ISFSI or MRS are limits on fuel or waste handling and storage conditions that are found to be necessary to protect the integrity of the stored fuel or waste container, to protect employees against occupational exposures and to guard against the uncontrolled release of radioactive materials . . . "

10 CFR 72.122(h)(1) states: "The spent fuel cladding must be protected during storage against degradation that leads to gross ruptures or the fuel must be otherwise confined such that degradation of the fuel during storage will not pose operational safety problems with respect to its removal from storage. This may be accomplished by canning of consolidated fuel rods or unconsolidated assemblies or other means as appropriate."

10 CFR 72.122(l) states: "Retrievability. Storage systems must be designed to allow ready retrieval of spent fuel, . . . for further processing or disposal."

---

[1]Formerly entitled "Damaged Fuel."

System-Related Regulations:

A transportation and storage system must satisfy all applicable regulations in 10 CFR Parts 71 or 72. A system-related regulation is a performance requirement placed on the fuel for the system (i.e., transportation or storage cask) to meet a regulation that does not specifically require performance capabilities of the SNF. Examples include:

10 CFR 71.55(e) states in part: "A package used for the shipment of fissile material must be so designed and constructed and its contents so limited that under the tests specified in 10 CFR 71.73 ('Hypothetical accident conditions'), the package would be subcritical."

Note: This regulation does not place a specific requirement on the SNF. However, if the package requires the SNF to maintain its geometric configuration to ensure subcriticality, then a function is imposed on the SNF.

10 CFR 72.122(h)(5) states: "The high level radioactive waste and reactor related GTCC waste must be packaged in a manner that allows handling and retrievability without the release of radioactive materials to the environment or radiation exposures in excess of Part 20 limits . . . "

10 CFR 72.124(a) states: "Design for criticality safety. Spent fuel handling, packaging, transfer, and storage systems must be designed to be maintained subcritical and to ensure that, before a nuclear criticality accident is possible, at least two unlikely, independent, and concurrent or sequential changes have occurred in the conditions essential to nuclear criticality safety. The design of handling, packaging, transfer, and storage systems must include margins of safety for the nuclear criticality parameters that are commensurate with the uncertainties in the data and methods used in calculations and demonstrate safety for the handling, packaging, transfer, and storage conditions and in the nature of the immediate environment, under accident conditions."

Note: If the SNF must have certain characteristics or behave in a specified manner to maintain the required margins, a function is placed on the SNF.

10 CFR 72.128 states in part: "Spent fuel storage . . . must be designed to ensure adequate safety under normal and accident conditions. These systems must be designed with (2) suitable shielding for radioactive protection under normal and accident conditions, (3) confinement structures and systems . . . "

Note: If proper functioning of the shielding or containment requires that the SNF maintain its configuration, then a function is placed on the SNF.

Applicability

This guidance applies to reviews of dry cask storage systems and transportation casks conducted in accordance with NUREG-1536, "Standard Review Plan for Dry Cask Storage Systems" (January 1997); NUREG-1567, "Standard Review Plan for Spent Fuel Dry Storage Facilities" (March 2000); or NUREG-1617, "Standard Review Plan for Transportation Packages for Spent Nuclear Fuel" (March 2000). This revision of ISG-1 supersedes any definitions of damaged, grossly damaged, or intact fuel in the above Standard Review Plans.

This revision supersedes ISG-1, Revision 1, "Damaged Fuel," in its entirety, and is applicable to both as-built and reconstituted fuel assemblies.

Definitions

1. Spent Nuclear Fuel (SNF) - See 10 CFR Part 72.3 for definition. This term has been used in the nuclear industry, at different times, to mean the fuel pellets, the rod, or entire fuel assembly. Unless specifically modified, the term will refer to both the rods and fuel assembly.

2. Damaged SNF - Any fuel rod or fuel assembly that cannot fulfill its fuel-specific or system-related functions.

3. Undamaged SNF - SNF that can meet all fuel-specific and system-related functions. As shown in Figure 1, undamaged fuel may be breached. Fuel assembly classified as undamaged SNF may have "assembly defects."

4. Breached spent fuel rod - Spent fuel rod with cladding defects that permit the release of gas from the interior of the fuel rod. A breached spent fuel rod may also have cladding defects sufficient to permit the release of fuel particulate. A breach may be limited to a pinhole leak or hairline crack, or may be a gross breach.

5. Pinhole leaks or hairline cracks - Minor cladding defects that will not permit significant release of particulate matter from the spent fuel rod, and therefore present a minimal as-low-as-is-reasonably-achievable concern, during fuel handling and retrieval operations. (See discussion of gross defects for size concerns.)

6. Grossly breached spent fuel rod - A subset of breached rods. A breach in spent fuel cladding that is larger than a pinhole leak or a hairline crack. An acceptable examination for a gross breach is a visual examination that has the capability to determine the fuel pellet surface may be seen through the breached portion of the cladding. Alternatively, review of reactor operating records may provide evidence of the presence of heavy metal isotopes indicating that a fuel rod is grossly breached. (See discussion for size concerns.)

7. Intact SNF - Any fuel that can fulfill all fuel-specific and system-related functions, and that is not breached. Note that all intact SNF is undamaged, but not all undamaged fuel is intact, since under most situations, breached spent fuel rods that are not grossly breached will be considered undamaged.

8. Can for Damaged Fuel - A metal enclosure that is sized to confine one damaged spent fuel assembly. A fuel can for damaged spent fuel with damaged spent-fuel assembly contents must satisfy fuel-specific and system-related functions for undamaged SNF required by the applicable regulations.

9. Assembly Defect - Any change in the physical as-built condition of the assembly with the exception of normal in-reactor changes such as elongation from irradiation growth or assembly bow. Examples of assembly defects: (a) missing rods; (b) broken or missing grids or grid straps (spacers); and (c) missing or broken grid springs, etc. An assembly with a defect is damaged only if it can't meet its fuel-specific and system-related functions required by the applicable regulations.

Note: See Appendix for default definition of damaged SNF.

Background

Damaged Fuel

Previous definitions of damaged fuel have identified specific characteristics of the fuel that classify it as damaged, irrespective of whether the fuel is being stored or transported and independent of the design of the storage or transportation system. In this guidance, damaged fuel is defined in terms of the characteristics needed to perform the fuel-specific and system-related functions. Thus, the characteristics of damaged spent fuel may depend on (1) whether the fuel is being stored or transported, and (2) the design of the storage or transportation system.

The materials properties, and possibly the physical condition, of a fuel rod or assembly can be altered during irradiation, storage, or transportation. If this alteration is large enough to prevent the fuel or assembly from performing its fuel-specific or system-related functions during storage, transportation, or both then the fuel assembly is considered damaged.

To determine whether a fuel assembly is undamaged, the following should be delineated:

1) Whether the definition is applicable to storage, transportation or both;

2) The functions the applicant has imposed on the fuel rods and assembly by either fuel-specific or system-related functions to meet a regulatory requirement for the designated phase (storage, transportation, or both);

3) The mechanisms of change (alteration mechanisms) or the characteristics of the fuel that could potentially cause the fuel to fail to meet its fuel-specific or system-related functions;

4) An acceptable analysis showing that the fuel with the designated characteristics will meet the fuel-specific and system-related functions when the mechanisms considered in item #3, above, are evaluated; and

5) The physical characteristics of the fuel, based on item #4, above, that could cause the fuel or assembly to be classified as "damaged."

The "Discussion" section illustrates this methodology in the example.

Damaged SNF, as defined in this guidance, will only be approved for the activity (storage, transportation, or both) for which the application is being submitted. Note that the "default" definition of damaged SNF, derived from ANSI N14.33-2005, is provided in the appendix of this

guidance for those that do not want to perform the assessment outlined in item numbers 1 through 5 above [2]. The default definition, however, may not take full advantage of the flexibility of the performance-based definition of damaged fuel provided in this guidance. This default definition may be more restrictive than necessary, depending on the design of the storage or transportation cask. For example, the default definition of damaged SNF indicates that SNF must be classified as damaged if an individual fuel rod is missing from an assembly. However, if an analysis shows that all fuel-specific and system-related functions will be met (e.g., subcriticality will be maintained, that the SNF assembly will be retrievable and that the structural properties of the assembly are not compromised by the missing rod) the assembly may be classified as undamaged, per this ISG.

Discussion

The performance-based definition [3,4] of damaged SNF provided in this ISG minimizes the quantity of damaged fuel requiring alternative handling paths, while still addressing applicable system-related regulations concerning criticality control, thermal limitations, structural integrity, confinement, and shielding.

A. Grossly Breached SNF Cladding

The regulations in 10 CFR 72.122(h) state “The spent fuel cladding must be protected during storage against degradation that leads to gross ruptures or the fuel must be otherwise confined such that degradation of the fuel during storage will not pose operational safety problems with respect to its removal from storage.” However, there is no such requirement in 10 CFR 71. Hence, grossly breached fuel is always considered damaged for storage, but may, or may not, be considered damaged for the purposes of transportation depending on whether other regulations, such as criticality, can be met.

In dry cask storage and transportation systems, a gross cladding breach should be considered as any cladding breach that could lead to the release of fuel particulate greater than the average size fuel fragment. A pellet is ~1.1 centimeters in diameter in 15 x 15 Pressurized-Water Reactor (PWR) assemblies. Pellets from a Boiling-Water Reactor (BWR) are somewhat larger, and those from 17 x 17 PWR assemblies are somewhat smaller. The pellet's length is slightly longer than its diameter. During the first cycle of irradiation in-reactor, the pellet fragments into 25-35 smaller interlocked pieces, plus a small amount of finer powder, due to, pellet-to-pellet abrasion. When the rod breaches, about 0.1 gram of this fine powder may be carried out of the fuel rod at the breach site [5]. Modeling the fragments as either spherical- or pie-shaped pieces indicates that a cladding-crack width of at least 2-3 millimeters would be required to release a fragment. Hence, gross breaches should be considered to be any cladding breach greater than 1 millimeter.

A review of reactor operating records, ultrasonic testing, and sipping (if done in a timely fashion) can be used to classify rods as unbreached or, breached. Evidence of only gaseous or volatile decay products (no heavy metals) in the reactor coolant system is accepted as evidence that a cladding breach is no larger than a pinhole leak or hairline crack. Records that show the presence of heavy metal isotopes that are characteristic of fuel release in the reactor coolant system indicate gross breaches in the cladding. Likewise, visual examination may also be used to determine if a cladding breach is gross, if the breached rod can be positively identified.

Because cladding openings larger than 1 millimeter should expose the fuel pellet to visual sighting, visual examination of the breached rod can be used to determine if a breach is gross. However, visual examination is not an acceptable method of confirming intact (undamaged) fuel for assemblies that have indicated leakage.

It should be noted; however, that undamaged spent-fuel rods with pinhole leaks and/or hairline cracks will expose the fuel pellets to the canister or cask atmosphere. If that atmosphere is oxidizing, then the fuel pellet may oxidize and expand, placing stress on the cladding. The expansion may eventually cause a large split in the cladding, resulting in spent fuel that must be classified as damaged (for storage and possibly also for transportation) due to gross breaches in the cladding. Since fuel oxidation and cladding splitting follow Arrhenius time-at-temperature behavior, fuel rods with pinholes or hairline cracks that are exposed to an oxidizing atmosphere may experience this type of additional cladding damage. ISG-22 “Potential Rod Splitting Due to Exposure to an Oxidizing Atmosphere During Short-Term Cask Loading Operations in LWR or other Uranium Oxide Based Fuels” [6] provides information regarding prevention of this phenomenon. Before handling undamaged rods with pinhole leaks and/or hairline cracks in an oxidizing atmosphere, the potential fuel and cladding degradation at the temperature of interest for the duration of the process should be assessed.

B. Fuel Assembly with Defects

Damage under this guidance refers to alterations of the fuel assembly that prevent it from fulfilling its fuel-specific or system-related functions. Defects such as dents in rods, bent or missing structural members, small cracks in structural members, missing rods, etc., need not be considered damaged if the applicant can show that the fuel assembly with these defects still fulfils its fuel-specific and system-related functions. This may be done using calculations based on approved codes, situation-specific data, or reasoned engineering arguments.

C. Canning Damaged Fuel

Spent fuel that has been classified as damaged for storage must be placed in a can designed for damaged fuel, or in an acceptable alternative. The purpose of a can designed for damaged fuel is to (1) confine gross fuel particles, debris, or damaged assemblies to a known volume within the cask; (2) to demonstrate that compliance with the criticality, shielding, thermal, and structural requirements are met; and (3) permit normal handling and retrieval from the cask. The can designed for damaged fuel may need to contain neutron-absorbing materials, if results of the criticality safety analysis depend on the neutron absorber to meet the requirements of 10 CFR 72.124(a).

D. Relationship of Spent Fuel Populations

The applicant will designate the population of spent fuel for which the cask system was designed (e.g., type of fuel, minimum cooling time, burnup limitations, arrays, manufacturers, cladding types, etc.) This population may contain breached rods. Some of these breached rods may be grossly breached. It may also contain assemblies with defects, such as missing rods, missing grid spacers, or damaged spacers. The populations of breached rods, grossly breached rods, and assemblies with defects are determined by in-reactor behavior and ex-reactor handling.

Each of these populations must be classified as damaged or undamaged after the storage or transportation system has been designated. For example, an applicant might propose the use of air as a cover gas in its design of a storage cask. The applicant might also propose this cask for use in storing spent fuel with cladding breaches that are hairline cracks or pinhole leaks. However, if the spent fuel in the cask will operate at a sufficiently high temperature for a long enough time, then oxidation of fuel pellets in breached rods could occur resulting in gross breaches. If this is the case, the breached spent fuel should be considered damaged because grossly breached rods do not meet the requirements of 10 CFR 72.122(h)(1). Also, in this case because the geometric form of the package contents could be substantially altered, the spent fuel would also be classified as damaged for transportation because the requirements of 10 CFR 71.55(d)(2) might not be met. If an inert atmosphere was used instead of air, only grossly breached rods would be considered damaged for storage. This concept is illustrated in Figure 1, "Relationship of Spent Fuel Populations."

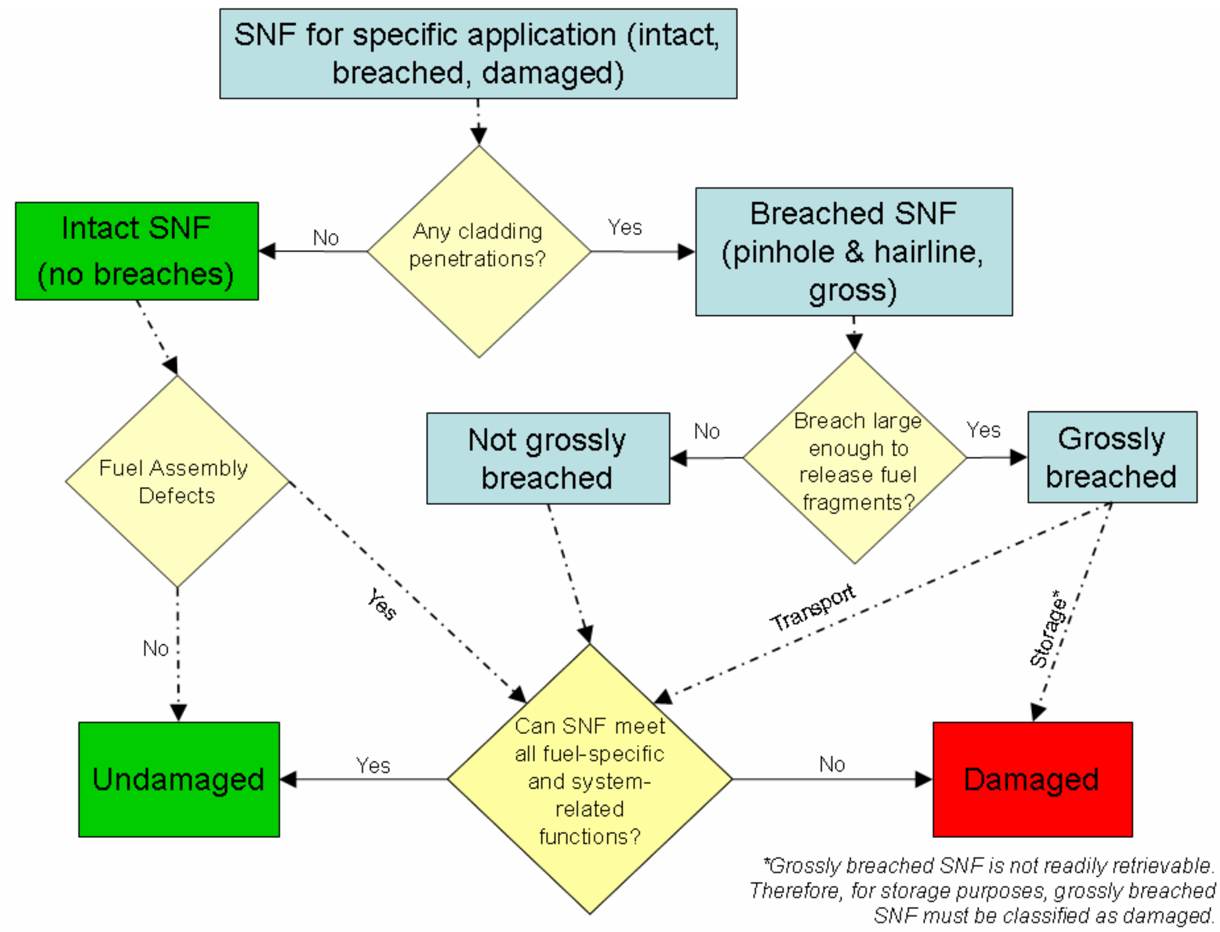

Figure 1 - Relationship of Spent Fuel Populations

E. Example of Methodology

The following example is given to illustrate the general methodology adopted in this ISG. This is only an example of the methodology and should not be construed as approved characterization of damaged fuel.

Example:

Situation - The vendor of a dual-purpose cask wants to store and transport low-burnup PWR fuel in an inert atmosphere and within the temperature limits recommended in ISG-11, Revision 3, “Cladding Considerations for the Transportation and Storage of Spent Fuel” [7]. The vendor wants to store assemblies having rods with breaches containing only pinholes or hairline cracks, and assemblies having one or more outer grid straps with defects at three or more grid locations without canning them. The vendor is only applying for a storage license at this time but wants to be reasonably certain that the fuel will also be transportable.

Activity - Storage and transportation

Fuel-specific or system-related functions imposed on rods and assemblies - 10 CFR 72.122(h)(1), regarding gross ruptures, and 10 CFR 72.122(l), concerning retrievability, must be met for storage. 10 CFR 71.55(d), requiring the system to remain subcritical and unchanged during normal transport, must be met. The vendor believes that all the remaining system requirements, except for the subcriticality requirement, can be met, without imposing any limitations on the fuel, if the fuel is within the bounds stated in the situation.

Mechanisms - There are no mechanisms for the pinhole leaks and hairline cracks to evolve into gross breaches since the atmosphere is inert and the temperature is controlled. To be retrievable, the assemblies with missing grid straps must be able to withstand design basis events in a storage cask. Since the applicant also wants these assemblies to be considered undamaged for transportation, the behavior of the assemblies under both normal and hypothetical accident transportation conditions in 10 CFR 71 must be evaluated. For example, for normal transportation conditions, the applicant must show that the assemblies with the most missing grid straps in the worst locations can withstand both normal vibration and a one-foot drop and remain in their original physical configuration. Additionally, for hypothetical accident conditions, the analysis must indicate, among other things, that the system will meet shielding and subcriticality requirements when placed under the mechanical and thermal loads specified in 10 CFR 71.

Analysis - The applicant conducts an analysis to satisfactorily demonstrate that the assembly with three missing grid straps in the worst configuration remains intact for 1) normal transportation conditions; 2) cask tip-over; and 3) regulatory accident conditions. Further acceptable analysis indicates that all the system-related regulations are met, if the fuel with the characteristic limitations (as noted in Characteristics section below), stays structurally intact.

Characteristics - Assemblies containing breached rods with up to three grid straps missing will be considered undamaged for the purposes of storage. Analysis shows that these assemblies could probably also be considered undamaged for transportation, but fuel with these characteristics will be evaluated and approved as part of a later application for the transportation cask certification.

Records

Records documenting the classification of spent fuel shall comply with the provisions of 10 CFR 72.174, “Quality Assurance Records”; 10 CFR 72.72, “Material Balance, Inventory, and Records Requirements for Stored Material”; 10 CFR 71.91, “Records”; and 10 CFR 71.135, “Quality Assurance Records.” Inspection records will be maintained for the lifetime of the container.

Quality Assurance

Activities related to inspection, evaluation, and documentation of damaged spent fuel for dry storage shall be performed in accordance with a quality assurance program, as required in 10 CFR Part 72, Subpart G, “Quality Assurance.” Activities related to inspection, evaluation, and documentation of damaged spent fuel for transport shall be performed in accordance with a quality assurance program, as required in 10 CFR Part 71, Subpart H, “Quality Assurance.”

Recommendations

The staff recommends that: (1) the definitions in NUREG-1536, NUREG-1567, NUREG-1617, ISG-8, Revision 2 and ISG-11, Revision 3 be revised to incorporate the definitions listed above; and (2) the appropriate chapters of each NUREG be revised to include the discussion section of this ISG.

In addition, the suggestion in NUREG-1617 (canning damaged fuel is necessary for the purposes of transportation) should be modified to be consistent with this ISG, nothing that canning damaged fuel may, in some cases, be necessary to meet the requirements of 10 CFR Part 71.

The words “intact fuel,” in the Applicability section of Revision 2 of ISG-8, “Burnup Credit in the Criticality Safety Analyses of PWR Spent Fuel in Transport and Storage Casks,” should be replaced with “undamaged fuel.” “Intact commercial spent fuel" in the last paragraph of the “Issue” section of Revision 3 of ISG-11, “Cladding Considerations for the Transportation and Storage of Spent Fuel,” should read “undamaged commercial spent fuel.” The first sentence of the Issue Section of ISG-22 should be modified to be consistent with the current definitions. “Rev 1,” should be changed to “Rev 2,” with the new title to ISG-1 Rev 2 and “intact fuel” should be changed to “unbreached fuel.”

and Transportation

Attachment: Appendix

APPENDIX

Default Definition of Damaged Fuel[2]

"Default" definition of damaged Spent Nuclear Fuel (SNF) - SNF assemblies must be classified as damaged, for both dry storage and/or transportation purposes, if any one of the following conditions exist:

On removal of SNF selected for dry storage or transport from the spent fuel pool, any of the following apply:

1. There is visible deformation of the rods in the SNF assembly. Note: This is not referring to the uniform bowing that occurs in the reactor. This refers to bowing that significantly opens up the lattice spacing.

2. Individual fuel rods are missing from the assembly. Note: The assembly may be reclassified as intact if a dummy rod that displaces a volume equal to, or greater than, the original fuel rod, is placed in the empty rod location.

3. The SNF assembly has missing, displaced, or damaged structural components such that either:

   3.1 Radiological and/or criticality safety is adversely affected (e.g., significantly changed rod pitch).

   3.2 The assembly cannot be handled by normal means (i.e., crane and grapple).

4. Reactor operating records (or other records) indicate that the SNF assembly contains fuel rods with gross breaches.

5. The SNF assembly is no longer in the form of an intact fuel bundle (e.g., consists of, or contains, debris such, as loose fuel pellets or rod segments).

6:00 p.m.

FACILITATOR CAMERON: Okay, good evening, everyone. My name is Chip Cameron, and I'd like to welcome all of you to the public meeting tonight.

I was going to make a joke and say welcome to the annual meeting of Local 89, but --

(Laughter.)

Okay, but -- all right, all right.

But we do have a serious topic tonight, and it's the decommissioning of the SONGS facility, and specifically, it's a meeting on what's known as the Post-Shutdown Decommissioning Activities Report.

We're going to try not to use many acronyms tonight. We are going to use NRC, for Nuclear Regulatory Commission, and you're probably going to hear the term PSDAR -- that's the Post-Shutdown Activities Report, Decommissioning Activities Report.

That document was submitted by Southern California Edison under the regulations that the NRC has for decommissioning, and you're going to hear a lot about that tonight.

I just want to go through some meeting process items for you so that you know what to expect

tonight, and I'd like to tell you about what the objectives are for the meeting, what the format is going to be, and just some simple ground rules that will help us to have a productive meeting tonight.

In terms of objectives for the meeting, one is to have the NRC provide you with a clear explanation of the NRC regulatory process for decommissioning, and the overview of what's in the PSDAR, the Southern California Edison document.

We also have Tom Palmisano doing a presentation for us tonight to go over the specifics of the post-shutdown report, and we'll be hearing from a panel of speakers including Tom in a few minutes.

So that's one objective, to clearly explain all that to you.

Second objective is to hear any comments, concerns you might have, and to also answer some questions that you might have about the presentations. And our panel reflects all the different organizations that are involved for the NRC in decommissioning, and Larry Camper, our lead senior official, is going to explain that to you in a few minutes.

I am going to have to ask your patience. We are going to have all the presentations before we go out to you for questions so you can get the whole picture,

but we might be here for 45 minutes talking, not at you, but to you, and the speakers are going to try to keep it brief.

But just let me ask your patience with that, and after that's done, we'll go out to you for questions and comments, and I would ask you to hold your questions until all the presentations are finished.

In terms of ground rules, first of all, hold your questions. Second of all, let's only have one person speaking at a time, whoever has the floor at the moment, whoever has the microphone. And that's just very simply so that we can give our complete attention to whomever is talking at the moment.

And I am going to have to ask you to be brief. We're not going to be able to have lengthy presentations by you tonight. We will have listened to your comments, but luckily, there's a relief valve -- if you don't get to say everything that you want to say tonight, the NRC is taking email, comments by email, on these issues, and they're also taking hard copy comments if you want to mail those in, and we'll put that address, the email address and the mail address up for you at -- all during the meeting, so that you can copy that down.

And if your question or concern has already been raised or has been answered, if you could try not

to repeat that -- and I know sometimes that's difficult, because you want to chime in with what you have to say and sometimes it's a little different, but let's try to keep it to what is necessary.

And the last ground rule is just please extend courtesy to everybody, and that goes for all of us, NRC, everybody. Just be courteous. You may hear opinions tonight that are different from your opinions, but just respect the person who is giving that opinion.

And when we do get to the discussion session, after the presentations, I am going to call for people, raise your hand if you have something to say -- I am going to do it section by section, and that is because we are taking camera, web -- and that's going to be for a webcast, and that will be available on the NRC website, so if you want to see what was said, that is going to be your record of the meeting, and also the NRC's record of the meeting tonight.

And I just thank you all for being here tonight, and I'm going to turn it over to Larry Camper.

MR. CAMPER: Thank you, Chip. Welcome, everybody. It's great to see such a great turnout, really. Thank you for taking time out of your busy lives to come and be with us this evening.

We were here last September, and I

commented at the time in my remarks what a beautiful place this is, and I can only repeat it again this evening. You really do live in a lovely spot, so it's good to be with you.

This evening we're going to conduct a meeting that is a required meeting by our regulations, and as Chip said, it's the Post-Shutdown Decommissioning Activities Report Meeting, or PSDAR.

The meeting that we were here for last September was an outreach meeting, as compared to a required meeting. So we're here to gather comments. We do have to share some information with you first, so bear with us as we do that.

Good. I mentioned we were here last September in an outreach meeting. Heard a lot of good input from citizens, and we appreciated hearing all that.

I'll cover the meeting agenda just briefly. In terms of facilitation, you know that Chip Cameron is going to be facilitating. He shared with you the ground rules so we can have a productive and meaningful interface tonight.

It's really about comments. We do have some subjects to cover, but -- we want all of you to be aware of the same information at the same time, but it

really is about getting comments from all of you here, or as many of you as want to speak.

We do have some meeting feedback forms outside on the table. I would ask you to take time to complete the meeting feedback form. We like to get some feedback as to how the meetings went, and did you find it valuable and useful.

We will be adjourning at 9:00 p.m., we have the room contractually until 9:00 p.m., so we do have to stop at that point in time. If we go over a few minutes, I don't think the hotel will come in here and run us out, but let's strive for that 9:00 p.m. objective.

During the September meeting, it was a meeting that we initiated although it was not required by our regulations. And we did that because there was a lot of things that had happened at this particular plant, and our agency, our chairman in particular, our senior management, all had an interest in seeing to it that we came out here, heard your concerns, and communicated about not only the decommissioning process, but anything that folks wanted to talk about, and we did that.

At that time, we had a government-to-government meeting with local elected

officials during the day, we did that again today. And we also had a meeting with non-government organizations at that time, and today we met with representatives from the Community Engagement Panel.

Each of those meetings about an hour and a half in duration, and we found them to be indeed very useful, with much good input. And I would -- I think it's fair to say that the elected officials and the Community Engagement Panel is listening. They shared a lot of very good information with us.

Last September, there were a myriad of topics that were talked about. I put down two in this particular slide, fuel management -- and I am sure we'll hear about fuel management again this evening -- as well as decommissioning timing, when will decommissioning start, how long will it take, what are the guidelines and the regulations by which they have to carry out their decommissioning activities?

For tonight, I want to start out by saying that I'm going to mention each of the speakers that are up here at the table tonight. Each of these will be making a presentation.

Chip alluded to the fact that our responsibility for decommissioning is spread out in several places, so we wanted to make sure we had the

right expertise here. But I also want to point out -- and I'd ask the NRC staff here, if you'd stand up for a moment and turn around and let the folks see you -- we have a number of NRC people here, and the reason for that is because we wanted to make sure we had the expertise here. Thank you very much.

And if some question comes up over the course of the evening that one of the staff feel that they can better answer, then they can certainly indicate, and we'll recognize them, and they'll do that.

Also, we'll take a quick break, and we'll be here just for a little bit after the meeting. Any of these folks are a source of information for you, especially if you're shy about getting up and asking questions or making comments during the program this evening.

First is Bruce Watson. Bruce will address the Post-Shutdown Decommissioning Activities Requirements.

Next to him is Doug Broaddus, and Doug will cover the review, our review of the PSDAR, and the licensing status of the facility at this point in time.

Al Csontos will address spent fuel safety.

Ray Kellar, who is with Region IV, will address our inspection program.

And last but not least is Tom Palmisano, who is actually with the SONGS unit and will provide the contents of the PSDAR itself.

I did also want to mention that of our staff sitting out here, Keith McConnell, Dr. McConnell, was the manager that was in charge of our recent waste confidence decision, our long-term storage rulemaking, and so Keith is prepared to answer some questions about that initiative if need be.

Chip will lead us into our public comment session, and then at the end I like to make some summary comments and share what I call aha moments, things that we heard that were a big deal.

So let me say that it's about our mission. Our mission, as you see on the slide, is to regulate the nation's civilian use of radioactive materials to protect public health and safety, promote the common defense, security, and protect the environment.

That's our mission during operations. That remains our mission during decommissioning. The entire decommissioning process will be carried out consistent with our regulations and our continuing regulatory oversight to achieve the objective that you see there on the slide defining our mission.

I would also point out that there is a great

deal of interest, of course, in things environmental, environmental impacts. There is a law called the National Environmental Policy Act of 1969, and we have regulations in our regulatory Part you see there, Part 51. This is where we carry out our regulatory responsibilities to fulfill the requirements of the National Environmental Policy Act.

An important part of that is that the PSDAR contains an updated environmental report, and Tom will speak to the contents of that during his remarks.

And then of course ultimately, when we ultimately receive a license termination plan for this facility, we will be conducting an environmental assessment as part of that licensing action.

Our regulations for decommissioning are a set Part in Part 20, so Part E. What's important is to -- what does the term mean. The term means to remove as a facility safely from service, and reduce radioactivity to a level that permits release of the property for unrestricted use and termination of the license, or release of the property under restricted conditions and termination of the license.

I would point out that no nuclear power plant to date has ever pursued the restricted release pathway, and the facility for SONGS 2 and 3 is not doing

that either, they're pursuing unrestricted release.

In terms of the release criteria for unrestricted release, in order for a site to be suitable for release in an unrestricted manner, the dose that must be achieve is a total effective dose equivalent, or TEDE, of equal to or less than 25 millirem, and as low as reasonably achievable.

And achieving that, that means the dose to the average member of the critical group, all pathways, including groundwater, and the period of performance is for 1,000 years.

You also see below it the dose criteria for restricted release. I would note that the criteria is the same except that there are provisions in place for institutional controls, and some criteria if those institutional controls fail, but that's not being pursued here.

Now when you see or you hear 25 millirem, what does that mean? Well, let me give you something to think about.

Millirem is a dose unit of exposure to people, radiation equivalent in man is what millirem stands for.

If you get on an airplane in Los Angeles and you fly to New York, you get about three millirem. The

natural background radiation in the United States, depending upon where you are, ranges from about 300 to 600 millirem.

There are places in the world, though, where the natural background radiation is much higher than that. Saskatchewan, Canada comes to mind, about 4,000 millirem per year.

So at least when you hear that term now, 25 millirem, you'll have some idea of what we're talking about.

I would point out that while our criteria is 25 millirem and as low as reasonably achievable, the decommissioning of nuclear power plants to date have all achieved a level of exposure much lower than 25 millirem, on the order of a few millirem, four, five, six millirem.

This is a very important slide for you as members of the public. In fact, I think it's probably the slide that, if I were you, I would be most interested in, because it tells you what happens in the process, and where in the process you have informational awareness, or where in the process you get a chance to make comments.

On the left you see what the licensee is required to do. In the center is what our agency does.

And on the right, of course, is the public.

There's an initial notification that takes place. It's a cessation of operations, and also a certification that the fuel has been removed from the reactor vessel.

Then, there comes a decommissioning report. That is the PSDAR. That is why we are here tonight.

Now you note that we review that, and we conduct a public meeting near the site, and you, the public, have an opportunity to comment.

I do want to be clear, though, that we don't approve the PSDAR. We review the PSDAR, and the licensee has to wait 90 days while we do that, while we carry out our review to ensure that our regulations are being satisfied, that the PSDAR is in fact adequate to satisfy those regulations. We also go about the comment-gathering process, and we will consider your comments as we continue to carry out our review.

Then actual decommissioning takes place. The reactor is completely decommissioned over a period of time, and Tom will specify tonight in his remarks how long this utility plans to take to accomplish that objective.

And then the next major milestone in the

process is a submittal of a license termination plan. The utility will submit that license termination plan approximately two years before it desires to terminate its Part 50 license, that's the Part of our regulations that we use to regulate power plants, or to shrink the footprint to the remaining independent spent fuel storage installation pad.

That process, that LTP, is something we do review, and either approve or deny, and I think very importantly for your awareness is that the LTP process is a licensing action that carries with it the opportunity to request a hearing.

And if parties, or a party, requests a hearing and achieves standing, then we will carry out a hearing through our adjudicatory process.

Then final decommissioning takes place, a number of final surveys are done, we conduct verification surveys, and all that information is available to you the public through the inspection reports that are generated as we go about monitoring the Final Status Surveys.

And the Final Status Surveys are designed to achieve that dose standard that I cited a moment ago.

This particular slide, the point of showing you this slide is to show you that we've decommissioned

a lot of sites. We've decommissioned on the order of 80 sites, including 11 nuclear power plants.

We have a lot of experience, we have a lot of expertise, and not to sound puffy, because that's not my intention, but I just want you to know we have a lot of experience. We've done this a number of times. And we're going to bring all that expertise and experience to bear as we go about monitoring the decommissioning of this facility as well.

There is a transition that goes on when we move from an operating power plant to a power plant in decommissioning. We have a number of program responsibilities. Just so you know who's on first, I put this slide in. It shows you that the Office of Nuclear Reactor Regulation continues project management until the post-shutdown defueled technical specifications are issued, Doug will mention that a bit in his commentary.

Then the project management is transferred to my division within the Office of Nuclear Material Safety and Safeguards, and we will shepherd it through the entire decommissioning process until the very end.

Inspections continue to take place, and that's transferred to the Division of Nuclear Materials Safety and Safeguards from the Division of Reactor

Projects, and of course, Region IV will carry out that inspection activity, and you'll hear about that from our Region IV representative.

And then, of course, support continues from the Nuclear Security and Incident Response Program within NRC.

So I will stop there. Bruce Watson will follow me and talk to you more about the PSDAR process. Bruce?

MR. WATSON: Thank you, and good evening, and thank you for all sharing your evening with us.

The NRC regulations which Larry went over that carry decommissioning have been in place for over 17 years. Larry went into a little more detail on the Part 20, but the key factor for the reactor decommissioning is in Part 50, specifically 50.82.

These regulations took into a lot of experience that we incurred over the years with some of the initial decommissioning of some reactors in the early 1980s and 1990s.

Some of the key milestones from SONGS so far have been that they ceased operations -- permanently ceased operations on June 7, 2013. We received the defueled certifications for the two units also during the summer of 2013, and on September 23, they submitted

the PSDAR for our review.

We issued a public notice for that PSDAR, and of course the public -- the PSDAR is available in ADAMS, which is our agency-wide document system, and there's the number for putting that in off the public website.

Our guidance allows three types of decommissioning options. The first is DECON, which basically means you're going to do prompt remediation, you're going to begin fairly quickly after you transition the reactor to a state where it can be decommissioned.

That transitioning typically takes one to two years, draining systems, isolating systems, isolating electrical systems and making the plant safer for disassembly.

The second option is SAFSTOR, in which you can allow the plant to stay in a sort of a mothballed state for a number of years.

And then ENTOMB, which we currently do not use and do not have any regulations for and no one has requested, and we don't expect anybody to request entombment, is another option, but not currently available.

But the bottom line is radiological

decommissioning, and I stress the radiological decommissioning, which is what we regulate, the radioactive part of the decommissioning has to be completed within 60 years.

Now San Onofre has chosen to do DECON in their PSDAR, so they're going to begin fairly quickly with their schedule that's in there.

With the PSDAR from SONGS, though, they meet the three criteria that we're reviewing. The first part, major requirement, is a description and schedule for the planned decommissioning activities, so it as a fairly high-level schedule on how they plan to accomplish the decommissioning.

The purpose in this is to allow the NRC to schedule our resource to support inspection activities throughout the decommissioning to ensure that we're there for major activities where we think we should be there to ensure that the work is done safely.

The second item that's required to be in a PSDAR is a site-specific decommissioning cost estimate, including the costs of managing the irradiated fuel. In most cases, this is a fairly extensive document and has good detail in it.

The third thing is that the PSDAR must require -- is required to provide a discussion that

provides the means for concluding that the environmental impacts associated with the decommissioning will be bounded by the appropriately -issued Environmental Impact Statement.

Now, we have a document called NUREG-0586, it's publically available. It is the generic Environmental Impact Statement document where you can look at all the things that have been previously reviewed.

The PSDAR regulations require that we hold a public meeting, which we are doing tonight. We are here to hear your comments and hopefully answer your questions. Like I said, the PSDAR is available for public comment. You can find it, again, at that ADAMS number. We also passed out a number of CDs for your use.

We will accept written comments, like Larry said, and also ones from the website.

The key thing here is that the licensee can begin major decommissioning 90 days after the PSDAR has been submitted to us.

Lastly, I wanted to mention that we have continued our transition activities. One of those transitioning activities is in the inspection area, and Senior Inspector Greg Warnick has been here a little over a year now, and will be here for the near term, as

part of that -- ensuring that the plant continues to be transitioned safely.

And with that, I'd like to turn it over to Doug Broaddus, who is going to talk about the reviews for the PSDAR.

MR. BROADDUS: Thank you, Bruce.

All right. So I am here tonight to talk to you tonight about our review process for the PSDAR, but I am also going to talk about some of the other review activities that we have ongoing associated with SONGS, both their licensing actions that they have, and some other related activities that we have under review.

As Bruce indicated, the -- our primary review is, you know, does the PSDAR contain the information that's required by the regulations? And Bruce talked about specifically those requirements.

The other area where we use as review guidance is in our Reg Guide 1.185. It's a Guide that provides the standard format and content of the PSDAR. So we -- that provides more details as to what information we expect to have in the PSDAR.

So the -- our review process, then, is that once we receive it, our project manager for the SONGS facility will send that out to all, and coordinate with the various different technical expertises that are

needed to look at the various different issues within the PSDAR.

And our general process is, if there's additional information that we need to either confirm that it meets the requirements or that there's specific information that's missing that we need, we'll ask for additional information of the licensee.

So what is our critera? What do we look for specifically from the standpoint of the PSDAR?

There are a number of things that could cause us to either need additional information on the PSDAR, or in fact, to possibly find it deficient.

One is that it doesn't contain the information that's required in the regulations, if it doesn't provide all the information that's specifically required.

The other is if the costs that the licensee have indicated would exceed the costs -- or the funding that they have available to them.

Another would be if they are -- if they haven't fully described the process that they're going to follow, or the process that they have described is one that could not actually be implemented. So we would -- that could cause us to have problems with that.

The other would be that the schedule is --

would not be completed within the 60 year required time frame that Larry mentioned earlier.

The one caveat to that is if the NRC determines that there's a specific reason why a longer than a 60 year period would be necessary, for example to protect public health and safety for a particular reason, then that time period could be extended, but that's something that we would have to specifically review and authorize the licensee to go beyond the 60 years.

All right. And the last thing, obviously, and the most important, is there -- are the activities going to endanger public health and safety?

One example would be if there's no waste disposal facility available, do they have to -- would they -- well actually, I'm sorry that's for the 60 years. If there wasn't a waste disposal available for disposal of the material, it could be that they need to go beyond the 60 years.

But from a health and safety standpoint, that's part of our criteria, just to make sure that the activities that they're doing are in compliance with our regulations and aren't in violation of our health and safety requirements.

All right. Next is, as part of the PSDAR,

a site-specific decommissioning cost estimate has to be provided, and this decommissioning cost estimate has to address the specific -- the overall cost of the decommissioning. It has to provide a good understanding of the costs, the basis for those costs, and it has to ensure, you know, provide enough information to us to be able to say that they have reasonable assurance that they have funds available to complete their decommissioning activities.

The other thing is if the licensee has to change their plans, or if they have unforeseen problems as they go through the decommissioning process, that they have a means of adjusting their cost estimate for identifying new, or identifying new funding mechanisms if they don't have enough money to pay for it.

And that's -- from that perspective, we've heard the question of, so what happens if they get into that type of situation?

So the licensee is required to maintain the level of funding. If they have to change their plans, they have to revise their cost estimate in the PSDAR and submit that to us for a review, and we would look at that to ensure that they've come up with another funding mechanism or some other type of mechanism, or they've changed their approach to ensure that they're going to

have the funding available to complete the decommissioning activities.

And these -- the licensee also has to submit a revision every year to this decommissioning cost estimate, so we're going to see changes as they're happening through the years, and so any problems that would occur, we would see them well before they would ever happen, and we would ensure that the licensee is taking action to adjust those.

As Larry indicated before, NEPA is part of the environmental process, is part of our review. In this case, the -- what the licensee would address in their PSDAR is that they've looked at the environmental impacts of the activities that they're going to take, they've looked at the previous environmental assessments that have been conducted, both for the site -- a site specific assessment that was done for the site as well as the generic final environmental assessment for decommissioning facilities -- looking at those to determine whether or not the environmental impacts they are going to incur for their activities would be bound by those prior estimates.

And so they would have to provide the basis for why they believe that it's met within, that it's within those prior environmental impacts.

All right. And the inspection we do have, as Bruce mentioned, we have an inspection program where they'll go out and they'll confirm that the activities they're doing are in accordance with the prior environmental impacts and that they have the appropriate analyses to support the fact that they don't believe that their activities are going to exceed those prior environmental impacts.

All right. So we are here tonight to get comments back from the public. We are also going to be, as Chip indicated, we are going to be receiving additional comments for the 90 day period after we have gotten the PSDAR, which is through December 22.

We'll take those comments and we'll look at them, we'll consider them in our review as we're reviewing the PSDAR.

In particular, we would be looking to determine whether or not there is any health and safety impacts that would be encountered by their plan.

If we have questions, we will ask additional information from the licensee, we will ask them to provide that additional information.

We -- as Larry indicated, we don't approve the PSDAR, but we will document the completion of our review and determining, if we've determined that

there's no additional information necessary, and we'll document the resolution of the comments that we would receive.

One thing that's important is the licensee cannot start major decommissioning activities until at least 90 days after the PSDAR has been received by the NRC. That gives us the time period to review the document, to receive public comments, and to be able to review those and act on them.

All right. One of the other areas that we are reviewing, it's called the Irradiated Fuel Management Plan.

Within two years after a licensee shuts down, they are required to submit to us an Irradiated Fuel Management Plan that addresses the costs of managing all spent fuel that's at the facility.

And this is not -- it's not -- it's a separate document from the PSDAR, but there is a relationship between the two, because the Decommissioning Cost Estimate has to include the cost of managing the spent fuel.

So although we're not asking specifically for comments on the Irradiated Fuel Management Plan, I wanted to make sure everybody understood that we are reviewing that as well. And that document does need --

was -- is required to be submitted for our review and preliminary approval.

Our review on that will also look to ensure that they've got a good plan for managing the irradiated fuel and that they are able to account for the cost for that as well, that's part of it.

And the other part of it is to ensure that their plan complies with all the requirements for possessing and storing irradiated fuel.

I think that's it. I'm sorry, I almost missed one.

So there are other licensing actions that we're also doing for the plant right now. So as the plant, once it shuts down, the plant transitions from an operating status to a decommissioning status. So to do that, the licensee comes in and requests a number of licensing actions.

Those licensing actions can either be submitted as a license amendment, they could be an exemption from a specific part of the regulations, or they could be a request to rescind an order or have relaxation of an order.

So the types of requests that we've received are for changing the staffing levels of the plant, to change the type of personnel that they'll have

there to focus more on the spent fuel and decommissioning activities; changes to the license condition to address, to more focus on the managing of the fuel activities; there's also been requests to change the emergency preparedness activities given the shutdown condition and the defueled condition of the plant; and we've received requests for previous orders for the licensee to, also to rescind some of those previous orders.

So those are the types of licensing actions that we've had, where we've approved a couple of them -- we're still in the process of reviewing a number of other ones, and we understand that the licensee is probably going to submit some more to us, and so I can't speak to those yet. So that's it.

MR. KELLAR: Good evening, I'm Ray Kellar, I'm from Region IV.

You've heard a little bit from Bruce and Doug, and you will be hearing from Al, about the regulations, the reviews for the licensing conditions, and also about safety reviews and evaluations here in a little bit, but I am going to talk about how it all comes together a little bit, and I am going to talk about the inspection program, particularly in Region IV, from a decommissioning and a spent fuel safety standpoint.

So how do we get safely from a operating plant to a plant that's been fully decommissioned? As Larry mentioned, there's been the opportunity for the Nuclear Regulatory Commission to have oversight of, I believe he said, 11 nuclear plants over the last recent period.

I know in Region IV, we've had several opportunities for decommissioning plants, specifically Trojan, which is near Portland, Oregon; SONGS Unit 1; and we're currently inspecting Humboldt Bay, which is in Northern California.

So how do we assure compliance? The NRC looks at the regulations, which is what we've been talking about; we look at the licensing-based conditions, including the technical specifications, decommissioning technical specifications; also guidance documents, which would be things such as NUREGs. These are all part of the licensing basis which are a part of the inspection when the inspectors go out to do their work.

Also, the safety reviews will be performed. Al will be talking some about the reviews, I am sure, relative to spent fuel storage. And that leads down to the NRC inspection activities, where the inspectors go out using the regulations, using the licensing-based

documents, and they perform the inspections to ensure that the licensee is doing things in accordance with what is safe and what they have been approved to do.

If we find that something is not right, then we will look at the NRC enforcement program and evaluate whether or not that would come into play.

So the regional-based inspection activities will consist of inspection of the spent fuel pool. We will generally look at the higher-risk activities, such as moving the fuel, such as loading the fuel into casks. Those will get extra attention.

During and after remediation activities, we will make sure that we're doing independent measurements to confirm the licensee's survey methodologies.

Additionally, inspection activities will include the spent fuel, that's also in my branch, as well as a movement to the (inaudible), which includes a series of operational tasks and oversight of those activities.

Physical security, while it's not my branch, will still be inspected according to the requirements. And there are a number of inspection plans that include oversight of activities including licensee management and organization; review of the

license safety evaluations, so making sure that their 50.59s have been done correctly; reviews of licensee self-assessments and audits; radiation exposures during decommissioning, transportation, and rad waste, making sure that all the requirements are met for that; as well as effluent environmental monitoring.

So the objectives of the inspection program include the independent verification of the safety of the licensee's activities, the adequacy of the licensee's controls and programs, ensuring that safety programs are promptly identified and the licensee puts effective corrective actions into place, identifying violations that occur and utilizing the agency-enforced policy to make sure that those are disciplined correctly, as well as review and examine any trends that develop dealing with the licensee's safety performance.

Using the inspection procedures, we planned some of the activities up to a year in advance, and the inspectors know what portion of those will occur at what time.

Those activities are coordinated with headquarters. We sometimes bring technical expertise along with us to the site to assist in those program inspections. They may be announced or unannounced, quite often they're announced, but we have the

opportunity to do an unannounced inspection if there's a need to.

We utilize inspection plans that document those procedures and those activities that we want to perform inspection activities of. We have exit meetings at the end of each of the inspections where we do an exit with the licensee and present their findings at that time, and if there's any potential enforcement actions, those are also discussed.

The inspection reports are normally issued 30 days after the exit, that would be for a -- not a team, but a team inspection consisting of three or more inspectors would normally be 45 days after the exit with the licensee before that report is issued.

The NRC enforcement policy, there is a link at the bottom of this slide that shows how you can get to the enforcement policy if you're interested in how the agency performs the enforcement activities.

So what happens after the inspection? After the inspection, the inspectors come back to the region. They brief the branch chief, and there is a debrief that includes NRC management where the findings are presented. And if enforcement actions need to be taken, those are also discussed, along with the enforcement officer, and those activities are followed

through with.

The inspection reports are available in ADAMS, those that are available publically. Security reports, the details are not available, but the cover letter is usually available with ADAMS.

You can go to the link that I show on the bottom half of this web -- this slide, and it shows how you can get to the ADAMS website, the document numbers -- docket numbers, are shown here as well, you can do a search using Advanced Search under those docket numbers using the website for ADAMS, and you can actually look up the inspection reports that way. And we also track and follow-up on inspection reports.

And that concludes my portion.

MR. CSONTOS: Hi, my name is Al Csontos. I am the Chief of the Renewals and Materials Branch in the Division of Spent Fuel Management in the Office of Nuclear Material Safety and Safeguards.

What does that all mean? That's a long-winded title. What we do is we develop and implement the licensing certification and inspection of spent fuel storage facilities, the dry cask storage systems, the radioactive material transportation packages, for the -- with the applicable regulations, 10 CFR Part 71 for transportation, 10 CFR Part 72 for

storage.

We also coordinate with federal agencies like the Department of Transportation, for example, for some of the transportation packages' certifications. Four international bodies, regulatory bodies, as well, IAEA, International Atomic Energy Agency, and our other colleagues around the world.

Some of the things that we've learned in what we've done has been from our interactions with these international participants, and also Native American tribes.

So what are these things? These are spent fuel storage casks. Over here at SONGS, you have the lower-left version. It's a NUHOMS System 1029, okay, certificate of compliance.

What they are is that once the fuel has been cooled in a spent fuel pool that are part of the reactor, it is loaded into these special canisters, for these canisters, they're stainless steel canisters, they're about 5/8ths of an inch thick, and they're designed for the specific fuel that's at these sites, these reactors -- either a pressurized water reactor or a boiling water reactor.

The canisters are then vacuumed down, take all the water out, and they are backfilled with inert

gas. That inert gas is usually helium, and it has a purpose of helping with the cooling of these canisters, and also to -- just to stop any kind of corrosion from occurring on the inside of the canisters.

So they're welded, they're vacuum-checked, they're leak-checked -- when they're vacuumed down, they're backfilled, and then they're checked for leaks, helium leaks. And then once they've passed all those rigorous tests and all the fabrication requirements and the quality assurance procedures, they are put into these casks.

And what these are, these concrete -- does this have a -- so right here, that's about five feet of concrete. And so that helps with the shielding, the bioshielding from radiation, as well as structural, for seismic concerns.

And so these are the ones that you have at SONGS presently. There is a third one, I know that you all were working with two vendors recently, and there's a third one that's -- this is a vertical system that multiple companies develop, and there's a third one that's an underground system that I didn't show here.

So we have a total of 71 total sites in the United States by this map. These are independent spent fuel storage installations.

There are, in 34 states, there are over 2,000 casks that have been fabricated and are in place, with over 82,000 fuel assemblies. They are all across the country. There's 56 in -- this is, it gets into some regulatory jargon here, but 56 General Licensed Sites and 15 Specific Licensed Sites.

And there are seven at decommissioned sites that will be similar to what is here at SONGS.

What is the difference between a general license versus a site-specific license? A general license is only granted to Part 50 licensees, reactor licensees. They require us at NRC, in our division, to review those cask designs.

We review them for certain things that I'll go into in a little bit, and then we do the site evaluations and such, and then the site-specific cases are specific to Part 50 reactor licensees or other applicants that would like to have -- would like to store this waste at their site.

So, like, for example at Private Fuel Storage in Utah, that is an SSC, a site-specifc, SSC, has no reactor there, but they were willing to take fuel if they were allowed.

So Part 72 regulations. What are our review areas? What do we do in our daily jobs? We

review the general design criteria, making sure that they meet the requirements for offsite radiation dose, subcriticality, and confinement.

What does all that mean? Confinement, we retain and make sure that the radionuclides in the fuel stay within the canister. For subcriticality, we don't allow any type of -- we make sure that the fuel is sitting in there so that they never get a place where they can go into a critical state. And offsite radiation dose, we have sensors around the associated pad to make sure that there is no dose that is beyond the requirements, the regulations.

We also have quality assurance programs, that's what Ray was talking about earlier. We fabricate these canisters -- or not we, but the licensee buys them from a fabricator -- and we make sure that they're done in a quality fashion.

Physical protection security, sighting, reporting requirements, and then training and certification of the personnel at the sites. We review all of those.

This takes a lot of people. And what we have is we have a cadre of subject-matter experts. We have structural engineers, we have thermal engineers, we have criticality specialists, we have health physics

folks who do the shielding and radiation protection.

We have materials folks like myself who look at all the materials issues, the corrosion issues, all the material properties issues, making sure that the confinement is maintained, and also making sure that the quality assurance folks are out there. Those are the inspectors, in a lot of ways.

So, what do we also look at? We look at three different types of scenarios -- normal, off-normal, and accident conditions. Normal and off-normal, normal occurs regularly, repeatedly. Off-normal is occasionally, once a year, maybe. And then accident conditions are things that we make sure that the licensees, make sure that these are fabricated to withstand these types of events -- tornado winds, missiles, earthquakes, seismic activity, floods, tsunamis, and fires and explosions.

Again, the technical reviews are quite long, and a lot of our reviews for new applications can be two, three years, okay?

We have structural engineers who look at the confinement that are maintained under all these accident -- the accident, normal, and off-normal conditions. We have criticality folks who look at making sure the fuel is sub-critical in all these three

cases. Shielding that meets the radiation dose requirements at the site boundaries -- and then the thermal, making sure the cladding temperature is maintained so we have a defense in depth, so we can rely on the cladding.

And then the materials folks, who look at the property or properties, and also aging effects, during the renewed operating period, and I'll go into that a little bit later.

So for transportation of these systems, the same technical reviews as for storage. There is a little bit more in terms of, you need to show us, to the licensees that are out there, you need to do a bunch of tests.

Those tests are drops, 30 foot drops, they're puncture tests, they're deep water immersion tests, making sure that nothing will ever come out of these canisters. Fire -- there is a 30 minute requirement for jet fuel, making sure it doesn't fail in that way -- and all these other normal types of transportation, vibration loads, small drops, heat and cold.

Cold is a big deal. Some licensees have been rejected because they can't meet the requirements for transportation at -40 degrees Celsius.

So now, storage renewal. So what are we doing now, the things that are changing on the landscape here.

There are two periods. There is the initial licensing period, which is the first 20 years. And then after that, it's between 20 and 60 years is the renewed operating period, okay?

The renewal, renewed operating period, has been going through some updates of late, and so what we've done is we've established a group at the agency, a strategy team, and what we've done is we've been trying to look at what we can do to update the guidance, because what we're looking to do is we're looking to change our approach to spent fuel management in the renewed period of operation to an operations-focused aging management, one that is learning from our operational experience.

It's proactive to get ahead of issues that, possibly, for degradation aging effects of canisters. You all know that your cars don't last 100 years, or 50 years. And they age. And the same thing happens to canisters, or anything that's manmade, and so we're trying to get ahead of these, and we're trying to be proactive and have a responsive aging management, so if we do find anything, we go over and fix it, or require the licensee to fix it.

So what that requires is aging management programs that we're developing in-house, and we're developing these guidance documents out there to help the licensees with how to manage aging as time goes on.

So two issues that have come up that have been recently dominating a lot of our discussions.

One is cladding integrity and high burnup fuel, in particular. And the second is chloride-induced stress corrosion cracking, which I'm sure we'll hear a lot about today.

We have spent at the agency over $9 million over the past eight, nine years. We have spent an inordinate amount of staff resources on these issues. We feel we're getting ahead of these issues now, okay?

We're developing aging management programs for both, and we're -- we'll discuss in a little bit, and you can ask a lot of questions, but in 1927, NUREG 1927, that will be coming out this springtime sometime, and we will have these aging management programs, these draft ones now, but they will be placed in there, to show how we are going to manage these aging effects.

But ultimately, we believe high burnup fuel is safe for storage and for transportation. We have licensed both high burnup fuel for storage and for transportation. Recently, we had the MP-197 that we've

approved for transportation casks for use of high burnup fuel, okay.

We have other research that we're doing right now, at Oak Ridge National Labs, and we also are also working with the Department of Energy for their Cask Demonstration Surveillance Project.

We have an information notice on chloride SCC, chloride stress corrosion cracking, I hate to use acronyms.

And we're also developing this aging management program that's part of the NUREG 1927 that we can talk about at length if you wish.

So in summary, our regulations in 10 CFR 71 and 72 ensure safety for both storing and transporting spent nuclear fuel. We have a large group of people who have a multi-disciplinary technical review for all of the different issues that I identified, and we are maintaining confinement under routine and accident scenarios for these canisters.

We're going forward with an operations-based aging management program, and it's going to be a learning, proactive, and responsive program for renewals and for aging management.

And you can read the rest. We're creating a stable, predictable, and efficient renewal regulatory

framework, with clear, open, and transparent, reliable, regulatory expectations to the licensees to manage aging.

I think that's it.

MR. PALMISANO: Good evening. I'm Tom Palmisano, Vice-President and Chief Nuclear Officer for the San Onofre Nuclear Plant.

I've seen a number of you before in community engagement panel meetings, and I am going to cover the specific Post-Shutdown Decommissioning Activities Report that we submitted, and summarize what's in the report, talk about the different periods for the decommissioning plan.

I'll summarize the Irradiated Fuel Management Plan, and I'll also summarize the Decommissioning Cost Estimate.

So before I get into the specific remarks, Southern California Edison and our other co-owners issued some decommissioning principles early this year to provide clarity and guidance in terms of the principles we will follow in developing the plan and executing the plan to decommission San Onofre.

Particularly, our principles are safety, stewardship, and engagement -- safety first, safety in terms of all the activities, safe storage of spent fuel;

stewardship in terms of being good stewards of the environment, good stewards of the decommissioning trust fund, recognizing this fund has been contributed by our rate payers; and engagement and transparency.

The Community Engagement Panel, which a number of you have been at the meetings, is part of our effort, our outreach effort, to engage the community, to be transparent in what we intend to do, and to listen actively to feedback.

I would encourage you to visit songscommunity.com. All the documents I am going to discuss tonight have been posted throughout the course of the last six months on songscommunity.com, so they're not only available on the NRC website, but they're readily available on our website, along with more detail.

So just to recap, you've seen some of these time frames before in the NRC presentations. June of 2013, we decided to permanently shut down both units 2 and 3. We certified permanent cessation of operations, one of the regulatory requirements.

We also at that point certified we had permanently defueled. The dates, I didn't put those dates on this slide, they were on the NRC's slide.

Through the course of 2013, we transitioned

from operating plant staffing to decommissioning staffing, and in January 2014, we developed a 20 year decommissioning plan that we submitted as part of the Post-Shutdown Decommissioning Activities Report.

As you've heard, by NRC regulations, we have up to 60 years to complete the radiological decommissioning of the plant.

As we look at the situation at San Onofre, as we listen to feedback from our stakeholders, as we look at where our trust fund is, we think the right thing to do is to go into the prompt decontamination and dismantlement process and decommission the plant in basically a 20 year time period, and I'll show you a little more detail in a minute.

And then in September 2014, we submitted the required decommissioning documents, the Post-Shutdown Decommissioning Activities Report, the Irradiated Fuel Management Plan, and the Decommissioning Cost Estimate.

So let me give you the highlights here. Those of you who have been at the Community Engagement Panel meeting have seen this slide before. This is a simple look at the 20 year timeline for decommissioning the plant.

The top line is not to scale. To the left

of the bold vertical line is between now and January 2016, so we are not in the major decommissioning phase at this point. We need to submit the NRC documents we have done. So everything we're doing to the left of that line is planning and preparatory activities, and the licensing submittals to change our design and licensing basis.

There's a variety of physical plant changes we make such as defueling the plant, draining systems, eliminating non-radioactive hazards.

There's the licensing submittals, this was referred to as some of the other licensing actions we've requested, for example defuel technical specifications that changes the conditions of the license to match the fact that the plants are defueled; the specific decommissioning submittals that I've talked about; and then the dry fuel storage system.

I am going to talk about dry fuel storage more in a minute. We already have a system on site with 50 canisters loaded with fuel that needs to be expanded to allow for the decommissioning process.

So we're in the process, and we've discussed this extensively at the Community Engagement Panel, of selecting the best plan to expand the system and load the remaining canisters.

Then to the right of the heavy bold line is actually the balance, first of all, of the decontamination and dismantle period. It's about a ten year period where we do the major decontamination and dismantlement, and then farther to the right, you see words like completion of remaining site restoration work -- that's the non-radiological site restoration, as well as the License Termination Plan.

On the NRC slides you saw, that's the formal process where we submit the License Termination Plan, submit the Final Survey Plan, and execute that plan subject to NRC review and approval.

And then at the end of that 20 year period, the plant is decommissioned, it's dismantled. What will remain is an independent spent fuel storage installation, and that will remain until the Department of Energy starts taking fuel off the site, and we'll see more about that in a minute.

Post-Shutdown Decommissioning Activities Report, we've heard a lot about that, so I'll just summarize this very quickly.

We have submitted a report that meets the regulatory requirements. It describes the planned decommissioning activities. It provides the schedule for the activities. It summarizes the expected cost.

And it has the discussion of the environmental impacts and concludes that our planned decommissioning activities are bounded by the site-specific environmental assessments that exist and the NRC's generic Environmental Impact Statement for decommissioning.

So our Post-Shutdown Decommissioning Activities Report meets the regulatory requirements. It is under review by the NRC.

So I want to go in a little more depth in terms of what the three elements of the PSDAR are. The license termination, and that is equivalent to radiological decommissioning; the used fuel management program; and site restoration, think about that as the non-radiological decommissioning to finish restoring the site.

This next graphic is just a bit hard to see. This actually runs out to 2052. I am going to show you more detail that's more readable here in a minute.

The green is going to be the license termination periods, or the radiological decommissioning periods; the orange in the middle, or the yellow in the middle, is actually the used fuel management periods that will go through the first 20 years and then extend out as far as 2052; and then the

red is the site restoration period, think about this as the non-radiological decommissioning, once the NRC aspects of decommissioning are complete.

So we've created some graphics based on some feedback from the public and the Community Engagement Panel to try to make this a little more visible.

Again, all these slides will be publically available on our websites, and I'm sure the NRC will post these as well.

So, and I've also tried to indicate the time periods and the types of activities.

So we're talking about license termination or radiological decommissioning on this slide. If you look from the left, June 2013-December 2013 defueling both reactors, certifying the reactors were defueled.

We're actually in Period 2 now, where we're doing the initial planning. And the initial planning is essentially complete, it's relatively high-level planning, and we're making the NRC submittals.

So this is the initial planning phase where we identify what the 20 year decommissioning plan is, the expected cost, and the summary of the activities.

Once we enter the major decommissioning phase, which we are not in, starting as early as July

of 2015, we'll start major decommissioning activities.

This will be system decontamination to reduce the radioactivity's level inside systems. This will be starting the planning, and then as we get into later in the period, removing the internals of the reactor vessel. This, other than the fuel, is the most radioactive part of the plant, done underwater. This is done early in the process.

This would be something 2017, late 2016, 2017, would be a rough timeline for that to start.

And later in this period, and I'll talk about spent fuel more in a minute, we will be offloading the spent fuel pools, actually moving fuel likely in the 2017 time frame to an expanded ISFSI (phonetic) system.

Period 4, then, once the fuel pools are offloaded, we'll get into the system-enlarged component removal. At this point, we've reduced the level of radioactivity in the plant, we've moved the fuel out of the spent fool pools into the ISFSI or dry fuel storage system, and then we'll start removing the major components inside those reactor containment buildings and the other safety-related buildings.

At the end of that period, then, October 2022 - July 2024, we're in a period where we're decontaminating the buildings, once the internals have

been removed, and ultimately in Period 6, 2024 to 2032, we're actually demolishing the buildings themselves.

So that's roughly what a 20 year plan from 2013 to 2032 looks like, for the radiological decommissioning of San Onofre.

Let me move on to used fuel or spent fuel storage. So this is a companion timeline. Again, we're in the planning period. We're now in Period 2. We're evaluating how to expand the independent spent fuel storage installation, preparing for the transfer of used fuel from the spent fuel pools to the ISFSI.

This period for spent fool management runs from 2014 to 2019. Our intent is to safely move spent fuel out of the spent fuel pools to the dry fuel storage pad in a safe and timely manner. We intend to finish that by mid-2019.

The following period you see, 2019 to 2031. This is an extended storage period where all the spent fuel is in dry fuel storage on the independent spent fuel storage pad.

Period 4, we're expecting the Department of Energy, at some point, to start taking fuel off our site and other sites around the country. Based on the current information we have from the Department of Energy, the old Unit 1 fuel, which is already partially

decommissioning, and all the Unit I fuel is already in the spent fuel system, would be removed first, starting roughly in 2031 through a 2035 time period.

And then the Unit 2 and 3 fuel, with what we currently understand the Department of Energy timing would be, would be removed from 2035 to 2049.

This is part of a bigger nationwide plan that the Department of Energy has to remove fuel from all the reactor sites, operating sites and decommissioning sites.

This is where we understand we would be in their queue to remove fuel from San Onofre.

And then ultimately, 2049 to 2051, with all the fuel offsite, we would then decontaminate and demolish and remove the independent spent fuel storage installation and go through a second license termination period related to the spent fuel storage system.

Site restoration, so think about this as now the non-radiological decommissioning. Again, we're in the planning period. You see a transition to site restoration.

We're actually -- the mesa is property on the other side of I-5, not part of the NRC's Part 50 license where we have warehouses and storage areas and

a training building, we're actually removing some buildings there presently. That's not a decommissioning activity, it's part of turning the facility back to the Navy.

You then see Period 3, and this is probably more operative for the power plant itself -- 2019 to 2024, you know, consistent with moving fuel out of the spent fuel pools, decontaminating systems, major component removal, we start the engineering for the sub-surface removal, engineering and permitting at that point.

And actual sub-surface structure removal is in the time frame 2028 to 2031. This will then follow the major component removal, the major building demolition, and then continue with sub-surface structure removal.

I think it's important to note at this point, San Onofre is on land owned by the Department of the Navy. So the power plant itself is under what's called an easement dating from the 1960s which granted the owners the right to build and operate a power plant on the facility.

So as we talk about completing decommissioning, we're committed to unrestricted, you know, release for unrestricted use, and you've heard

some of what that implies earlier, but ultimately the end use will be determined by the Department of the Navy.

So we have some work to do with the Department of the Navy to finalize exactly what their end use is, exactly what condition they would like to leave the -- use to leave the site in.

For example, most facilities that have been decommissioned don't necessarily remove every below-grade structure once the radiological decommissioning is complete.

So that's something that is up to the Department of the Navy. When I talk about the cost estimate, I'll tell you we've conservatively assumed we remove it all until they specify differently.

So this is what the completion then of the site restoration -- you see at the far end the ISFSI demolition.

Again, after the fuel is removed from the site by the Department of Energy, the remaining step will be the radiological clean-up of the spent fuel storage installation, followed by the demolition, and then a second licence-termination period.

That's a brief summary of what's in the Post-Shutdown Decommissioning Activities Report, I really encourage you go to songscommunity.com and take

a look at it.

We've shared it extensively with the Community Engagement Panel and other interested members of the public, but it's available to everybody.

Our Irradiated Fuel Management Plan, it was mentioned that this is not a PSDAR document itself, although it is summarized in the PSDAR and the Cost Estimate. But it's another important submittal.

Excuse me.

So the current dry fuel storage situation in San Onofre, we already have 50 canisters loaded with fuel. As was mentioned earlier, we have the horizontal NUHOMS systems by AREVA TRANSNUCLEAR -- 50 canisters of fuel, I have one canister of what's called greater than Class C waste from the Unit 1 decommissioning. This is the internals of the reactor vessel.

On the upper left, you see a picture of the site, and to the upper left of that, you see a rectangular box. That's where the facility is located.

And then on the lower right you see a close-up of the above-ground horizontal system that is currently in use.

Our current state on spent fuel storage, on the left side, we have 2,668 fuel assemblies in the two spent fuel pools, roughly 50/50 between Unit 2 and Unit

3, right.

Below that, you see existing dry fuel storage pad, it has Unit 1, 2, and 3 fuel in 50 canisters, 1,187 assemblies.

What has to happen, the 2,668 assemblies in the pools called wet storage will be transferred into approximately 100 canisters. The exact number of canisters will be determined once we finalize our decision on which canister design to go with.

Those of you who have been at the Community Engagement Panel meetings know that we're looking at a couple alternatives.

That's an approximate number of canisters, the number of fuel assemblies is accurate. It also includes 1,115 high burnup assemblies, and you've just heard a bit about high burnup fuel for storage and transportation.

So ultimately, we will have roughly 125 to 150 canisters, again, depending on the final design, on the independent spent fuel storage pad by mid-2019, awaiting removal by DOE offsite.

The Irradiated Fuel Management Plan itself is required by 10 CFR 50.54(bb). Again, there is a specific NRC format, specific NRC content guidelines.

It provides a written notification

discussing the plan that's required within two years following permanent cessation of operation, we filed that September 23.

It describes the program by which we will manage fuel and funding until the Department of Energy picks it up.

Our program is wet storage until 2019, followed by dry storage.

I've already given you these numbers -- 2,668 assemblies in the pools, an assumed start date of Department of Energy taking fuel from the industry of 2024, our target removal date from all our fuel off site is 2049.

We demonstrate that we have adequate funds already collected and invested in our trust fund for spent fuel management for this period.

And it also describes how we're going to maintain the spent fuel pools while they are in service.

Moving on to the third NRC document we submitted, it's the Site-Specific Decommissioning Cost Estimate.

And you've heard this alluded to, so I just want to summarize this.

Again, it's a required filing. This needs to demonstrate that we have adequate funding,

principally for radiological decommissioning.

Think of this as a companion, then, with the Irradiated Fuel Management Plan that discusses adequate funding for spent fuel management.

It also discusses the funding we have available for the non-radiological decommissioning. The NRC's focus is radiological decommissioning, and separately, spent fuel management. Our focus is that as well as site restoration.

So the plan discusses the decommissioning plan, describes funding, breaks down costs by the periods that I just showed you briefly, summarizes the things like the cost of services, undistributed cost, and outlines the cost for license termination, spent fuel management, and site restoration.

There are some key assumptions. We have developed a very conservative decommissioning cost estimate.

And I just want to highlight a couple things, for example, substructure excavation. This gets back to what the Department of the Navy will require.

For the cost estimate, we have assumed all the structure has to come out. So we've estimated the cost to assure we have adequate funds if the Navy would

like us to remove all the structures in accordance with the amendment, the current easement, we have adequate money to do that.

We've assumed the ocean conduits, these are the large pipes that bring intake water and discharge water from the plant into the ocean, that they are removed, and the cost of that is in the cost estimate.

For the Unit 1 decommissioning, the State Lands Commission approved a plan to abandon the horizontal conduits in place as more -- a more preferable alternative, as opposed to removing them, form an environmental standpoint.

I expect we will have the same treatment for Unit 2 and 3, from a more preferable alternative, but I have not assumed that for cost purposes. I have assumed the cost of removing them completely.

And you see some other things in terms of low level waste burial escalation, cost -- consumer price index for the D&D period followed by a higher escalation rate until we demolish the ISFSI.

So the real picture here, in 2014 dollars, the total cost estimate down at the lower right is about $4.4 billion, to decommission San Onofre completely, manage spent fuel through 2052 and decommission the independent spent fuel storage installation, and

remediate the site in accordance with the current direction of the Department of the Navy.

You see the breakdown. The green is actually the radiological decommissioning portion, $2.1 billion.

Down at the lower left, the yellow would be $1.276 billion. That is spent fuel management through 2052.

And then $1 billion for site restoration, the non-radiological cleanup of the site and removal of buildings.

As I mentioned in the stewardship principle, the trust fund is really rate payer money that we have collected and we have invested, and through prudent investment, the fund has grown significantly.

We are adequately and fully funded today. Oversight of the trust fund -- it's overseen by a five member committee, two of whom are internal to company, three external, nominated by management, confirmed by the Edison board, and the three external members approved by the PUC.

So the fund has good oversight with independence from the PUC, from a regulatory oversight. The NRC, the second bullet, regulates all radiological decommissioning, and the NRC regulates used fuel

management.

I cannot -- I am limited as to what I can spend on the decommissioning fund from an NRC perspective until the documents we have just filed are reviewed, the 90 day period is elapsed to allow them time to review and comment on it.

However, probably more fundamentally, the Public Utility Commission regulates the fund closely. So before monies can be withdrawn out of the fund and used for decommissioning, not only do we satisfy the NRC requirements, we have a Public Utilities Commission process to satisfy as well.

And both groups, the NRC and the PUC, will be involved in an ongoing basis in the -- ensuring the fund remains adequate, and then the PUC, making sure the fund is spent prudently.

In terms of open communication, public engagement, and education, there is a lot of things we're doing -- I have mentioned the Community Engagement Panel, and everything I have just covered, we have covered in multiple Community Engagement Panel meetings, and it has been posted on the website.

We really want this information available to the public, we really welcome questions.

We have held decommissioning education

fairs. We have had one in the local area. We've got another one coming up in the evening, where members of the public can come in and we talk about decommissioning.

We have public walking tours. We have now held two tours, open to the public to sign up, typically ten people.

We welcome anybody to come walk through the plant. We stay outside of the protected area, but you get a good view of the plant, and our staff explains our decommissioning plan and the decommissioning process.

Private tours for key stakeholders, be they elected officials or other interested parties, as well as a robust website with all this information and more -- and again, we want to make sure we're doing everything we can to communicate openly and listen actively.

And with that, I'll close and turn it back to the NRC.

FACILITATOR CAMERON: Thank you, Tom.

And there's a lot of information, and we're going to go out to you now.

And there were some sign-in sheets when you came in. I am going to try to follow those, but you may have a question, you didn't sign up that you wanted to speak, but there is going to be a meeting summary

prepared by the NRC that will be on the website, and there will also be the webcast.

So let's hear from a few people, and then you've been sitting for a long time, so we'll take a short break then, but you've heard the Community Engagement Panel mentioned, and we have several members here from the Community Engagement Panel.

But I am going to go to Dan Stetson first, for some comments from the Panel.

MR. STETSON: Thank you very much. My name is Dan Stetson, and I am the secretary for the Community Engagement Panel.

I want to once again compliment SONGS, Southern California Edison, for putting it together. We've had quite a number of public meetings where you've been able to come and ask questions, and we welcome those.

We've even had continuing workshops at the Ocean Institute where I work on an ongoing basis.

A couple of us had the opportunity to come and meet this morning -- David Victor, who is chairman of the CEP, Tim Brown, myself, and we were able to meet with some members of the NRC, and I just wanted to share with you just a couple quick takeaways from that meeting.

Number one, a big takeaway for me was that the NRC is not going away. They are here with us every step of the way. There are eyes, there are ears, there are inspectors, and they're the ones that are really going to walk us through this entire process, through the decommissioning and then also through the continued storage of the fuel there on site.

So that process is going to be very important, and we are really looking to them to manage this.

Also, as I looked out in that room this morning, I couldn't help but be impressed with the depth of experience of the folks that are there.

Quite honestly, they are different than you and I. We think we all speak English, but so much of it comes across as Greek. But I want to thank them for trying to bring it to a level, even this evening, something that we can all really understand.

But no matter what, I think we're all really interested in one thing, and that's the ongoing safety for this storage.

We know that the fuel is going to be there for an extended period of time. We don't really know how long. We want it out of there as soon as possible.

But as Al was saying, none of our cars are

going to last for 100 years, and something is going to need to be done if something comes up, so all of us are interested, if the worst case happens, do we have the plan and the resources to take care of us?

All of us want to trust, but we need the NRC to validate our trust. Thank you.

FACILITATOR CAMERON: Thank you, Dan. Another organization that started very soon after the decision was made to shut the plants down was the Coalition to Decommission San Onofre, and we're going to go to Gene Stone.

MR. STONE: Hi. I am Gene Stone from Residents Organized for a Safe Environment. I am also a member of the California Edison CEP, and I am happy to do that and happy to be here tonight.

I would like to thank the NRC for hearing our comments today, and I am happy to see so many friends that are here to support this whole process and the environment.

I must say that I am not really happy because I no longer believe that California Edison is considering doing the state-of-the-art decommissioning that they promised at the first Community Engagement Panel, nor do I believe that the NRC will demand or require that of them, but, unfortunately, a more

standard approach to decommissioning.

The NRC should have a more proactive approach to California's PSDAR. The fact that the NRC does not approve or disapprove this minimalist approach to the safe storage of nuclear waste is very disappointing and alarming to me.

Going forward with a plan that uses canisters that were designed for short-term storage does not make sense. It seems that we would be better served if the NRC would take a stronger approach in leading the industry into developing a much more robust canister system with defense in depth, not just talking about defense in depth, but real action items that the public can see that will help us in any situation that might arise.

Thank you very much.

(Applause.)

FACILITATOR CAMERON: Okay, thank you. Okay. And we're going to try to get to you, as many of you, as possible.

And unfortunately, it is just going to be one bite at the apple, so to speak, okay.

And if you have a question, you may want -- we can give you a follow-up on that, and the NRC has also told me that besides the comments that are going to come

in, the written comments, that if you send a question into them, that they will try to answer that question.

So if you don't get a chance tonight, we'll do that. And let's go to Donna Gilmore. Donna?

MS. GILMORE: Hi. I have been studying the issue, and what Gene said is correct.

We do not have a defense in depth system. We have 5/8s inch thick stainless steel that's the only thing keeping us from having a radiological accident that could result in us evacuating.

The canisters are subject to something called stress corrosion cracking. We do not know, of any of the canisters that are currently at San Onofre, we don't know if they have corrosion on them, we don't know if they have stress corrosion cracking, because they haven't looked at any of them, it's too dangerous for the workers to do that.

The canisters cannot be repaired. We're looking at potentially replacing canisters. There's no money in the decommissioning fund for replacing canisters.

There are canisters used in Europe and other countries that are much thicker, up to 20 inches thick, that were designed for maintenance, that were designed to be able to replace them, when and if they

wear out, and the ones we have are welded, weren't designed being opened.

Their part of the plan is to get rid of the pools. If we needed to replace a canister, we need the pools, but the NRC plans to allow them to get rid of them.

So yeah, I am not happy with this plan. I have got a website, sanonofresafety.org, and I have been keeping track of this. Everything is resourced with technical documents.

There was a lot of misinformation in the presentations, a lot of half-truths in the presentations, so I encourage you to check the sanonofresafety website to learn the part that was left out of this meeting. Thank you.

(Applause.)

FACILITATOR CAMERON: Thank you, thank you Donna. Let's go to Rochelle, Rochelle Becker.

MS. BECKER: I'd like to frame my comments on several NRC regulations that you pointed out that you're going to follow in this process.

The problem with you pointing out that you have NRC regulations, policies, processes, is a recent OIG report that said that didn't work when you replaced the steam generators.

So I have no idea why we're supposed to

trust you with the back end of the nuclear industry.

You didn't do the job right. You didn't require a license amendment request. We are sitting in the Public Utilities Commission trying to decide how much Edison gets, how much rate payers get back.

Rate payers are disgusted with this process. When the NRC fails, it is my wallet that this money comes out of, not yours.

When Edison fails, they try to argue that shareholders deserve more money than rate payers. Rate payers have very little input in this process. Rate payers pay virtually every penny of this process.

We are very tired of you telling us you have a policy, a procedure, a process that works. You don't. And we don't know that until it fails, and when it fails, we pay, and we're tired of doing so.

(Applause.)

FACILITATOR CAMERON: And Marnie (phonetic)?

MS. GLICKMAN: Thank you, I don't even know where to begin.

I have the Environmental Impact Report here that hasn't even been talked about, that anyone who reads it knows that it has to be old information. It can't possibly be what we know today about the hazards

for San Onofre becoming a long-term nuclear waste dump.

I am asking so much that you, both in Edison and our Nuclear Regulatory Commission, actually get involved with not passing the buck, not saying it's not our fault, we just have to stick to what we have as our possibilities.

I see that the regulation on the re-licensing these casks that now can't even possibly last with salt corrosion on the ocean as long as you're going to allow them to stay there, even if it's the minimum of 40 years.

It's not until spring that your 1927 regulation is going to talk about how we even take care of the process of checking these. We know now we don't have a way to.

I am asking for leadership at all levels and changes of the law. We can't leave that fuel on the ocean. It has to be moved. The fact that this plan is backwards, it is decommissioning the contamination that most of us could survive first, with our $2 billion.

They've changed even the term so that it seems like it's more important. None of us care if those domes go away.

We've gotten used to seeing them. We're not going near them. Leave them and leave the money in

the rate payers trust fund until all the fuel is off of location, somewhere away from the ocean. It is dangerous every day.

We have both security that I ask you to look for. You say you can't approve, but you do get to choose, you get to give waivers. Don't reduce the security.

Force an inspection of the 50 casks already there. Don't change the rate payer trust fund priority. Leave all $4 billion until all the fuel is gone.

And please, make sure that we don't lose priority in the government, DOE, coming to get our fuel by some way of Edison and the DOE changing the priority.

We need your help. We need our legislators' help. Let's get it moved to a place in the desert, away from the ocean, having the DoD help us get it there now, tomorrow. Thank you.

(Applause.)

FACILITATOR CAMERON: Thank you, Marnie.

We're going to go to Cathy Allen.

MS. ALLEN: Good evening. My name is Cathy Allen. I work at Age Well Senior Services in south Orange County.

We serve approximately 400,000 seniors

annually in south Orange County, and I have -- on behalf of them, I have a two part question for the NRC.

What is the NRC's process over time that there are enough funds available to maintain the dry cask storage on site indefinitely until the DOE resolves the regulatory issue?

What frequency do you perform an analysis, and what is the level of effort?

Thank you.

FACILITATOR CAMERON: When you say "level of effort," can you just explain that a little bit?

MS. ALLEN: The level of effort for your analysis.

FACILITATOR CAMERON: Okay. Do you understand the question, Larry?

MR. CAMPER: I was just going to say, is it financial analysis?

FACILITATOR CAMERON: Okay. So we're talking about finances. Can we -- who wants to give a -- okay, this is Mike Dusaniwskyj. Mike?

MR. DUSANIWSKYJ: Good evening. My name is Michael Dusaniwskyj. I am an economist with the Nuclear Regulatory Commission, and I am charged with making sure that the kind of question that the last question raised is my responsibility and my team's

responsibility, to ascertain the reasonableness that there will be enough funds to decommission and to take care of spent nuclear fuel for the foreseeable future.

The point that must be remembered is that the spent fuel is really the property of the Department of Energy.

Once it leaves the San Onofre Nuclear Generating Station's footprint, it is no longer in the custody of the licensee.

Until that time, there is enough funds to take care of the foreseeable future. Now, as far as what the lady is asking, is what happens beyond a certain period of time, I will be frank and honest with you.

Whatever possibilities may happen into the future, which all of us can postulate their own possibilities, we have to reason only with what is reasonable to what is required by the regulations, and what the Department of Energy's foreseeable future is in stake.

I am going to have to say something you are not going to like, and that is the fact that if you postulate some possibilities that the funds do run out, the solutions will not be popular. The financial solutions will not be popular.

But the point that must be remembered is

that the NRC does not regulate commerce. That is under the jurisdiction of the state Public Utility Commission, and it is our responsibility to make sure that all activities are done safely and completely.

And we recognize that safety takes money. Therefore, the NRC will not compromise on any level the safety of taking care of the decommissioning and the spent fuel nuclear -- excuse me, the spent fuel that's on site.

As far as how often we do the analysis, by regulation the licensees have to submit to us certain financial information that we look at to make sure that the foreseeable forecast is reasonable.

We want to make sure that the money is used exclusively for decommissioning. We check this once a year.

We also check on how much money is left. We keep checking on this until the license is terminated.

FACILITATOR CAMERON: Okay, thank you. Thank you for that question.

I am going to go to this gentleman here, this gentleman here, and then to Ace and Sharon Hoffman, and then we're going to take a break and come back. Yes, sir.

PARTICIPANT: Thank you. In regards to

the economic analysis you're performing, I want to know if the NRC, and you specifically sir that just answered the question, have you taken into account that recently at Diablo Canyon, you found the conditions for stress corrosion cracking after only two years in the task?

And you certified these, the NRC certified these, that they would be good for 30 years.

Now, my guess is, sir, that that two years takes your analysis and puts it on its head. And I want to know if you've considered that.

Furthermore, Tom, you've got some stones, talking about the California Public Utility Commission with all the news in the paper today about how they're under investigation, and how they're submitting all their paperwork. Really?

Now, as far as the car analysis goes, the casks that you guys are considering won't crack for -- excuse me, the casks that you won't consider won't crack in a marine environment.

Again, the casks that you guys are refusing to consider have the ability to be repaired. Everybody wants to repair their car. We also want the casks to be repaired.

The casks that you are not considering do not have the ability to inspect the exterior of the

canister.

You're saying that the industry has to come up with the solution in five years, but the NRC has given time and time again extensions to these kinds of rules.

We want it done now before it is approved. You guys, or the NRC, excuse me -- the casks that you guys are not considering do not have an early warning system before a radiation leak, i.e., you have no oil light for your car.

That's a major problem. You're expecting the public to accept the fact that you're going to go around and kick the tires on the car to ensure that there's some sort of integrity. That's a joke.

FACILITATOR CAMERON: I am going to have to ask you to finish up, sir.

PARTICIPANT: Thank you.

(Applause.)

FACILITATOR CAMERON: All right. Let me -- is Val (phonetic) here?

Oh, good, Val tries to keep control of Local 89.

MR. MACEDO: Thank you, sir.

Yes, that is not a hard task to do, is take care of Local 89. Local 89 has been taking care of the power plant for many years.

Local 89 was involved in the process since day one. Unit 1, Unit 2 -- decommissioning of Unit 1 as well, and then the building before the decommissioning of Unit 1 of the Units 2 and 3.

With that being said, I just want to start off by saying thank you for allowing me to be a part of the Community Engagement Panel, it's been an education for me to better represent my members.

I hate to use the word my members -- Local 89's membership, because I've heard different opinions from both sides, and I respect everybody, and I've heard a lot of safety concerns come into play.

My background, in the early 90s I was involved in the decommissioning of a uranium enriched -- U-235 enriched uranium processing plant in Sorrento Valley.

Of course, NRC was involved, Bechtel was the contract at the time.

So I'm very familiar with the decommissioning process at that scale. This is a much larger scale. I am thankful to be a part of the CEP panel.

I want to disclose something here. For years, for years, Southern California Edison has a huge amount of respect for me, for the safety that has been

put in place for our membership, for allowing me to be a part of the CEP panel -- it goes beyond that, as far as safety goes.

Local 89 has engaged in training. A lot of the members here, that are here today, don't have orange shirts on. There is no need to try to control the membership.

They are honest people. They are rate payers that built the power plant, that have the same voice as other people, and we're going to continue to respect everybody.

Those members that have been laid off, lost their jobs, because of the power plant going down, it's understandable.

But make no mistake, these members have gone through a serious curriculum in terms of training, on a daily basis, we have a large training facility, we have mobile sites, for not only Southern California Edison San Onofre decommissioning, but other contractors and other sectors of the market as well.

And I just want to say that I'm very thankful for the professionals to put all the information together, for allowing us to be a part of the process.

And let's give these members back their

jobs. These professionals are disclosing full-on information that's beneficial to the safety and the decommissioning of this project, and I ask that you vote and get this thing going, and let's put these people back to work.

And let's continue to have SCE allow whichever vendor, whichever contractor steps up to the plate and becomes the awarding body for the decommissioning project to follow the safety process that it's had for years and make sure that all of our members, and anybody else that joins whichever union that goes into the decommissioning of this project, that allows them to go home safe to their families.

I thank you for the opportunity to speak.

(Applause.)

FACILITATOR CAMERON: Thank you, Val.

And thank you very much, and we're going to hear from Gary Headrick. We're going to go to Ace and Sharon. And we're going to take a break quick for ten minutes, and we're going to keep going. Gary?

MR. HEADRICK: Thank you. Can you hear me? There we go. My name is Gary Headrick, founder of San Clemente Green, and we've been concerned about our safety ever since being contacted by some of the great workers at San Onofre, who we have a lot of respect and

concern for.

Just one note about Val, I -- you know, we had a conversation shortly after the plant was announced to be shut down, and Val was concerned that the NR -- that he was being reassigned to fight fires when he hadn't been trained to do that in a radiological environment, but I think he's since been trained, so I am glad that's happened.

But the point I want to make about what I've heard tonight is, actually, the most encouraging words I've heard is that you're trying to keep ahead of this.

You are recognizing that you are not ahead of this issue about how we are going to deal with the nuclear waste on site, and deal with it safely, and I appreciate that.

But the problem is, we're still rushing ahead to this -- expedite this decommissioning thing, which we all want to see happen as quick as possible, but we all agree that it has to be as safe as possible.

And I believe that you need to seriously look at this problem longer, and not play word games about whether you approve it or not.

You are the regulators. You make the regulations. And you're also guilty of making exemptions for regulations whenever the industry wants

it, and that's a real problem you have to get over if you want to earn the public's trust.

So I'm appealing to Tom Palmisano, who I appreciate and respect in depth. I think Edison is the one who we can thank for having shut down the nuclear power plant and done the responsible thing when the NRC did not step in and do -- prevent them from restarting a broken reactor without fixing it first.

You know, so Tom, please, give us some time. Let's look at that more sturdy cask system. Let's not rush into this, regardless of what the NRC decides.

We need you to do the right thing, and we're putting a lot of faith in you. We've got to get this right. Thank you.

(Applause.)

FACILITATOR CAMERON: Thanks, Gary.

And Ace, why don't you come here so that they can get you on the camera? Okay, go ahead.

MR. HOFFMAN: I agree that the people who worked at that plant were good all along.

I've been fighting them for 20 years. I've never had a problem at any of these meetings. Nobody has ever come up to me and said anything nasty or mean. I think you're all good people.

And if we decommission that plant right

now, one of them is going to die, on average, because of the difference in the amount of radiation that they're going to be exposed to. And I wonder if they're ready to pick which one of them it's going to be, or whether it's going to be a multitude of them that are going to get some kind of cancer.

Now that is what is going to happen, because the NRC's own statistics say that there's going to be a couple hundred rem dosage if we do it now, and it's only going to be a couple dozen rem if we do it later.

So I'd like to see us wait. But what I'd really like to talk about is that 5/8ths inch thick protection against a -- that's the radiological barrier for the next 60 years, is that 5/8ths inch stainless steel.

The 3 to 5 inches of concrete is virtually irrelevant because it's designed with vents, so if something gets in there and damages the casks, we are going to have a problem.

ISIS is training six year old kids to be suicidal terrorists. ISIS is interested in a multi-generational attack against America. ISIS is producing videos in which they are recruiting people in order to attack America.

Now, Tom, I am sure that you are aware that

there are many, many weapons that can go through 5/8ths inches of steel. This is a multitude of them.

We have to protect that plant better. We can't pretend that this -- that just because we're no longer a nuclear power plant, that we're no longer a target.

We are most definitely a target because of where we are and who we are, and because of our freedoms, and because we can have a meeting like this. This makes us vulnerable.

So you have to consider not just the things that they tell you to consider, but everything that your heart tells you to consider.

That's really all I have to say, this is practically the last meeting that we're going to need to attend here.

And I want to thank all of the workers at San Onofre. I don't believe any one of them did a bad job.

(Applause.)

FACILITATOR CAMERON: Thanks Ace, and last commenter before the break is Sharon.

MS. HOFFMAN: Good evening everybody, and thank you for giving me an opportunity to speak tonight.

I have a few questions.

The first question is really kind of simple. Does anybody have the ability to say no? In a business environment, there's a big difference between the people who can say yes and the people who can say no.

And I didn't hear anybody from the NRC say I am the guy, I can say no, I can say stop, I can say we need more information.

And I think that's important. Somebody should be able to say no.

I also want to say to the gentleman who spoke about the finances that realistically, assuming that the DOE is going to take all the fuel from San Onofre by 2052 is not realistic.

If you look back to 1988, say, we would have said all that fuel that has already been accumulated would be gone by now. And it's not. So let's be more realistic than that.

And last but not least, let's not be in a rush to put this fuel into casks. It -- keeping it in the pools gives us an opportunity to observe it, gives us -- gives SCE and the NRC the opportunity to learn something about the aging of casks.

We're talking about leaving fuel in casks for hundreds if not thousands of years, and we have no

experience in that. So what's the rush? Thank you.

(Applause.)

FACILITATOR CAMERON: Okay, thank you, Sharon. Let's come back around, let's come back around five to 8:00, that's like seven or eight minutes, and we'll get started down here, okay, and we'll keep going. Thank you.

(Whereupon, the meeting went off the record at 7:48 and resumed shortly thereafter.)

FACILITATOR CAMERON: All right. Are you ready, are you ready to go? And please introduce yourself.

MS. JOHNSTON: Hello. My name is Chris Johnston. I thank you all for coming, and I want to believe that your safety recommendation is number one.

And I'm concerned about our community, I'm concerned about eight and a half million people.

I would not want to be sitting in your shoes. You have a very grave responsibility before you.

I have concerns about the canisters, as other people have expressed -- the NUHOMS canister that's 5/8ths inch thick, that you have done some salt spray testing on at Diablo Canyon, and found stress corrosion cracking.

And we are talking about atmospheric corrosion here at San Onofre. So deeply concerned that these casks, these canisters, are not going to withstand atmospheric pressure.

And beyond that, I'm also wondering, and I believe this is a question for Al, regarding the seismic rating for cracked canisters. Can you answer that?

MR. CSONTOS: Can you hear me?

MS. JOHNSTON: Yes.

MR. CSONTOS: All right, first of all, let me get to your -- one point you mentioned about seeing stress corrosion cracking at Diablo, it has not happened, okay?

MS. JOHNSTON: It has the potentiality to happen.

MR. CSONTOS: There are chlorides there, okay?

MS. JOHNSTON: Yes.

MR. CSONTOS: There were chlorides that were found at Calvert Cliffs, there were chlorides that were found at Hope Creek, as well.

They were on brackish water. Diablo is right there, that's the coast.

That's one of the reasons why the EPRI went ahead and did that analysis, or went ahead and had

volunteer sites -- these three were volunteers, okay. They didn't need to do it, they weren't required to do it, they just volunteered to do it, okay?

So that showed a lot of stewardship on their part, to do that.

Now, about two weeks ago -- all right, so about July, we held a public meeting. We went out there and showed our cards, and we said, this is the Aging Management Program that we want for stainless steel canisters, period, okay?

That required inspections, that required operational experience evaluations, that inquired -- that required corrective actions, quality assurance, all that, okay?

Two, let's see here, about -- that meeting was, after that meeting there was another meeting on chloride stress corrosion cracking. And I know several folks were on that phone call, okay?

That meeting went very long. We were kicked out of the room because we had so many questions, which is great.

I talked to Donna after that meeting about these issues. That meeting was the prelude to the report that EPRI was about to provide. Now that report was published two weeks ago.

MS. JOHNSTON: I read it, yes.

MR. CSONTOS: No, that's a different one, I think it -- the Flaw Evaluation and Growth Calculations, have you heard of that one?

MS. JOHNSTON: No.

MR. CSONTOS: Let me give that to you. You can go to the EPRI's website, and I am going to pull that up here.

Oh, it's back here. It's report number 3002002785. Do you want me to repeat that?

MS. JOHNSTON: Yes. I, I, yes, it's okay, I will be watching the -- she's got it.

MR. CSONTOS: So -- so in that report they did a calculation, a much more sophisticated calculation than what we had intended to do, where we just did a quick calc, okay, for Calvert in specific.

Now what they evaluated is they looked at all the conditions, they went to the Camp Pendleton -- is it Pendleton? -- Pendleton site here, and they pulled out all the information on the atmospherics, the weather, and everything.

Pulled out some of the calcs that they did, were very, were very sophisticated based on that.

Their worst case scenario, okay, this is -- there's two, you've got to remember, there's two, two

-- two stages of stress corrosion cracking for chlorides.

There's the incubation period, where you get all the environments, you get all the conditions that could start cracking, okay.

Then you have the actual crack growth. Okay, there's two stages -- incubation plus initiation, and then crack growth.

They just only looked at crack growth. They did not look at how long it would take to get to that stage, because just having chlorides there is not sufficient to have cracking to start, okay?

You need to be in a relative humidity environment, you need to have the material conditions, you need to have a lot of things that have to play out to get this to start cracking.

We raised this issue nearly nine, ten years ago. We're at the stage now where we're trying to act on it.

The calcs that came out, okay, and I'm going to give these numbers to you -- for ambient plus 15 degrees, that means 70 degrees plus 15 degrees Celsius, so that's about what, 20, 25 degrees Fahrenheit, roughly -- to get a 50 percent through-wall crack, this is just not assuming how long it takes to start, to get the

incubation period to begin, that could take years to decades, okay -- you have 18.2 years, okay, by their calcs, to go through-wall of a half-inch thick canister.

To go through-wall, completely through-wall, it's 60 years, over 60 years, okay. To go 75 percent through-wall it's about 40 years.

Okay, now if you take it to the 5/8ths inch canister, you're talking about, worst case now, worst case, 28 years to go halfway through wall, and to go full through wall, over 86 years.

So I want you to understand that this is the -- we're, we're trying to get ahead of this. That is what I am trying to say.

MS. JOHNSTON: What is your defense in depth, in that case, if it does happen?

MR. CSONTOS: If it does happen, you know, this is why we're doing the inspections, okay?

MS. JOHNSTON: How can you inspect canisters that can't be inspected?

MR. CSONTOS: Well, you mentioned that they already did inspections at Diablo, and I mentioned Hope Creek, and I mentioned the volunteer inspections there.

There are also Calvert Cliffs, the inspection for their license renewal, Oconee and Surry

did as well. Those are visual exams --

MS. JOHNSTON: Okay, you're saying you can go all around the canisters and you can see everything, every potential crack?

MR. CSONTOS: So -- part of what, well, what we do here, and that's where in the meeting that we had that was back in that July time frame, we talked about a Koeberg plant, that was a South African plant, Donna, you showed me that slide that I showed you earlier, or that we had at that meeting.

The Koeberg plant had cracking in a 304 tank and a pipe, okay?

And they went ahead and inspected, and they repaired it. So there are repair technologies, and we have seen inspection technologies that are out there, okay?

MS. JOHNSTON: Okay, now back to the final question, is the seismic -- the seismic rating for cracked canisters back to --

MR. CSONTOS: So we did a calc on that --

FACILITATOR CAMERON: Thank you, Chris. Seismic.

MR. CSONTOS: -- so let me talk about the calc on seismic, all right.

What San Onofre did is they analyzed to six

G's, which is ten times what their design basis was for for this 1029 system.

We went ahead and analyzed for the loads that would occur for the six G's, so that's ten times what a earthquake would be here for, what the design-basis earthquake, okay, ten times that.

You would have to lose over 80 percent of the entire canister thickness, the entire canister thickness, before you would have any issues, okay, for a ten time seismic.

That's the robustness in this design. That is what I am trying to get across, that this design and these systems are so over-designed for these types of conditions.

Now, yes, you know, we don't want to ever get to a crack that is 75 percent through-wall.

That's why we're doing this inspection. That's why we're doing these aging management plans. That's why we're trying to get ahead of this, okay?

The first -- the renewal for San Onofre will be in 2023, okay? 2023 is right around the corner.

At that time, we will inspect, probably the worst -- the worst, in terms of our environmental, our, you know, evaluation.

EPRI, that's the Electric Power Research

Institute, that did this Flaw Evaluation Study, is doing a compendium that's coming out this year sometime.

That's looking at the environmental factors, the prioritization. And from that, we're going to prioritize which canisters, how we can focus our inspections on a specific canister, okay?

At that time, that's what we're going to be doing for -- by the time that San Onofre comes around, this technology will have been used.

We have put into the Calvert Cliffs renewal, we have put in there what they need to be able to inspect, okay, within the three years.

FACILITATOR CAMERON: Okay, thank you. And we did get an extension until 20 after 9:00, okay, so we have some more time, but one other suggestion is, and this all depends on Al's goodwill and schedule and all that stuff, but we need to be out of this room by 20 after 9:00, but there's no reason why you can't have an informal conference with Al out there somewhere, okay?

So I am glad you are not listening, Al, because I got you committed. Okay, great.

Let's go to Kevin, Kevin Blanch, back here, and then we're going to spend some time here, go to Richard McPherson, we'll go over that side of the room.

Kevin, go ahead.

MR. BLANCH: Well, I want to first say that the NRC, which I call you guys the Nuclear Rallying Cheerleaders, I don't want any of you to take this personal, what I'm about to say.

I would be more than happy, I am staying at the hotel, to sit down and have a beer with any one of you, and I'll even buy, because we always buy.

I have been fighting San Onofre since I was a little boy. I was given two months to live three years ago. My father was nuked to death in the Nevada test site from Pendleton. I have been anti-nuclear.

I want to ask this simple question to the NRC, and again, do not take this personally, I call you the Nuclear Rallying Cheerleaders.

You have no Congressional powers whatsoever, none. You are the Nuclear Regulatory Commission. You are not the executive branch, you are not the legislative branch, you are not the judicial branch, none of the above.

Congress makes law, not you. And when you come out and slide in and say oh, we're turning America into America Toxic. We are going to take every one of these catastrophes, which is the biggest mistake in human history called nuclearism and turn them into

official nuclear waste dump sites.

Only Congress has that ability to do that, not you. Not the NRC. I know Allison. I am glad Allison resigned, and hopefully on November 4th, maybe Harry Reid, who is protected from putting this monster in Yucca Mountain, which Congress was promised to put in Yucca Mountain.

I sat right here in the 60s and listened to these same ridiculous conversations about what we're going to do with the waste, where we're going to put it.

That stuff needs to come off that cliff yesterday. San Onofre is the poster-child for everything wrong with the nuclear industry. It is a catastrophe, and if it was up to the Nuclear Rallying Cheerleaders, it was all the grassrooters.

And I would like to say thank you, and get this into the public domain, to the grassroot activists in Southern California.

I live in Utah, which you parked the generator in my backyard, illegally.

I would like to say thanks to Gene, Ace, all these people that have fought this tooth and nail. It was us as grassrooters that exposed the lies that was going on by PG&E, the great crimes against humanity.

You protected them. The lie on the

exchange of the generator, these crimes against humanity that were taking place -- you are not Congress.

Yucca Mountain is a bad idea. Shooting it into space is a bad idea. But I'll tell you what's really a bad idea. Nuclear. Building a nuclear site on a cliff, on the most beautiful beach in the world, on a cliff, and then storing the waste there for 40 years when it's not built to dispose of the waste.

Dry cask is a catastrophe, it's a pathetic, stupid idea. Yes, Yucca Mountain is pathetic, but Congress passed Yucca Mountain. You're not Congress.

Ship it to Yucca Mountain. Yeah, I know that's a horrible debate and Congress can't get anything done, but we still have a Constitution. And it was approved and passed to be in Yucca Mountain decades ago.

And Harry Reid blocks it. Yeah, I understand. Born and raised at Yucca Mountain, he has to get elected, his power.

But again, don't take this, any of it, personally, but I consider the NRC to be nothing but a group of criminals who protect other criminals.

San Onofre are criminals, period, period. What they pulled on the exchange, the crimes against humanity -- nuclear fallout is leukemia. My father died of it, and now I'm fighting for my life with it.

So many are.

That stuff needs to come off that cliff before we get an earthquake. Dry cask, whatever you will -- not stay there. It is a catastrophe, ticking time bomb. Thank you.

(Applause.)

FACILITATOR CAMERON: Okay, Kevin.

We're going to go to Alan.

MR. WOO: My name is Alan Woo. I am with the Asian Pacific Planning Council of Orange County.

I used to be chair of the Low Income Oversight Board with the CPUC. So I understand a little about the rate payer and what regulatory agencies kind of look at.

I could kind of appreciate Southern California Edison though, in making a decision to stop operation.

They did that voluntary. There might have been some encouragement, but nevertheless, here we are, right? We're closed, we shut it down, we're trying to come up with a plan to contain it, store it, and then go forward as those policies that the federal government has to yet come into place.

Something has to be done now because I did a calculation when 2052 would be, that's 38 years from

now.

I may not be around, and maybe most of you guys are not going to be around, and most of the activists here won't be around too, but we leave in place what we start today.

And I could appreciate that you thought about inspections, you thought about containment, you thought about storage, you thought about all these things, and that each one of you pledged that you are going to become good stewards in terms of making sure of the future.

So at least now, I could see the faces of people who are committed to doing something to decommissioning it in a responsible way, to contain this situation that we have, and to move forward.

I don't know what's going to happen in 38, 40 years, who may be sitting up there, if there is anyone, whether anyone cares in Washington, or whatever.

But I know today, you know, there's people in the community that cares.

I know that we have a utility company that cares and has been transparent, and has been talking to us in the community about the impact on us, and you had a lot of workers here who need to go back to work who

know and care how to clean up this thing.

So that's all I'd like to say, I just think that you presented a large plan here, it covers every area including environmental impact, we just got to see, if we don't start now, and we postpone it, you know, you are just postponing a problem and you're not getting started.

FACILITATOR CAMERON: Thank you, Alan. Donia?

MS. MOORE: Good evening. My name is Donia Moore, I am with the San Clemente Chamber of Commerce.

I'd like to thank the NRC and Edison for having this forum and allowing us to speak here.

I am aware, of course, as you've discussed often tonight, that the NRC gave Edison 60 years to do the decommissioning process, and they voluntarily decided to do it on a 20 year timeline, which I think is very commendable.

And I understand the need to remove the waste that's being stored currently at San Onofre.

However, I have a question, and that is that one of the things that hasn't really come up much is that, as I understand it, it's actually the federal government that is the body that is giving permission

to remove the waste, and as where to put it, and there's no repository at this moment.

And I haven't heard anything about when there will be a repository to remove the waste to, so it's great to talk about removing the nuclear waste, but how are we going to do that if we don't have any place to store it?

And as I understand it, that's up to the federal government, is that correct?

FACILITATOR CAMERON: Should we go to Keith McConnell for a little bit of history on this? This is Keith McConnell, who is the Director of the Waste Confidence Directorate who did the Environmental Impact Statement and Rulemaking called Continued Storage.

But Keith, do you want to provide some information to Donia on that?

MR. MCCONNELL: Yes, it is the Department of Energy's responsibility to manage the disposition of spent nuclear fuel from all the power plants across the country.

The Department of Energy's most recent issuance in terms of a repository was put out in January of 2013.

What they envisioned at that time was a stage process where there would be a pilot effort to take

the spent fuel to a centralized interim storage facility, and then there would be a full scale interim storage fuel facility in the 2020, mid-2020s time frame.

And then a process where they would go through and solicit interest in development of a geological repository other than Yucca Mountain.

And that's all in this strategy that they issued in 2013. Now there is legislation required to allow that strategy to proceed, and it also depends on community involvement and state involvement in terms of looking for a repository.

But that repository would not be available until the 2048 time frame, and that ties into the presentation that San Onofre gave today.

Does that help?

MS. MOORE: Yes, thank you, it does.

FACILITATOR CAMERON: Thank you, Keith. And let's go to Heather and Steve, and then we're going to go to Richard, and then we'll go over to Ray and everybody over there. Heather?

MS. JOHNSTON: My name is Heather Johnston, I am the Executive Director of the Dana Point Chamber of Commerce.

And I am interested in more of the process, so my question is, is what will be the daily

responsibilities of the NRC resident inspector? How are their activities changed as the project progresses? And how are you going to communicate that to the community and to our local businesses?

MR. KELLAR: I think that's probably a question for me.

There is currently a senior resident on site. That person stayed on site after San Onofre had shut down.

Long-term, that position will not be there, day-to-day, but will be a regional-based inspector that will be in concert, or not in concert, but in contact with the licensee, and they will be aware of any of the higher risk activities as well as the activities that the licensee is undertaking.

So the resident inspector will not be there, but the inspector from the region, the teams and the individuals will be going out and performing the inspections, particularly based on the higher-risk activities.

Now, what I mean by that is, as the licensee prepares to move the fuel from the spent fuel pool to the ISFSI, that would be a higher-risk activity. Some of the dismantlement of the different systems that had radiation and radioactivity would also be a higher risk

activity.

So we would have inspectors that would be there and watch those higher risk activities, as well as, I tried to explain during the presentation, there are certain aspects of the day-to-day operations that also are inspected on a routine basis, such as the organization of the licensee, how they maintain the business, how they perform their audits, how they perform their self-evaluations.

All those are looked at, and they're planned in advance, and the inspection teams would go out and inspect those, as well as the higher-risk activities.

MS. JOHNSTON: Thank you.

MR. KELLAR: You're welcome.

FACILITATOR CAMERON: Okay. Is this Laurie (phonetic)? Okay, why don't we stop here. Go ahead.

PARTICIPANT: Hi. I would like to ask the question of this gentleman on the end here, okay.

The gentleman on the end here made a statement about dose rates, and you said that you compared it to background radiation in certain areas of the world.

And I just wanted to state that what's in

the casks there at San Onofre is not background radiation, it's the most dangerous manmade radionuclides in the world. And you can't compare that to background.

And if the rest of the NRC stands behind that statement, then that's a criminal act.

FACILITATOR CAMERON: And you're talking about Mr. Camper on the end? Larry, do you want to clarify anything on that one?

MR. CAMPER: Yes, I will. Thank you for the question.

What I was trying to do was to draw a comparison as to what it means in our standard that we require.

When that site is ultimately decommissioned, it has to meet that dose standard to be released, and that's 25 millirem and ALARA.

What I was trying to give some perspective on what is 25 millirem, because a lot of folks look at that and they say, well, what is 25 millirem?

So I was trying to draw a comparison. If you get on an airplane and you fly to New York, it's three millirem. The natural background radiation in the United States, as I said, is 300 to 600 millirem, depending on where you are.

I agree -- I beg your pardon?

PARTICIPANT: That's not massive radiation.

MR. CAMPER: Oh, I agree with that, I agree with your point fully. If you're saying that there's a dose -- I'm sorry?

PARTICIPANT: The problem at San Onofre is not the background radiation.

MR. CAMPER: Oh, I agree with you fully, it's not background radiation. Of course it's not.

FACILITATOR CAMERON: Okay. Sounds like there's some agreement here, but let's let Larry finish, and then we're going to go to some other people, thank you, Laurie. Larry?

MR. CAMPER: No, I agree with you that it's not background radiation. I was simply trying to draw some reference to what 25 millirem meant when that site is decommissioned to satisfy that dose standard.

FACILITATOR CAMERON: Okay. Steve?

MR. ADAMS: I am Steve Adams (phonetic), a resident in Laguna Niguel.

And reading through the report, I had a question, couple of questions.

The term "islanding" of the pool, the spent fuel pools, was used, and I'm not clear on what islanding

would be in those pools.

And then my next question is based on listening to some of the previous commentations. Is it safer for the spent fuel to be in pools, or is it safer for it to be in the casks that are proposed right now?

FACILITATOR CAMERON: Well those are good questions. And who would like to take the islanding on?

MR. PALMISANO: So let me take that on, because I think that came off our slides.

FACILITATOR CAMERON: Okay.

MR. PALMISANO: That is a term that refers to taking the current spent fuel pool cooling system which are installed plant equipment that will be taken out of service.

When we say "islanding," that means putting in dedicated standalone cooling systems for the spent fuel pools. So we essentially island it and separate it from, disconnect it from the rest of the installed plant equipment. That's what the term islanding means.

FACILITATOR CAMERON: Okay. And does anybody want to talk to the question that's been percolating for a while now about is it safer in pools or dry storage? Doug?

MR. BROADDUS: So, the -- our requirements are that both processes have to be safe, and so we

consider them, and we've looked at them in the past, you know, to see, is there benefits one way or the other?

And there was recent -- there was a recent study that was actually put up to the Commission, to our Commission, to see whether there was a need for their to be an expedited transfer of fuel from the spent fuel pools to dry cask storage.

And the determination was that there is no real benefit from that standpoint to do it in an expedited manner, so to get in there sooner.

In some cases, you can't actually take the fuel and put it into spent -- in dry cask storage, within -- until after a certain amount of time, because it just can't get into the casks, the casks can't handle the amount of heat that's going to be generated by that, so it has to stay in the spent fuel pools.

But the spent fuel pools are build to be very -- very rugged structures that are going to withstand the same seismic types of loads and such that the casks would have to be able to withstand as well, to be able to dissipate the heat in the same manner as the casks would, but just through a different process.

They're dissipating it through the water that they're in, whereas the casks are dissipating it through the transfer into the air, or the atmosphere

that's within the casks themselves. So it's a different process.

(Off mic question.)

FACILITATOR CAMERON: Let me -- let me just, this will be the last question, but go ahead.

MR. ADAMS: No, I was referring to the comment that was made about, like, a terrorist attack. Is it being in a pool, is that safer than being encased in stainless steel and concrete?

MR. BROADDUS: All right, so, from the standpoint of terrorist attacks, obviously with -- you can't quantify, it's very difficult to quantify what type of a terrorist attack has to occur.

So what we've tried to do, and what we've done, is establish what's called a design-basis threat, and that's a threat that has been established to provide assurance, very high assurance, of that they're going to be able to, the licensee would be able to thwart an adversary coming in to, and then attacking it.

So that's what the -- from a terrorist standpoint, our defense in depth is to ensure that they have a good strong security program to ensure that the terrorists are not going to be successful in whatever attack that they would do.

FACILITATOR CAMERON: Okay, thank you,

thank you for that. Richard McPherson.

MR. MCPHERSON: Good evening. I hear a lot of negative information, about 90 percent of the people are talking negatively about nuclear power, something they don't really know about.

50 years ago, I suited up in NICs (phonetic) for the first time, and I participated in a defueling of a reactor and a refueling of a reactor.

And I have been involved in that process ever since. I was even selected to represent the United States at the International Atomic Energy Agency for four years on something called Nuclear Fuel Cycle Facilities, which is the front end and the back end, the environment and public opinion.

And I have now been involved for almost 51 years in nuclear power. I have little or no concerns over what you are presenting here because I've seen it presented so many times, and I've seen it be successful.

It's unfortunate that there's so much misinformation out there and there's so much misinformation that's generated on purpose to cause fear in people.

But as an operator of five nuclear power plants, and I've been involved in refuelings and been involved in the back end of the fuel cycle since, a lot,

since 1992, I appreciate everything you are saying and doing and I think we're going to be safe.

Thank you very much.

(Applause.)

FACILITATOR CAMERON: Yes, sir.

MR. GARDNER: Yeah. God evening, I'm Richard Gardner (phonetic) from Capistrano Beach.

I feel that the process is in place to lead us to a safe condition, even though I think I agree with everyone that getting the spent fuel out of the, off the site and in a permanent repository would probably be the long-term benefit, and that's not in your hands.

What I am here to suggest is that the San Onofre Nuclear Generating Station should be re-purposed into a reverse osmosis drinking water facility, at least for the intake structures and the turbine buildings.

And I believe that, you know, without actually doing the, you know, preliminary design, that it would be easy to have 50 million gallons a day, or 100 million gallons a day.

And that water would be provided, and it would be adequate supplies for the Marine Corps that live on the base, and also it would satisfy the demands of at least 25 percent of south Orange County, which goes, which covers a great distance.

So I think that's a much higher and more important use, considering if this drought does not -- if we don't get some rain pretty soon, we could be drawing Lake Mead down, and we may be in a position where we would have hundreds of thousands, if not millions, of people dependent on a water source that isn't there.

So that's why I think it would be best if there was a planning, a planning facility where we would look at a contingency of converting or re-purposing the plant, and doing it in a way that the transition could occur, to whoever the third party is, and it could be Southern Cal Edison but it could be anyone else, and that the discussions with the Navy happen immediately so that we could save Southern Cal Edison over $130 million for the demo of the turbine buildings alone, and we would save the water authority another $100 million for the new facilities.

And you know, the plant here in Carlsbad is costing $1 billion for an RO plant to produce 50 million gallons a day.

So we could have that, and I think we should begin to focus on that's more important than many of the things that we are now concerned about that are hypothetical.

So if anyone can figure out how to get

through the right departments within the federal government and in the state, to think about how it affects Southern Cal Edison's planning process, I would like to be actively involved. Thank you.

FACILITATOR CAMERON: Okay, thank you. Let's go over here to, let's go to Ray. And then we'll go to --

MR. LUTZ: Okay, hello, my name is Ray Lutz, I am with citizensoversight.org.

I wanted to bring up some of the things that concern the public about the process and where we are today.

I am one of those that are very happy that the plant is shut down. I don't think that nuclear power is a good idea, I don't think that it's safe to have all this waste around.

That's the definition, the non-definition of green. If you have a whole bunch of waste at the end, it's not green energy.

And we have a whole bunch, 3.2 million pounds of highly radioactive waste that we've got to deal with now.

The problem is that it almost seems like we're seat-of-the-pants operation here. Almost nothing has been really planned ahead -- you say, we've

decommissioned all these other plants, but we really don't really have a solution for this fuel, still.

It's really not a good plan yet. And no one is sitting here saying, here is our plan for the next ten, twenty, thirty years. There is no plan. All we got is here. That's the end of the plan, a foreseeable future.

You say, for the foreseeable -- what the hell is that? What is a foreseeable future? Ten years? Is that it? Is that the foreseeable future for the NRC? 20 years? I mean, what is foreseeable?

Because right now the only plan is leave it here on the coast. Edison doesn't have a plan for the next ten years, the next place. Everybody is pointing fingers. The Department of Energy's responsibility, not us.

NRC, we don't even have to approve the damn plan. It's not our responsibility. If it goes south, eh, we didn't approve it. That was their problem, because we have a way out, we've covered our butts. We don't have to approve the plan.

Who came up with this? Who came up with the fact that the actual license amendment process is at the very end? When everything is done, we finally talk about whether we should approve it.

Like, in 50 years from now, we're going to talk about what we did was 50 years ago, was okay.

The NRC is all backwards. You have the license amendment for the termination at the very, very end, instead of doing it -- why did they do that? And it's because they said, oh, there's going to be some activists that are going to be out there and they're going to put blocks in what we're doing, so I'll tell you what, let's put the license termination plan at the very end, so that no one can block it.

That's where we are now. The NRC doesn't even have to approve it.

Seat-of-the-pants operation, no approval, no long-term or even 10, 20 year plan. These are all big problems in our minds.

The fact that the license termination is at the very end of the process. It should have been now. And you're saying we don't have to approve it.

My proposal is, you are going to have to work around this system. Stop pointing fingers at the Department of Energy.

Southern California Edison, thank you for shutting it down. Now you need to do your part by planning, here is what we are going to do with the fuel over the next twenty, thirty years. Make a plan. It's

not going to be perfect, but at least get it started.

NRC, do your part by approving this plan. I don't care if they say it's not your, you can't approve it -- do it anyway. Say, we are approving this, and you're putting your butt on the line.

And I expect you to be able to say we're not approving it, and Southern California Edison will cooperate. And they'll say, you know what, you guys haven't approved it yet, there are some problems? We're going to fix those. I know Tom Palmisano would love to do that. He would love to fix any problems that you've got.

So don't say, oh, it's the end of the clock -- we're not done yet, but go ahead. Make sure that everything is done, all the i's are dotted and all the t's are crossed.

I think it's right. You know, this thing about the fuel pools, the guy just asked, he's not here anymore. That study that you said, oh, it's the expediting the fuel out of the fuel pools into the dry casks -- the only reason they said that was because of cost.

That wasn't because of a safety issue, and the whole system that you guys use at the NRC is screwed up because you start with the cost analysis before

you've ever gotten done with the first, the safety analysis. They jump right away into the -- whether it's cost effective or not.

And so that's why they came up with that. It probably is better to put them in the dry casks. Let's face it. If you have a terrorist attack, the fuel pools are not as safe as a dry cask. And that should be the answer.

Sir, you answered that? Your answer should be, the fuel pools are not as safe as a dry cask in a terrorist attack.

You know, you've got to say something -- you think they're just equally as safe? Is there an answer?

MR. BROADDUS: I explained that it's the design-basis threat, and the licensee has to protect against the design-basis threat, and regardless of whether they are attacking the spent fuel pools or they're attacking the casks, they have to be able to thwart, they have to be able to thwart the adversary --

FACILITATOR CAMERON: Okay.

MR. BROADDUS: So it -- and prevent the attack from being successful --

FACILITATOR CAMERON: Thank you.

MR. BROADDUS: -- so it doesn't matter where they attack.

FACILITATOR CAMERON: All right. Ed.

DR. SIEGEL: Yeah, hi, my name is Dr. Edward Siegel (phonetic), a graduate of Berkeley, Michigan, Michigan State, MIT, Westinghouse Combustion Engineering GE, PSEG, and the IAEA, many years. Son of Sidney Siegel, co-director of Oak Ridge in the beginning.

What I heard today is summarized best by a Harry Belafonte lyric, "It was clear as mud but it covered the ground."

One of the problems that occurs is in this document, which I just got from someone here, which I presume is available, my goodness, people at Southwest Research Institute found that alloy composition dominates things. That's in the scientific literature from the 50s.

People like Sidney Siegel, or, you know, my father, Alvin Weinberg, director of Oak Ridge, fired for doubting allow safety, embrittlement in nuclear plants, around 1970.

What is San Onofre? It's a crime scene. What's the crime? Well, if I ripped off one of you for $5.3 billion, I'd be in prison forever, even after I was dead.

So the question that has to be asked is what

happened? The surfers at San Onofre, which I'm too fat and old to be one of, for thirty years wanted the reactors removed.

So what's the rush? And by the way, what happened in San Onofre isn't the worst thing. There's an old paperback about a meltdown, like Fukushima -- that would mean evacuation of Riverside, San Diego, and Orange County for centuries. It would bankrupt the United States if no one is killed, and that's a big "if."

Who did it? Well, I don't know. Certainly Southern California Edison had something to do with it -- they crushed EPRI, EPRI is their public relations arm. I was interviewed by Chauncey Starr (phonetic) and Ed Zebrowski (phonetic), and when they heard about alloy 182 weld embrittlement, they were horrified, I was on an interview.

They didn't hire me. I worked for a nasty Jewish P-R-I-C-K named Hyman Rickober (phonetic) -- he wasn't just afraid of Soviets, he was afraid of everyone, he was paranoid schizophrenic. He knew what he was doing. He won the Cold War from us, as this fellow from the nuclear Navy can attest.

I have two books I'd just like to bring to people's attention, and by the way, if you want to find out about me, Google "A-N-N-A Mayo, If Leaks Could

Kill," and if you want to find an article by me, go to flickr.com and put in the word "giant magneto-resistance read page 312."

This is a book on fractography. What you do is you look at things with a microscope, just like a crime scene where someone is murdered, and you see what you see.

Once it's put away in Idaho, they'll never find it again. It has to be examined here. Why? Because there's $5.3 billion in bills we're going to have to pay. Who is going to pay them?

My feeling about nuclear fuel is that people who produce it should eat it for dinner, and the Securities and Exchange Commission is watching very carefully.

Lastly, in closing, a very interesting book which you all can buy online -- it's called De re metallica, I'll show you the front page, you can buy it from Dover for 30 dollars, by Georgius Agricola, it's the first book on metallurgy.

It talks about why Roman -- you see, there's nothing needed, you don't need anything hard in a nuclear reactor, any woman knows this, your cuticles when you're skiing -- hard things are brittle, they brink.

You're not machining with a nuclear reactor, or nuclear weapons, or jet engines.

De re metallica, translated by Herbert Clark Hoover, President of the United States -- publication date is interesting, 1550, half a millennium ago. Hard things break. Roman swords which stab through Hebrew and bronze shields, and Greek, broke, because they were brittle.

Why doesn't DOE, where the sins come from -- NRC shouldn't be badly blamed -- I'm, my thinking is Soviet sabotage, when I was a little boy.

Not my father or Alvin Weinberg, not Eugene Wigner who founded it -- I have some names, I've been looking at this for 40 years.

How come the NRC, but especially DOE, the only person doing anything in the DOE is Lofaro, look up anything by Robert Lofaro, alloy embrittlement mitigation -- and what happened at San Onofre may have saved us from a much worse thing, core meltdown.

But why should we pay for it? If someone would like to pay my part of the stranded costs, I'll give you my name, if anyone wants to give me a business card, I can email you lots of stuff. Thank you.

FACILITATOR CAMERON: Okay, thank you. Thank you, Ed.

(Applause.)

Yes, sir.

MR. JOHNSON: Thank you. Roger Johnson, San Clemente.

Earlier this evening you showed a slide, I think it was slide 20, on which you listed the reasons why this plan should be denied.

One of the reasons was that it would endanger public health and safety. And I think this plan does endanger public health and safety.

And I think a lot of other people do too, and one of the things that has been ignored in your report, and it's been touched on here briefly, I'd like to focus on this, is terrorism.

The National Academy of Sciences was very concerned about this. In 2006, they wrote a report called Safety and Security of Commercial Spent Nuclear Fuel Storage, and they addressed the whole report on that.

I noticed on slide 38, you ignored terrorism. You listed all the possible things that could go wrong, and you ignored terrorism.

One of the first things that the National Academy of Sciences said is that nearly all the studies on the dangers of nuclear power plants focus on

accidents related to equipment failure, and they completely ignore some of the other ones.

So after 9/11, terrorism became a reality. So here are a few things that they said. They say, attacks, this is page 35, attacks by a knowledgeable terrorist with access to advanced weapons might cause considerable physical damage to spent nuclear plants.

Then they go on to point out the U.S. commercial nuclear power plants are not required by the NRC to defend against air attacks, that's page 31.

They go on to say that nuclear power plants are not designed to resist external terror attacks. There are currently no requirements in place to defend against large-scale terrorist attacks.

Then they go on to say, this committee, the National Academy of Sciences, judges that some attacks involving aircraft would be feasible and could be carried out, and a zirconium cladding fire would melt the fuel pellets, could release some of the radionuclides in the atmosphere, and could be transported hundreds of miles downwind.

Some of the other observations about dry casks. Dry casks were designed to ensure storage, they were not designed to resist terrorist attacks.

And when they talk about fuel pools, they

said, "This Commission concludes that there are scenarios that could lead to partial failure of the spent fuel pool walls, thereby resulting in partial or complete loss of fuel pool coolant."

So it goes on and on, and the one other thing they noticed is that a problem with terrorism is they're site specific, and the NRC has come up with this generic plan, which means that all plants are equal.

So it does not recognize that you have chosen to store waste on earthquake faults in a tsunami zone, in the middle of metropolitan areas, and in an area which is easily accessible by terrorists, it's two or three hundred feet from public highways, any truck bomb could go in there.

The Commission also said that to defend against truck bombs, you needed to have at least 400 feet of setback. Old Pacific Highway is 300 feet, anybody can drive and park there and blow up a truck bomb. There's hardly a day in the week when truck bombs don't go off somewhere in the world.

So this is a very dangerous site that you've chosen, and I think one thing that you should -- should be considered, and is not being considered, is that this is meant to be a temporary long-term, an oxymoron, storage facility, and if you're going to store it

long-term temporary, let's store it long-term temporary somewhere else, like in a remote region where it's safe.

You don't need a permanent solution.

(Applause.)

FACILITATOR CAMERON: Thank you, thank you Roger. We're going to go over to this side of the room, and we'll be coming back to you.

But let's -- let's go to Dan. Dan?

MR. DOMINGUEZ: My name is Daniel Dominguez, I am the Chief Officer for the local union that represents the maintenance and operators at the plant.

I'll keep my statements short. I have worked at the plant for 32 years, 25 years as a reactor operator, and of those 32 years, my primary goal was to operate -- was to protect the health and safety of the public, and in the process, generate electricity for the benefit of society.

There has been a lot of talk. I want to cover one point is that in my 32 years, I have had lots and lots of interaction with the NRC.

And in my interactions, I've always found them very professional, and I've always found them that they had the same goal that I had, which was to protect the health and safety of the public.

When the gentleman, I forget who it was that said they put no price on safety, they do not put a price on safety. I can attest to that. That's been my experience.

And finally, the question about whether it's safer in the pool or safer in the ISFSI. For the last 15 years I've monitored the ISFSI pad, and it is safer in the ISFSI. Thank you.

FACILITATOR CAMERON: Okay, thanks Dan. We're going to go to Patricia and Reuben, and Carlos, we're coming back to you, I didn't forget.

MS. BORCHMANN: Thank you. My name is Patricia Borchmann, I live in Escondido.

I am concerned about the safety of this proposed decommissioning plan that Edison has prepared, and they are trying to expedite, and, you know, make it appear as if it's no, not going to be any problem, or nothing has been overlooked, or nothing has -- there are no unforeseen risks.

I disagree. I think that a lot of the technical comments that have been made are very credible, and I think -- well, I think arguments on both sides have been made that are very technical and very credible, so if I understand there's a dilemma, and, you know, the job is not finished.

But what I would like to emphasize is that you have the authority right now, there's nothing holding you back -- you don't have to wait 90 days to -- until this 90 day limit is up, to ask for additional information. You have that authority right now.

And I think that based on the concerns that have been presented at your Community Engagement Panel through the series of public meetings held by Southern California Edison and their technical experts, there has been plenty of technical, highly technical, incredible concerns raised that aren't covered in Edison's plan.

Edison -- you know, NRC, you are saying, as a lot of people have said, they put no -- there is no cost placed, there is no price limit placed on safety.

I agree with that, because Edison, Edison is supposed to be the one absorbing the cost issues, and they're not. This plan they prepared is the shortcut, walk-away, cheapest possible method. And it's not good enough for southern California.

And there's no reason that -- I don't think people realize, you know, they have better options, that are used internationally, that provide the kind of protections that this densely populated area deserves.

Thank you.

(Applause.)

FACILITATOR CAMERON: Thanks, Patricia. And Reuben?

MR. FRANCO: Thanks, Chip.

Thank you all for letting me speak here today. I am Reuben Franco, I am the President and CEO of the Orange County Hispanic Chamber of Commerce, and I live in south Orange County.

Given that we have a lack of leadership in Washington for any long-term solution to the problem of long-term storage, it's my belief that moving the spent fuel like the plan suggests, from the fuel -- from the pool to the cask storage, would be a lot better solution, a lot safer solution, and hopefully we can move down that road.

So I'd like to thank Edison and the NRC and the employees there for doing their part and trying to come to a solution to this and a resolution, so thank you.

(Applause.)

FACILITATOR CAMERON: Thank you, Reuben.

And let's go to this gentleman right here, and then we'll go over to Carlos, and then I'm going to see if I can find some people.

MR. ALDINGER: Thank you.

Hi, my name is Karl Aldinger. I am a concerned citizen from Fallbrook.

My question is, will there be a contingency plan for when, inevitably, a cask cracks or fractured?

I know Mr. Csontos, you mentioned the ability to weld them. It appears to me that that's the way these are formed in the first place. You create the container, insert the fuel, weld it, so naturally, you should be able to weld up any problems you have.

Has the commission planning process considered having additional storage containers manufactured ahead of time so if we do have a catastrophic failure, you're not standing there looking around for who is going to create this thing that could take five years to create?

We've seen, in the past, it takes an enormous amount of time to build stuff that you guys require.

Our steam generators took five, seven years, and I don't expect these containers to take that long, but who knows what situation we're in 40 years from now. It may not be that easy for us to get more of those, and so it may make sense to try to procure those now.

I wanted to point out that Hanford and WIPP both indicate that a failure to plan for contingency

creates a toxic mess that's very hard, if not impossible, to attend to quickly.

So I hope that, in your thinking, that it's not we build the casks, we build the cement surrounding, and then we pray. I hope that there's an easy way to clean up any problem that you do determine, that there is made with a cask -- that you've thought about this ahead of time and said, it's okay, we've got this. We're not going to send in troops for four or seven months to go slowly clean up a mess.

In talking about the desalination plant, it's worth noting that the Western hemisphere's largest desalination plant is currently being constructed five miles from this room we are standing in.

That plant will provide human drinking water to many sitting in this building. And unlike Japanese officials, who have been very slow at lying through their teeth about the amount of emissions their ongoing nuclear disaster is leaking directly into the Pacific Ocean three and one half years after the earthquake and tsunami, we will not be so polite if and when an accident at San Onofre spent fuel storage poisons our drinking water.

The reverse osmosis system being built there is not designed to and is not likely capable of

filtering out radionuclides. Thank you.

(Applause.)

FACILITATOR CAMERON: Okay, thank you. So do you want to offer anything about what happens if a cask breaks, Al?

MR. CSONTOS: Sure. So first, what we're trying to do in these aging management programs is to set up the guidelines, or the guidance, that says, you know, this much and no further, okay, in terms of degradation and what is acceptable, okay?

That's first. Second is, is that stainless steel repairs have been done in the nuclear industry for decades, probably longer than I've been alive.

And it has -- they've had thousands, in the 80s and 90s, thousands of welds that have had cracking in the reactor system, the stainless steel, same stainless steel that these are made out of and others are made out of, that have been repaired.

Overlays have been done for decades. So there are technologies out there. When there are unique issues, like what happened, and I've been bringing up Koeberg, that's a plant that had, that's right near the coast, breaking waves right next to it, in South Africa, that had this same issue.

And their tank was very thing, so the typical methods of doing repairs was not appropriate, okay?

So they went off and they did some quick R&D and got repairs done very quickly. It was an overlay, okay, but it was a unique overlay.

So the capabilities out there are, they're there. They're there now, okay?

Just bringing it to bear to this side of the house, which is the dry cask storage side, is not that big of a deal, in my opinion.

FACILITATOR CAMERON: Okay.

MR. CSONTOS: But, and then the other issue was, you said, for casks that have been damaged beyond our threshold, or to a point where, you know, we need to do something.

We have casks that are transfer casks, as well as transportation casks, that are at different sites that we could pull together, or, you know, sometimes they are on individual site-specific sites -- site-specific licensees will tend to have them right there on their site, and they can be stored within them and held and stopped, if we're having any issues.

FACILITATOR CAMERON: All right. Thank you, thank you Al. Carlos?

MR. OLVERA: Thank you. I'll try to make this short.

I am referring to off-site emergency planning. My name is Carlos Olvera (phonetic) from the city of Dana Point.

When we became a city in 1989, Southern California Edison installed an emergency response center at city hall. We have not had to use that for San Onofre, but we did use it a couple years ago when we had a tsunami. It only measured six inches, but nevertheless, it was nice to have it.

So I would just ask you, will that facility be maintained throughout decommissioning?

MR. PALMISANO: Let me speak to that.

We've submitted a defueled emergency plan for, you know, that is based on the scenarios that can occur in decommissioning plants.

We will, we have some offsite facilities the utility maintains. The offsite facilities that the counties and cities maintain will really be up to them in the future.

We've talked to the Interjurisdictional Planning Commission, which is the agency which coordinates all offsite emergency planning, not just for nuclear issues, but for all hazards, and that

question really is for them.

They are certainly going to keep their emergency capabilities in place while the fuel pools are in service.

FACILITATOR CAMERON: Okay, and we do have someone from FEMA, but -- the Interjurisdictional Planning Committee, they couldn't be here tonight, but they did give me something that they wanted me to read into the record, very short.

"The members of the SONGS Interjurisdictional Planning Committee have committed to maintaining emergency response capabilities related to nuclear preparedness throughout the SONGS decommissioning process, and to continue our multi-agency partnership to accomplish this goal."

And I'll read more of this if we have time, but I just wanted to get that on the record, and if you could just introduce yourself to us.

MR. GRUNDSTROM: My name is Richard Grundstrom, and I am the Technological Hazards Branch Chief for FEMA Region IX.

And part of what we do is we oversee the radiological emergency preparedness program around the offsite agencies around the nuclear power plants.

The IPC, all the Interjurisdictional

Planning Committee and all the local communities, have a very, very robust emergency response plan, and it's been exercised for years in its -- in a transition over the period of time, like the gentleman mentioned, it was activated for the tsunami. It's now becoming an all-hazards plan.

Just because the San Onofre Nuclear Power Plant is going to shut down, the plan is going to remain in place. They are still going to have the robust EOC (phonetic), and they're still going to have the planning efforts that they do now.

FACILITATOR CAMERON: Okay. And we're going to go to Jacqueline Woo (phonetic), and I'll just read more of the Interjurisdictional Planning Committee as I'm walking over there.

"As a part of our ongoing emergency planning, we will retain the ability to receive information, independently monitor and assess conditions, and take actions to protect our residents, visitors, and emergency workers." This is Jacqueline.

MS. WOO: Thank you.

I have been following the San Onofre whole spectacle through the news, and it's really eye-opening to come here and to hear form all these different perspectives, especially from those who actually work

onsite, who put their lives on the line.

My question is, is there a list of other agencies that we're working in collaboration with for the decommissioning effort, and if so, how can the public participate, will there be any public hearings?

FACILITATOR CAMERON: Okay. Anybody want to take that on?

I think it was a pretty straightforward question. Do you understand it up there?

MR. BROADDUS: When you're talking about other -- other agencies, are you talking about federal agencies, state agencies?

I mean, what -- ?

FACILITATOR CAMERON: I think any, any other agencies that might be involved.

MR. PALMISANO: Let me just make one quick comment.

We've focused our discussions tonight on NRC requirements for decommissioning and the Post-Shutdown Decommissioning Activities Report, the Irradiated Fuel Management Plan.

Realize also, the state of California, through the California Environmental Quality Act, also has some permitting reviews they will do, similar to what we did on Unit 1 activities in some cases.

So there will be some state agencies involved. That is, you know, starting in the near future.

I don't have a list per se. But if you pay attention to our songscommunity.com website as we proceed through the state permitting process for decommissioning activities, that information would be available.

FACILITATOR CAMERON: Yes, and FEMA, FEMA obviously, right. Go ahead, Larry.

MR. CAMPER: No, I was going to say that, for example, Department of Transportation regulations that apply to the waste that will be leaving the site when decommissioning is going on, we actually enforce those regulations, but they are Department of Transportation regulations.

There are also certain EPA considerations that we carry out as part of our regulatory process.

With regards to the hearing question part of it, I mentioned that when the License Termination Plan is submitted, there is an opportunity for a hearing. And if a body, if a group or an individual seeks a hearing and is granted standing, then it goes to an adjudicatory process. But that's an actual legal hearing.

FACILITATOR CAMERON: Okay.

MR. CAMPER: It's not a public exchange of information, it's an adjudicatory hearing.

FACILITATOR CAMERON: As opposed to a meeting. Thank you, Larry.

MR. BROADDUS: Yes, if I could --

FACILITATOR CAMERON: Let's go -- go ahead, Doug.

MR. BROADDUS: -- if I could say one other thing, which is just that for any of the other licensing amendments that San Onofre has submitted to us for review as well, it's just like with the License Termination Plan, there's an opportunity for a hearing provided on each of those as well.

So anyone who is interested or, you know, wants to participate in that can make their request for those as well, such as the emergency plan that Mr. Palmisano talked about previously, that's one of the licensing actions that are under review right now.

FACILITATOR CAMERON: Okay, thank you. Thank you, Doug.

And we're going to go to this gentleman here, but I wondered, is Steve Adams, Francis Bauer (phonetic), or Dave Peiser still here?

Okay, Dave?

MR. PEISER: I am Dave Peiser, and I am running for Congress right here in the 49th District, and San Onofre is obviously part of this District, and I am running against Darrell Issa, in case you wanted to know that.

So the first thing I want to say is thank you for all your hard work to make sure that -- to make sure of the safety and well-being of our District, with all the actions that you are taking, and I want to thank everybody who is in this audience, too, to bring your concerns.

And the one concern of mine is that, according to the timeline, the Department of Energy is going to take this fuel offsite, and I'm concerned that that's never going to happen, considering the history that has been going on so far with trying to find a permanent site for nuclear spent fuel.

So for that reason I have two points. One is I have, because of my serious concerns, I'd really like to see us put a plan in place to get the fuel offsite as soon as possible.

And number two, if you cannot figure out a way to do that, I really think we should look at a longer term containment strategy with the cast iron type casks, something more permanent and durable that's going to

last longer than the timeline that you've put together.

Thanks.

(Applause.)

FACILITATOR CAMERON: Okay, thank you. And let's go to Ted, Ted Quinn.

MR. QUINN: Hi, I am Ted Quinn, and also a CEP member, like Dan, and Gene Stone, I think.

I'd like to thank the NRC for sponsoring this meeting. It's a pleasure to see the factual data, and I'm going to emphasize the word factual data, being presented.

In the CEP we've had multiple meetings, two workshops, to foster public and plant owner exchanges on key issues, and it's continued tonight, even though this isn't a CEP meeting.

The public interactions have been great to see, particularly the ones that are on a factual basis.

I would just like to comment, if Dr. Siegel is still here, there's a good book about threats called One Second After by William Forstchen on the loss of electricity in a North Carolina town, that I think is quite an interesting read.

Thank you.

FACILITATOR CAMERON: Okay. Thank you, Ted.

Francis Bauer? Steve Adams?

Okay, and Alice has left. Do you want to ask that question, Sharon?

Okay, we have a request for clarification from Sharon on a couple of dates. Go ahead.

MS. HOFFMAN: The gentleman who spoke about the DOE and the waste confidence gave a date of 2048 for building an interim facility, and yet Mr. Palmisano talks about all the waste being removed by 2049.

There is something wrong with those dates. And I would just like somebody to clarify how those two dates work together.

FACILITATOR CAMERON: Okay, and I think -- I think Keith's 2048 was based on what DOE actually stated, they thought a repository would be ready in 2048.

So why don't you talk, and then we'll ask --

MR. MCCONNELL: The distinction is that there were two facilities in DOE's strategy.

The first was a centralized interim storage facility. That would be located somewhere in the U.S. And that would occur in the 2020s, so the fuel would be removed from the reactor facilities to this centralized

facility.

That would then be staged for a repository that would be available in 2048 for the final disposition of spent fuel.

FACILITATOR CAMERON: Okay, and Tom, do you want to add anything?

MR. PALMISANO: No, I think that clarifies it.

The dates we're working from are based on Department of Energy information for the interim facility, so for a planning basis, that's what we're using at this point.

We're obviously monitoring the situation. The 2048 is a permanent repository. So our goal, quite frankly, is for the fuel to be removed as soon as DOE can remove it to an interim facility, and that's what our dates are based on.

FACILITATOR CAMERON: Okay. And I just wanted to thank all of you, you've been a tremendous, tremendous group, and I am going to turn this over to the senior NRC official, Larry Camper, to close the meeting out for us.

Al Csontos will be held hostage after the meeting, okay?

So go ahead, Larry.

MR. CAMPER: Thank you, Chip.

Before I make my closing comments and observations, I do want to ask Duane (phonetic), who is in our Office of Nuclear Security Incident Response -- several times terrorism has come up.

And I asked Duane to say something about a concept called safeguards. We have other ways than environmental impact statements or safety reviews for addressing terrorism, and it's under the umbrella of safeguards.

So Duane, would you make a few comments about that to clarify for people how that works, without getting into the details you can't get into?

DUANE: Yes, I'll try to. That's one thing about security, a little bit more sensitive subject, so we don't talk about it as much.

But one thing that's been mentioned a lot during our discussions is that security is going to go away, or go down -- so I do want to let you know that NRC does have a process, and so security will remain in place.

We have a high -- we require high assurance that security -- that all of the sites, from operating, as it starts off operating, to decommissioning through the ISFSI, that they maintain a specific level to go

against what we call our design-basis threat.

And so that design-basis threat is basically scenarios that have been made up of different types of threats, and each reactor, each decommissioning site, has to make sure they maintain those -- their security at that level.

When we say that security is being changed, basically what we're saying is because the operations of the facility from an operating facility to a decommissioning facility changes.

You reduce the area, because, for example, you no longer have the reactor, you no longer have the auxiliary equipment that protects the reactor, so of course you don't have as much area to have to secure, so it's not that security goes away, it's just that it changes the instructions so that we can maintain that same level of security.

So we wanted to make sure it was clear that security is going to be there. The NRC does a very good job, we have a whole office dedicated to ensuring that different plants, including SONGS, will maintain their security even as they make changes -- they have to submit those changes to us, and we do review those changes to make sure that they still have that high level of assurance.

So I just wanted to make that point so that it's clear that the site will still be protected, and that's what, also, Doug was saying in regards to the difference between spent fuel pool and the dry canisters, and that the plant itself will be still secured. So that's why it wouldn't matter.

So I hope that helps.

MR. CAMPER: Great.

FACILITATOR CAMERON: Thank you.

MR. CAMPER: Thank you, thank you.

FACILITATOR CAMERON: And Larry.

MR. CAMPER: Okay, thank you.

First of all, let me thank everyone for all the comments -- very insightful comments, and let me assure you that the meeting is being transcribed. The staff will review the transcript as we go through our review process, you know, tracking against the 90 day clock that's been mentioned several times over the evening.

The staff will caucus following this meeting and discuss the various things that we heard, and we'll caucus as we look at the transcript, and your comments will in fact be considered as we conduct our review.

The second thing I want to mention is, and

I'll go back to the term who can say no? Who can say no? We can say no.

It is correct that we do not approve the PSDAR, consistent with the existing Commission policy. Why is the policy that way? Because in 1996-1997, the Commission determined that the activities that are conducted during decommissioning are bounded by the operations and safety considerations that take place during an operating reactor, there's nothing that is taking place during decommissioning that is extraordinary as compared to the safety and environmental considerations of an operating reactor.

And therefore the Commission put in place the process that we have today, whereby the PSDAR would be submitted, certain information would be provided in that PSDAR, and you've seen the contents of that in some of the slides today -- and then the emphasis is put then upon the ultimate end state of the site.

What does the site look like from a radiological standpoint when that license is prepared to be terminated?

Now, one can criticize that process, I understand that. I am merely offering an explanation as to why it is the way that it is.

Now we ask questions, we have asked

questions, of other PSDARs in the past that have been submitted. We may find ourselves asking questions about this PSDAR.

But I want to point out that the reason we ask the questions, and the reason that we review the PSDAR, is to ensure that our regulations are in fact met.

We have the authority to stop this decommissioning or any other decommissioning at the PSDAR state if we can't get answers to the questions that lead us to believe that our regulations would be complied with. We have regulatory tools that would let us do that.

So we have the authority to say no, even though we don't approve the PSDAR as such, for the reasons I've just explained.

So do understand that we do have that authority to say no.

There's been a great deal of talk about moving the fuel. I think we all think that that's a very legitimate concern. Our country, our -- we do not have a national policy at this point in place that leads to moving of the fuel to another location from the coast here.

I think we all prefer, would prefer, that we did. But that's a national policy decision. It's

not a decision that SCE can make, it's not a decision that we can make, it's a national policy issue.

What we have to do is make sure that this decommissioning takes place in a safe manner, and that the fuel that remains in dry cask storage on the pad is done safely and in a way that will protect public health and safety.

I hear a great deal of interest in the cask of choice, in the cask performance considerations. Those are very fair questions, those are very fair concerns. And we'll do everything that we can to continue to put information on our website that will enunciate the various studies and things that we're working on that Al commented on in his presentation as he answered questions.

Why exemptions? Another fair question. The reason that we grant exemptions for things such as emergency preparedness and certain security considerations, operator qualifications when reactors move into decommissioning, is because our regulations currently in Part 50 are designed around an operating reactor.

We have not yet put in place a set of regulations that would be appropriate once the reactor had gone from operations into decommissioning.

The reason that we haven't is in the year 2000 the staff started down the pathway of a Rule that would articulate specifically what are the conditions that the reactors must be in when in a decommissioning mode. That Rulemaking was put on the back burner, it was postponed, by the Commission, because at the time, it was determined that we had higher priority Rulemakings to work on that dealt with security in a post-9/11 environment.

So, I'll stop there. I think there has been some excellent comments. We thank you for those. We will consider them. And we'll look forward to communicating with you more as we go through the process.

FACILITATOR CAMERON: Okay. And thank you, Larry.

And here's where you can submit email comments or hard comments, hard copy comments, right there. That will remain up there, and there are copies of the Post-Shutdown Report, compact disks out on the table there. So, thank you.

(Whereupon, the meeting went off the record at approximately 9:00 p.m.)

NRC ISFSI Pad Surveys at San Onofre Nuclear Generating Station

Scope:

To perform independent measurements and verifications of radiological conditions at San Onofre Independent Spent Fuel Storage Installation (ISFSI). The measurement locations included background areas, public access areas in the owner controlled areas, protected areas of the facility, and representative measurement areas on both generally licensed ISFSI Pads: Transnuclear, (TN) Inc. Nuclear Horizontal Modular Storage (NUHOMS) and Holtec HI-STORM UMAX dry fuel storage systems.

Equipment Used:

The NRC used a Ludlum Model 19, a sodium iodide instrument calibrated to Cesium-137, which is representative of the gamma energy level at the facility. The instrument used was NRC Tag Number 033906, serial number 84259, with an annual calibration due date of July 23, 2019.

Survey Methodology:

On October 22, 2018, all surveys were performed by the NRC Inspectors.

The survey methodology for the Holtec HI-STORM UMAX systems consisted of a gamma exposure rate at 16 points on each Vertical Ventilated Module (VVM) that was loaded. The points encompassed 8 inlet air vents (Figure 1), 4 points on the closure lid at locations representing 0º, 90º, 180º, and 270º (Figure 2), and at 4 points on the outlet air vent at locations representing 0º, 90º, 180º, and 270º (Figure 2).

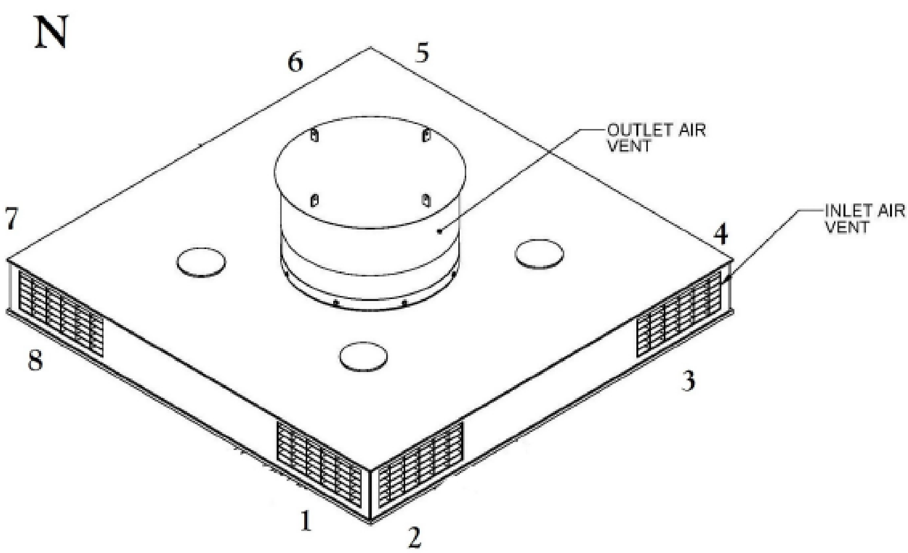

Figure 1

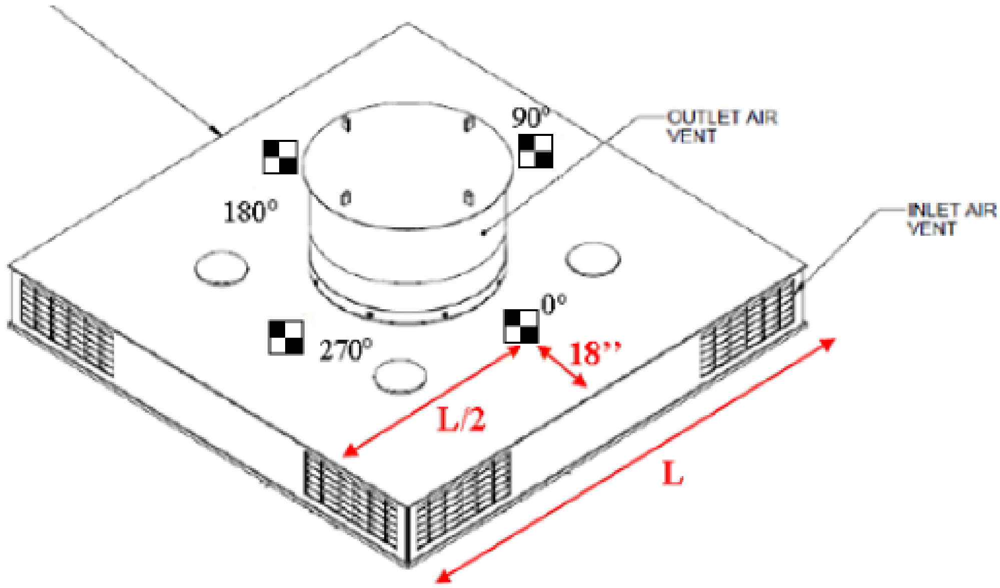

Figure 2

The survey methodology for the TN NUHOMS systems consisted of a gamma exposure rate survey at two points on the air inlet vent for each loaded TN system. These measurement points consisted of a contact survey measurement on the air inlet vent and at 1 foot away from the air inlet vent (Figure 3), for each of the loaded TN systems.

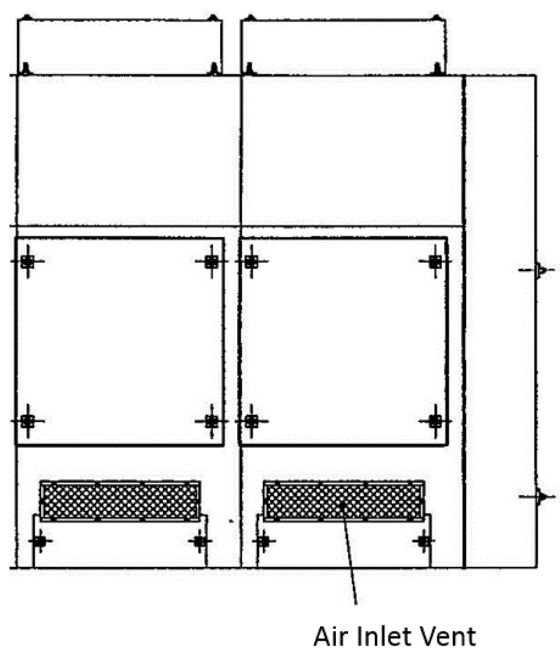

Figure 3

In addition, the NRC performed survey measurements at many locations around the ISFSI pad, Unit 1 Reactor Pressure Vessel, behind the sea wall of the plant, in the upper parking lot of the plant access, and along the bluff overlooking the ISFSI pad. The NRC identified the survey measurement location for each data point on maps of the site layout and documented the data on data point sheets for each of the loaded canister systems.

Results of NRC Surveys:

Holtec HI-STORM UMAX:

Highest gamma measurement was from VVM #33:
Inlet air vents: 330 μR/hr
Closure lid: 18 μR/hr
Outlet air vent: 240 μR/hr

Lowest gamma measurement was from VVM #22:
Inlet air vents: 160 μR/hr
Closure lid: 15 μR/hr
Outlet air vent: 120 μR/hr

General area gamma exposure rate on the Holtec UMAX pad ranged between: 8-15 μR/hr

TN NUHOMS:

Highest gamma measurement was from TN #21:
Inlet Vent on Contact: 1,600 μR/hr, 1 Foot Away from Inlet Vent: 1,100 μR/hr

Lowest gamma measurement was from TN #15:
Inlet Vent on Contact: 100 μR/hr, 1 Foot Away from Inlet Vent: 70 μR/hr

General area gamma exposure rate on the TN pad ranged between: 4-14 μR/hr

Other survey measurement results include the following locations:

Unit 1 Reactor Vessel: Highest Gamma Measurements: 20 μR/hr
Lowest Gamma Measurements: 6 μR/hr (both sides)

Along the beach behind the sea wall ranged between: 5-10 μR/hr

Along the bluff overlooking the ISFSI Pad ranged between: 3-6 μR/hr

Upper Parking Lot ranged between: 4-8 μR/hr

Southern California Edison Dose Rate Limits:

Holtec HI-STORM UMAX: (Technical Specification 5.3.3)

Locations	Neutron	Gamma	Total
Closure Lid Cover Plate	200 µR/hr 0.2 mR/hr	400 µR/hr 0.4 mR/hr	600 µR/hr 0.6 mR/hr
Outlet Vents	1,000 µR/hr 1.0 mR/hr	1,800 µR/hr 1.8 mR/hr	2,800 µR/hr 2.8 mR/hr

TN NUHOMS:

There are no cask related technical specifications.

Conclusion:

Based on the surveys performed on October 22, 2018, the NRC has no safety or regulatory concerns with the loaded spent fuel canisters on the ISFSI Pads at San Onofre. The independent surveys performed by the NRC using NRC survey instruments which are calibrated annually, were all well below the applicable technical specifications values. The highest dose rate values that were measured were the TN NUHOMS System at 1,600 µR/hr on contact and 1,100 µR/hr at 1 foot away from the Inlet Vent.

Revision 1

Standard Review Plan for Renewal of Specific Licenses and Certificates of Compliance for Dry Storage of Spent Nuclear Fuel

Final Report

Manuscript Completed: May 2016
Date Published: June 2016

Office of Nuclear Material Safety and Safeguards

ABSTRACT

This Standard Review Plan is intended for use by the U.S. Nuclear Regulatory Commission (NRC) reviewer. It provides guidance for the safety review of renewal applications for specific licenses of independent spent fuel storage installations and certificates of compliance (CoCs) of dry storage systems, as codified in Title 10 of the *Code of Federal Regulations* (10 CFR) Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel, High-Level Radioactive Waste, and Reactor-Related Greater Than Class C Waste."

This Standard Review Plan provides guidance for the review of general information, scoping evaluation information, and aging management information, included in a renewal application. The guidance provides information on review of time-limited aging analyses and aging management programs (AMPs), including learning AMPs that consider and respond to operating experience. The guidance provides example AMPs for welded stainless steel canisters, reinforced concrete structures, and a high burnup fuel monitoring and assessment program. It also provides guidance on considerations for CoC renewals and the general license framework, including guidance on general licensees' implementation of AMPs.

The NRC expects to periodically revise and update this Standard Review Plan to clarify the content, correct errors, and include new information, knowledge, and experience regarding aging management considerations. Comments, suggestions for improvement, and notices of errors or omissions should be sent to the Director, Division of Spent Fuel Management, U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001.

Paperwork Reduction Act Statement

This NUREG contains information collection requirements that are subject to the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 et seq.). The Office of Management and Budget (OMB) approved these information collections under OMB control number 3150-0132.

Public Protection Notification

The NRC may not conduct or sponsor, and a person is not required to respond to, a request for information or an information collection requirement unless the requesting document displays a currently valid OMB control number.

INTRODUCTION

This Standard Review Plan (SRP) is intended to provide guidance to the U.S. Nuclear Regulatory Commission (NRC) staff for the safety review of renewal applications for specific licenses of independent spent fuel storage installations (ISFSIs) and certificates of compliance (CoCs) of dry storage systems (DSSs), as codified in Title 10 of the *Code of Federal Regulations* (10 CFR) Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel, High-Level Radioactive Waste, and Reactor-Related Greater Than Class C Waste."

To renew a specific license, an applicant (i.e., the licensee) must submit a license renewal application at least 2 years before the expiration of the license, in accordance with the requirements of 10 CFR 72.42(b). To renew a CoC, an applicant (i.e., CoC holder, user, or user's representative) must submit a renewal application at least 30 days before the expiration of the associated CoC in accordance with the requirements of 10 CFR 72.240(b). The NRC may renew a specific license or a CoC for a term not to exceed 40 years, in accordance with 10 CFR 72.42(a), or 10 CFR 72.240(a), respectively.

The NRC-approved DSSs listed in 10 CFR 72.214, "List of Approved Spent Fuel Storage Casks," may be used by any 10 CFR Part 72 general licensee in accordance with 10 CFR 72.212, "Conditions of General License Issued Under § 72.210." The term of a general license is tied to the term of the CoC being used. Within the general license term, each DSS has its own storage term that begins when that DSS is placed into service at the ISFSI (see Appendix F for a discussion of storage terms). When a CoC is renewed, the associated users' general licenses are also renewed. If the CoC holder chooses not to apply for the renewal of a particular CoC or is no longer in business, a licensee, licensee's representative, or another certificate holder may apply for renewal of the CoC in place of the CoC holder.

Both the specific-license and the CoC renewal applications must contain requirements and operating conditions (fuel storage, surveillance and maintenance, and other requirements) for the ISFSI or DSS that address aging mechanisms and aging effects that could affect structures, systems, and components relied upon for the safe storage of spent fuel. Renewal applications must include (1) time-limited aging analyses, if applicable, that demonstrate that structures, systems, and components important to safety will continue to perform their intended function for the requested period of extended operation, and (2) aging management programs for management of issues associated with aging that could adversely affect structures, systems, and components important to safety. Licensees and applicants are encouraged to meet with the NRC staff at public pre-application meetings to discuss their proposed plans for the renewal application.

The technical review of the renewal application is primarily a materials engineering effort. The materials discipline should coordinate its review of the renewal application with other disciplines, such as the structural, radiation protection, thermal, criticality, and quality assurance disciplines, as appropriate, to help ensure that relevant aspects of the application and review have been addressed.

This SRP defines an acceptable method for the NRC staff to review and determine if the applicant demonstrates that the specific-licensed ISFSI or the certified DSS will continue to meet the applicable regulatory requirements of 10 CFR Part 72 during the period of extended operation. The reviewer should be aware that additional interim staff guidance may have been issued to clarify or address issues following the publication of this guidance. This SRP defines

an acceptable method for satisfying the applicable regulatory requirements; it is not a regulatory requirement. An applicant may propose alternate means for satisfying the appropriate regulatory requirements. However, deviation from this guidance in whole or in part may result in an extended NRC staff review schedule.

The NRC expects to periodically revise and update this SRP to clarify the content, correct errors, and include new information, knowledge, and experience regarding aging management considerations. Comments, suggestions for improvement, and notices of errors or omissions will be considered by, and should be sent to the Director, Division of Spent Fuel Management, Office of Nuclear Material Safety and Safeguards, U.S. Nuclear Regulatory Commission, Washington, DC 20555-0001.

The guidance document is not intended to be used for the review of other 10 CFR Part 72 renewal applications, such as those for wet storage facilities or monitored retrievable storage installations.

This guidance document is also not intended to be used as the sole guidance for the review of a specific license application for an “interim consolidated storage facility” (ICSF), where a DSS structure, system, and component (SSC) has been in storage at one location for some period of time and then is transported to a second location (ICSF) for subsequent storage. Guidance for review of an application for a 10 CFR Part 72 specific license is located in NUREG-1567, “Standard Review Plan for Spent Fuel Dry Storage Facilities.” However, as the DSS SSCs that will be in storage at a potential ICSF enter the period of extended operation, this guidance document is applicable to the aging management of such DSS SSCs.

Figure A is a flowchart of the specific-license and CoC renewal process.

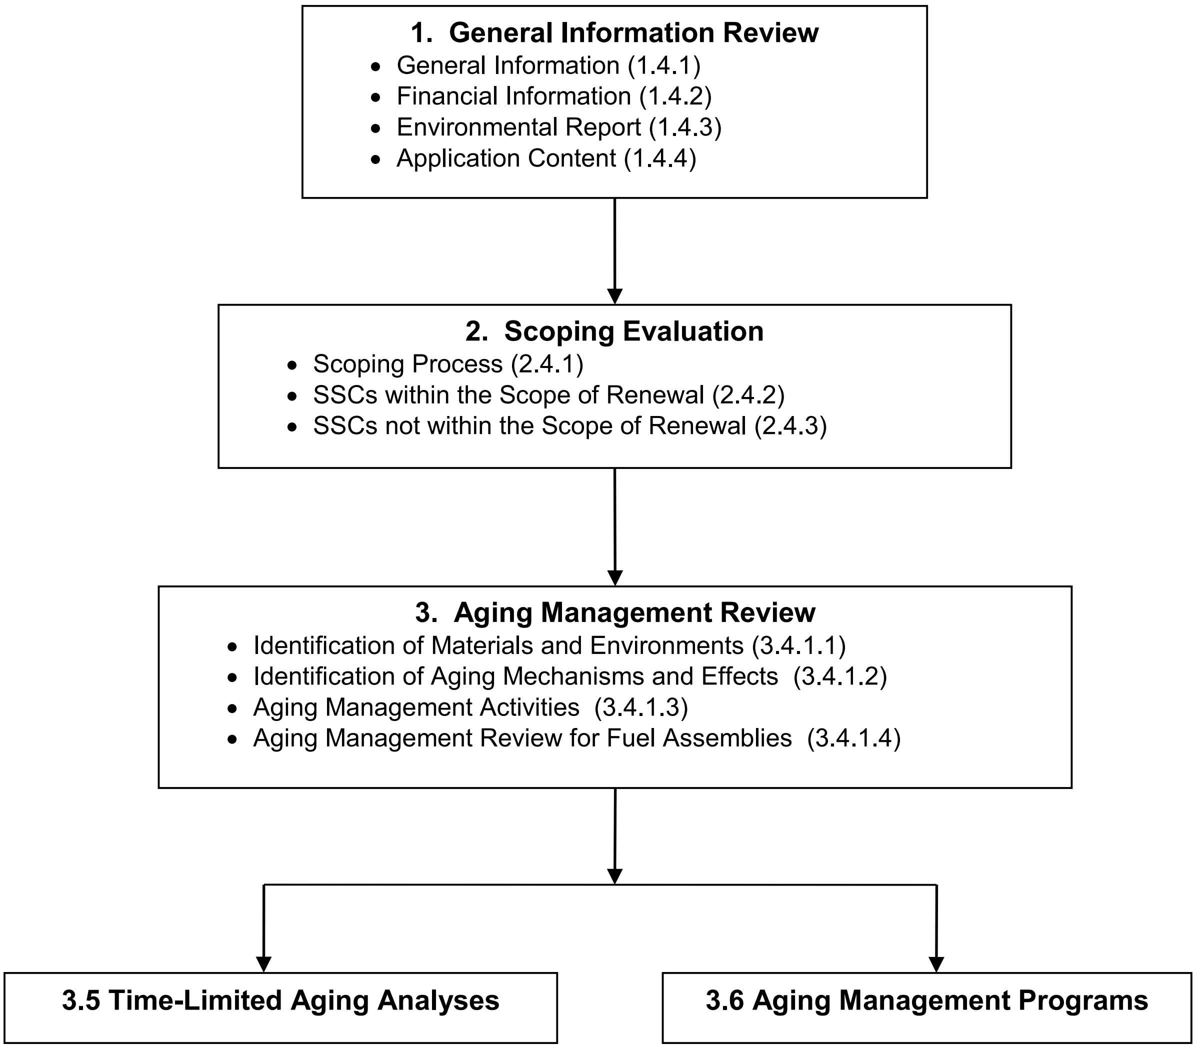

Figure A. Specific-license and CoC renewal process

Revision 1

Based on lessons learned from reviews of specific-license and CoC renewal applications and input received from the public and industry, the NRC staff proposed changes to NUREG-1927, Revision 0, to add greater detail and clarity. The staff held public meetings, including a public meeting on July 14–15, 2014, to solicit stakeholder input on the staff's considerations for revisions to the guidance. The staff subsequently took stakeholder input into consideration and developed the draft NUREG-1927, Revision 1, which was published for public comment on July 7, 2015 (80 FR 38780). The staff considered public comments received on the draft guidance in preparing the final NUREG-1927, Revision 1. The public comments are located in the Agencywide Documents Access and Management System (ADAMS) Package Accession No. ML15356A560. The staff also prepared responses to the public comments, at ADAMS Accession No. ML16125A534.

This revision of NUREG-1927 focuses on expanding guidance on application content, scoping evaluation, aging management review, time-limited aging analyses, and elements of an aging management program (AMP), including evaluation of AMPs and ensuring these programs respond to operating experience to remain adequate throughout the period of extended operation (i.e., learning AMPs). This revision of NUREG-1927 also includes new guidance in the areas of: (1) timely renewal, (2) amendment applications submitted during renewal reviews and after the renewal is issued, (3) use of terms, conditions, and specifications for ensuring AMPs remain adequate during the period of extended operation, (4) commencement of AMPs for CoC renewals and implementation of AMPs, (5) example AMPs, (6) use of a demonstration program as a surveillance tool for high burnup fuel performance, and (7) storage terms (and calculation of length of time that a dry storage system can remain loaded).

This revision to NUREG-1927 was developed in parallel with an ongoing effort by the Nuclear Energy Institute (NEI) to develop guidance for the industry in the preparation of applications for renewal of specific licenses and CoCs. NEI 14-03, Revision 1, "Format, Content and Implementation Guidance for Dry Cask Storage Operations-Based Aging Management" (ADAMS Accession No. ML15272A329), includes guidance on the continued evaluation of operating experience (see Section 3.6.1.10 of NUREG-1927, Revision 1). One of the principles introduced in NEI 14-03 is the use of "tollgates" as a structured approach for assessing operating experience and data from applicable research and industry initiatives. In addition, NEI 14-03 describes an initiative to aggregate and disseminate aging-related operating experience, research results, monitoring feedback, and inspection data between licensees. The staff provided comments on NEI 14-03, Revision 0, "Guidance for Operations-Based Aging Management for Dry Cask Storage" (ADAMS Accession No. ML14266A225), to NEI on January 21, 2015 (ADAMS Accession No. ML15013A201). At the time of publication, the staff was continuing its review of NEI 14-03, Revision 1, for proposed NRC endorsement. However, until a time when NEI 14-03 may be endorsed by NRC, Section 3.6.1.10 of NUREG-1927, Revision 1, provides guidance to reviewers regarding information in NEI 14-03 that may be used or referenced by applicants for specific license or CoC renewals.

Standard Review Plan Structure

Each chapter of this SRP contains the following sections:

Review Objective: This section provides the purpose and scope of the review and establishes the major review objectives for the chapter. It also discusses the information needed, or coordination expected, from other NRC staff to complete the technical review.

Areas of Review: This section describes the structures, systems, and components; analyses, data, or other information; and their sequence in the discussion of acceptance criteria.

Regulatory Requirements: This section summarizes the regulatory requirements in 10 CFR Part 72 pertaining to the scoping process, aging management review, and aging management activities that include the time-limited aging analyses review. This list is not all-inclusive, and the reviewer should be aware that other parts of the regulations, such as 10 CFR Part 20, “Standards for Protection against Radiation,” are assumed to apply to all licensees. The reviewer should read the complete language of the current version of 10 CFR Part 72 to determine the proper set of regulations for the section being reviewed.

Review Guidance: This section discusses the specific technical information that should be included in the application and reviewed for regulatory compliance. The review guidance can be supplemented by interim staff guidance, NUREGs, etc.

Evaluation Findings: This section provides sample summary statements for evaluation findings to be incorporated into the safety evaluation report (SER) for each area of review. The reviewer prepares the evaluation findings based on the satisfaction of the regulatory requirements. The NRC publishes the findings in the SER.

1. GENERAL INFORMATION REVIEW

1.1 Review Objective

The purpose of the general information review is to ensure that the specific-license or certificate of compliance (CoC) renewal application meets the requirements listed in Section 1.3 below.

1.2 Areas of Review

Areas of review addressed in this chapter include the following:

- general information (specific license only)
- financial information (specific license only)
- environmental report (specific license only)
- application content

Areas specifically excluded from the renewal review include the following:

- structures, systems, and components (SSCs) associated with physical protection of the independent spent fuel storage installation (ISFSI) or dry storage system (DSS), under Title 10 of the *Code of Federal Regulations* (10 CFR) Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste, and Reactor-Related Greater Than Class C Waste," Subpart H, "Physical Protection"

- SSCs associated with the ISFSI emergency plan, under 10 CFR 72.32, "Emergency Plan"

1.3 Regulatory Requirements

Table 1-1 presents a matrix that identifies the specific regulatory requirements pertaining to application content, general information about the specific licensee or CoC holder, financial information, and the environmental report. Additional regulatory requirements for the environmental report can be found in 10 CFR Part 51, "Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions."

Table 1-1. Relationship of Regulations and General Information Review

Areas of Review	72.22 [a] (a), (b), (c), (d)	72.22 [a] (e)	72.30(c) [a]
Application Content	•		
General Information	•		
Financial Information		•	•

Areas of Review	72.34 [a]	72.42 [a]	72.48(d)	72.240 [b] (b), (c), (d)
Application Content		●	●	●
General Information				
Financial Information				
Environmental Report	●			

[a] These regulations apply only to specific license renewals per 10 CFR 72.13, "Applicability."
[b] These regulations apply only to CoC renewals per 10 CFR 72.13.

1.4 Review Guidance

This section provides review guidance for general information (Section 1.4.1), financial information (Section 1.4.2), environmental report (Section 1.4.3), and application content (Section 1.4.4). This section also provides information on timely renewal (Section 1.4.5), amendment applications submitted during the renewal review or after the renewal is issued (Section 1.4.6) and license and CoC conditions (Section 1.4.7).

1.4.1 General Information

The U.S. Nuclear Regulatory Commission (NRC) project manager (PM) should ensure that the specific licensee has provided information under 10 CFR 72.22(a)–(d), including the specific licensee's full name, address, and description of the business or occupation. If the specific licensee is a partnership, the application should identify the name, citizenship, and address of each partner, and the principal location where the partnership does business. If the specific licensee is a corporation or an unincorporated association, the application should specify the State in which it is incorporated or organized and the principal location at which it does business, along with the names, addresses, and citizenships of its directors and principal officers. If the specific licensee is acting as an agent or representative of another person in filing the application, the application should provide the above information for the principal. If the specific licensee is the U.S. Department of Energy, then the application should specify the organization responsible for the construction and operation of the ISFSI and describe any delegations of authority and assignments of responsibilities.

1.4.2 Financial Information

In general, the PM should ensure that the renewal application for a specific license contains the necessary documentation regarding financial data, under 10 CFR 72.22(e), which shows that the specific licensee can carry out the proposed activities for the requested duration. Information should state where the activity will be performed, the general plan for carrying out the activity, and the period of time for which the specific license is requested. The PM should

ensure that the renewal application is based only on the approved design bases and does not include additional construction costs beyond the design bases. The application should identify other costs related to activities associated with managing aging mechanisms and effects, and it should identify ISFSI operating and decommissioning costs that have been revised from those specified in the original specific-license application for construction, operation, and decommissioning. In addition, the application should include a decommissioning funding plan that identifies any changes in decommissioning costs and the extent of contamination, pursuant to 10 CFR 72.30(c).

The scope of this standard review plan (SRP) does not include specific guidance for reviewing financial information. Financial reviews should be coordinated with financial reviewers in the Performance Assessment Branch of the Office of Nuclear Material Safety and Safeguards (NMSS) or the Office of Nuclear Reactor Regulation.

1.4.3 Environmental Report

The PM should ensure that the specific-license renewal application contains an environmental report or supplement, as required by 10 CFR 51.60, "Environmental Report—Materials Licenses" and 10 CFR 72.34, "Environmental Report." The supplemental report may be limited to incorporating by reference, updating, or supplementing the information previously submitted to reflect any significant environmental changes, including those that may result from operating experience as related to environmental conditions, or a change in operations or proposed decommissioning activities.

The environmental report should also meet the general requirements of 10 CFR 51.45, "Environmental Report," as applicable. As required by 10 CFR 51.45(c), the environmental report should contain sufficient data to aid the NRC in its development of an independent analysis.

The review of the environmental report should be coordinated with the Environmental Review Branch of NMSS.

1.4.4 Application Content

The reviewer should look for a map or guide to the renewal application to assist in its review, because the format may vary from that of a standard safety analysis report (SAR). The PM or reviewer should verify that the renewal application for both CoC and specific-license renewals contain all of the following sections:

- general Information (specific license only)
- scoping evaluation
- aging management review (AMR)
- time-limited aging analyses (TLAAs)
- aging management programs (AMPs)
- information pertaining to granted exemptions and their implication to aging management

- changes or additions to technical specifications or to the specific license or CoC

- supplement to the final safety analysis report (FSAR), including:

  - scoping results
  - table of AMR results
  - summary of TLAAs and TLAAs' conclusions
  - summary of AMPs

- annotations to show 10 CFR 72.48 ("Changes, Tests, and Experiments") changes since last biannual update as required by 10 CFR 72.48(d)(2) or any other changes from either the SAR pages included with the last approved amendment (or initial) application, or the FSAR, whichever is most recent

For CoC renewal applications that involve multiple amendments, the PM or reviewer should verify that the renewal application also includes:

- a description of the organization of the renewal application as it relates to the different amendments (i.e., for the CoC as a whole)

  - This could be in the form of a guide to the renewal application to identify the sections or appendices applicable to each CoC amendment.

- a clear description of each amendment

  - That is, what each amendment changed from (or added to) the initial certificate (i.e., "amendment 0"), or what each amendment changed from (or added to) the previous amendments, should be described.

- a clear description of the scope and content of the renewal application as it applies to each amendment

  - If there are different SSCs, materials, contents specifications, or environments described in the different CoC amendments, the application should specify any differences in the scoping evaluation, aging management review, TLAAs, and AMPs, for each individual amendment.

A CoC renewal includes the initial certificate ("amendment 0") and all subsequent amendments. The subsequent amendments have the same termination date as the initial certificate. The CoC holder has the option to request that only certain (i.e., not all) amendments under a CoC be renewed. If amendments are not renewed, upon expiration, casks loaded under that amendment would need to be removed from service when they reach the end of their storage term (see Appendix F for calculation of storage terms). As a means to extend the storage term, a general licensee (cask user) also may have the option to apply changes authorized by another amendment to the CoC that has been renewed, to a cask loaded under an amendment that has not been renewed following the requirements in 10 CFR 72.212.

Drawings provided as part of the renewal application should be clear and legible. If information in drawings is unclear or illegible, the PM should ask the applicant for additional, larger or full-size drawings. The reviewer should ensure that dimensions, materials, and other details on

the drawings are consistent with those described in both the text of the renewal application and the FSAR supplement.

The reviewer should verify that the applicant has updated the appropriate drawings to reflect any changes made to the design of the SSCs through the application of 10 CFR 72.48. Reviewers should be familiar with NUREG/CR-5502, "Engineering Drawings for 10 CFR Part 71 Package Approvals," issued May 1998. Although NUREG/CR-5502 was developed for transportation packages, the criteria for drawings are consistent for storage designs and therefore useful to the review process.

If the applicant provided drawings and descriptions as proprietary information in the application and requested them to be withheld from the public, the PM should review the request for withholding and ensure all the necessary information is available for the NRC to make a decision on the withholding request, in accordance with the requirements of 10 CFR 2.390, "Public Inspections, Exemptions, Requests for Withholding." The applicant should also submit a nonproprietary version of the document to be made available to the public.

The reviewer should ensure the specific-license or CoC renewal application does not include any changes to the design bases. Changes to the design bases must be requested through a separate amendment process. However, the renewal application may include editorial changes or corrections that do not change the design bases.

1.4.5 Timely Renewal

To renew a specific license, an applicant must submit a renewal application at least 2 years before the expiration of the license in accordance with the requirements of 10 CFR 72.42(b). To renew a CoC, an applicant must submit a renewal application at least 30 days before the expiration of the CoC in accordance with the requirements of 10 CFR 72.240(b). When the applicant has submitted a timely application for renewal, the existing specific license or CoC will not expire until a final decision concerning the application for renewal has been made by the Commission. Therefore, any DSSs loaded during the initial license or CoC period may remain in service until the review of the renewal application is complete.

1.4.6 Amendment Applications Submitted during the Renewal Review or after the Renewal Is Issued

By regulation, applicants must demonstrate that SSCs important to safety will continue to perform their intended function(s) for the requested period of extended operation as a part of the renewal request. For *concurrent amendment and renewal applications*, the amendment application should include a scoping evaluation and an AMR for that amendment to document the evaluation of the amendment's SSCs (and associated subcomponents) for extended operation, or the renewal application should be supplemented to address the proposed amendment to document the evaluation of the amendment's SSCs (and associated subcomponents) for extended operation. Any *amendment application submitted after the renewal has been issued* (*post-renewal amendment applications)* should include a scoping evaluation and an AMR for that amendment.

For post-renewal amendment applications or concurrent amendment applications that include a scoping evaluation and an AMR, the amendment application should either: (1) show that the in-scope SSCs (and associated subcomponents) described in the amendment are already encompassed in the TLAAs or AMPs included in the specific-license or CoC renewal

application, or (2) include revised or new TLAAs or AMPs to address aging effects of any new in-scope SSCs (and associated subcomponents) proposed in the amendment application. The PM and technical reviewers should verify that the following information is included in the amendment application (see also Section 1.4.4):

- a scoping evaluation that identifies any new SSCs (and associated subcomponents) included in the amendment request and discusses whether the SSCs (and associated subcomponents) are included or excluded from the scope of renewal, following the guidance in Chapter 2

- an aging management review that identifies any applicable aging mechanisms and effects for the new SSCs (and associated subcomponents) within the scope of renewal

- changes to the FSAR, which should include:

  - scoping results and identification of any new in-scope SSCs

  - revised table of AMR results

  - identification of the approved TLAAs (or the TLAAs included in the renewal application, for concurrent amendments) that address the new in-scope SSCs, or identification and a summary of any revised or new TLAAs and the TLAAs' conclusions that support the amendment

  - identification of the approved AMPs (or the AMPs included in the renewal application, for concurrent amendments) that encompass the new in-scope SSCs (and associated subcomponents), or a summary of proposed changes to approved AMPs (or the AMPs in the renewal application, for concurrent amendments) or new AMPs that will apply to the new in-scope SSCs (and associated subcomponents)

For concurrent amendment and renewal applications, if there are different PMs assigned to the renewal review and the amendment review, the PMs and technical reviewers should coordinate across the reviews to ensure that renewal aspects are covered for the amendment. Note that, before proceeding with the review of an amendment submitted *during* the renewal review, the PMs should consider how each review may affect the other, and decide, in conjunction with Branch and Division management, whether to proceed with both reviews, or to delay one review until the other is complete. For additional guidance, refer to Regulatory Issue Summary (RIS) 2004-20, "Lessons Learned from Review of 10 CFR Parts 71 and 72 Applications, (NRC 2004)."

The NRC staff may include a condition in the renewed license or CoC noting all future amendments would need to address aging management.

1.4.7 Terms, Conditions, and Specifications for Specific Licenses and CoCs in the Period of Extended Operation

In renewing a license or CoC, the staff should consider whether any terms, conditions, or specifications are needed to ensure the safe operation of the ISFSI or DSS during the period of extended operation, including but not limited to, terms, conditions, and specifications that will require implementation of any AMPs. Several conditions are likely to be included in the license or CoC.

Generally, NRC staff will renew the license or CoC with a condition requiring the specific licensee or CoC holder, respectively, to incorporate a renewal supplement into the FSAR, as submitted in the renewal application and revised through the review process (see Section 1.4.4). The specific licensee will be required to continue to update the FSAR under the requirements in 10 CFR 72.70. The CoC holder will be required to continue to update the FSAR under the requirements in 10 CFR 72.248.

NRC staff may renew a license or CoC with a condition requiring licensees to implement the activities in the AMPs (e.g., update, revise, or create programs or procedures for AMP implementation) by a specific date (see Section 3.6.3). These programs and procedures will be subject to NRC inspection to ensure they are maintained, implemented, and periodically updated to respond to operating experience, while providing reasonable assurance that the pertinent SSCs will continue to perform their intended functions in the period of extended operation.

As the entirety of the AMP may not be included in the license, CoC, or technical specifications, site procedures for AMP implementation may later be changed without prior NRC review and approval. Therefore, the staff should consider whether additional conditions or specifications are needed in the specific license or CoC to ensure elements of the AMPs, which are the basis of the staff's findings and the decision to issue the renewal, are effectively retained or implemented (e.g., timeframes for development of inspection or examination methods). These conditions should be specific to information in the AMP described in the renewal application which staff relied upon to make the requisite safety findings of reasonable assurance of adequate protection of public health and safety, and the environment.

The entire AMPs may be included as an appendix to the staff's safety evaluation report (SER), for complete documentation of the staff's safety evaluation, findings, and decision to issue the renewal. The staff should include a separate section in the SER that includes any new or modified terms, conditions, or specifications that were added to the license or CoC as a result of the renewal review. This section should include the basis for each new or revised term, condition, or specification, or it should include a reference to the other sections of the SER that discuss the staff's evaluation and findings that form the basis for the new or revised term, condition, or specification.

For CoC renewals, additional terms, conditions, or specifications may be needed to ensure the safe operation of the cask during the renewal term, including but not limited to, terms, conditions, and specifications that will require the implementation of an AMP, in accordance with 10 CFR 72.240(e). Such conditions may include requirements for a future or existing general licensee (cask user) to include in its 10 CFR 72.212(b)(5) evaluation (including the results of the review and determination per 10 CFR 72.212(b)(6) and 10 CFR 72.212(b)(8)) how it will meet the new CoC terms, conditions, or specifications for aging management (see Appendix E).

The NRC staff may also include a condition in the renewed license or CoC to ensure that all future amendments address the renewed design bases for the ISFSI or CoC, including any aging management considerations. See Section 1.4.6 for guidance on post-renewal amendments.

In addition, the applicant may also propose additional license or CoC conditions as part of its application, if these support the technical basis for the application and the proposed TLAAs or AMPs that ensure the safe operation of the ISFSI or DSS during the period of extended operation.

1.5 Evaluation Findings

The reviewer prepares a summary statement and evaluation findings based on compliance with the regulatory requirements in Section 1.3. The summary statement and evaluation findings should be similar in wording to the following example (the finding number is for convenience in cross-referencing within the SRP and SER):

The NRC staff has reviewed the general information provided in the renewal application and supplemental documentation. The NRC staff performed its review following the guidance provided in NUREG-1927, Revision 1, "Standard Review Plan for Renewal of Specific Licenses and Certificates of Compliance for Dry Storage of Spent Nuclear Fuel," and relevant interim staff guidance. Based on its review, the NRC staff finds:

F1.1 The information presented in the renewal application satisfies the requirements of 10 CFR 72.2, 72.22, 72.30, 72.34, 72.42, 72.48, and 72.240, as applicable.

F1.2 The applicant has provided a tabulation of all supporting information and docketed material incorporated by reference, in compliance with 10 CFR 72.42 or 72.240, as applicable.

2. SCOPING EVALUATION

2.1 Review Objective

The scoping evaluation should identify the structures, systems, and components (SSCs) of the independent spent fuel storage installation (ISFSI) or dry storage system (DSS) that should be reviewed for aging mechanisms and effects.

2.2 Areas of Review

The reviewer should ensure that the applicant has included information about the following areas of review:

- scoping process
- SSCs within the scope of specific-license or certificate of compliance (CoC) renewal
- SSCs not within the scope of specific-license or CoC renewal

2.3 Regulatory Requirements

The U.S. Nuclear Regulatory Commission (NRC) bases a specific-license or CoC renewal on the continuation of the approved design bases throughout the period of extended operation. The entire design bases of the specific license or CoC is considered to be renewed when NRC issues a renewed license or CoC. However, the NRC's renewal review is focused on the maintenance of the intended functions of (a) SSCs important to safety and (b) SSCs failure of which may affect a safety function, as discussed in Section 2.4.2. This guidance document refers to such SSCs as those that are within the scope of renewal, and these are the SSCs that are further reviewed for aging mechanisms and effects, as discussed in Chapter 3, "Aging Management Review."

If new safety-related deficiencies in the design bases are discovered, they must be addressed and rectified through the specific-license or CoC amendment process. The renewal process cannot be used to facilitate approval of design changes.

Table 2-1 presents a matrix of regulatory requirements for renewal related to the scoping review.

Table 2-1. Relationship of Regulations and Scoping Review

Areas of Review	10 CFR Part 72 Regulations					
	72.3	72.24 [a] (b), (c), (d)	72.24 [a] (g)	72.42 [a] (b)	Subpart F: Applicable Sections 72.120, 72.122, 72.124, 72.126, 72.128	72.236 [b] Applicable Sections
Scoping Process			●	●		●
SSCs within the Scope of Specific-License or CoC Renewal	●	●	●		●	●
SSCs not within the Scope of Specific-License or CoC Renewal		●	●		●	●

[a] These regulations apply only to specific-license renewals per Title 10 of the *Code of Federal Regulations* (10 CFR) 72.13.
[b] These regulations apply only to CoC renewals per 10 CFR 72.13.

2.4 Review Guidance

This section provides review guidance for the scoping evaluation. Section 2.4.1 explains the scoping process, Section 2.4.2 discusses SSCs within the scope of renewal, while Section 2.4.3 provides guidance for SSCs not within the scope of renewal.

2.4.1 Scoping Process

Figure 2-1 provides a flowchart of the scoping evaluation process. The reviewer should ensure that the application provides documentation of the scoping process that includes the following:

- a description of the scoping process and method for the inclusion or exclusion of SSCs (and associated subcomponents) from the renewal scope
- a list of the SSCs (and associated subcomponents) that are identified as within the scope of renewal, their intended function, and safety classification or basis for inclusion in the renewal scope
- a list of the SSCs (and associated subcomponents) that are identified as *not* within the scope of renewal and basis for exclusion
- a list of the sources of information used
- any discussion or drawings needed to clarify the process, SSC intended functions and safety classifications

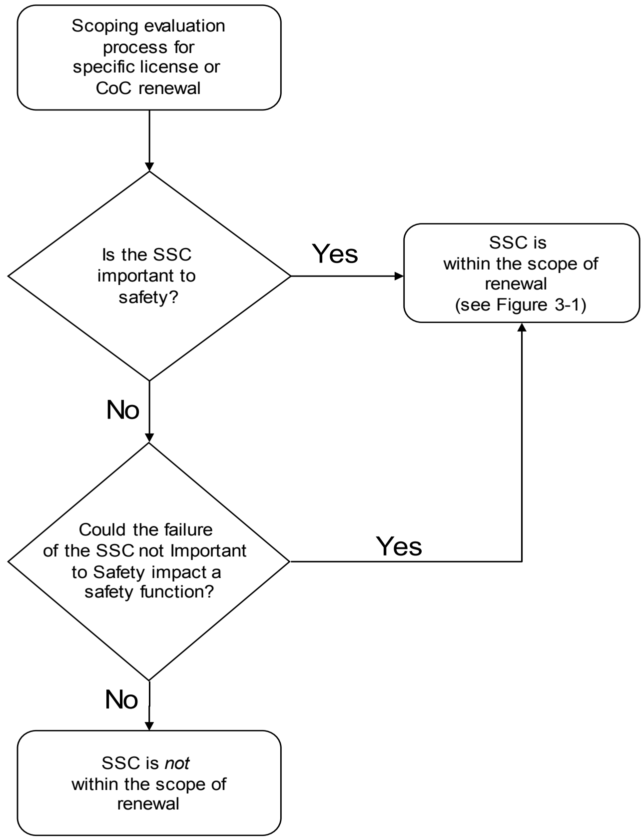

Figure 2-1. Flowchart of scoping evaluation process

The application should include a list and description of reference sources used to support the scoping evaluation. Sources may include the following:

- safety analysis reports (SARs), including final SARs (FSARs), updated FSARs, and topical SARs
- license or CoC
- technical specifications
- approved exemptions
- operating procedures
- design-bases documents (e.g., calculations, specifications, design change documents)
- drawings

- quality assurance plan or program
- docketed correspondence
- operating experience reports (site-specific or industrywide, as applicable)
- Title 10 of the *Code of Federal Regulations* (10 CFR) 72.48 (“Changes, Tests, and Experiments”) evaluations and screenings
- vendor information
- applicable NRC guidance

The reviewer can refer to NUREG/CR-6407, “Classification of Transportation Packaging and Dry Spent Fuel Storage System Components According to Importance to Safety,” as a reference for classification of components as important to safety to determine the accuracy and completeness of the scoping evaluation. The reviewer should ensure that the scoping evaluation has evaluated *all* SSCs identified in the design-bases documents and properly differentiated them as either within or *not* within the scope of renewal. In addition, the identification of SSCs and SSC subcomponents in the scoping evaluation should be consistent throughout the application.

2.4.2 Structures, Systems, and Components within the Scope of Renewal

The reviewer should verify that the SSCs (and associated subcomponents) within the scope of renewal fall into the following scoping categories:

(1) They are classified as important to safety, as they are relied on to do one of the following functions:

  i. maintain the conditions required by the regulations, specific license, or CoC to store spent fuel safely

  ii. prevent damage to the spent fuel during handling and storage

  iii. provide reasonable assurance that spent fuel can be received, handled, packaged, stored, and retrieved without undue risk to the health and safety of the public

  These SSCs ensure that important safety functions are met for (1) confinement, (2) radiation shielding, (3) sub-criticality control, (4) heat-removal capability, (5) structural integrity, and (6) retrievability.

(2) They are classified as <u>not</u> important to safety but, according to the design bases, their failure could prevent fulfillment of a function that is important to safety.

The reviewer should verify that SSCs within the scope of renewal are screened to identify and describe the subcomponents with intended functions. The reviewer should recognize that SSC subcomponents may degrade by different modes, or have different criteria for evaluation from the overall component (i.e., different materials or environments).

The scoping evaluation should clearly (1) define the intended function of each SSC subcomponent and (2) differentiate SSC subcomponents per scoping criteria 1 and 2, as defined above. The reviewer should ensure that this information is tabulated or adequately described in the application. The reviewer should confirm that this information is comprehensive and accurate (i.e., SSC subcomponents are not missing from the scoping evaluation; SSC subcomponent naming is consistent with the design bases; intended functions are properly described) by comparing the results of the scoping evaluation to appropriate final safety analysis report (FSAR) drawings or tables.

2.4.2.1 Scoping of Fuel Assemblies

Traditional light water reactor spent nuclear fuel consists of fuel rods and assembly hardware. In turn, the fuel rods consist of uranium oxide pellets inside a cladding tube. The spent fuel cladding and assembly hardware provide structural support to ensure that the spent fuel is maintained in a known geometric configuration. The safety analyses for an ISFSI or DSS (e.g., criticality and shielding analyses) may rely on the fuel assembly having a specific configuration (e.g., geometric form, a certain number of fuel rods or solid replacement filler rods in the assembly lattice). As the renewal of a specific license or CoC is based on continuation of the approved design bases throughout the period of extended operation (as discussed in Section 2.3), for these ISFSIs or DSSs, the renewal application should demonstrate that the analyzed fuel configuration is maintained during the period of extended operation. Therefore, the condition of the fuel assembly and cladding are within the scope of renewal and should be reviewed for any aging mechanisms and effects that may lead to a change in the analyzed fuel configuration. If a licensee or CoC holder wishes to revise the safety analyses for the approved design-bases fuel configuration (i.e., analyzed fuel configuration), it should pursue such a change through an amendment or revision request, and not as part of the renewal application.

2.4.2.2 Scoping of Structures, Systems, and Components, Depending on Individual Design Bases

In some cases, transfer casks, transporter devices, reinforced concrete pads, and other engineered features (e.g., earthen berms, shield walls, or engineered fill within an underground ISFSI) may be classified as important to safety or safety-related (under 10 CFR Part 50) in the design bases of various ISFSIs or DSSs. The reviewer should review the FSAR to determine how these SSCs are used in the FSAR evaluations and described in the license or CoC, to understand whether these SSCs are considered part of the design bases, and thus whether they are considered to be within the scope of renewal.

2.4.3 Structures, Systems, and Components Not within the Scope of Renewal

For those SSCs (and associated subcomponents) excluded from the scope of renewal, the reviewer should verify that they do not meet either of the criteria described in Section 2.4.2. The reviewer should ensure that the applicant has properly justified any exclusions by referencing the design bases (i.e., FSAR description, drawings, or tables).

The following SSCs may be excluded from the scope of renewal, provided that they do not meet either of the criteria in Section 2.4.2 above:

- equipment associated with cask loading and unloading, such as (1) welding and sealing equipment, (2) lifting rigs and slings, (3) vacuum-drying equipment, (4) portable radiation

survey equipment, and (5) other tools, fittings, hoses, and gauges associated with cask loading and unloading

- Instrumentation and other active components/systems (i.e., not passive or long-lived, but subject to a change in configuration or replacement based on a qualified life or service time period)

- miscellaneous hardware that does not support or perform any function that is important to safety

2.5 Evaluation Findings

The reviewer prepares the summary statement and evaluation findings based on compliance with the regulatory requirements described in Section 2.3. The summary statement and evaluation findings should be similar in wording to the following example (the finding number is for convenience in cross-referencing within the Standard Review Plan (SRP) and safety evaluation report (SER)):

The NRC staff reviewed the scoping evaluation provided in the renewal application and supplemental documentation. The NRC staff performed its review following the guidance provided in NUREG-1927, Revision 1, "Standard Review Plan for Specific Licenses and Certificates of Compliance for Dry Storage of Spent Nuclear Fuel," and relevant ISGs. The NRC staff used the information provided in NUREG/CR-6407 ("Classification of Transportation Packaging and Dry Spent Fuel Storage System Components According to Importance to Safety") in its review as a reference for classification of components as important to safety to determine the accuracy and completeness of the scoping evaluation. Based on its review, the NRC staff finds:

F2.1 The applicant has identified all SSCs important to safety and SSCs failure of which could prevent an SSC from fulfilling its safety function, per the requirements of 10 CFR 72.3, 10 CFR 72.24, 10 CFR 72.42, 10 CFR 72.120, 10 CFR 72.122, 10 CFR 72.124, 10 CFR 72.126, 10 CFR 72.128 and 10 CFR 72.236, as applicable.

F2.2 The justification for any SSC determined not to be within the scope of the renewal is adequate and acceptable.

3. AGING MANAGEMENT REVIEW

3.1 Review Objective

The purpose of the aging management review (AMR) is to assess the proposed aging management activities (AMAs) for structures, systems, and components (SSCs) determined to be within the scope of renewal. The AMR addresses aging mechanisms and effects [1] that could adversely affect the ability of the SSCs (and associated subcomponents) from performing their intended functions during the period of extended operation. The reviewer should verify that the renewal application includes specific information that clearly describes the AMR performed on SSCs within the scope of renewal.

3.2 Areas of Review

The reviewer should ensure that the AMR in the renewal application provides the following content with adequate technical bases:

- identification of materials and environments for those SSCs and associated subcomponents determined to be within the scope of renewal

- identification of aging mechanisms and effects requiring management

- identification of time-limited aging analyses (TLAAs), if applicable, and aging management programs (AMPs) for managing the effects of aging

Figure 3-1 contains a flowchart for the AMR process. The final safety analysis report (FSAR) and supporting documents related to the design are the primary documents that describe the safety classification, intended function, materials, and service environments for SSCs of independent spent fuel storage installations (ISFSIs), dry storage systems (DSSs), or both, identified to be within the scope of renewal (see Section 2.4.1).

The reviewer should consult applicable consensus codes and standards that provide additional guidance on the applicability of aging mechanisms and effects. The use of ambiguous terminology from any standard (e.g., “change in material properties”) should be properly defined or referenced in the application. Refer to Appendix A for assessing non-quantifiable terms.

1 To effectively manage an aging effect, it is necessary to determine the aging mechanisms that are potentially at work for a given material and environment application. Therefore, the aging management review process identifies both the aging effects and the associated aging mechanisms that cause them.

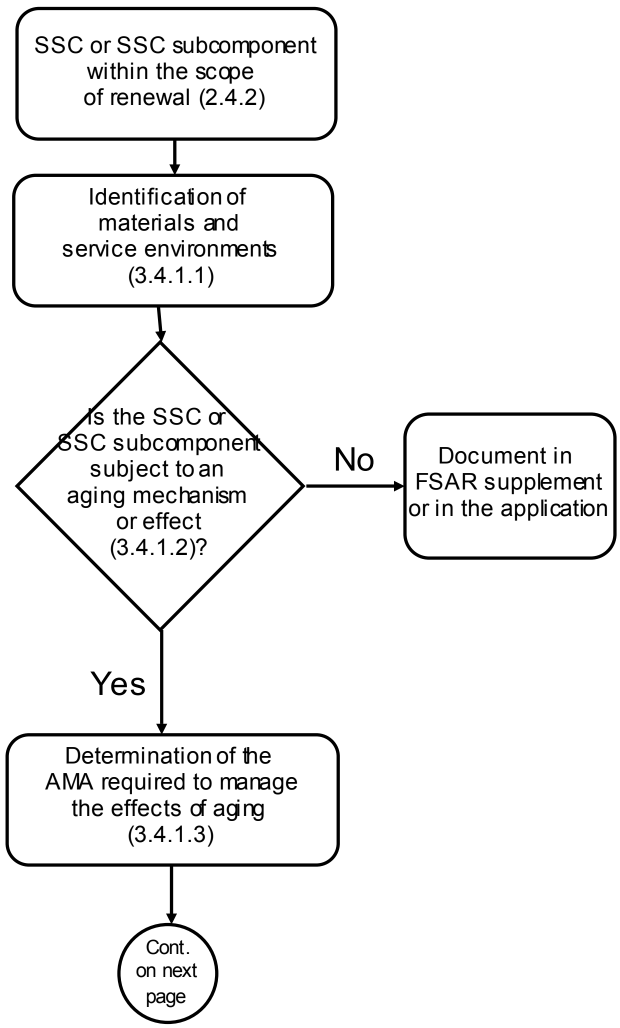

Figure 3-1. Flowchart of AMR process

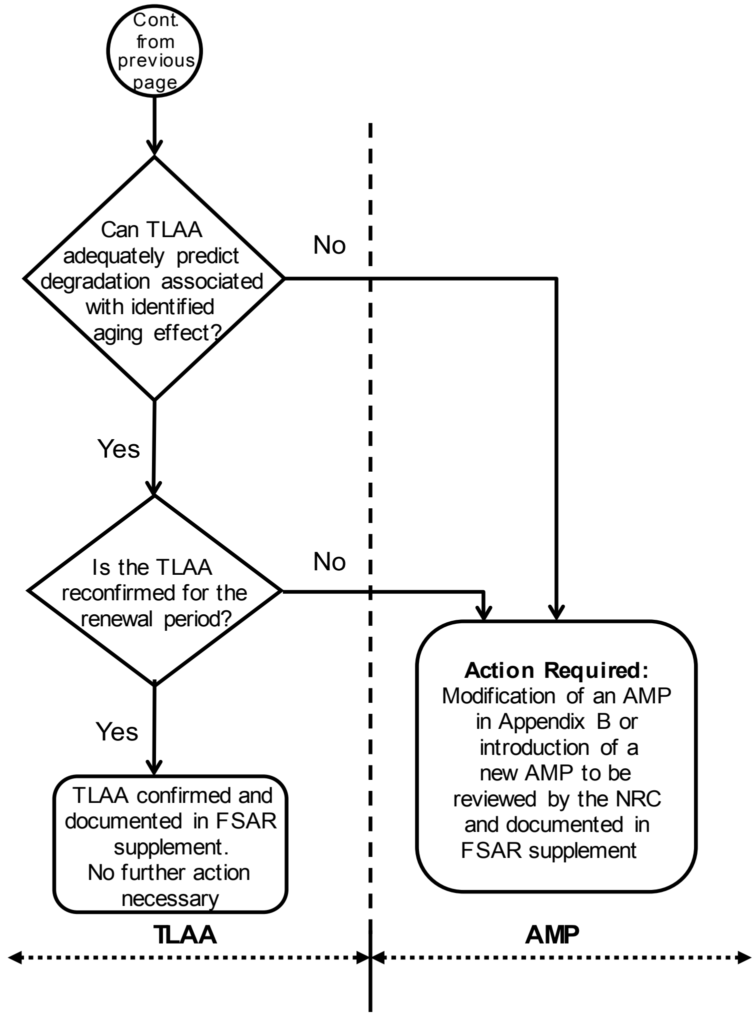

Figure 3-1. Flowchart of AMR process (continued)

3.3 Regulatory Requirements

Title 10 of the *Code of Federal Regulations* (10 CFR) 72.42 and 10 CFR 72.240 provide the overarching requirements for aging management activities for renewal of specific licenses and certificates of compliance (CoCs). Table 3-1 presents a matrix of regulatory requirements that must continue to be met to ensure that the intended functions of SSCs of ISFSIs and DSSs are maintained during the period of extended operation. Other parts of 10 CFR Part 72 may also apply.

3.4 Materials, Service Environments, Aging Mechanisms and Effects, and Aging Management Activities

3.4.1 Review Guidance

This section provides review guidance for the aging management review. Section 3.4.1.1 describes the identification of materials and their environments. Section 3.4.1.2 describes the identification of aging mechanisms and effects. Section 3.4.1.3 describes the review of aging management activities. Section 3.4.1.4 describes the aging management review for spent fuel assemblies.

3.4.1.1 Identification of Materials and Environments

The AMR process includes the identification of the materials of construction and the service environments for each SSC (or SSC subcomponent) within the scope of renewal. The identification of SSCs and SSC subcomponents in the AMR process should be consistent with the identification in the scoping evaluation. The reviewer should ensure that the renewal application has provided environmental data (and referenced the source of the data) such that the range of operating and service conditions of the SSCs can be determined. The pertinent environmental data is that which has a direct bearing on aging and the proposed aging management approach, and may include:

- temperature
- wind
- relative humidity
- relevant atmospheric pollutants and deposits
- exposure to precipitation
- marine fog, salt, or water exposure
- radiation field (gamma and neutron)
- the service environment (e.g., embedded, sheltered, or outdoor)
- gas compositions (e.g., external: air; internal: inert gas such as helium)

The reviewer should verify that the applicant considered the specific environment and material combinations in the DSS design for the evaluation of observed and potential aging mechanisms and effects that may lead to a loss of intended function. Particular attention should be paid to dissimilar metal combinations that may result in galvanic effects such as hydrogen uptake or galvanic corrosion. For sheltered environments that are in contact with the site atmosphere, the potential deposition and accumulation of atmospheric deposits should be evaluated. For example, chloride salt deposits that can promote accelerated corrosion of SSCs may be relevant in locations near salt water, adjacent to cooling towers, or in close proximity to roads that are treated with deicing salts.

3.4.1.2 Identification of Aging Mechanisms and Effects

The reviewer should ensure that the applicant has provided an analysis and documentation that identify aging mechanisms and effects pertinent to the SSCs determined to be within the scope of renewal. The AMR should include aging mechanisms and effects that could reasonably be expected to occur, as well as those that have actually occurred, based on industry and site-specific operating experience and component testing. The reviewer should ensure that the CoC renewal evaluates all potential environments where the DSS may be used and provides applicable operating experience to justify the AMR conclusions.

The reviewer should review the applicant's synopses of information used to identify applicable aging mechanisms and effects. Identification of applicable aging mechanisms and effects may be through review of:

- site maintenance, repair, and modification records
- corrective action reports, including root cause evaluations
- pre-application inspection results (see below)
- maintenance and inspection records from ISFSI sites with similar SSC materials and operating environments
- industry records
- applicable operating experience outside the nuclear industry
- applicable consensus codes and standards
- U.S. Nuclear Regulatory Commission (NRC) reports
- other applicable guidance for determining if an aging mechanism or effect should be managed for the period of extended operation

Examples of potential aging mechanisms and effects that may be identified by reviewing the sources of information cited above include: (1) cracking or loss of strength as a result of cement aggregate reactions in the concrete, (2) cracking or loss of material as a result of freeze-thaw degradation of the concrete (requires the presence of moisture combined with temperatures below freezing), (3) reinforcement corrosion and concrete cracking as a result of chloride ingress, (4) accelerated corrosion of steel structures and components and stress corrosion cracking of austenitic stainless steels as a result of atmospheric deposition of chloride salts.

The reviewer should ensure that, if the applicant relies on operating experience, it is specifically applicable to the SSC subcomponent/material/environment, and is not just a compendium of references on similar topics.

The applicant is not required to take further action if an SSC is determined to be within the scope of renewal but is found to have no potential aging effects for the period of extended operation. The reviewer should verify that the applicant's exclusion of an aging mechanism or effect is consistent with maintenance records, operating experience, and information obtained during pre-application inspection(s). The reviewer should also ensure that the FSAR supplement or other application materials document the applicant's determination of SSCs requiring no further review.

Pre-Application Inspections

Because inspections of DSSs are not typically conducted during the initial storage period, or are narrow in scope, the reviewer may have limited information regarding applicable aging mechanisms and effects for the specific design, environment, and operational parameters. Although there is no specific regulatory requirement for a pre-application inspection, it is one means by which an applicant can demonstrate that an aging effect does or does not require management. It can provide valuable operating experience and can be used to verify the condition of SSCs and SSC subcomponents is as-expected. The pre-application inspection is performed before submittal of the specific-license or CoC renewal application, and the inspection results become part of the technical bases for renewal.

Pre-application inspections should bound the site conditions, system designs, material combinations, and operating parameters that may contribute to the potential aging mechanisms and effects for SSCs and SSC subcomponents within the scope of renewal. For example, if chloride-induced stress corrosion cracking (CISCC) of a stainless steel canister is a potential aging mechanism, then the pre-application inspection should be conducted on the canister that has the greatest susceptibility to CISCC. The determination of susceptibility may involve the initial heat load of the canister, expected temperature variations on the canister surface with priority given to the coolest locations and welds, and the canister location if it is determined that some DSSs at a site may be located closest to or oriented toward a source of atmospheric chlorides. To address such variables, particularly for CoC renewal applications, pre-application inspections may involve SSCs in multiple DSSs at an ISFSI, and DSSs at multiple ISFSIs, as applicable.

Pre-application inspections may not include transfer casks or other similar SSCs that are leased or otherwise not actually on site. The latter SSCs are generally subject to maintenance requirements before use. Records from these maintenance activities may be included in the application in support of their respective aging management programs. Applicants are encouraged to discuss their considerations for selecting the system(s) to inspect with NRC staff in pre-application meetings before submitting the renewal application.

The reviewer should ensure that the scope, methods, and acceptance criteria for pre-application inspections align with the guidance for the AMP elements described in Section 3.6.1 of this document. The reviewer may use technical information in the example aging management programs in Appendix B as a reference when reviewing the adequacy of pre-application inspections. The reviewer should ensure that the application provides a description of any initiated corrective actions (including results from actions to verify extent of condition) due to conditions identified in the pre-application inspection(s).

The reviewer may accept the use of surrogate inspections (inspections conducted at other sites as a substitute for inspections conducted at the site(s) within the subject license or CoC) for identifying the relevant aging mechanisms and effects in the renewal application, but only when the technical basis is supported by substantial operating experience. Differences in materials, fabrication practices, design modifications, and environmental conditions at various sites could make comparisons between different ISFSI sites invalid.

The CoC holder is responsible for providing the technical basis for the proposed approach to aging management at multiple sites (where the CoC is and can be used). Therefore, pre-application inspections are likely only practical at a subset of sites that use the CoC. In this case, the reviewer should ensure that the chosen subset of sites is bounding with respect to the susceptibility of the various potential aging effects. Although CoC holders do not have the authority to conduct pre-application inspections at general licensee ISFSI sites, CoC holders could work within their user groups to identify bounding systems for the pre-application inspections. If pre-application inspections are not performed for each of the sites with the subject license or CoC, the reviewer should ensure that aging management programs include baseline inspections at each site upon entering the period of extended operation.

During baseline inspections, or the first inspections conducted per the AMPs, each licensee should assess the condition of SSCs: (1) to confirm the results of pre-application inspections that were conducted at other sites are bounding, or (2) to verify the adequacy of the AMPs and the conclusions of the TLAAs, when pre-application inspections were not performed. Also, the reviewer should consider whether uncertainties in SSC degradation due to the lack of a pre-application inspection warrant conditions in the license or CoC to require baseline inspections immediately upon entering the period of extended operation (see Section 1.4.7).

3.4.1.3 Aging Management Activities

The reviewer should ensure that the applicant has identified those aging mechanisms and effects requiring either an AMP or TLAA. Figure 3-1 illustrates the process for handling those SSCs that are determined to be within the scope of renewal and subject to a potential aging effect. The AMR defines two methods for addressing potential aging mechanisms and effects: TLAA (Section 3.5) and AMP (Section 3.6).

The NRC may condition the approval of a renewal on the requirements of a given AMP being met during the period of extended operation (see Section 1.4.7). The CoC user (general licensee) would ordinarily carry out the activities described in this AMP. Under 10 CFR 72.212(b)(11) and 10 CFR 72.240(e), the NRC may add the appropriate condition(s) or technical specification(s) to the renewed CoC for general licensee implementation of the AMP. Specific licenses may also be similarly conditioned (see Section 1.4.7).

3.4.1.4 Aging Management Review for Fuel Assemblies

Because the DSS interior and cladding cannot be reasonably inspected, the reviewer should rely on lessons learned from NUREG/CR-6745, “Dry Cask Storage Characterization Project—Phase 1; CASTOR V/21 Cask Opening and Examination,” (Bare et al., 2001), and NUREG/CR-6831, “Examination of Spent PWR Fuel Rods after 15 Years in Dry Storage,” (Einziger et al., 2003). This research demonstrated that low burnup fuel cladding and other cask internals had no deleterious effects after 15 years of storage. This research confirmed the basis for the guidance on creep deformation in Interim Staff Guidance (ISG) 11, “Cladding Considerations for the Transportation and Storage of Spent Fuel,” Revision 3, (NRC 2003). The

NRC staff has indicated in ISG 11, Revision 3 that the spent fuel configuration is expected to be maintained as analyzed in the safety analyses for the ISFSI or DSS, provided certain acceptance criteria (regarding maximum fuel clad temperature and thermal cycling) are met, and the fuel is stored in a dry inert atmosphere. These research results suggest that degradation of low burnup fuel cladding and assembly hardware should not occur during the first renewal period, provided that the cask or canister internal environment is maintained.

The reviewer should assess whether the applicant has considered the most recent revision of ISG-11 and research results in this area, especially with respect to high burnup (HBU) fuel. Research into fuel performance in storage is an ongoing effort.[2] The reviewer should ensure that the applicant has monitored new research developments to ensure it has identified any new potential aging mechanisms and effects and provided new supporting data demonstrating HBU fuel performance during the period of extended operation. Although NRC has confidence based on short-term testing (i.e., laboratory scale testing up to a few months) that there is no degradation of HBU fuel that would result in spent fuel being in an unanalyzed configuration in the period of extended operation, there is no operational data to demonstrate this as was done in the aforementioned demonstration on low burnup fuel.

Guidance for one acceptable approach to demonstrate the HBU fuel performance during the period of extended operation is provided in the “Example of a High Burnup Fuel Monitoring and Assessment Program” in Appendix B. This is a licensee program that monitors and assesses data and other information regarding HBU fuel performance, to confirm that the analyzed HBU fuel configuration is maintained during the period of extended operation. Guidance for determining if a surrogate demonstration program can provide the data to support a licensee’s HBU Fuel Monitoring and Assessment Program is given in Appendix D. Alternative approaches to that presented in Appendix B may be used, as appropriately justified by an applicant.

3.4.2 Evaluation Findings

The reviewer prepares the summary statement and evaluation findings based on compliance with the regulatory requirements in Section 3.3. The summary statement and evaluation findings should be similar in wording to the following example (the finding number is for convenience in cross-referencing within the Standard Review Plan (SRP) and safety evaluation report (SER)):

The NRC staff reviewed the aging management review provided in the renewal application and supplemental documentation. The NRC staff performed its review following the guidance provided in NUREG-1927, Revision 1, “Standard Review Plan for Renewal of Specific Licenses and Certificates of Compliance of Dry Storage of Spent Nuclear Fuel,” and relevant ISGs. Based on its review, the NRC staff finds:

F3.1 The applicant’s AMR process to be comprehensive in identifying the materials of construction and associated operating environmental conditions for those SSCs within the scope of renewal and has provided a summary of the information in the renewal application and FSAR supplement.

---

[2] For example, research programs at Argonne National Laboratory (for NRC and the U.S. Department of Energy (DOE)), and other programs performed for the Nuclear Regulation Authority (formerly Japan Nuclear Energy Safety Organization) have studied hydride reorientation effects; Oak Ridge National Laboratory has also studied bending responses of the fuel.

F3.2 The applicant's AMR process to be comprehensive in identifying all pertinent aging mechanisms and effects applicable to the SSCs within the scope of renewal and has provided a summary of the information in the renewal application and FSAR supplement.

3.5 Time-Limited Aging Analyses

TLAAs are calculations or analyses used to demonstrate that in-scope SSCs will maintain their intended function throughout an explicitly stated period of extended operation (e.g., 40 years). These calculations or analyses may be used to assess fatigue life (number of cycles to predicted failure), or time-limited life (operating timeframe until expected loss of intended function). TLAAs should account for environmental effects. Under 10 CFR 72.3, "Definitions," TLAAs are those calculations and analyses meeting all six of the following criteria:

(1) Involve SSCs important to safety within the scope of the specific-license renewal, as delineated in Subpart F of 10 CFR Part 72, or within the scope of the spent fuel storage CoC renewal, as delineated in Subpart L of 10 CFR Part 72, respectively.

(2) Consider the effects of aging.

(3) Involve time-limited assumptions defined by the current operating term.

(4) Were determined to be relevant by the specific licensee or certificate holder in making a safety determination.

(5) Involve conclusions or provide the basis of conclusions related to the capability of SSCs to perform their intended safety functions.

(6) Are contained or incorporated by reference in the design bases.

Under 10 CFR 72.42(a)(1) or 72.240(c)(2), the reviewer should ensure that the application includes a list of TLAAs. The NRC staff uses the FSAR and other documents where the design bases are detailed to perform the review and confirm that the applicant did not omit any TLAAs submitted as part of the approved design bases. The number and type of TLAAs vary depending on the design bases of the ISFSI or DSS. The reviewer should ensure that all six criteria set forth in 10 CFR 72.3 (and repeated in this section) are satisfied to conclude that a calculation or analysis is a TLAA.

The following examples illustrate analyses that are not TLAAs and need not be addressed under 10 CFR 72.42(a)(1) or 72.240(c)(2):

- Analyses with time-limited assumptions defined short of the initial license or CoC term, for example, an analysis for a component based on a service life that would not reach the end of the initial license or CoC term.

- Analyses *not* contained or incorporated by reference in the design bases. Although not TLAAs by definition, the reviewer should note that these analyses may be included in the renewal application to justify the proposed attributes of an AMP (e.g., inspection frequency, sample size) for a particular SSC within the scope of renewal. These analyses may further be used in the AMR to justify the exclusion of an aging mechanism/effect or SSC subcomponent from the scope of an AMP (i.e., not requiring

any aging management activities), if the analysis is approved by the staff and included or summarized in the application.

3.5.1 Review Guidance

The reviewer should ensure that the applicant has appropriately identified TLAAs by applying the six criteria described below for SSCs within the scope of renewal:

(1) *Involve SSCs important to safety within the scope of the specific-license or CoC renewal*. Chapter 2 of this SRP provides the reviewer guidance on the scoping methodology.

(2) *Consider the effects of aging*. The effects of aging include but are not limited to loss of material, change in dimension, change in material properties, loss of strength, settlement, and cracking. The reviewer should ensure that any calculations or analyses relying on environmental susceptibility criteria are adequately supported by a valid technical basis, such as NRC endorsed criteria or operating experience. An AMP might be more applicable in these cases.

(3) *Involve time-limited assumptions defined by the current operating term*. The defined operating term should be explicit in the analysis. Simply asserting that the SSC is designed for a DSS or ISFSI service life is not sufficient. Calculations, analyses, or testing that explicitly include a time limit should support the assertions.

(4) *Were determined to be relevant by the licensee or certificate holder in making a safety determination*. Relevancy is a determination that the applicant makes based on a review of the information available. A calculation or analysis is relevant if it can be shown to have a direct bearing on the action taken as a result of the analysis performed. Analyses are also relevant if they provide the basis for a safety determination, and, in the absence of analyses, the applicant might have reached a different conclusion.

(5) *Involve conclusions or provide the basis of conclusions related to the capability of SSCs to perform their intended safety functions*. The TLAA should provide conclusions or a basis for conclusions regarding the capability of the SSC to perform its intended function through the end of the period of extended operation. If the TLAA does not provide a conclusion supporting the capability of the SSC to perform its intended function through the end of the period of extended operation, then the TLAA is not confirmed, and the applicant should propose an AMP to address/manage the aging mechanism or effect on the SSC. Analyses that do not affect the intended functions of SSCs are not TLAAs.

(6) *Are contained or incorporated by reference in the design bases*. TLAAs should already be contained or incorporated by reference in the design-bases documents. Such documentation includes the (1) FSAR, (2) technical specifications, (3) correspondence to and from the NRC, (4) quality assurance plan, and (5) topical reports included as references in the FSAR. The reviewer should ensure that the applicant has provided any references cited in design-bases documents that may be needed to clarify the assumptions, methods, or values used in TLAAs.

The reviewer should ensure that the applicant has appropriately dispositioned an identified TLAA by one of the following methods:

- Demonstrate the existing analysis remains valid for the period of extended operation, has already considered the requested period of extended operation, and concludes that the SSC will continue to perform its intended function through the end of the requested period of extended operation.

- Revise or update the existing analysis to demonstrate that it has been projected to the end of the requested period of extended operation and concludes that the SSC will continue to perform its intended function through the end of the requested period of extended operation.

- Manage the effects of aging on the SSC for the requested period of extended operation through an AMP.

3.5.2 Evaluation Findings

The reviewer prepares the summary statement and evaluation finding based on compliance with the regulatory requirements in Section 3.3. The summary statement and evaluation finding should be similar in wording to the following example (the finding number is for convenience in cross-referencing within the SRP and SER):

The NRC staff reviewed the TLAAs provided in the renewal application and supplemental documentation. The NRC staff performed its review following the guidance provided in NUREG-1927, Revision 1, “Standard Review Plan for Renewal of Specific Licenses and Certificates of Compliance for Dry Storage of Spent Nuclear Fuel,” and relevant ISGs. The NRC staff verified that the TLAA assumptions, calculations, and analyses are adequate and bound the environment, and aging mechanism or aging effect for the pertinent SSCs. Based on its review, the NRC staff finds:

F3.3 The applicant identified all aging mechanisms and effects pertinent to SSCs within the scope of renewal that involve TLAAs. The methods and values of the input parameters for the applicant’s TLAAs are adequate. Therefore, the applicant’s TLAAs provide reasonable assurance that the SSCs will maintain their intended function(s) for the period of extended operation, require no further aging management activities, and meet the requirements in 10 CFR 72.42(a)(1) or 10 CFR 72.240(c)(2), as applicable.

3.6 Aging Management Programs

AMPs monitor and control the degradation of SSCs within the scope of renewal so that aging effects will not result in a loss of intended functions during the period of extended operation. An AMP includes all activities that are credited for managing aging mechanisms or effects for specific SSCs, including activities conducted during the initial storage period. An effective AMP prevents, mitigates, or detects the aging effects and provides for the prediction of the extent of the effects of aging and timely implementation of corrective actions before there is a loss of intended function.

AMPs should be informed, and enhanced when necessary, based on the ongoing review of both site-specific and industrywide operating experience, including relevant international and non-nuclear operating experience. Operating experience provides direct confirmation of the effectiveness of an AMP and critical feedback for the need for improvement. As new knowledge and data become available from new analyses, experiments, and operating experience,

licensees and CoC holders should revise existing AMPs (or pertinent procedures for AMP implementation) to address program improvements or aging issues.

3.6.1 Review Guidance

An AMP should contain the following 10 elements:

(1) scope of program
(2) preventive actions
(3) parameters monitored or inspected
(4) detection of aging effects
(5) monitoring and trending
(6) acceptance criteria
(7) corrective actions
(8) confirmation process
(9) administrative controls
(10) operating experience

Review of the AMPs should include an assessment of the 10 program elements to verify their technical adequacy. In general, the reviewer should examine the details of these 10 elements for managing the aging mechanisms and effects identified by the aging management review (AMR) process. The reviewer should recognize that an applicant may develop AMPs following a different format or style. For such reviews, the NRC staff should ensure that sufficient detail (i.e., supporting technical bases) is provided in the alternate format in comparison with the 10 AMP elements of this guidance.

The reviewer should determine if the proposed AMP is adequate for managing the aging mechanisms and effects of the SSCs identified by the AMR. The following sections provide specific guidance for the review of each element of an AMP.

3.6.1.1 Scope of Program

The scope of the program should list the specific SSCs and subcomponents covered by the AMP and the intended functions to be maintained. In addition, the element should state the specific materials, environments, and aging mechanisms and effects to be managed. The reviewer should verify that the scope defined for the AMP is clear and specific.

3.6.1.2 Preventive Actions

Preventive actions are used to prevent aging or mitigate the rates of aging for SSCs through the activities in the AMP. The reviewer should verify that these activities, if applicable, are described. For example, an applicant may cite a ground dewatering system to ensure control of long-term settlement of structures or the continuance of inspections to ensure that air inlet/outlet vents are not blocked. Some condition or performance monitoring programs do not rely on preventive actions and thus this information need not be provided.

The reviewer should ensure that any proposed preventive action will not result in an unintended consequence to the ability of an SSC to fulfill its intended function(s). For example, if the applicant has proposed to change a coating system to prevent loss of material due to corrosion, the reviewer should ensure that the applicant has verified coating compatibility to confirm that the proposed action will not compromise the intended function(s) of the SSC.

3.6.1.3 Parameters Monitored or Inspected

This program element should identify the specific parameters that will be monitored or inspected and describe how those parameters will be capable of identifying degradation or potential degradation before a loss of intended function. The use of the parameters should be demonstrated to be capable of:

- monitoring the effectiveness of activities that prevent or mitigate aging (e.g., environmental controls)
- monitoring the performance of SSCs as an indirect indicator of degradation (e.g., radiation rate monitoring at the external surface of a cask)
- detecting, through direct inspection, the presence and severity of conditions or discontinuities that may have an effect on the function of SSCs (e.g., nondestructive examination of a component surface)

The reviewer should ensure that this program element provides a clear link between the aging effects identified in the scope of the program and the parameters monitored or inspected.

3.6.1.4 Detection of Aging Effects

Detection of aging effects should occur before there is a loss of intended function for any SSC identified within the scope of the program. This element should include inspection and monitoring details, including method or technique (i.e., visual, volumetric, surface inspection), frequency, sample size, data collection, and timing of inspections to ensure timely detection of aging effects. In general, the information in this element describes the "when," "where," and "how" of the AMP (i.e., the specific aspects of the activities to collect data as part of the inspection or monitoring activities).

The reviewer should ensure that the applicant has provided sufficient details on the following aspects of the inspection or monitoring activities:

- Method or technique: Consistent with quality assurance requirements, the method should be demonstrated to be capable of evaluating the condition of the SSC against the acceptance criteria for the specific aging mechanism or effect being monitored or inspected (as defined in AMP Element 6). For example, the applicant should provide a valid technical basis that a particular visual inspection method or instrument has sufficient resolution to identify a specific crack or defect dimension. Inspections should utilize consensus codes and standards, as applicable.
- Frequency: The reviewer should ensure that the proposed intervals for inspection or monitoring are consistent with applicable site-specific, design-specific, or industrywide operating experience. Inspections should have sufficient frequency to ensure that intended functions will be maintained until the next scheduled inspection.
- Sample size and selection of SSCs for inspection: For a limited sample size, the applicant should identify and justify the number of SSCs to be evaluated per inspection, including the extent of the inspection for each SSC (e.g., all accessible areas of five concrete overpacks in service), and criteria for selection of the specific SSCs for inspection based on parameters that may contribute to the operable aging mechanisms

and effects. Consideration should also be given to event-driven fabrication or operational issues that may contribute to degradation when selecting SSCs for inspection (e.g., welding repairs, occurrence of natural or man-induced events, exposure to potentially corrosive environments before the storage term, duration of time between fabrication of an SSC and the start of the storage term). The reviewer should ensure the applicant has justified using a limited sample size (e.g., one cask per pad) with a technical basis, which should include applicable site-specific, design-specific and industrywide operating experience. The application should also define the areas that have been determined to be inaccessible or below-grade and propose how the condition of the inaccessible SSCs will be assessed. The reviewer should ensure that the scope of each inspection is properly defined for both accessible and inaccessible (including below-grade) areas.

- Data collection: The application should reference any specific methods to be used for data acquisition and documentation, including any applicable consensus codes and standards. For example, the application may reference field evaluation guides for evaluating and documenting cracks in concrete (e.g., ACI 224.1R, ACI 201.1R).

- Timing of inspections: If pre-application inspections were not performed for each of the sites covered by or using the subject license or CoC, the reviewer should ensure that AMPs include baseline inspections at each site upon entering the period of extended operation. Baseline inspections, or the first inspections conducted within the AMPs, should assess the condition of SSCs to confirm the results of the pre-application inspections that were conducted at other sites or to verify the technical justification provided in the application when pre-application inspections were not performed. The reviewer should also consider any specific information on the proposed inspection schedule (e.g., time of the year) to support the effective detection of aging effects before a loss of intended function.

3.6.1.5 Monitoring and Trending

Monitoring and trending should provide for an evaluation of the extent of the effects of aging and the need for timely corrective or mitigative actions. This element describes how the data collected will be evaluated. This includes an evaluation of the results against the acceptance criteria and an evaluation regarding the rate of degradation to ensure that the timing of the next scheduled inspection will occur before a loss of intended function. For most cases, this element should have a baseline established before or at the beginning of the period of extended operation. The reviewer should determine if a baseline inspection is necessary to establish the parameters to be monitored and the trending analysis and, if so, whether the proposed baseline inspection is adequate.

Although the licensee may have the flexibility to inspect different SSCs or SSC subcomponents during subsequent inspections, the selection of different components for the inspections defined in the AMP relative to the components inspected in the baseline inspection may present issues for purposes of monitoring and trending. If subcomponents from different systems will be inspected over the period of extended operation, the monitoring and trending element should address how a given operable degradation mode will be adequately trended.

3.6.1.6 Acceptance Criteria

The acceptance criteria, against which the need for corrective action will be evaluated, should ensure that the SSC intended functions and the approved design bases are maintained during the period of extended operation. The proposed acceptance criteria should be appropriately justified.

The acceptance criteria could be specific numerical values or could consist of a discussion of the process for calculating specific numerical values of conditional acceptance criteria to ensure that the design bases are maintained. The reviewer should ensure that the acceptance criteria:

- Include a quantitative basis (justifiable by operating experience, engineering analysis, consensus codes/standards).
- Avoid use of non-quantifiable phrases (e.g., significant, moderate, minor, little, slight, few; see Appendix A).
- Are achievable and actionable.

The acceptance criteria may be taken directly from the design bases information included in either the final safety analysis report (FSAR) or technical specifications. The acceptance criteria also may be established by methods provided in NRC-approved topical reports or appropriate codes and standards.

3.6.1.7 Corrective Actions

Corrective actions are the measures to be taken when the acceptance criteria are not met. Timely corrective actions, including root cause determination and prevention of recurrence for significant conditions adverse to quality, are critical for maintaining the intended functions of the SSCs during the initial storage period as well as the period of extended operation.

Corrective actions should be described in adequate detail or referenced to source documents. An applicant may reference the use of a Corrective Action Program (CAP) approved under 10 CFR Part 50, Appendix B, “Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants,” or 10 CFR Part 72, Subpart G, “Quality Assurance,” to capture and address aging effects identified in the period of extended operation. At a minimum, all conditions that do not meet the AMP acceptance criteria should be entered into the CAP. The QA Program ensures that corrective actions are completed within the specific or general licensee’s CAP and includes provisions (as applicable) to:

- Perform functionality assessments.
- Perform apparent cause evaluations and root cause evaluations.
- Address the extent of condition.
- Determine actions to prevent recurrence for significant conditions adverse to quality.
- Justify non-repairs.

- Ensure corrective actions are adequately and effectively performed and do not have an adverse effect (aging-related or otherwise) on the subject component or other SSCs.

- Trend conditions.

The CAP should be able to respond to and adequately address any ISFSI or DSS aging issues. Also, the CAP's response to addressing any ISFSI or DSS aging issues should include any specific corrective actions specified in the license or CoC renewal application.

In some cases, the reviewer may determine the need for specific corrective actions, rather than referring only to the use of the CAP. For example, when very limited information exists on the condition of an SSC or the applicability of an aging effect at the time of the application, the application should include specific follow-up activities when AMP acceptance criteria are not met. Thus, the reviewer should review the corrective actions element with consideration of the safety-significance of the SSC and the ISFSI site-specific, DSS design-specific, and industrywide operating experience to ensure that the proposed corrective actions are adequate and effective.

3.6.1.8 Confirmation Process

This element of the program is intended to verify that preventive actions are adequate and that appropriate corrective actions have been completed and are effective. The confirmation process is commensurate with the specific or general licensee QA Program approved under 10 CFR Part 72, Subpart G, or 10 CFR Part 50, Appendix B. The QA Program ensures that the confirmation process includes provisions to preclude repetition of significant conditions adverse to quality. The reviewer should ensure the confirmation process describes or references procedures to:

- determine follow-up actions to verify effective implementation of corrective actions
- monitor for adverse trends due to recurring or repetitive findings or observations

The reviewer should be aware that the effectiveness of prevention and mitigation programs should be verified periodically. For example, in managing corrosion of carbon steel components, a mitigation program (coating) may be used to minimize susceptibility to corrosion. However, it also may be necessary to have a condition monitoring program (visual or other types of inspections) to verify that corrosion is being prevented or controlled to prevent a loss of intended function.

3.6.1.9 Administrative Controls

Administrative controls provide a formal review and approval process. Thus, any aging management programs must be administratively controlled and included in the FSAR supplement. The administrative controls are in accordance with the specific or general licensee QA Program approved under 10 CFR Part 72, Subpart G or 10 CFR Part 50, Appendix B, respectively. The QA Program ensures that the administrative controls include provisions, such as those that define:

- instrument calibration and maintenance
- inspector requirements
- record retention requirements
- document control

3.6.1.10 Operating Experience

The reviewer should verify that the operating experience element of the program supports a determination that the effects of aging will be adequately managed so that the SSC intended functions will be maintained during the period of extended operation. Operating experience is useful in providing justification for the effectiveness of each AMP program element and critical feedback for enhancement. The reviewer should verify that any degradation in the referenced operating experience has been clearly identified as either age-related or event-driven, with proper justification for that assessment.

The reviewer should verify that the AMP references and evaluates applicable operating experience, including, but not necessarily limited to:

- internal and industrywide condition reports
- relevant international and non-nuclear operating experience
- pre-application inspection results (see below)
- licensee event reports
- vendor-issued safety bulletins
- NRC Generic Communications
- updated consensus codes, standards, or guides
- applicable industry-initiatives (e.g., Department of Energy or Electric Power Research Institute sponsored inspections)

The reviewer should consider operating experience of existing programs, including past corrective actions resulting in program enhancements or additional programs. A past failure would provide feedback from operating experience and should have resulted in appropriate program enhancements or new programs. This information can demonstrate where an existing program has been implemented correctly and where it has shortcomings in detecting degradation in a timely manner. This information should provide objective evidence to support or refute the conclusion that the effects of aging will be managed adequately so that the SSC intended functions will be maintained during the period of extended operation.

Pre-Application Inspections

Because inspections of DSSs and ISFSI SSCs are not typically conducted during the initial storage period, or are narrow in scope, the reviewer may have limited information regarding the extent and rate of operable degradation mechanisms for the specific design, environment, and operational parameters. In this case, the reviewer should ensure that the scope, methods, frequencies and acceptance criteria for monitoring and inspection activities in the aging management programs are sufficiently conservative, such that a loss of SSC-intended functions does not occur during the period of extended operation. Pre-application inspections are one means by which an applicant can provide operating experience to justify the specific information in the 10 elements of the proposed aging management programs. In addition, pre-application inspections may provide data to support a TLAA or other analysis that justifies that an aging

effect will not challenge a SSC's ability to perform its function(s) (see Section 3.5). The staff considers the results of a pre-application inspection, in conjunction with other relevant operating experience in its review of the renewal application.

Section 3.4.1.2 discusses the acceptable characteristics of a pre-application inspection, including the selection of bounding systems, the use of surrogate inspections, and ensuring that the inspection scope, methods, and acceptance criteria align with the guidance for the AMP elements described in Section 3.6.1 of this document. Section 3.4.1.2 also discusses the use of baseline inspections in an AMP upon entering the period of extended operation to assess the condition of SSCs at sites that were not the subject of a pre-application inspection. Furthermore, when pre-application inspections are not performed, the reviewer should consider whether uncertainties in the degradation of SSCs warrant the addition of conditions to the license or CoC to require the baseline and other specific inspections to ensure the AMPs are adequate, including for all potential user sites in the case of a renewed CoC (see Section 1.4.7).

Learning AMPs

The reviewer should ensure that the application includes provisions to conduct future reviews of site-specific, design-specific, and industrywide operating experience, including relevant international and non-nuclear operating experience, to confirm the effectiveness of the AMPs or identify a need to enhance or modify an AMP. The reviewer should verify that the applicant: (1) references a specific system to be used to obtain, aggregate, and enter site-specific, design-specific, and industrywide operating experience (e.g., Institute of Nuclear Power Operations database), and (2) has discussed how it intends to provide timely reporting of operating experience to this system.

The commitment to future reviews should ensure that, as knowledge and data become available from new analyses, experiments, and operating experience, the licensees and CoC holders will revise the existing AMPs (or pertinent procedures for AMP implementation) as necessary to address any lessons learned identified during the review of operating experience.

If an applicant follows this approach, the reviewer should ensure that the description of the periodic assessments includes specific performance criteria (e.g., program-specific performance indicators for each of the 10 AMP elements) and proposed actions based on the assessment findings. The reviewer should also ensure that the timing of the assessments appropriately considers the rate of aging degradation and the anticipated availability of data from industry initiatives. The reviewer should consider the frequency, acceptance criteria, and proposed corrective actions for these assessments for the requisite finding of reasonable assurance.

Nuclear Energy Institute (NEI) 14-03, "Format, Content, and Implementation Guidance for Dry Cask Storage Operations-Based Aging Management," Revision 1, provides a proposed framework for learning AMPs through the use of "tollgates." NEI 14-03 defines "tollgates" as periodic points within the period of extended operation when licensees would be required to evaluate aggregate feedback and perform and document a safety assessment that confirms the safe storage of spent fuel. Tollgates are described as an additional set of in-service assessments beyond the normal continual assessment of operating experience, research, monitoring, and inspections on DSS component and ISFSI SSC performance that is part of normal ISFSI operations for licensees during the initial storage period as well as the period of extended operation. The reviewer should be aware that an applicant may reference the use of "tollgates" in the renewal application. The reviewer should (1) assess the applicant's proposed periodic assessments of operating experience and other relevant data, and (2) make a

determination regarding the ability of these assessments to ensure the continued effectiveness of AMPs. The reviewer should ensure that tollgates determined to be necessary to demonstrate the continued effectiveness of the AMPs are included in the application.

NEI 14-03, Revision 1, also describes a framework for the aggregation and dissemination of operating experience across the industry through the use of an aging-related operating experience "clearinghouse," titled the ISFSI Aging Management Institute of Nuclear Power Operations Database (ISFSI AMID). Whether the applicant references the ISFSI AMID described in NEI 14-03 or proposes an alternative means to seek out operating experience, the reviewer should ensure that the application describes how industrywide operating experience and results of industry initiatives will be accessed, utilized, and assessed to ensure that AMPs are modified as appropriate.

At the time of publication, the staff was continuing its review of NEI 14-03, Revision 1, for proposed NRC endorsement, as discussed in the Introduction.

The NRC will inspect licensees' implementation of AMPs in the period of extended operation, including any licensee actions taken as part of the "learning" aspect of AMPs. The NRC will inspect licensees' periodic assessments of AMP effectiveness and any adjustments licensees have made to AMPs to respond to operating experience and ensure AMPs are effective for addressing aging effects in the period of extended operation.

3.6.2 Commencement of AMP(s) for CoC Renewals

An AMP for a renewed CoC commences at the end of the initial storage period for each loaded DSS (see Appendix F for discussion of storage terms, including an explanation of when storage begins). Activities in an AMP may start at different timeframes (e.g., an AMP can be implemented before the period of extended operation to capture baseline data and AMPs may have different frequencies of implementation). Additional considerations for CoC renewals and general licensee implementation of AMPs are provided in Appendix E.

3.6.3 Implementation of AMP(s)

Generally, licensees should develop the infrastructure for AMP implementation (e.g., procure equipment or contracts, train personnel, or update, revise, or develop procedures for implementing AMP activities) before entering the period of extended operation. However, this may not be possible when the initial storage term ends shortly after the license or CoC is renewed or if a license or CoC is in the period of timely renewal (Section 1.4.5). In such cases, the development of the infrastructure for AMP implementation generally should be no later than one year from the date the NRC issues a renewed specific license or CoC. The reviewer should ensure that the timing of implementation for each AMP is addressed in the application in a clear manner and is appropriately justified if it exceeds the above guidance. Additional considerations for CoC renewals and general licensee implementation of AMPs are provided in Appendix E.

3.6.4 Evaluation Findings

The reviewer prepares the summary statement and evaluation finding based on compliance with the regulatory requirements in Section 3.3. The summary statement and evaluation finding should be similar in wording to the following example (the finding number is for convenience in cross-referencing within the SRP and SER):

The NRC staff reviewed the aging management programs provided in the renewal application and supplemental documentation. The NRC staff performed its review following the guidance provided in NUREG-1927, Revision 1, "Standard Review Plan for Renewal of Specific Licenses and Certificates of Compliance for Dry Storage of Spent Nuclear Fuel" and relevant ISGs. Based on its review, the NRC staff finds:

F3.4 The applicant has identified programs that provide reasonable assurance that aging effects will be managed effectively during the period of extended operation, in accordance with 10 CFR 72.42(a)(2) or 10 CFR 72.240(c)(3), as applicable.

5. GLOSSARY

Accident condition: The extreme level of an event or condition, which has a specified resistance, limit of response, and requirement for a given level of continuing capability, which exceeds off-normal events or conditions. Accident conditions include both design-basis accidents and conditions caused by natural and manmade phenomena.

Aging effect: The manifestation of an aging mechanism (e.g., cracking, loss of fracture toughness, loss of material).

Aging management activity (AMA): An application of either the aging management program (AMP) or time-limited aging analyses (TLAAs) to provide reasonable assurance that the intended functions of structures, systems, and components (SSCs) of independent spent fuel storage installations (ISFSIs) and dry storage systems (DSSs) are maintained during the period of extended operation.

Aging management program (AMP): A program for addressing aging effects that may include prevention, mitigation, condition monitoring, and performance monitoring. See Title 10 of the *Code of Federal Regulations* (10 CFR) 72.3, "Definitions."

Aging management review (AMR): An assessment conducted by the licensee or certificate of compliance (CoC) holder that addresses aging mechanisms and effects that could adversely affect the ability of SSCs from performing their intended functions during the period of extended operation.

Aging mechanism: The degradation process for a given material and environment which results in an aging effect (e.g., freeze-thaw degradation, neutron irradiation, erosion).

Amendment of a license or CoC: An application for amendment of a license or a CoC must be submitted whenever a holder of a specific license or CoC desires to amend the license or CoC (including a change to the license or CoC conditions). The application must fully describe the changes desired and the reasons for such changes, and following as far as applicable the form prescribed for original applications. See 10 CFR 72.56, "Application for Amendment of License," and 10 CFR 72.244, "Application for Amendment of a Certificate of Compliance".

Baseline inspection: The first inspection of an AMP to assess the condition of SSCs to either: (1) confirm that the results of pre-application inspections conducted at other sites are bounding of the subject site, or (2) verify the adequacy of the AMPs and the conclusions of the TLAAs when pre-application inspections were not performed.

Burnup: The measure of thermal power produced in a specific amount of nuclear fuel through fission, usually expressed in GWd/MTU (gigawatt days per metric ton uranium).

Can for damaged fuel: A metal enclosure that is sized to confine one damaged spent fuel assembly. A fuel can for damaged spent fuel with damaged spent-fuel assembly contents must satisfy fuel-specific and system-related functions for undamaged spent nuclear fuel (SNF) required by the applicable regulations.

Canister (in a dry storage system for SNF): A metal cylinder that is sealed at both ends and may be used to perform the function of confinement. Typically, a separate overpack performs the radiological shielding and physical protection function. See NUREG-1536, "Standard Review Plan for Spent Fuel Dry Storage Systems at a General License Facility."

Certificate of compliance (CoC) (for a dry storage system for SNF): The certificate issued by the NRC that approves the design of a spent fuel storage cask in accordance with the provisions of 10 CFR Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel, High-Level Radioactive Waste, and Reactor-Related Greater than Class C Waste," Subpart L, "Approval of Spent Fuel Storage Casks." See 10 CFR 72.3.

Certificate of compliance holder (CoC holder): A person who has been issued a CoC by the U.S. Nuclear Regulatory Commission (NRC) for a spent fuel storage cask design under 10 CFR Part 72. See 10 CFR 72.3.

Certificate of compliance user (CoC user): The general licensee that has loaded, or plans to load, a dry storage system (DSS) in accordance with a CoC issued under 10 CFR Part 72.

Confinement (in a dry storage system for spent nuclear fuel): The ability to limit or prevent the release of radioactive substances into the environment.

Confinement systems: Those systems, including ventilation, that act as barriers between areas containing radioactive substances and the environment. See 10 CFR 72.3.

Controlled area: The area immediately surrounding an ISFSI for which the licensee exercises authority over its use and within which it performs ISFSI operations. See 10 CFR 72.3.

Criticality: The condition wherein a system or medium is capable of sustaining a nuclear chain reaction.

Degradation: Any change in the properties of a material that adversely affects the performance of that material; adverse alteration. See NUREG-1536.

Design bases:[4] Information that identifies the specific function(s) to be performed by SSCs (both important-to-safety and not important-to-safety) of a facility or of a spent fuel storage cask and the specific values or ranges of values chosen for controlling parameters as reference bounds for design. These values may be (1) restraints, derived from generally accepted "state-of-the-art" practices for achieving functional goals, or (2) requirements, derived from analysis (based on calculation, experiments, or both) of the effects of a postulated event under which SSCs must meet their functional goals. See 10 CFR 72.3.

Dry storage: The storage of spent nuclear fuel in a DSS, which typically involves drying the DSS cavity and backfilling with an inert gas.

---

[4] The NRC has removed references to either "current licensing basis" (CLB) or "licensing basis", and replaced them with "design bases" in this guidance revision. Neither "current licensing basis" nor "licensing basis" is defined in 10 CFR Part 72. In addition, in the Statement of Considerations for the 2011 Part 72 rulemaking change (NRC, 2011), the NRC stated "The NRC does not believe that it is appropriate for the CLB to be applied to cask CoC renewals, which are generic."

Dry storage system (DSS): A system that typically uses a cask or canister in an overpack as a component in which to store spent nuclear fuel in a dry environment. A DSS provides confinement, radiological shielding, sub-criticality control, structural support, and passive cooling of its spent nuclear fuel during normal, off-normal, and accident conditions.

General license: Authorizes the storage of spent fuel in an ISFSI at power reactor sites to persons (i.e., general licensee) authorized to possess or operate nuclear power reactors under 10 CFR Part 50 ("Domestic Licensing of Production and Utilization Facilities") or Part 52 ("Licenses, Certifications, and Approvals for Nuclear Power Plants"). The general license is limited to (1) that spent fuel which the general licensee is authorized to possess at the site under the specific Part 50 or Part 52 license for the site, and (2) storage of spent fuel in casks approved under the provisions of 10 CFR Part 72, Subpart L. See 10 CFR 72.210 ("General License Issued") and 72.212(a)(1)–(2).

High burnup (HBU) fuel: Spent nuclear fuel with burnups generally exceeding 45 GWd/MTU.

Horizontal storage module: A reinforced, heavy-walled concrete structure designed to store dry spent fuel canisters in a horizontal position at an independent spent fuel storage installation. The horizontal storage module provides physical protection of canisters and radiological shielding, while allowing passive cooling.

Important to safety (ITS): See structures, systems, and components (SSCs) important to safety.

Independent spent fuel storage installation (ISFSI): A complex designed and constructed for the interim storage of spent nuclear fuel, solid reactor-related greater-than-Class-C (GTCC) waste, and other radioactive materials associated with spent fuel and reactor-related GTCC waste storage. See 10 CFR 72.3.

Inspection: The examination of an SSC, using a nondestructive testing technique, to determine its current condition and if there is any damage, defect, or degradation that could have an adverse effect on the function of that SSC.

Intended function: A design-bases function defined as either (1) important to safety or (2) failure of which could impact a safety function.

Interim staff guidance (ISG): Supplemental information that clarifies important aspects of regulatory requirements. An ISG provides review guidance to NRC staff in a timely manner until standard review plans are revised accordingly. See NUREG-1536.

Monitored retrievable storage installation (MRS): A complex designed, constructed, and operated by the U.S. Department of Energy for the receipt, transfer, handling, packaging, possession, safeguarding, and storage of spent nuclear fuel aged for at least 1 year, solidified high-level radioactive waste resulting from civilian nuclear activities, and solid reactor-related GTCC waste, pending shipment to a HLW repository or other disposal. See 10 CFR 72.3.

Monitoring: Data collection (from activities performed in either the initial storage period or the period of extended operation) to determine the status of a DSS, ISFSI, or both, and to verify the continued efficacy of the system, on the basis of measurements of specified parameters, including temperature, direct radiation, radioactive effluents, functionality, and characteristics of components of the system. Monitoring could thus be described as those activities that periodically or continuously monitor performance as an indirect indicator of degradation (e.g., monitoring groundwater chemistry) or monitor the effectiveness of preventive measures. With respect to direct radiation and radioactive effluents, according to 10 CFR 20.1003, "Definitions," monitoring means the measurement of radiation levels, concentrations, surface area concentrations or quantities of radioactive material, and the use of the results of these measurements to evaluate potential exposures and doses. See NUREG-1536.

Normal events or conditions: The maximum level of an event or condition expected to routinely occur. Events and conditions that exceed the levels associated with "normal" are considered to be, and to have the response allowed for, "off-normal" or "accident-level" events and conditions. See NUREG-1567, "Standard Review Plan for Spent Fuel Dry Storage Facilities."

Off-normal events or conditions: The maximum level of an event or condition that, although not occurring regularly, can be expected to occur with moderate frequency (once per calendar year) and for which there is a corresponding maximum specified resistance, specified limit of response, or requirement for a specified level of continuing capability. Off-normal is considered to include "anticipated occurrences" as used in 10 CFR Part 72. See NUREG-1536.

Overpack: A heavy-walled concrete, metal, or combined concrete and metal structure designed to store spent fuel canisters at an ISFSI. The overpack provides physical protection of canisters and radiological shielding, while allowing passive cooling.

Pre-application inspection: An inspection performed at the discretion of the licensee or CoC holder before submittal of the renewal application to provide operating experience to support the aging management review, proposed AMP activities, or evaluation of TLAAs.

Radiation shielding: ISFSI and DSS SSCs that are designed so that dry storage operations at an ISFSI meet the requirements of 10 CFR 72.126(a)(6) and 10 CFR 72.128(a)(2) and the requirements of 10 CFR 72.104(a) and 10 CFR 72.106(b), when both direct radiation and radioactive effluents are considered.

Renewal of a license or CoC: A certificate holder may apply for renewal of the design of a spent fuel storage cask for a term not to exceed 40 years. In the event that the certificate holder does not apply for a cask design renewal, any licensee using a spent fuel storage cask, a representative of the licensee, or another certificate holder may apply for a renewal of that cask design for a term not to exceed 40 years. See 10 CFR 72.240, "Conditions for Spent Fuel Storage Cask Renewal." Specific licenses may be renewed by the Commission at the expiration of the license term upon application by the licensee for a period not to exceed 40 years. See 10 CFR 72.42, "Duration of License; Renewal."

Retrievability: Storage systems must be designed to allow ready retrieval of spent fuel, high-level radioactive waste, and reactor-related GTCC waste for further processing or disposal. See 10 CFR 72.122(l). ISG-2 provides guidance on the fuel retrievability, including ready retrieval.

Safety analysis report (SAR): The document that a CoC holder, specific licensee, an applicant for a CoC, or an applicant for a specific license supplies to the NRC for evaluation. For specific-license renewals, the SAR must contain information required in 10 CFR 72.24, "Contents of Application; Technical Information." For CoC renewals, the SAR must meet the requirements of 10 CFR 72.240(b). The SAR provides references and drawings of the DSS, ISFSI, or both; details of construction; materials; and standards to which the SSC has been designed or fabricated. For clarification, SAR is a general term; while FSAR indicates the document that is submitted within 90 days after the issuance of the license or CoC that is based on the SAR in the license or CoC application and reflects any changes or applicant commitments developed during the license or CoC approval and/or hearing process. Both FSAR and updated final safety analysis report (UFSAR) are terms that are used to indicate the FSAR update that is required every 2 years. A specific licensee or CoC holder shall update the FSAR in accordance with 10 CFR 72.70 ("Safety Analysis Report Updating") or 10 CFR 72.248, ("Safety Analysis Report Updating") respectively.

Safety evaluation report (SER): The document that the NRC publishes at the completion of a licensing or certification review. The SER contains all of the NRC staff findings and conclusions from the licensing or certification review.

Safety function: A function defined as ITS. The ITS functions that structures, systems, and components are designed to maintain include:

- structural integrity
- content temperature control (i.e., heat-removal capability)
- radiation shielding
- confinement
- sub-criticality control
- retrievability

See NUREG-1536.

Service conditions: Conditions (e.g., time of service, temperatures, environmental conditions, radiation, and loading) that a component experiences during storage.

Specific license: A license for the receipt, handling, storage, and transfer of spent fuel, high-level radioactive waste, or reactor-related GTCC waste that is issued to a named person (i.e., specific licensee) on an application filed under regulations in 10 CFR Part 72, Subpart B, "License Application, Form, and Contents."

Spent fuel storage cask or cask: All the components and systems associated with the container in which spent fuel, or other radioactive materials associated with spent fuel, is stored at an ISFSI. See 10 CFR 72.3.

Spent nuclear fuel or spent fuel: Nuclear fuel that has been withdrawn from a nuclear reactor after irradiation, has undergone at least a 1-year decay process since being used as a source of energy in a power reactor, and has not been chemically separated into its constituent elements by reprocessing. Spent fuel includes the special nuclear material, byproduct material, source material, and other radioactive materials associated with fuel assemblies. See 10 CFR 72.3.

Structures, systems, and components (SSCs) important to safety: See 10 CFR 72.3. Those features of the ISFSI and spent fuel storage cask whose functions are at least one of the following:

- to maintain the conditions required to safely store spent fuel, high-level radioactive waste, or reactor-related GTCC waste
- to prevent damage to the spent fuel, the high-level radioactive waste, or reactor-related GTCC waste container during handling and storage
- to provide reasonable assurance that spent fuel, high-level radioactive waste, or reactor-related GTCC waste can be received, handled, packaged, stored, and retrieved without undue risk to the health and safety of the public

Time-limited aging analysis (TLAA): See 10 CFR 72.3. A licensee or CoC holder calculation or analysis that has all of the following attributes:

- involves SSCs important to safety within the scope of license or CoC renewal
- considers the effects of aging
- involves time-limited assumptions defined by the current operating term, for example, 40 years
- was determined to be relevant by the licensee or CoC holder in making a safety determination
- involves conclusions or provides the basis for conclusions related to the capability of the SSCs to perform their intended safety functions
- is contained or incorporated by reference in the design bases

Transfer cask: A shielded SSC used to transfer the fuel canister between the spent fuel handling area and the overpack or storage module.

APPENDIX A

NON-QUANTIFIABLE TERMS

Appendix A

Non-Quantifiable Terms

It is preferred that renewal applications use quantifiable terms and quantitative information, where it exists. However, the following non-quantifiable terms, as well as others, may appear in the renewal application, safety analysis report (SAR), and updates to final SARs:

- large
- small
- slight
- slightly
- significant
- significance
- moderate
- moderately
- low
- minor
- many
- few
- little
- routine
- some
- major
- undetectable
- visible
- measurable
- unchanged
- changed
- no loss of

Table A-1 may be used as guidance for the terms listed above, for additional consideration, or to provide quantitative measures or information.

Table A-1. Screening Criteria for Non-Quantifiable Terms

	Terms	Actions
Screened In	**The term requires additional consideration if it is used for one of the following:** • characterizing an aging effect (e.g., degradation, cracking, fatigue, corrosion, loss of material, change in material properties) • providing important information about the operations, functions, or other characteristics of an in-scope SSC • describing dose, environmental impact, or other hazard, such as combustible material or dust	**If the term screens in, one of the following must be provided:** • quantitative information, if it is available • additional descriptions • definition of the meaning of the term (e.g., “insignificant” means the function of the SSC is not impaired)
Screened Out	**The term is considered immaterial to the SAR and ISFSI/DSS UFSAR for one of the following reasons:** • The term is included in the title of reference document. • The term is included in a quote. • The term is explained by adjacent quantitative information (e.g., small: less than 20 percent). • Use of the term is NOT related to any of the following: – in-scope SSCs per AMR results – aging effect – dose, environment impact, or other hazard (e.g., combustible material) • Use of the term does not provide important information. It is merely descriptive and the meaning of the statement is not changed if the term is deleted (e.g., the word “small” could be deleted from the following statement without altering the meaning: “Water in the grapple ring is drained through a small hole”).	No action

APPENDIX B

EXAMPLES OF AGING MANAGEMENT PROGRAMS

Appendix B

Examples of Aging Management Programs

Appendix B contains example aging management programs (AMPs) for:

- localized corrosion and stress corrosion cracking of welded stainless steel dry storage canisters (Table B-1)
- reinforced concrete structures (Table B-2)
- high burnup (HBU) fuel monitoring and assessment program (Table B-3)

This appendix provides examples of acceptable AMPs for staff reference during review of renewal applications.

Example AMP for Localized Corrosion and Stress Corrosion Cracking of Welded Stainless Steel Dry Storage Canisters

Welded stainless steel canisters are used in the majority of the dry storage systems in the United States for spent nuclear fuel from commercial power reactors at both specific-licensed and general-licensed independent spent fuel storage installations (ISFSIs). The welded stainless steel canisters are the primary confinement boundary during storage. Although there are no known operational occurrences of aging or localized corrosion of welded stainless steel canisters, operating experience with nuclear reactors that were located close to an open ocean or bay has shown that pitting corrosion, crevice corrosion, and chloride-induced stress corrosion cracking (CISCC) can occur in welded stainless steel components as a result of atmospheric deposition and deliquescence of chloride-containing salts. Laboratory and natural exposure tests suggest that CISCC can occur with sufficient surface chloride concentrations and that, with those concentrations of chloride, crack propagation rates can be of engineering significance for welded stainless steel canisters during the period of extended operation.

Based on reactor operating experience as well as laboratory and field testing, localized corrosion and CISCC are potential aging mechanisms for welded stainless steel canisters. Environments where chloride-containing salts may be deposited on welded stainless steel canisters include coastal locations near salt water and locations that are close to cooling towers or roads that are salted. ASME Section XI has formed a Task Group to develop a code case to establish the requirements for inservice inspection and acceptance criteria for dry storage system canisters. However, the development of a consensus based code case for inservice inspection of dry storage system canisters may take several years to complete. To address potential aging effects as a result of localized corrosion cracking and stress corrosion cracking in the absence of an acceptable code case, the U.S. Nuclear Regulatory Commission (NRC) has provided an example AMP for welded stainless steel canisters used in dry storage systems that relies on guidance from consensus codes and standards for inservice inspection of nuclear power plant components. Elements of an NRC staff developed example AMP are provided in Table B-1.

Table B-1. Example AMP for Localized Corrosion and Stress Corrosion Cracking of Welded Stainless Steel Dry Storage Canisters

Element	Description
1. Scope of Program	Inspection of welded stainless steel dry storage canister confinement boundary external surfaces for atmospheric deposits, localized corrosion, and stress corrosion cracking. Examinations should be focused on areas with the following attributes: • canister fabrication welds and weld heat affected zones • closure welds and weld heat affected zones • areas of the canister to which temporary supports or attachments were attached by welding and subsequently removed • locations where a crevice is formed on the canister surface • horizontal (±30°) surfaces where deposit accumulation may accumulate at a faster rate compared to vertical surfaces • canister surfaces that are cold relative to the average surface temperature • canister surfaces with higher amounts of atmospheric deposits Effort should be made to identify and prioritize examinations of areas on canisters that have two or more of the above attributes (e.g., canister surface that is cold relative to average surface temperature and also has a weld/weld heat affected zone).
2. Preventive Actions	None, AMP is for condition monitoring. However, dry storage system canister designs may include preventative actions, such as fabrication procedures and surface modification methods to impart compressive residual stresses on the canister welds and weld heat affected zones to reduce the potential for stress corrosion cracking. Preventative actions may also include the use of dry storage system canister confinement boundary materials that are resistant to localized corrosion and stress corrosion cracking. For such cases the preventative actions described should be supported with an analysis and data demonstrating the preventative actions are effective.
3. Parameters Monitored or Inspected	Parameters monitored/inspected should include: • visual evidence of discontinuities and imperfections, such as localized corrosion, including pitting corrosion, crevice corrosion and stress corrosion cracking of the canister welds and weld heat affected zones • size and location of localized corrosion and stress corrosion cracks • appearance and location of deposits on the canister surfaces

Element	Description
4. Detection of Aging Effects	Visual examination of deposits on the canister surfaces and to identify corrosion products that may be indicators of localized corrosion and stress corrosion cracking in the welds and weld heat affected zones. Visual examination instrumentation with demonstrated sizing and depth measurement capability may be useful in the determination of the size and depth of pits open to the surface. Visual examination may also detect the presence of cracks originating from pits. However, the ability to detect cracks on clean metal surfaces using visual examination methods is dependent on several factors and can be difficult for tight crack opening displacements (Cumblidge et al., 2004; 2007). The presence of significant corrosion product accumulation may also interfere with the identification of stress corrosion cracks using visual examination methods. Volumetric examination is necessary to characterize stress corrosion cracking. Volumetric examination of pits and areas immediately adjacent to pits is necessary when pits are within 25 mm (1 inch) of a through thickness weld or within 25 mm (1 inch) of an area where an temporary attachment was known to be located. <u>Visual Examination</u> Pitting and crevice corrosion that is open to the surface can potentially be detected by visual testing (ASME Section V, Table A-110). Because of the high neutron and gamma radiation fields near the surface of the stainless steel dry storage canisters, direct visual examination is not possible. Procedures for remote visual examination should be performance demonstrated; procedure attributes including equipment resolution, lighting requirements, etc., should reference applicable standards, such as ASME Section XI, Article IWA-2200 for VT-1 and VT-3 examinations (ASME, 2007) and BWRVIP-03 (Selby 2005) for EVT-1 examinations. <u>Volumetric Examination</u> Additional assessment is necessary for suspected areas of localized corrosion or stress corrosion cracking. In these cases, the severity of degradation must be assessed including the dimensions of the affected area and the depth of penetration with respect to the thickness of the canister. For accessible areas where adequate cleaning can be performed, remote visual examination meeting the requirements for VT-1 Examination (ASME Section XI, IWA-2211) may be used to determine the type of degradation present (e.g., pitting corrosion or stress corrosion cracking) and the location of degradation. Examinations to characterize the extent and severity of localized corrosion or stress corrosion cracking should be conducted using surface or volumetric examination methods consistent with the requirements of ASME Section XI, IWB-2500 for category B-J components (ASME, 2007).

Element	Description
4. Detection of Aging Effects (cont'd)	Sample Size For sites where inspections are necessary, a minimum of one canister at each site. Preference should be given to the canisters with the greatest susceptibility for localized corrosion or SCC. Factors to be considered include older and colder canisters with the greatest potential for the accumulation and deliquescence of deposited salts that may promote localized corrosion and stress corrosion cracking, types of systems used at site, canister location with respect to potential sources of atmospheric deposits, system design, and operating experience. Industry guidance on evaluating susceptibility has been published by EPRI (Fuhr et al., 2015). Justification for not conducting inspections for localized corrosion or stress corrosion cracking should be provided on a case-by-case basis for each ISFSI site where welded stainless steel canisters are in use. Acceptable justification may be based on a comparison of susceptibility for the ISFSI location versus at least two other ISFSI sites determined to have greater susceptibility but showed no evidence of localized corrosion or stress corrosion cracking in inspections completed within 5 years of the time of the assessment. The justification must consider the full range of available ISFSI susceptibility assessments and welded stainless steel canister examination results. Data Collection Canister Examination: Documentation of the examination of the canister, location, and appearance of deposits. Assessment of the suspect areas where corrosion products were observed as described in corrective actions. Bounding Analysis: A complete listing of other sites considered, susceptibility assessments for those sites and results of examinations conducted at those sites. Justification for not including other sites where examinations showed evidence of localized corrosion and/or stress corrosion cracking. Frequency Once every 5 years

Element	Description
4. Detection of Aging Effects (cont'd)	<u>Timing of Inspections</u> The timing of the inspections includes the pre-application inspection or general-licensee baseline inspection, performed per Sections 3.4.1.2 and 3.6.1.10 of this NUREG, and at the frequency specified by the AMP. Alternative detection methods or techniques may be provided. For these cases: • The method or technique should be adequate and proven to be capable of evaluating the condition of the external surface of the canister against the acceptance criteria for the detection of localized corrosion and stress corrosion cracking. • The proposed intervals for inspection or monitoring are consistent with applicable site-specific, design-specific, or industrywide operating experience and should have sufficient frequency to ensure that the confinement function will be maintained until the next scheduled inspection. • The data collection methods should be sufficient for evaluating localized corrosion and stress corrosion cracking and should reference specific methods to be used for data acquisition including any applicable consensus codes and standards.

5. Monitoring and Trending	Monitoring and trending methods are in accordance with ASME Section XI evaluation criteria.
	
	Monitoring and trending methods reference plans/procedures used to:
	• Establish a baseline before or at the beginning of the period of extended operation.
	• Track trending of parameters or effects not corrected following a previous inspection, including:
	  – the locations and size of any areas of localized corrosion or the stress corrosion cracking
	  – the disposition of canisters with identified aging effects and the results of supplemental canister inspections
	
	Monitoring and trending should also include:
	• documentation of the appearance of the canister, particularly at welds and in crevice locations, with images and video that will allow comparison in subsequent examinations
	• changes to the size and number of any rust colored stains as a result of iron contamination of the surface in subsequent inspections

<table>
<tr>
<td>6. Acceptance Criteria</td>
<td>
No indications of localized corrosion pits, etching, crevice corrosion, stress corrosion cracking, red-orange colored corrosion products emanating from crevice locations, or red-orange colored corrosion products in the vicinity of canister fabrication welds, closure welds, and welds associated with temporary attachments during canister fabrication.
Confirmed or suspected areas of crevice corrosion, pitting corrosion and stress corrosion cracking must be assessed in accordance with acceptance standards identified in ASME Section XI, IWB-3514. Flaws exceeding the acceptance standards in IWB-3514.1 must be evaluated using the acceptance criteria identified in IWB-3640.
<u>Indications Requiring Additional Evaluation</u>
Although shop and handling procedures include controls to prevent iron contamination of the stainless steel surfaces, contamination does occur and is usually identified by rust-colored surface deposits. Iron contamination can exacerbate CISCC in stainless steels. In accessible locations, removal of the deposits and rust stains that reveal undamaged welds (i.e., absence of pits, crack, localized attack, or etching) and the original machining/grinding marks on the stainless steel base metal, including weld heat affected zones, may be used to confirm that localized corrosion or stress corrosion cracking have not been initiated.
Indications of interest that are subject to additional examination and disposition include:

localized corrosion pits, crevice corrosion, stress corrosion cracking, and etching (note that these indications may be covered by obstructions (i.e., crevices)); deposits; or corrosion products
discrete red-orange colored corrosion products that are 1 mm in diameter or larger especially those adjacent to fabrication welds, closure welds, locations where temporary attachments may have been welded to and subsequently removed from the stainless steel dry storage canister, and the weld heat affected zones of these areas
linear appearance of any color of corrosion products of any size parallel to or traversing fabrication welds, closure welds, locations where temporary attachments may have been welded to and subsequently removed from the stainless steel dry storage canister, and the weld heat affected zones of these areas
red-orange colored corrosion products greater than 1 mm in diameter combined with deposit accumulations in any location of the stainless steel canister
red-orange colored corrosion tubercles of any size
red-orange corrosion products present at the mouth of a crevice that includes a portion of the canister surface

Alternative acceptance criteria may be provided. For such cases, the acceptance criteria should:

Include a quantitative basis (justifiable by operating experience, engineering analysis, consensus codes/standards).
Avoid use of non-quantifiable phrases (e.g., significant, moderate, minor, little, slight, few).
Be achievable and clearly actionable.

</td>

Element	Description
7. Corrective Actions	The corrective actions are in accordance with the specific or general licensee Quality Assurance (QA) Program approved under 10 CFR Part 72, Subpart G, or 10 CFR Part 50, Appendix B. The QA Program ensures that corrective actions are completed within the specific or general licensee's Corrective Action Program (CAP), and include provisions to: • Perform functionality assessments. • Perform apparent cause evaluations, and root cause evaluations. • Address the extent of condition. • Determine actions to prevent recurrence for significant conditions adverse to quality; ensure justifications for non-repairs. • Trend conditions. • Identify operating experience actions, including modification to the existing AMP (e.g., increased frequency). • Determine if the condition is reportable per 10 CFR 72.75. Example provisions are provided below, for assessment of extent of condition and evaluation criteria for canisters with aging effects, following from the example acceptance criteria. Alternative corrective actions to those provided below may be appropriate, per the licensees CAP evaluation to determine appropriate corrective actions to be taken if AMP acceptance criteria are not met. <u>Extent of Condition</u> Confirmation of localized corrosion or stress corrosion cracking may warrant inspection of additional canisters at the same ISFSI location to determine the extent of condition. Priority for additional inspections should be to canisters with similar time in service and initial loading. Canisters with confirmed localized corrosion or stress corrosion cracking must be evaluated for continued service. Canisters with localized corrosion or stress corrosion cracking that do not meet the prescribed evaluation criteria must be repaired or replaced.

Element	Description
7. Corrective Actions (cont'd)	<u>Evaluation Criteria for Canisters with Aging Effects</u> For austenitic stainless steel canisters covered by an AMP that utilizes the inspection and acceptance criteria in ASME B&PV code Section XI for Class 1 piping system, the disposition of canisters should be commensurate with in-service inspection results: • Canisters with no evidence of corrosion are permitted to remain in service and will continue to be evaluated at 5-year intervals. • Canisters with rust deposits that are determined to be a result of iron contamination but do not have evidence of localized corrosion or stress corrosion cracking are permitted to remain in service and will continue to be evaluated at 5-year intervals. • Canisters that show evidence of localized corrosion or stress corrosion cracking that does not exceed the acceptance standards in IWB-3514.1 are permitted to remain in service and will be evaluated at 5-year intervals. Sample size should be increased to assess canisters with similar susceptibility assessments. • Canisters that show evidence of localized corrosion or stress corrosion cracking that exceeds the acceptance standards in IWB-3514.1 but meet the acceptance criteria identified in IWB-3640 including the required evaluation per IWB-3641(a) using the prescribed evaluation procedures, are permitted to remain in service and should be evaluated at 3-year intervals. Sample size should be increased to assess canisters with similar susceptibility assessments. • Canisters that show evidence of localized corrosion or stress corrosion cracking that exceeds acceptance criteria identified in IWB-3640 are not permitted to remain in service without an engineering analysis and/or mitigation actions. Sample size should be increased to assess canisters with similar susceptibility assessments.
8. Confirmation Process	The confirmation process will be commensurate with the specific or general licensee Quality Assurance (QA) Program approved under 10 CFR Part 72, Subpart G or 10 CFR Part 50, Appendix B. The QA Program ensures that the confirmation process includes provisions to preclude repetition of significant conditions adverse to quality. The confirmation process describes or references procedures to: • Determine follow-up actions to verify effective implementation of corrective actions. • Monitor for adverse trends due to recurring or repetitive findings or observations.

Element	Description
9. Administrative Controls	The administrative controls are in accordance with the specific- or general-licensee QA Program approved under 10 CFR Part 72, Subpart G, or 10 CFR Part 50, Appendix B, respectively. The QA Program ensures that administrative controls include provisions that define: • instrument calibration and maintenance • inspector requirements • record retention requirements • document control The administrative controls describe or reference: • methods for reporting results to the NRC per 10 CFR 72.75 • frequency for updating AMP based on site-specific, design-specific, and industrywide operating experience

Element	Description
10. Operating Experience	The AMP references and evaluates applicable operating experience, both before renewal and will continue to do so as new operating experience is developed and made available after renewal, including: • internal and industrywide condition reports • internal and industrywide corrective action reports • vendor-issued safety bulletins • NRC Generic Communications • applicable DOE or industry initiatives (e.g., EPRI- or DOE-sponsored inspections) The AMP clearly identifies any degradation in the referenced operating experience as either age-related or event-driven, with proper justification for that assessment. Past operating experience supports the adequacy of the proposed AMP, including the method/technique, acceptance criteria, and frequency of inspection. The AMP references the methods for capturing operating experience from other ISFSIs with similar in-scope SSCs. CISCC of austenitic stainless steels is a known degradation mechanism for aqueous environments; however, operating experience in aqueous environments is not directly applicable in assessing the potential for atmospheric CISCC for austenitic stainless steel dry storage canisters. Atmospheric CISCC of austenitic stainless steels has been reported in a range of industries including welded stainless steel components and piping in operating nuclear power plants. <u>Spent Fuel Storage</u> Inspections of dry storage canisters after 20 years in service have been conducted at a few independent spent fuel installation (ISFSI) sites. Details of the inspection conducted at the Calvert Cliffs nuclear power plant ISFSI are documented in a recent EPRI report (Waldrop et al., 2014; Bryan and Enos, 2015). No evidence of localized corrosion was identified but some amount of chloride-containing salts were determined to be present and corrosion products believed to be related to iron contamination were identified. <u>Operating Power Reactors</u> NRC Information Notice 2012-20 (NRC, 2012) documents previous cases of atmospheric CISCC of welded stainless steel piping systems and tanks at operating reactor locations. Atmospheric CISCC growth rates determined from operating experience at both domestic and foreign nuclear power plants including events at San Onofre, Turkey Point, St. Lucie, and Koeberg (South Africa) range from 3.6×10^{-12} m/s to 2.9×10^{-11} m/s for components at ambient temperatures.

Element	Description
10. Operating Experience (cont'd)	Relevant Literature and Testing Electric Power Research Institute (EPRI) has recently conducted a literature review of CISCC which summarizes the results of many previous laboratory investigations (Gorman et al., 2014). The NRC has recently published the results of a completed investigation of CISCC testing of type 304, 304L and 316L stainless steel and welds (He, et al., 2014). This study indicates that SCC was initiated at stresses just above the yield strength in tests conducted using 304 stainless steel C-ring specimens. Testing with U-bend specimens showed that CISCC was observed with the lowest simulated sea salt concentrations tested (100 mg salt/m^2 or ~55 mg chloride/m^2) at temperatures of 52°C (125.6°F) using a maximum absolute humidity of 30 g/m^3, which is generally accepted as being near the maximum absolute humidity in a natural environment. Both laboratory and field investigations have been conducted by Central Research Institute of Electric Power Industry (CRIEPI) and Tokyo Electric Power Company (TEPCO). This includes the early work by Tokiwai et al. (1985) who reported the critical surface chloride concentrations of 8 mg/m^2 for CISCC on sensitized Type 304 stainless steel. Kosaka (2008) reported crack growth rates of 9.6×10^{-12} m/s obtained in natural exposure tests on Miyakojima Island with Type 304 base metals and welds, Type 304L welds and Type 316LN welds. Hayashibara, et al. (2008) reported activation energy for crack growth in Type 304 stainless steel of 5.6 to 9.4 kcal/mol (23 to 39 kJ/mol) based on testing conducted at temperatures of 50 to 80°C (122 to 176°F).

Example AMP for Reinforced Concrete Structures

An example aging management program (AMP) for reinforced concrete structures is provided below. The AMP consists of condition monitoring, performance monitoring, mitigation and prevention activities. The program includes periodic visual inspections by personnel qualified to monitor reinforced concrete for applicable aging effects, such as those described in the American Concrete Institute (ACI) guides 349.3R-02, ACI 201.1R-08, and American National Standards Institute/American Society of Civil Engineers guidelines (ANSI/ASCE) 11-99. Identified aging effects are evaluated against acceptance criteria derived from the design bases or industry guides and standards, including ACI 349, ACI 318, ACI 349.3R-02 and the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code, Section XI, Subsection IWL.

The program also includes periodic sampling and testing of groundwater and the need to assess the impact of any changes in its chemistry on below-grade concrete structures. Additional activities include radiation surveys to ensure the shielding functions of the concrete structure are maintained and daily inspections to ensure the air convection vents are not blocked, if applicable (per the requirements of the approved design bases). The program also includes provisions where modifications may be appropriate for specific license renewals.

Table B-2. Example AMP for Reinforced Concrete Structures

Element	Description
1. Scope of Program	The scope of the program includes the following aging management activities: 1. visual inspection of above-grade (accessible, inaccessible) and below-grade (underground) concrete areas (See Element 4 for sample size and justification of areas to be inspected) 2. groundwater chemistry monitoring program to identify conditions conducive to below-grade (underground) aging mechanisms: • corrosion of embedded steel • chemical attack (chloride and sulfate induced degradation 3. radiation surveys to: • Ensure compliance with 10 CFR 72.104 (i.e., dose equivalent requirements beyond the controlled area during normal and off-normal conditions of storage). • Monitor performance of the concrete as a neutron/gamma shield at near system locations as an indicator of concrete degradation. The program provides means to address the following aging effects and mechanisms, as described in ACI 349.3R-02 and ASCE/SEI 11-99: • cracking or loss of material (spalling, scaling) due to freeze-thaw degradation • cracking or loss of material (spalling, scaling) due to chemical attack (chloride, sulfate induced) • cracking and loss of strength due to cement aggregate reactions • cracking, loss of material, and loss of bond due to corrosion of embedded steel • increase in porosity/permeability and loss of strength due to leaching of calcium hydroxide ($Ca(OH)_2$) • cracking and distortion due to long-term settlement • cracking and reduction in strength due to gamma and neutron irradiation Calculations or analyses (time-limited aging analyses, when appropriate) may be used to demonstrate that aging effects due to irradiation do not require an AMP. More specifically, the renewal application may demonstrate that no part of the concrete exceeds critical cumulative fluences of 10^{17} neutrons/m^2 or 10^{10} rad (gamma dose), per ACI 349.3R-02.[a] Additional site-specific AMPs may be required for the following scenarios: • A dewatering system is used to prevent long-term settlement. • The design bases includes embedded aluminum subcomponents without a protective insulating coating. • Protective coatings are relied upon to manage the effects of aging for a subcomponent.

Element	Description
2. Preventive Actions	Preventive actions include (1) continuance of inspections to ensure that air inlet and outlet vents are not blocked, or (2) temperature monitoring, if applicable, to ensure design temperature limits are not exceeded. These inspections would be part of the approved design bases and be continued for the sample size and inspection frequency identified in the respective technical specification. Additional preventive actions are not required for structures designed and fabricated in accordance to ACI 318 or ACI 349, as specified in the design bases. Otherwise, a site-specific AMP may be required.
3. Parameters Monitored or Inspected	For visual inspections, the parameters monitored/inspected quantify the following aging effects: • cracking • material loss (spalling, scaling) • loss of bond • increased porosity/permeability The AMP references the following parameters for characterizing the above aging effects, as appropriate:[b] • affected surface area • geometry/depth of defect • cracking, crazing, delaminations, drummy areas • curling, settlements or deflections • honeycombing, bug holes • popouts and voids • exposure of embedded steel • staining/ evidence of corrosion • dusting, efflorescence of any color The parameters evaluated consider any surface geometries that may support water ponding and potentially increase the rate of degradation. For the groundwater chemistry program, the parameters monitored/inspected include: • water pH • concentration of chlorides and sulfates in the water For radiation surveys, the parameters monitored/inspected include gamma dose rate and/or neutron fluence rate.

Element	Description
4. Detection of Aging Effects	<u>Method/Technique</u> The method/technique achieves the acceptance criteria, as defined in AMP Element 6. An engineering justification or technical bases is provided, which references applicable consensus guides, codes and standards, or calibration procedures that ensure the method or technique will provide reliable data. For visual inspections, the method/technique is defined as: • visual method for normally accessible areas (e.g., feeler gauges, crack comparators) • visual method for normally inaccessible areas (site-qualified remote inspection system) Procedures for remote visual inspections should be demonstrated to ensure the acceptance criteria in ACI 349.3R is achievable; procedure attributes should include equipment resolution, lighting requirements, etc. and reference applicable standards when possible. For the groundwater chemistry program, the method/technique is defined as a chemical analysis method with a valid measurement range relative to the acceptance criteria. For radiation surveys, the method/technique is defined as calibrated neutron and gamma detectors with valid energy ranges. <u>Frequency of Inspection</u> The proposed inspection schedule is commensurate with ACI 349.3R-02. Alternative inspection frequencies provide a valid technical basis (engineering justification, operating experience data) for any deviation from ACI 349.3R-02. For visual inspections, the frequency of inspection is defined as: • for above-grade (accessible and inaccessible) areas: ≤ 5 years • for below-grade (underground) areas: ≤ 10 years, and when excavated for any reason • the use of opportunistic inspections in lieu of planned inspections per the above schedule provides a valid technical basis (engineering justification, operating experience data). For the groundwater chemistry program, the frequency of monitoring is justified (e.g., quarterly, semiannual). For radiation surveys, the frequency of monitoring is justified (e.g., quarterly).

<table>
<tr><th>Element</th><th>Description</th></tr>
<tr><td>4. Detection of Aging Effects (cont'd)</td><td><u>Sample Size</u>

Visual inspections cover 100 percent of readily accessible surfaces of all reinforced concrete structures in operation (e.g., all normally accessible exterior surfaces of all loaded overpacks), and 100 percent of normally inaccessible surfaces for a justified subset of the reinforced concrete structures in operation (e.g., interior surfaces of two overpacks, including the overpack earliest loaded and the overpack loaded with the highest heat-load canister). The extent of inspection coverage should be specified and demonstrated to sufficiently characterize the condition of the structure.

For the groundwater chemistry program and radiation surveys, the sample size clearly identifies and justifies specific locations where inspection/monitoring will be conducted to sufficiently characterize the condition of the structure (e.g., periodic dose rate measurements will be performed at same locations specified in the technical specifications for dose rate measurements at loading).

<u>Data Collection:</u>

Data collection for visual inspections is commensurate with applicable consensus codes/standards/guides:
• for example, ACI 224.1R for quantitative analysis (crack width, extent), ACI 562, ACI 364.1R.

The AMP references a clearinghouse for documenting inspection/monitoring operating experience.

<u>Timing</u>

The timing of the inspections includes the pre-application inspection or general-licensee baseline inspection, performed per Sections 3.4.1.2 and 3.6.1.10 of this NUREG, and at the frequency justified by the AMP.</td></tr>
<tr><td>5. Monitoring and Trending</td><td>Monitoring and trending methods are commensurate with defect evaluation guides and standards (e.g., ACI 201.1R, ACI 207.3R, ACI 364.1R, ACI 562, or ACI 224.1R for crack evaluation).

Monitoring and trending methods reference plans/procedures used to:
• Establish a baseline before or at the beginning of the period of extended operation.
• Track trending of parameters or effects not corrected in a previous inspection, for example:
  • crack growth/extent
  • pore/void density and affected areas
  • dose rates</td></tr>
</table>

Element	Description
6. Acceptance Criteria	For visual inspections, the acceptance criteria are commensurate with the three-tier quantitative criteria in ACI 349.3R-02: • acceptance without further evaluation • acceptance after review • acceptance requiring further evaluation The acceptance criteria clearly identify when a condition is to be entered in the Corrective Action Program (e.g., when Tier 2 acceptance per ACI 349.3R-02 is exceeded). For the groundwater chemistry program, the acceptance criteria are commensurate with ASME Code Section XI, Subsection IWL, which states that an aggressive below-grade environment is defined as: • pH < 5.5, chlorides > 500 ppm, or sulfates > 1500 ppm For radiation surveys, the acceptance criteria are justified and sufficient to ensure compliance with 10 CFR 72.104 and identify dose rates that statistically exceed calculated/expected dose rates at pre-determined measurement locations. The adequacy of the acceptance criteria considers measured dose rates versus calculated/expected dose rates for a dry storage system (DSS) given the DSS contents and accounting for the decay of the source term since the DSS loading. Measurement locations should be consistent with those specified in the license/CoC conditions/technical specification (if any) and/or locations where dose rates were calculated in the FSAR and likely measured at the time of loading. Alternative acceptance criteria may be provided. For such cases, the acceptance criteria should: • Include a quantitative basis (justifiable by operating experience, engineering analysis, consensus codes/standards). • Avoid use of non-quantifiable phrases (e.g., significant, moderate, minor, little, slight, few). • Be achievable and clearly actionable.
7. Corrective Actions	The corrective actions are in accordance with the specific- or general-licensee QA Program approved under 10 CFR Part 72, Subpart G, or 10 CFR Part 50, Appendix B, respectively. The QA Program ensures that corrective actions are completed within the specific or general licensee's CAP, and include provisions to: • Perform functionality assessments. • Perform apparent cause evaluations, and root cause evaluations. • Address the extent of condition. • Determine actions to prevent recurrence for significant conditions adverse to quality; ensure justifications for non-repairs. • Trend conditions. • Identify operating experience actions, including modification to the existing AMP (e.g., increased frequency). • Determine if the condition is reportable to the NRC per 10 CFR 72.75. The AMP references applicable concrete rehabilitation guides or standards, for example: • cracking: ACI 224.1R, ACI 562, ACI 364.1R, and ACI RAP Bulletins • spalling/scaling: ACI 562, ACI 364.1R, ACI 506R, and ACI RAP Bulletins

Element	Description
8. Confirmation Process	The confirmation process is commensurate with the specific- or general-licensee QA Program approved under 10 CFR Part 72, Subpart G, or 10 CFR Part 50, Appendix B, respectively. The QA Program ensures that the confirmation process includes provisions to preclude repetition of significant conditions adverse to quality. The confirmation process describes or references procedures to: • determine follow-up actions to verify effective implementation of corrective actions • monitor for adverse trends due to recurring or repetitive findings or observations
9. Administrative Controls	The administrative controls are in accordance with the specific- or general-licensee QA Program approved under 10 CFR Part 72, Subpart G, or 10 CFR Part 50, Appendix B, respectively. The QA Program ensures that the administrative controls include provisions that define: • instrument calibration and maintenance • inspector requirements (commensurate with ACI 349.3R-02) • record retention requirements • document control The administrative controls describe or reference: • methods for reporting results to the NRC per 10 CFR 72.75 • frequency for updating the AMP based on industrywide operating experience
10. Operating Experience	The AMP references and evaluates applicable operating experience, both before renewal and will continue to do so as new operating experience is developed and made available after renewal, including: • internal and industrywide condition reports • internal and industrywide corrective action reports • vendor-issued safety bulletins • NRC Generic Communications • applicable DOE or industry initiatives (e.g., EPRI- or DOE-sponsored inspections) The AMP clearly identifies any degradation in the referenced operating experience as either age-related or event-driven, with proper justification for that assessment. Past operating experience supports the adequacy of the proposed AMP, including the method/technique, acceptance criteria, and frequency of inspection. The AMP references the methods for capturing operating experience from other ISFSIs with similar in-scope SSCs.

[a] The staff recognizes the critical cumulative fluence in ACI 349.3R-02 as adequately conservative. The applicant may choose to justify a higher critical cumulative fluence if a technical bases is provided.
[b] Terminology consistent with ACI standard CT-13.

Example of a High Burnup Fuel Monitoring and Assessment Program

An example of a High Burnup (HBU) Fuel [1] Monitoring and Assessment Program is provided below. This is a licensee program that monitors and assesses data and other information regarding HBU fuel performance, to confirm that the design-bases HBU fuel configuration is maintained during the period of extended operation. This example HBU Monitoring and Assessment Program relies on a surrogate demonstration program to provide data on HBU fuel performance. Guidance for determining if a surrogate demonstration program can provide the data to support a licensee's HBU Fuel Monitoring and Assessment Program is given in Appendix D. Although this example focuses on the use of a surrogate demonstration program, a licensee may use alternative approaches that are appropriately justified.

The aging management review is not expected to identify any aging effects that could lead to fuel reconfiguration, as long as the HBU fuel is stored in a dry inert environment, temperature limits are maintained, and thermal cycling is limited (see Sections 2.4.2.1 and 3.4.1.4). Short-term testing (i.e., laboratory scale testing up to a few months) and scientific analyses examining the performance of HBU fuel have provided a foundation for the technical basis that storage of HBU fuel in the period of extended operation may be performed safely and in compliance with regulations. However, there has been relatively little operating experience, to date, with dry storage of HBU fuel.

Therefore, the purpose of a HBU Fuel Monitoring and Assessment Program is to monitor and assess data and other information regarding HBU fuel performance to confirm there is no degradation of HBU fuel that would result in an unanalyzed configuration during the period of extended operation. The following description of an example HBU Fuel Monitoring and Assessment Program presents the applicable information in a format using each element of an effective aging management program, to provide a framework for such a monitoring and assessment program.

---

[1] Fuel assemblies with discharge burnup greater than 45 gigawatt-days per metric ton of uranium (GWd/MTU)

Table B-3. Example of a High Burnup Fuel Monitoring and Assessment Program

Element	Description
1. Scope of the Program	The scope of the program provides a description of: (1) the design-bases characteristics of the HBU fuel, (2) the surrogate demonstration program that will be used to provide data on the applicable design-bases HBU fuel performance, and (3) how the parameters of the surrogate demonstration program are applicable to the design-bases HBU fuel. Aging effects will be determined for material/environment combinations through an alternative surrogate demonstration program meeting the guidance in Appendix D. Example language to address this "scope of the program" element follows: Fuel stored in a *[define cask/canister model]* is limited to an assembly average burnup of *[define design-bases limit]* GWd/MTU. The cladding materials for the HBU fuel are *[define types of cladding],* and the fuel is stored in a dry helium environment. HBU fuel was first placed into dry storage in a *[define cask/canister model]* on *[start date of storage term of first storage of HBU fuel].* The program relies on the joint Electric Power Research Institute (EPRI) and Department of Energy (DOE) "HBU Dry Storage Cask Research and Development Project" (HDRP) (EPRI 2014), conducted in accordance with the guidance in Appendix D, as a surrogate demonstration program that monitors the performance of HBU fuel in dry storage. The HDRP is a program designed to collect data from a spent nuclear fuel storage system containing HBU fuel in a dry helium environment. The program entails loading and storing a AREVA TN-32 bolted lid cask (the "Research Project Cask") at Dominion Virginia Power's North Anna Power Station with intact HBU fuel (of average assembly burnups ranging between 53 GWd/MTU and 55.5 GWd/MTU). The fuel to be used in the program include four kinds of cladding (Zircaloy-4, low-tin Zircaloy-4, Zirlo^{TM}, and M5^{TM}). The Research Project Cask is to be licensed to the temperature limits contained in Interim Staff Guidance (ISG) 11, Rev. 3 (NRC 2003), and loaded such that the fuel cladding temperature is as close to the limit as practicable. *[If an alternative surrogate demonstration program is used, provide a description of the program.]*

Element	Description
1. Scope of the Program (cont'd)	The parameters of the surrogate demonstration program are applicable to the design-bases HBU fuel, as the: (1) maximum assembly-average burnup of the design-bases HBU fuel *[define value]* is less than the assembly-average burnup of the fuel in the surrogate demonstration program *[define value]*; (2) the cladding type of the design-bases HBU fuel *[define type]* is the same as the surrogate demonstration program *[define type]*; and (3) the peak temperatures in the surrogate demonstration program *[define values]* bound the peak temperatures of the loaded systems (or design bases) *[define values]*.[a]
2. Preventive Actions	There are no specific preventive actions associated with this HBU Fuel Monitoring and Assessment Program. However, the applicant should discuss the design-bases characteristics of the licensed/certified dry storage system, in terms of initial cask loading operations, to show the HBU fuel is stored in a dry inert environment. Example language follows: During the initial loading operations of the cask/canister, the design and ISFSI Technical specifications (TS) require that the fuel be stored in a dry inert environment. TS *[name and number]* demonstrates that the cask/canister cavity is dry by maintaining a cavity absolute pressure less than or equal to *[value]* for a *[time period]* with the cask/canister isolated from the vacuum pump. TS *[name and number],* requires that the cask/canister then be backfilled with helium. These two TS requirements ensure that the HBU fuel is stored in an inert environment thus preventing cladding degradation due to oxidation mechanisms. TS *[name and number]* also requires that the helium environment be established within *[time]* hours of commencing cask/canister draining. The cask/canister is loaded in accordance with the criteria of ISG-11.
3. Parameters Monitored or Inspected	The applicant identifies the parameters monitored and inspected in a surrogate demonstration program that are applicable to its particular design-bases HBU fuel and describes how this meets the guidance of Appendix D.
4. Detection of Aging Effects	The applicant identifies the detection of aging effects in a surrogate demonstration program that are applicable to its particular design-bases HBU fuel and describes how this meets the guidance of Appendix D.

Element	Description
5. Monitoring and Trending	As information/data from a surrogate demonstration program or from other sources (such as testing or research results and scientific analyses) becomes available, the licensee will monitor, evaluate, and trend the information via its operating experience program and/or the Corrective Action Program (CAP) to determine what actions should be taken. The licensee will evaluate the information/data from a surrogate demonstration program or from other sources to determine whether the acceptance criteria in Element 6 are met. • If all of the acceptance criteria are met, no further assessment is needed. • If any of the acceptance criteria are not met, the licensee must conduct additional assessments and implement appropriate corrective actions (see Element 7). Formal evaluations of the aggregate information from a surrogate demonstration program and other available domestic or international operating experience (including data from monitoring and inspection programs, NRC generic communications, and other information) will be performed at specific points in time during the period of extended operation, as delineated in Table B-4.
6. Acceptance Criteria	The High Burnup Fuel Monitoring and Assessment Program acceptance criteria are: • Hydrogen content—maximum hydrogen content of the cover gas over the approved storage period should be extrapolated from the gas measurements to be less than the design-bases limit for hydrogen content. • Moisture content—the moisture content in the cask/canister, accounting for measurement uncertainty, should be less than the expected upper bound moisture content per the design-bases drying process.[b] • Fuel condition/performance—nondestructive examination (e.g., fission gas analysis) and destructive examination (e.g., to obtain data on creep, fission gas release, hydride reorientation, cladding oxidation, and cladding mechanical properties) should confirm the design-bases fuel condition (i.e., no changes to the analyzed fuel configuration considered in the safety analyses of the approved design bases). The applicant should provide information on the design-bases characteristics of the dry storage system or ISFSI, with regard to these criteria. The applicant should reference the source of specific values, or explain any assumptions made, for defining design-bases characteristics of the fuel condition/performance.

Element	Description
7. Corrective Actions	The corrective actions are in accordance with the specific- or general-licensee QA Program approved under 10 CFR Part 72, Subpart G, or 10 CFR Part 50, Appendix B, respectively. Corrective actions should be implemented if data from a surrogate demonstration program or other sources of information indicate that any of the High Burnup Fuel Monitoring and Assessment Program acceptance criteria (in Element 6) are not met. If any of the acceptance criteria are not met, the licensee will: (1) Assess fuel performance (effects on fuel and changes to fuel configuration). (2) Assess the design-bases safety analyses, considering degraded fuel performance (and any changes to fuel configuration), to determine the ability of the dry storage system/ISFSI to continue to perform its intended functions under normal, off-normal, and accident conditions. The licensee will determine what corrective actions should be taken to: (1) Manage fuel performance, if any. (2) Manage impacts related to degraded fuel performance to ensure that all intended functions for the dry storage system/ISFSI are met. In addition, the licensee will obtain the necessary NRC approval in the appropriate licensing/certification process for modification of the design bases to address any conditions outside of the approved design bases.
8. Confirmation Process	The confirmation process is commensurate with the specific- or general-licensee QA Program approved under 10 CFR Part 72, Subpart G, or 10 CFR Part 50, Appendix B, respectively. The QA Program ensures that the confirmation process includes provisions to ensure corrective actions are adequate and appropriate, have been completed, and are effective. The focus of the confirmation process is on the follow-up actions that must be taken to verify effective implementation of corrective actions. The measure of effectiveness is in terms of correcting the adverse condition and precluding repetition of significant conditions adverse to quality. Procedures include provisions for timely evaluation of adverse conditions and implementation of any corrective actions required, including root cause evaluations and prevention of recurrence where appropriate. These procedures provide for tracking, coordinating, monitoring, reviewing, verifying, validating, and approving corrective actions, to ensure effective corrective actions are taken.
9. Administrative Controls	The administrative controls are in accordance with the specific- or general-licensee QA Program approved under 10 CFR Part 72, Subpart G, or 10 CFR Part 50, Appendix B, respectively. The QA Program ensures that the administrative controls include provisions that define: • formal review and approval processes • record retention requirements • document control

Element	Description
10. Operating Experience	The program references and evaluates applicable operating experience, both before renewal and will continue to do so as new operating experience is developed and made available after renewal, including: • internal and industrywide condition reports • internal and industrywide corrective action reports • vendor-issued safety bulletins • NRC Generic Communications • applicable DOE or industry initiatives (e.g., HDRP) • applicable research (e.g., Oak Ridge National Laboratory studies on bending responses of the fuel, Argonne National Laboratory and Central Research Institute of Electric Power Industry studies on hydride reorientation effects) The review of operating experience clearly identifies any HBU fuel degradation as either age-related or event-driven, with proper justification for that assessment. Past operating experience supports the adequacy of the HBU Fuel Monitoring and Assessment Program. Surrogate demonstration programs with storage conditions and fuel types similar to those in the licensed ISFSI/certified dry storage system that meet the guidance in Appendix D are a viable method to obtain operating experience. New data/research on fuel performance from both domestic and international sources that are relevant to the licensed/certified HBU fuel in the dry storage system/ISFSI should be evaluated on a periodic basis and the AMP updated and revised as needed.

[a] The AMP should provide a technical basis that supports the conclusion that the demonstration fuel is reasonably characteristic of the licensee's stored fuel, in the event of differences in burnup, cladding composition (alloy types) and peak cladding temperatures observed during loading (See Appendix D).
[b] The applicant will need to provide the expected upper bound moisture content based on its design-bases drying process. For example, if the design-bases drying process involves a vacuum drying method of evacuating a cask/canister to less than or equal to 3 torr and maintaining a constant pressure for 30 minutes after the cask/canister is isolated from the vacuum pump, the expected water content is about 0.43 gram-mole. (See NUREG-1536, Rev. 1.)

Table B-4. Formal Evaluations of Aggregate Information on HBU Fuel Performance

	Year	Assessment
1	Date—before HBU fuel exceeds the initial storage term [a]	Evaluate information obtained from a surrogate demonstration program for loading and initial period of storage along with other available sources of information. If surrogate demonstration program nondestructive examination (NDE) (i.e., cask/canister gas sampling, temperature data) data has not been obtained at this point, then the licensee has to provide evidence that the acceptance criteria in Element 6 are met or initiate a corrective action.
2	Date—10 years after Assessment 1 above	Evaluate, if available, information obtained from the destructive examination and NDE of the fuel placed into storage in a surrogate demonstration program along with other available sources of information. If the destructive examination data from a surrogate demonstration program has not been obtained at this point, then the licensee has to provide evidence to the NRC, by opening a cask/canister or separate effects surrogate experiments, that the acceptance criteria in Element 6 are met or initiate a corrective action.
3	Date—10 years after Assessment 2 above	Evaluate any new information.

[a] See Appendix F for a discussion of storage terms.

APPENDIX C

[RESERVED]

Upon consideration of public comments received on Draft NUREG-1927, Revision 1, the concepts regarding lead system inspections originally presented in Appendix C of the Draft NUREG-1927, Revision 1, have been incorporated into Chapter 3, "Aging Management Review," of this Final NUREG-1927, Revision 1. Therefore, the content in Appendix C has been deleted, and Appendix C is reserved for future use.

APPENDIX D

SUPPLEMENTAL GUIDANCE FOR THE USE OF A DEMONSTRATION PROGRAM AS A SURVEILLANCE TOOL FOR CONFIRMATION OF INTEGRITY OF HIGH BURNUP FUEL DURING THE PERIOD OF EXTENDED OPERATION

Appendix D

Supplemental Guidance for the Use of a Demonstration Program as a Surveillance Tool for Confirmation of Integrity of High Burnup Fuel During the Period of Extended Operation

This guidance provides the U.S. Nuclear Regulatory Commission (NRC) staff a basis for reviewing if a demonstration of high burnup (HBU) fuel has the necessary properties to qualify as one method that an applicant might use in license and certificate of compliance renewal applications to confirm the integrity of HBU fuel during continued storage.

D.1 Discussion

The experimental confirmatory basis that low burnup fuel (≤45 GWd/MTU) will maintain its integrity in dry cask storage over extended time periods was provided in a demonstration test (NRC, 2003; Bare, et al., 2001; Einziger, et al., 2003). A similar confirmation test, which includes information over a similar length of the time available for low burnup fuel, does not exist for other light water reactor (LWR) fuels, HBU fuel [1] and mixed oxide fuels. Certification and licensing HBU fuel for storage was permitted for an initial 20-year-term using the guidance contained in Interim Staff Guidance (ISG) 11 (NRC 2003), which was based on short-term laboratory tests and analysis that may not be applicable to the storage of HBU fuel beyond 20 years, particularly with the current state of knowledge regarding HBU fuel cladding properties.

One concern stated in ISG-11 was the potential detrimental effects, such as reduced ductility, of hydride reorientation on cladding behavior (NRC, 2003). Research performed in Japan and the United States indicated that: (1) hydrides could reorient at a significantly lower stress than previously believed (Billone, et al., 2013; Kamimura, 2010; Daum, et al, 2006), and (2) the radial hydrides could raise the cladding ductile-to-brittle transition temperature enough to compromise the ability of the cladding to withstand stress without undergoing brittle failure (Billone, et al., 2013). This phenomenon could influence the retrievability of HBU fuel assemblies and result in operational safety concerns in the handling of individual assemblies as HBU fuel cooled. Circumferential zirconium hydrides in the fuel cladding regions would dissolve into the fuel cladding during drying and reprecipitate (reorient) as radial hydrides as the fuel cladding cooled. Thus, fuel cladding with radial hydrides that is below a ductile-to-brittle transition temperature could be too brittle to retrieve (remove from the DSS) on an assembly basis. The maximum temperatures and internal rod pressures in ISG-11 were recommended to mitigate hydride reorientation and are applicable to HBU fuel during the initial 20-year storage, as the decay heat of HBU fuel is expected to maintain cladding temperatures above a ductile-to-brittle transition temperature (about 200 degrees Celsius, or about 392 degrees Fahrenheit).

There is no evidence to suggest that HBU fuel cannot similarly be stored safely and then retrieved for time periods beyond 20 years, but the supporting experimental data is not extensive. Therefore, confirmatory data or a commitment to obtain data on HBU fuel and taking appropriate steps in an aging management plan (AMP) will provide further information that will be useful in evaluating the safe handling of individual assemblies of HBU fuel for extended durations.

---

[1] High burnup fuel is fuel with burnup ≥ 45 GWd/MTU.

A demonstration program could provide an acceptable method for an applicant to demonstrate compliance with the cited regulations for storage of light water reactor fuels (LWR) for periods of greater than 20 years by:

- confirming the expected fuel conditions, based on technical arguments made in ISG-11 (NRC, 2003), after a substantial storage period that is sufficiently long (about 10 years) to extrapolate the findings to the storage duration of interest (The behavior of the cladding for the period of extended operation will depend on its physical condition at the end of the initial 20-year storage period.)
- providing data for benchmarking, confirming predictive models, and updating aging management plans
- confirming the time-limited aging analysis (TLAA) cladding creep predictions that are the basis for the guidance recommendation for the maximum temperature in ISG-11 (NRC, 2003) are not exceeded and that sufficient creep margin exists for the extended storage period
- determining the system is sufficiently dry to eliminate moisture-driven degradation from consideration
- providing operating experience on the fuel behavior and drying procedure as input to an AMP on the behavior of the fuel
- identifying any aging effects that may be missed through short-term accelerated studies and analyses

Monitoring of the fuel temperatures, gas composition, and other conditions in the canister or cask combined with physical examination of the fuel at periodic intervals should be able to provide confirmation if:

- The models of the phenomena used for the first 20-year predictions can be used for the TLAA beyond 20 years.
- The condition of the fuel, after an appropriately long period of storage, does not degrade.
- New degradation mechanisms are not being exhibited.

Extrapolation outside the recorded data carries risk, but that risk can be minimized if the length of the extrapolation is reduced and those extrapolations are updated as the demonstration continues to monitor and measure fuel properties.

D.2 Technical Review Guidance

The applicant may use the results of a completed demonstration or an ongoing demonstration if the conditions of the demonstration meet the requirements stated below for the fuels and conditions of storage for which the term is to be renewed. The approach in this guidance can be applied to a generic demonstration program or a site/system-specific program as long as the demonstration's parameters are reasonably applicable to the applicant's fuel type and characteristics.

The technical reviewers should establish that the following conditions are met if the demonstration is to be used by the applicant to support fuel assembly conditions for storage of HBU fuel beyond 20 years and to be applicable to support a license or certificate application:

(1) That the maximum burnup of the fuel in the application is less than the burnup of the fuel in the demonstration. If the burnup is higher than that in the demonstration, the applicant should provide evidence, based on characteristics of the fuel, derived either from reactor rod qualification testing or other separate effects tests, that the demonstration fuel is reasonably characteristic of the stored fuel and the added burnup will not change the results determined by the demonstration. Similarly, if there is a different cladding type used, arguments based on comparison of composition and fabrication technique (e.g., stress-relieved and annealed, recrystallized) should justify the use of the demonstration results.

(2) If the applicant uses direct observations of the rod behavior to imply the condition of the rods in its system, either (1) the temperatures in the demonstration must bound the temperatures in the application, or (2) if the applicant uses predictive tools that have been confirmed by the demonstration, then the temperatures of the rods in the application do not have to be bounded by the temperature of the rods in the demonstration. The temperature models used in the application should either be benchmarked (1) against the demonstration temperature data, or (2) against actual measured rod temperature data in the same temperature range.

(3) If the applicant is using gas analysis or another gas detection method to establish the condition of the fuel, then the interior of a demonstration canister or cask should be quantitatively monitored for, at a minimum, moisture, oxygen, and fission gas. The duration and frequency of the gas monitoring should be determined by analysis of the potential degradation. Gases should always be quantitatively monitored before opening of the canister. If the applicant claims that no galvanic degradation is feasible, then, if after drying, moisture is detected in the canister, moisture and hydrogen should be monitored at a reasonable frequency to be determined by the applicant until the moisture disappears. Gas monitoring is not expected during movement of the canister. If the applicant is using the gas analysis to show no breaches would occur during transport, gas quantitative monitoring must be conducted before and after transport.

(4) Temperature monitoring should be conducted at a frequency that is suitable for determining the profile over the duration of the demonstration.

(5) If possible, some population of stored rods should be examined whenever the system is opened. These rods should be extracted from the fuel assembly to determine properties of the rods that affect degradation such as cladding creep, fission gas release, hydride reorientation, cladding oxidation, and mechanical properties.

(6) The demonstration program fuel shall include at least two full fuel assemblies. The assemblies may be reconstituted.

(7) Data from the demonstration program must be indicative of a storage duration long enough to justify extrapolation to the total storage time requested but no less than

10 years if the data is to be used to support license extension from the initial 20 years to an additional 40 years.[2]

[2] A demonstration is to provide that there was satisfactory performance during the first 20 years and that the results could be extrapolated to support an additional 40 years. The NRC staff agreed that a demonstration of ≤ 10 years storage duration is insufficient to support these goals.

APPENDIX E

CONSIDERATIONS FOR RENEWALS OF CERTIFICATES OF COMPLIANCE

Appendix E

Considerations for Renewals of Certificates of Compliance

E.1 Development of Time-Limited Aging Analyses and Aging Management Programs

From Title 10 of the *Code of Federal Regulations* (10 CFR) 72.240, "Conditions for Spent Fuel Storage Cask Renewal," the certificate of compliance (CoC) renewal application must include time-limited aging analyses (TLAAs), if applicable, and aging management programs (AMPs). The CoC holder, as the applicant for the CoC renewal and the owner of the storage cask or dry storage system (DSS) design, will develop the TLAAs and AMPs. The renewal application should address age-related degradation of the DSS design in a bounding manner (i.e., fully address pertinent aging mechanisms and effects in all possible service environments where the DSS is being used and can be used). If there is an AMP that may not be applicable to certain general licensees, because of the service environment in which the DSS is located, the AMP should specify this. In addition, the CoC holder and the staff should consider the need for a CoC condition to specify this potential limited use of the AMP, so it is clear for general licensee implementation.

For a CoC renewal that encompasses CoC amendments with different design bases, the CoC holder will need to address in the renewal application how the TLAAs or AMPs apply to each amendment covered by the CoC. For example, if different materials are used or different SSCs are part of the DSS design in different CoC amendments, or if different environments (e.g., underground vs. aboveground system) are reflected in different CoC amendments, then there may be different TLAAs or AMPs specified for the individual amendments.

E.2 Implementation of AMPs

In approving the renewal of the DSS design, the U.S. Nuclear Regulatory Commission (NRC) may revise the CoC to include terms, conditions, and specifications that will ensure the safe operation of the DSS during the period of extended operation, including but not limited to, terms, conditions, and specifications that will require the implementation of an AMP by a general licensee, in accordance with 10 CFR 72.240(e). General licensees' implementation of AMPs is subject to NRC inspection.

Regulations in 10 CFR 72.212, "Conditions of General License Issued under § 72.210," provide requirements for general licensees using approved CoCs. Regulations in 10 CFR 72.212(b)(11) require general licensees to comply with the terms, conditions, and specifications of the CoC, including but not limited to, the requirements of any AMP put into effect as a condition of the NRC approval of a CoC renewal application in accordance with 10 CFR 72.240.

General licensees (CoC users) are responsible for implementing the AMPs. To document the licensee's compliance with the renewed CoC, a future or existing general licensee should include in its 10 CFR 72.212(b)(5) evaluation (including the results of the review and determination per 72.212(b)(6) and 72.212(b)(8)) how it will meet the new CoC terms, conditions, or specifications for aging management. Note that the renewed CoC may include a condition for the general licensee to do so. As part of this evaluation, general licensees should consider any granted exemptions or 10 CFR 72.48 changes that could affect aging management.

The general licensee should update the 10 CFR 72.212(b)(5) evaluation before entering the period of extended operation. Considering timely renewal provisions (See Section 1.4.5), update of the 10 CFR 72.212(b)(5) evaluation before the loaded systems enter the period of extended operation may not be possible. In such cases, the reviewer should ensure that timing for update of the 10 CFR 72.212(b)(5) evaluation is addressed in the application in a clear manner. Also, any CoC condition related to the update of the 10 CFR 72.212(b)(5) evaluation may include timing provisions.

The AMP-related information in the DSS FSAR will be implemented by general licensees as-written. If a general licensee wishes to deviate from the DSS FSAR, it must evaluate any such deviation under the provisions of 10 CFR 72.48. If AMP details in the FSAR specify that the AMP is not applicable for certain users (e.g., if it is not applicable in certain climates or environments), the general licensee can include the technical justification in its 10 CFR 72.212 report for not implementing such an AMP. The general licensee would need to evaluate any changes to the 10 CFR 72.212 report or any deviations from the DSS FSAR, using the requirements of 10 CFR 72.48 (See NRC Regulatory Issue Summary 2012-05, "Clarifying the Relationship Between 10 CFR 72.212 and 10 CFR 72.48 Evaluations").

E.3 Corrective Actions

As discussed in Section 3.6.1.7, corrective actions are measures to be taken when the AMP acceptance criteria are not met. Corrective actions are critical for maintaining the intended functions of the structures, systems, and components during the initial storage term as well as the period of extended operation. The CoC holder should discuss in its renewal application any applicable and appropriate corrective actions to be taken if the AMP acceptance criteria are not met.

A general licensee will use its Corrective Action Program (CAP) (that is consistent with the criteria in 10 CFR Part 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants") to capture and address aging effects identified in the period of extended operation. At a minimum, all conditions that do not meet the AMP acceptance criteria should be entered into the CAP. The general licensee's CAP should be able to respond to and adequately address and rectify any ISFSI or DSS aging issues. Also, the CAP's response to address any DSS aging issues should include any specific corrective actions specified in the CoC renewal application.

APPENDIX F

STORAGE TERMS

Appendix F

Storage Terms

F.1 Introduction

This appendix provides a flow chart for calculating storage terms of a dry storage system (DSS) or a DSS structure, system, and component (SSC) loaded during either the initial storage period or renewal period(s) of a certificate of compliance (CoC).

F.2 Storage Term Defined

The storage term (length of time a DSS can remain loaded) is determined by the period specified in the applicable CoC in effect at the time the DSS is placed into service (from Title 10 of the *Code of Federal Regulations* (10 CFR) 72.212(a)(3) and Ref. 1). The storage period begins when the DSS is first used by the general licensee to store spent fuel (10 CFR 72.212(a)(3)).[1] The clock starts when the loaded cask has been deployed in the independent spent fuel storage installation (76 FR 8872). If a CoC is not renewed, upon expiration, casks loaded under that CoC would need to be removed from service when they reach the end of their storage term. An AMP for a renewed CoC commences at the end of the initial storage period for each loaded DSS (see Section 3.6.2).

- If the DSS is loaded during the initial CoC term (e.g., 20 years) and the CoC is not renewed, the storage term is the entirety of the initial CoC term (e.g., 20 years).
- If the DSS is loaded during the initial CoC term and the CoC is renewed once, the storage term is the remaining time in the initial CoC term added to the entirety of the first renewal period.
- If the DSS is loaded during the first renewal period (e.g., 40 years), and the CoC is not subsequently renewed, the storage term is the entirety of the first renewal period (e.g., 40 years).
- If the DSS is loaded during the first renewal period, and the CoC is subsequently renewed, the storage term is the remaining time in the first renewal period added to the entirety of the subsequent renewal period (cumulative).

F.3 Flowchart for Calculating Storage Terms

A flowchart is provided below to assist the user in calculating the storage term for a DSS loaded under a CoC.

[1] The storage period for a particular DSS SSC begins when it is first used to store spent fuel, regardless if the SSC is later stored at a different location.

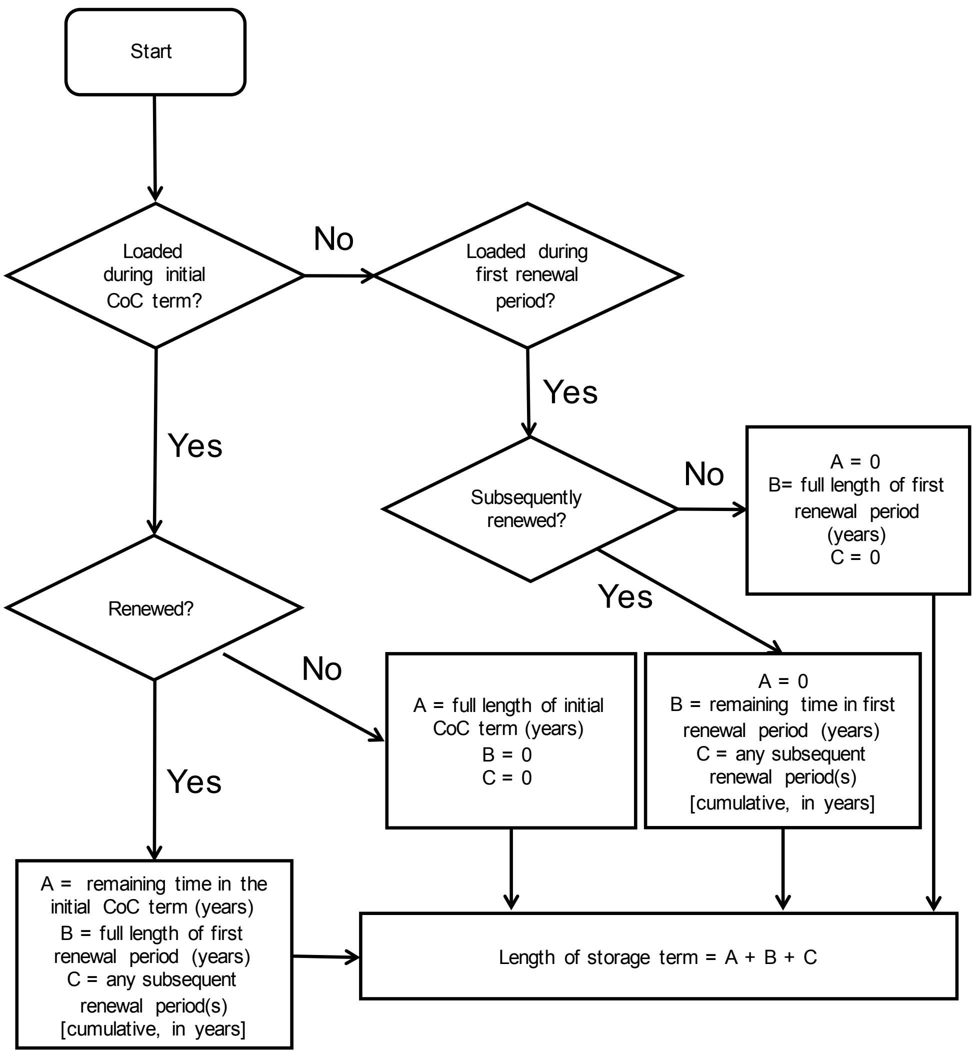

Figure F-1. Flowchart for calculating storage terms

10. SUPPLEMENTARY NOTES

11. ABSTRACT (200 words or less)

This Standard Review Plan is intended for use by U.S. Nuclear Regulatory Commission (NRC) reviewers. It provides guidance for the safety review of renewal applications for specific licenses of independent spent fuel storage installations and certificates of compliance (CoCs) of dry storage systems, as codified in Title 10 of the Code of Federal Regulations (10 CFR) Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel, High-Level Radioactive Waste, and Reactor-Related Greater Than Class C Waste."

To renew a specific license, an applicant (i.e., licensee) must submit a license renewal application at least 2 years before the expiration of the license in accordance with the requirements of 10 CFR 72.42(b). To renew a CoC, an applicant (i.e., CoC holder, user, or user's representative) must submit a renewal application at least 30 days before the expiration of the associated CoC in accordance with the requirements of 10 CFR 72.240(b). The NRC may renew a specific license or a CoC for a term not to exceed 40 years, in accordance with 10 CFR 72.42(a), or 10 CFR 72.240(a), respectively.

Division of Spent Fuel Storage and Transportation
Interim Staff Guidance - 1, Revision 2
Classifying the Condition of Spent Nuclear Fuel for Interim Storage and Transportation Based on Function[1]

Issue

This Interim Staff Guidance (ISG) provides guidance to the staff on classifying spent nuclear fuel as either (1) damaged, (2) undamaged, or (3) intact, before interim storage or transportation. This is not a regulation or requirement and can be modified or superseded by an applicant with supportable technical arguments.

Regulatory Basis

Fuel-Specific Regulations:

A fuel-specific regulation means a characteristic or performance requirement of the fuel specifically named in the applicable Code of Federal Regulations (CFR). These are regulations that specify capabilities that the spent nuclear fuel (SNF) must have. Examples include:

10 CFR 71.55(d) states, in part: "A package used for the shipment of fissile material must be so designed and constructed and its contents so limited that under the tests specified in 10 CFR 71.71 ('Normal conditions of transport')

(1) The contents would be subcritical.
(2) The geometric form of the package contents would not be substantially altered."

10 CFR 72.44(c) states, in part: "Technical specifications must include requirements in the following categories: (1) Functional and operating limits . . . (I) . . . for an ISFSI or MRS are limits on fuel or waste handling and storage conditions that are found to be necessary to protect the integrity of the stored fuel or waste container, to protect employees against occupational exposures and to guard against the uncontrolled release of radioactive materials . . . "

10 CFR 72.122(h)(1) states: "The spent fuel cladding must be protected during storage against degradation that leads to gross ruptures or the fuel must be otherwise confined such that degradation of the fuel during storage will not pose operational safety problems with respect to its removal from storage. This may be accomplished by canning of consolidated fuel rods or unconsolidated assemblies or other means as appropriate."

10 CFR 72.122(l) states: "Retrievability. Storage systems must be designed to allow ready retrieval of spent fuel, . . . for further processing or disposal."

---

[1]Formerly entitled "Damaged Fuel."

System-Related Regulations:

A transportation and storage system must satisfy all applicable regulations in 10 CFR Parts 71 or 72. A system-related regulation is a performance requirement placed on the fuel for the system (i.e., transportation or storage cask) to meet a regulation that does not specifically require performance capabilities of the SNF. Examples include:

10 CFR 71.55(e) states in part: "A package used for the shipment of fissile material must be so designed and constructed and its contents so limited that under the tests specified in 10 CFR 71.73 ('Hypothetical accident conditions'), the package would be subcritical."

Note: This regulation does not place a specific requirement on the SNF. However, if the package requires the SNF to maintain its geometric configuration to ensure subcriticality, then a function is imposed on the SNF.

10 CFR 72.122(h)(5) states: "The high level radioactive waste and reactor related GTCC waste must be packaged in a manner that allows handling and retrievability without the release of radioactive materials to the environment or radiation exposures in excess of Part 20 limits . . . "

10 CFR 72.124(a) states: "Design for criticality safety. Spent fuel handling, packaging, transfer, and storage systems must be designed to be maintained subcritical and to ensure that, before a nuclear criticality accident is possible, at least two unlikely, independent, and concurrent or sequential changes have occurred in the conditions essential to nuclear criticality safety. The design of handling, packaging, transfer, and storage systems must include margins of safety for the nuclear criticality parameters that are commensurate with the uncertainties in the data and methods used in calculations and demonstrate safety for the handling, packaging, transfer, and storage conditions and in the nature of the immediate environment, under accident conditions."

Note: If the SNF must have certain characteristics or behave in a specified manner to maintain the required margins, a function is placed on the SNF.

10 CFR 72.128 states in part: "Spent fuel storage . . . must be designed to ensure adequate safety under normal and accident conditions. These systems must be designed with (2) suitable shielding for radioactive protection under normal and accident conditions, (3) confinement structures and systems . . . "

Note: If proper functioning of the shielding or containment requires that the SNF maintain its configuration, then a function is placed on the SNF.

Applicability

This guidance applies to reviews of dry cask storage systems and transportation casks conducted in accordance with NUREG-1536, "Standard Review Plan for Dry Cask Storage Systems" (January 1997); NUREG-1567, "Standard Review Plan for Spent Fuel Dry Storage Facilities" (March 2000); or NUREG-1617, "Standard Review Plan for Transportation Packages for Spent Nuclear Fuel" (March 2000). This revision of ISG-1 supersedes any definitions of damaged, grossly damaged, or intact fuel in the above Standard Review Plans.

This revision supersedes ISG-1, Revision 1, "Damaged Fuel," in its entirety, and is applicable to both as-built and reconstituted fuel assemblies.

Definitions

1. Spent Nuclear Fuel (SNF) - See 10 CFR Part 72.3 for definition. This term has been used in the nuclear industry, at different times, to mean the fuel pellets, the rod, or entire fuel assembly. Unless specifically modified, the term will refer to both the rods and fuel assembly.

2. Damaged SNF - Any fuel rod or fuel assembly that cannot fulfill its fuel-specific or system-related functions.

3. Undamaged SNF - SNF that can meet all fuel-specific and system-related functions. As shown in Figure 1, undamaged fuel may be breached. Fuel assembly classified as undamaged SNF may have "assembly defects."

4. Breached spent fuel rod - Spent fuel rod with cladding defects that permit the release of gas from the interior of the fuel rod. A breached spent fuel rod may also have cladding defects sufficient to permit the release of fuel particulate. A breach may be limited to a pinhole leak or hairline crack, or may be a gross breach.

5. Pinhole leaks or hairline cracks - Minor cladding defects that will not permit significant release of particulate matter from the spent fuel rod, and therefore present a minimal as-low-as-is-reasonably-achievable concern, during fuel handling and retrieval operations. (See discussion of gross defects for size concerns.)

6. Grossly breached spent fuel rod - A subset of breached rods. A breach in spent fuel cladding that is larger than a pinhole leak or a hairline crack. An acceptable examination for a gross breach is a visual examination that has the capability to determine the fuel pellet surface may be seen through the breached portion of the cladding. Alternatively, review of reactor operating records may provide evidence of the presence of heavy metal isotopes indicating that a fuel rod is grossly breached. (See discussion for size concerns.)

7. Intact SNF - Any fuel that can fulfill all fuel-specific and system-related functions, and that is not breached. Note that all intact SNF is undamaged, but not all undamaged fuel is intact, since under most situations, breached spent fuel rods that are not grossly breached will be considered undamaged.

8. Can for Damaged Fuel - A metal enclosure that is sized to confine one damaged spent fuel assembly. A fuel can for damaged spent fuel with damaged spent-fuel assembly contents must satisfy fuel-specific and system-related functions for undamaged SNF required by the applicable regulations.

9. Assembly Defect - Any change in the physical as-built condition of the assembly with the exception of normal in-reactor changes such as elongation from irradiation growth or assembly bow. Examples of assembly defects: (a) missing rods; (b) broken or missing grids or grid straps (spacers); and (c) missing or broken grid springs, etc. An assembly with a defect is damaged only if it can't meet its fuel-specific and system-related functions required by the applicable regulations.

Note: See Appendix for default definition of damaged SNF.

Background

Damaged Fuel

Previous definitions of damaged fuel have identified specific characteristics of the fuel that classify it as damaged, irrespective of whether the fuel is being stored or transported and independent of the design of the storage or transportation system. In this guidance, damaged fuel is defined in terms of the characteristics needed to perform the fuel-specific and system-related functions. Thus, the characteristics of damaged spent fuel may depend on (1) whether the fuel is being stored or transported, and (2) the design of the storage or transportation system.

The materials properties, and possibly the physical condition, of a fuel rod or assembly can be altered during irradiation, storage, or transportation. If this alteration is large enough to prevent the fuel or assembly from performing its fuel-specific or system-related functions during storage, transportation, or both then the fuel assembly is considered damaged.

To determine whether a fuel assembly is undamaged, the following should be delineated:

1) Whether the definition is applicable to storage, transportation or both;

2) The functions the applicant has imposed on the fuel rods and assembly by either fuel-specific or system-related functions to meet a regulatory requirement for the designated phase (storage, transportation, or both);

3) The mechanisms of change (alteration mechanisms) or the characteristics of the fuel that could potentially cause the fuel to fail to meet its fuel-specific or system-related functions;

4) An acceptable analysis showing that the fuel with the designated characteristics will meet the fuel-specific and system-related functions when the mechanisms considered in item #3, above, are evaluated; and

5) The physical characteristics of the fuel, based on item #4, above, that could cause the fuel or assembly to be classified as "damaged."

The "Discussion" section illustrates this methodology in the example.

Damaged SNF, as defined in this guidance, will only be approved for the activity (storage, transportation, or both) for which the application is being submitted. Note that the "default" definition of damaged SNF, derived from ANSI N14.33-2005, is provided in the appendix of this

guidance for those that do not want to perform the assessment outlined in item numbers 1 through 5 above [2]. The default definition, however, may not take full advantage of the flexibility of the performance-based definition of damaged fuel provided in this guidance. This default definition may be more restrictive than necessary, depending on the design of the storage or transportation cask. For example, the default definition of damaged SNF indicates that SNF must be classified as damaged if an individual fuel rod is missing from an assembly. However, if an analysis shows that all fuel-specific and system-related functions will be met (e.g., subcriticality will be maintained, that the SNF assembly will be retrievable and that the structural properties of the assembly are not compromised by the missing rod) the assembly may be classified as undamaged, per this ISG.

Discussion

The performance-based definition [3,4] of damaged SNF provided in this ISG minimizes the quantity of damaged fuel requiring alternative handling paths, while still addressing applicable system-related regulations concerning criticality control, thermal limitations, structural integrity, confinement, and shielding.

A. Grossly Breached SNF Cladding

The regulations in 10 CFR 72.122(h) state "The spent fuel cladding must be protected during storage against degradation that leads to gross ruptures or the fuel must be otherwise confined such that degradation of the fuel during storage will not pose operational safety problems with respect to its removal from storage." However, there is no such requirement in 10 CFR 71. Hence, grossly breached fuel is always considered damaged for storage, but may, or may not, be considered damaged for the purposes of transportation depending on whether other regulations, such as criticality, can be met.

In dry cask storage and transportation systems, a gross cladding breach should be considered as any cladding breach that could lead to the release of fuel particulate greater than the average size fuel fragment. A pellet is ~1.1 centimeters in diameter in 15 x 15 Pressurized-Water Reactor (PWR) assemblies. Pellets from a Boiling-Water Reactor (BWR) are somewhat larger, and those from 17 x 17 PWR assemblies are somewhat smaller. The pellet's length is slightly longer than its diameter. During the first cycle of irradiation in-reactor, the pellet fragments into 25-35 smaller interlocked pieces, plus a small amount of finer powder, due to, pellet-to-pellet abrasion. When the rod breaches, about 0.1 gram of this fine powder may be carried out of the fuel rod at the breach site [5]. Modeling the fragments as either spherical- or pie-shaped pieces indicates that a cladding-crack width of at least 2-3 millimeters would be required to release a fragment. Hence, gross breaches should be considered to be any cladding breach greater than 1 millimeter.

A review of reactor operating records, ultrasonic testing, and sipping (if done in a timely fashion) can be used to classify rods as unbreached or, breached. Evidence of only gaseous or volatile decay products (no heavy metals) in the reactor coolant system is accepted as evidence that a cladding breach is no larger than a pinhole leak or hairline crack. Records that show the presence of heavy metal isotopes that are characteristic of fuel release in the reactor coolant system indicate gross breaches in the cladding. Likewise, visual examination may also be used to determine if a cladding breach is gross, if the breached rod can be positively identified.

Because cladding openings larger than 1 millimeter should expose the fuel pellet to visual sighting, visual examination of the breached rod can be used to determine if a breach is gross. However, visual examination is not an acceptable method of confirming intact (undamaged) fuel for assemblies that have indicated leakage.

It should be noted; however, that undamaged spent-fuel rods with pinhole leaks and/or hairline cracks will expose the fuel pellets to the canister or cask atmosphere. If that atmosphere is oxidizing, then the fuel pellet may oxidize and expand, placing stress on the cladding. The expansion may eventually cause a large split in the cladding, resulting in spent fuel that must be classified as damaged (for storage and possibly also for transportation) due to gross breaches in the cladding. Since fuel oxidation and cladding splitting follow Arrhenius time-at-temperature behavior, fuel rods with pinholes or hairline cracks that are exposed to an oxidizing atmosphere may experience this type of additional cladding damage. ISG-22 “Potential Rod Splitting Due to Exposure to an Oxidizing Atmosphere During Short-Term Cask Loading Operations in LWR or other Uranium Oxide Based Fuels” [6] provides information regarding prevention of this phenomenon. Before handling undamaged rods with pinhole leaks and/or hairline cracks in an oxidizing atmosphere, the potential fuel and cladding degradation at the temperature of interest for the duration of the process should be assessed.

B. Fuel Assembly with Defects

Damage under this guidance refers to alterations of the fuel assembly that prevent it from fulfilling its fuel-specific or system-related functions. Defects such as dents in rods, bent or missing structural members, small cracks in structural members, missing rods, etc., need not be considered damaged if the applicant can show that the fuel assembly with these defects still fulfils its fuel-specific and system-related functions. This may be done using calculations based on approved codes, situation-specific data, or reasoned engineering arguments.

C. Canning Damaged Fuel

Spent fuel that has been classified as damaged for storage must be placed in a can designed for damaged fuel, or in an acceptable alternative. The purpose of a can designed for damaged fuel is to (1) confine gross fuel particles, debris, or damaged assemblies to a known volume within the cask; (2) to demonstrate that compliance with the criticality, shielding, thermal, and structural requirements are met; and (3) permit normal handling and retrieval from the cask. The can designed for damaged fuel may need to contain neutron-absorbing materials, if results of the criticality safety analysis depend on the neutron absorber to meet the requirements of 10 CFR 72.124(a).

D. Relationship of Spent Fuel Populations

The applicant will designate the population of spent fuel for which the cask system was designed (e.g., type of fuel, minimum cooling time, burnup limitations, arrays, manufacturers, cladding types, etc.) This population may contain breached rods. Some of these breached rods may be grossly breached. It may also contain assemblies with defects, such as missing rods, missing grid spacers, or damaged spacers. The populations of breached rods, grossly breached rods, and assemblies with defects are determined by in-reactor behavior and ex-reactor handling.

Each of these populations must be classified as damaged or undamaged after the storage or transportation system has been designated. For example, an applicant might propose the use of air as a cover gas in its design of a storage cask. The applicant might also propose this cask for use in storing spent fuel with cladding breaches that are hairline cracks or pinhole leaks. However, if the spent fuel in the cask will operate at a sufficiently high temperature for a long enough time, then oxidation of fuel pellets in breached rods could occur resulting in gross breaches. If this is the case, the breached spent fuel should be considered damaged because grossly breached rods do not meet the requirements of 10 CFR 72.122(h)(1). Also, in this case because the geometric form of the package contents could be substantially altered, the spent fuel would also be classified as damaged for transportation because the requirements of 10 CFR 71.55(d)(2) might not be met. If an inert atmosphere was used instead of air, only grossly breached rods would be considered damaged for storage. This concept is illustrated in Figure 1, "Relationship of Spent Fuel Populations."

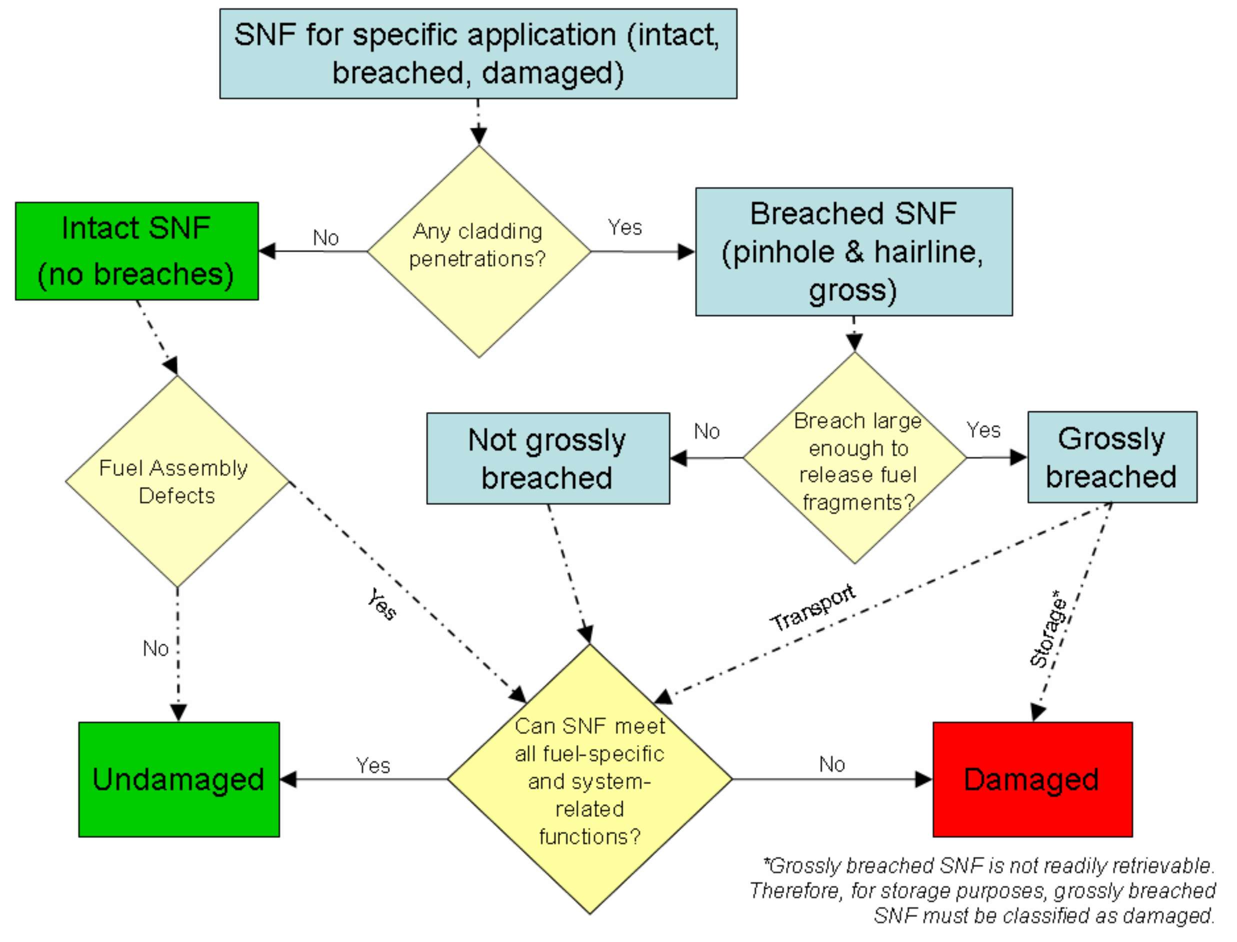

Figure 1 - Relationship of Spent Fuel Populations

E. Example of Methodology

The following example is given to illustrate the general methodology adopted in this ISG. This is only an example of the methodology and should not be construed as approved characterization of damaged fuel.

Example:

Situation - The vendor of a dual-purpose cask wants to store and transport low-burnup PWR fuel in an inert atmosphere and within the temperature limits recommended in ISG-11, Revision 3, “Cladding Considerations for the Transportation and Storage of Spent Fuel” [7]. The vendor wants to store assemblies having rods with breaches containing only pinholes or hairline cracks, and assemblies having one or more outer grid straps with defects at three or more grid locations without canning them. The vendor is only applying for a storage license at this time but wants to be reasonably certain that the fuel will also be transportable.

Activity - Storage and transportation

Fuel-specific or system-related functions imposed on rods and assemblies - 10 CFR 72.122(h)(1), regarding gross ruptures, and 10 CFR 72.122(l), concerning retrievability, must be met for storage. 10 CFR 71.55(d), requiring the system to remain subcritical and unchanged during normal transport, must be met. The vendor believes that all the remaining system requirements, except for the subcriticality requirement, can be met, without imposing any limitations on the fuel, if the fuel is within the bounds stated in the situation.

Mechanisms - There are no mechanisms for the pinhole leaks and hairline cracks to evolve into gross breaches since the atmosphere is inert and the temperature is controlled. To be retrievable, the assemblies with missing grid straps must be able to withstand design basis events in a storage cask. Since the applicant also wants these assemblies to be considered undamaged for transportation, the behavior of the assemblies under both normal and hypothetical accident transportation conditions in 10 CFR 71 must be evaluated. For example, for normal transportation conditions, the applicant must show that the assemblies with the most missing grid straps in the worst locations can withstand both normal vibration and a one-foot drop and remain in their original physical configuration. Additionally, for hypothetical accident conditions, the analysis must indicate, among other things, that the system will meet shielding and subcriticality requirements when placed under the mechanical and thermal loads specified in 10 CFR 71.

Analysis - The applicant conducts an analysis to satisfactorily demonstrate that the assembly with three missing grid straps in the worst configuration remains intact for 1) normal transportation conditions; 2) cask tip-over; and 3) regulatory accident conditions. Further acceptable analysis indicates that all the system-related regulations are met, if the fuel with the characteristic limitations (as noted in Characteristics section below), stays structurally intact.

Characteristics - Assemblies containing breached rods with up to three grid straps missing will be considered undamaged for the purposes of storage. Analysis shows that these assemblies could probably also be considered undamaged for transportation, but fuel with these characteristics will be evaluated and approved as part of a later application for the transportation cask certification.

Records

Records documenting the classification of spent fuel shall comply with the provisions of 10 CFR 72.174, “Quality Assurance Records”; 10 CFR 72.72, “Material Balance, Inventory, and Records Requirements for Stored Material”; 10 CFR 71.91, “Records”; and 10 CFR 71.135, “Quality Assurance Records.” Inspection records will be maintained for the lifetime of the container.

Quality Assurance

Activities related to inspection, evaluation, and documentation of damaged spent fuel for dry storage shall be performed in accordance with a quality assurance program, as required in 10 CFR Part 72, Subpart G, “Quality Assurance.” Activities related to inspection, evaluation, and documentation of damaged spent fuel for transport shall be performed in accordance with a quality assurance program, as required in 10 CFR Part 71, Subpart H, “Quality Assurance.”

Recommendations

The staff recommends that: (1) the definitions in NUREG-1536, NUREG-1567, NUREG-1617, ISG-8, Revision 2 and ISG-11, Revision 3 be revised to incorporate the definitions listed above; and (2) the appropriate chapters of each NUREG be revised to include the discussion section of this ISG.

In addition, the suggestion in NUREG-1617 (canning damaged fuel is necessary for the purposes of transportation) should be modified to be consistent with this ISG, nothing that canning damaged fuel may, in some cases, be necessary to meet the requirements of 10 CFR Part 71.

The words “intact fuel,” in the Applicability section of Revision 2 of ISG-8, “Burnup Credit in the Criticality Safety Analyses of PWR Spent Fuel in Transport and Storage Casks,” should be replaced with “undamaged fuel.” “Intact commercial spent fuel" in the last paragraph of the “Issue” section of Revision 3 of ISG-11, “Cladding Considerations for the Transportation and Storage of Spent Fuel,” should read “undamaged commercial spent fuel.” The first sentence of the Issue Section of ISG-22 should be modified to be consistent with the current definitions. “Rev 1,” should be changed to “Rev 2,” with the new title to ISG-1 Rev 2 and “intact fuel” should be changed to “unbreached fuel.”

APPENDIX

Default Definition of Damaged Fuel[2]

"Default" definition of damaged Spent Nuclear Fuel (SNF) - SNF assemblies must be classified as damaged, for both dry storage and/or transportation purposes, if any one of the following conditions exist:

On removal of SNF selected for dry storage or transport from the spent fuel pool, any of the following apply:

1. There is visible deformation of the rods in the SNF assembly. Note: This is not referring to the uniform bowing that occurs in the reactor. This refers to bowing that significantly opens up the lattice spacing.

2. Individual fuel rods are missing from the assembly. Note: The assembly may be reclassified as intact if a dummy rod that displaces a volume equal to, or greater than, the original fuel rod, is placed in the empty rod location.

3. The SNF assembly has missing, displaced, or damaged structural components such that either:

    3.1 Radiological and/or criticality safety is adversely affected (e.g., significantly changed rod pitch).

    3.2 The assembly cannot be handled by normal means (i.e., crane and grapple).

4. Reactor operating records (or other records) indicate that the SNF assembly contains fuel rods with gross breaches.

5. The SNF assembly is no longer in the form of an intact fuel bundle (e.g., consists of, or contains, debris such, as loose fuel pellets or rod segments).
