

DAVIS-BESSE NUCLEAR POWER STATION UNIT NO. 1

SECTION 4.0

APPENDIX 4, SECTION III.G. EVALUATION

and

FIRE HAZARD EVALUATION

4.0 APPENDIX R, SECTION III.G EVALUATION

4.1 Introduction

The purpose of this section is to evaluate the fire protection features that assure Safe Shutdown capability as required by Section III.G of Appendix R to 10 CFR 50. The components and circuits required for Safe Shutdown were identified by the methodology described in Section 3.

Section 5 provides a discussion of the identification and routing information for Associated Circuits. The circuit routing information for Safe Shutdown Circuits and Associated Circuits was sorted by fire area (Refer to Appendices B-2 and C-2, respectively). This made possible the evaluation of Safe Shutdown System components and circuits, as well as Associated Circuits, to the requirements of Section III.G criteria.

The following aspects of the existing plant configuration were considered during the evaluations of each of the fire area's compliance with Section III.G:

- 1) the barriers rated from 1 to 3-hours,
- 2) the fire suppression systems,
- 3) the fire detection systems,
- 4) the combustible loading and
- 5) the safe shutdown systems,

This information is provided for each fire area in Section 4.6 when credit is taken for barriers in addition to those defining the fire area. Specific items not in compliance with Section III.G, as well as their resolutions, are identified.

4.2 Requirements

The requirements for fire protection of Safe Shutdown capability is defined in Appendix R, Section III.G. This regulation requires that fire protection be provided to ensure that one train of equipment necessary to achieve and maintain Safe Shutdown remains available in the event of a fire at any location within the plant. For Hot Standby conditions, one train of the necessary systems must be free of fire damage (III.G.1.a). For Cold Shutdown conditions, both trains of equipment necessary to achieve and maintain Cold Shutdown conditions may be damaged by a single fire, including an exposure fire, but damage must be limited so that at least one train can be repaired within 72-hours using "in place" procedures and materials available onsite (III.G.1.b).

Section III.G.2 lists specific options to provide adequate protection for redundant trains of Safe Shutdown equipment. For any fire area outside of primary Containment, the options are as follows:

- a. Separation by a fire barrier having a 3-hour rating (III.G.2.a), or
- b. Separation by a horizontal distance of at least 20 feet with no intervening combustibles and with fire detection and automatic fire suppression installed in the fire area (III.G.2.b), or
- c. Enclosure of one train in a fire barrier having a 1-hour rating in addition to having fire detection and automatic suppression installed in the fire area (III.G.2.c).

Davis-Besse Unit 1 Fire Hazard Analysis Report

For a noninerted Primary Containment, Section III.G.2 specifies one of the above three protection options, or any of the following:

- a. Separation by a horizontal distance of at least 20 feet with no intervening combustibles or fire hazards (III.G.2.d).
- b. Fire detection and automatic fire suppression installed in the fire area (III.G.7.e).
- c. Separation of redundant trains by a noncombustible radiant energy shield (III.G.2.f).

If the protection required by Section III.G.2 is not provided or the systems of concern are subject to damage from fire suppression activities, Section III.G.3 of the rule requires that an alternate or dedicated Shutdown capability be provided which is independent of the area of concern. Appendix R Section III.L dictates the requirements for such cases.

For situations in which fire protection does not meet the requirements of Section III.G, plant modifications or plant procedural changes must be made to achieve compliance. However, if existing protection is deemed to be adequate for the specific situation, the rule allows the licensee to request an exemption on a case-by-case basis. Such exemption requests must be submitted to the NRC for review and approval and must be justified by the licensee on a technical basis. Generic Letter 86-10 provides additional guidance on which deviations require such an exemption and which others can be justified in a licensee evaluation without prior NRC approval.

4.3 Assumptions

In the course of performing the Section III.G separation analysis, several positions or assumptions needed to be established, as follows:

1. The availability of component status indication need not be assured. Each indicating circuit is, however, to be assessed for potential impact on the ability of the components to perform its function.
2. Passive mechanical components are assumed to remain available after a fire. these components include heat exchangers, manual, relief and check valves, piping and tanks.
3. NFPA Handbook has been utilized as guidance in determining that 80,000 Btu/ft² of Class A combustibles constitutes a 1-hour fire loading.
4. Components that have been determined not to be required for Safe Shutdown (i.e. not required to be operable or not a spurious actuation concern for Appendix R considerations), and hence, are not included on the SSCL (Appendix A), are not to be addressed for consequences of fire-induced failures.
5. Cables located in conduit embedded in concrete walls, floors and ceilings are to be considered as part of the fire area. Credit is taken for separation where adequate protection is provided by the concrete enclosing the conduit (Reference Section 1, Table 1, exemption 11).

6. A fire is the total heat energy which can be released based on the combustible loading.
7. Only one fire and its effects are postulated to occur at a time and the fire will not propagate past the rated barriers. However, credit is taken for horizontal separation within a fire area based on the combustible loading, the spatial separation, the type of suppression and physical barriers.

4.4 Evaluation Methodology

The Safe Shutdown and Associated Circuits were routed on the plant Electrical Raceways and Grounding Drawings (Reference 2.1.G) to identify in which fire areas the circuits are located. the specific details of this task are described in Section 3.8.

Where separation within a fire area was a concern, the Safe Shutdown Circuits and Associated Circuits were identified, where required, by color coding the corresponding conduits/cable trays. These marked-up physical drawings were used to support the separation evaluation described below.

Fire protection features information was derived from the FHAR and Fire Protection Drawings (A-220F through A-231F, Reference 2.1.D), and Fire Protection System Sprinkler Drawings (M-269 series, Reference 2.1.L) and the Barrier Function List (C-1594 Reference 2.1.R).

With the amount of separation, types and quantities of combustibles, and the existence (if any) of detection and suppression in the area identified, a method of compliance with Appendix R, Section III.G criteria was developed. Any required physical or procedural changes are identified in Section 4.6.

4.5 Methods of Achieving Compliance

The results of the detailed separation analyses described in the preceding sections indicate:

1. The fire areas which meet the criteria of Appendix R, Section III.G,
2. The fire areas requiring procedural revisions or physical modifications to meet the criteria, and
3. The fire areas that incorporate equivalent protection and for which exemptions are requested.

4.6 Fire Area Evaluations

The evaluation of each fire area is presented in this subsection. Each fire area evaluation includes the basis for the conclusions of compliance, and a summary of the approved exemption request(s).

Each of the fire area evaluations included in this subsection were developed using a standard format as follows (note that the “-“ refers to the Fire Area designation):

Davis-Besse Unit 1 Fire Hazard Analysis Report

Note: Room descriptions shown are nominal. Variations of the room descriptions may exist and be shown on various documents, however, the design functions of these rooms have not changed.

- 4.6._.1 Fire Area Description - This subsection provides an overview of the room numbers and descriptions that comprise the fire area in addition to the fire protection features.

The purpose of this subsection is to provide the above information at a glance. For detailed information relating to the fire area boundaries, the fire protection systems, and the combustible loading are contained in other portions of Section 4 of this report.

- 4.6._.2 Safe Shutdown Systems in the Fire Area - This subsection provides an overview of the Shutdown Systems and components located in the fire area. The component Train, type and description are also provided. (Note: Appendices B2 and C2 provide a listing of cables/circuits).

The purpose of this subsection is to provide at a glance information as to which Safe Shutdown Systems and components could be impacted by a fire in this fire area

- 4.6._.3 Fire Propagation Control - This subsection provides an overview of the means of ensuring that a fire originating in the fire area does not spread to an adjoining fire area. The fire barriers, fire doors, and any openings located in the fire area are identified. Any analyses of non-rated openings and of combustible loading restrictions are identified.

- 4.6._.4 Fire Detection and Suppression - This subsection provides an overview of the fire detection and suppression features located in the fire area.

- 4.6._.5 Fire Area Safe Shutdown Summary - The summary specifies which Train is being assured for Shutdown, the availability of certain critical Safe Shutdown components required operable for providing RCS pressure and Pressurizer Level Control and for maintaining Hot Standby are identified for a fire in the particular fire area.

- 4.6._.6 Detailed Analysis For Safe Shutdown - This information is presented in tabular form (Table 1). All circuits and components for the accredited Train, as well as the disposition of each, are identified. It provides information concerning each circuit with regard to an abbreviated justification for compliance. The table also references the notes that explain the justification.

Certain Safe Shutdown components serve as either Train 1 or Train 2 components depending on which train the component is supporting. For example, CCW Pump 3 is a "swing" pump in that it may either service Train 1 or Train 2 of the CCWS.

All such components are designated as "1/2" components. These "swing" components may have Channels 1, 2 and 3 circuits. If Train 1 was being assured for Shutdown and circuits for such a component passed through the fire area under consideration, only the channel 1 and 3

Davis-Besse Unit 1 Fire Hazard Analysis Report

circuits would appear on Table 1. Channel 2 circuits would not appear since no credit is taken for these circuits. In a Train 2 area the reverse will apply.

Certain Safe Shutdown components are identified as “boundary valves” and/or “High/Low Interfaces” which means that the valve is required to remain closed to preclude flow diversion. Such components need to be evaluated for all fire areas where circuits for the component are located regardless of the Train being assured for Shutdown. As an example, the Pilot-Operated Relief Valve (PORV), despite having Train 2 circuits, must be addressed for all fire areas so that the possible spurious actuation of the valve does not result in a loss of RCS pressure or inventory control.

Certain Safe Shutdown components for the nonaccredited Train are included because their potential automatic actuation from spurious or actual signals (e.g. SFAS or SFRCS) may require compensatory operator action. For these components, any circuits located in the fire area are included regardless of their Train.

Table 1 provides component specific information as follows:

Column

1. System - Safe Shutdown System (e.g. HPIS, RCS, etc.)
2. Component - Plant I.D. Number (e.g. SW1382)
3. Description - Describes the component
4. Type - Nature of component (e.g. SOV, PUMP, MOV, etc.)
5. Comp Loc (Component Location) - Fire area in which the component is physically located.
6. TRN - Specifies the component's Train. Components identified as “1/2” are special components such as High/Low Interface valves as discussed above.
7. Normal Mode - Specifies the position of the component during normal plant operation.
8. Shutdown Mode - Specifies the desired position of the component if the component were to be utilized for Shutdown. It does not necessarily state what the position will be for a fire in a particular fire area. For example, the shutdown mode of the SW Pumps 1, 2, and 3 is “on” since that is their desired operational mode if credit was taken for the individual pump. However, in actuality, only one of the pumps would be operated for Shutdown while the other two would be off.
9. Fail - Identifies the position to which the component fails on loss of power.
10. Backup for - Specifies if the component under consideration is a backup for another component which would be identified in this column.
11. Compon Info (Component Information) - This column receives single and double letter designators which reference the legend on the bottom of the page. Hence,

Davis-Besse Unit 1 Fire Hazard Analysis Report

letters H, for example, indicate that the component is required for Hot Standby (H).

12. Circuit - Circuit(s)/Subcomponents of concern in the fire area.
13. Interlock - Identifies various circuit interlocks.
14. Required Change - Identifies many of the physical or procedural changes that were required to achieve compliance with Appendix R.
15. Justification - Provides an abbreviated description of the justification that appendix R requirements are met in spite of failure of the circuit. The full justification is contained in the Notes referenced for each affected circuit.
16. Notes - These Notes provide the justification for concluding that Appendix R requirements are met in spite of failure of the circuit.

FIRE AREA A

4.6.A.3 Fire Propagation Control

Fire Area A is located in the Auxiliary Building consisting primarily of the eastern half of the first 4 levels (545', 555', 565', 585') of the Aux Bldg and the eastern half of the Containment Annulus, as shown on drawings A-221 F through A-223F. The area includes numerous rooms, pipe/cable chases and ventilation openings which prevent further subdivision by 3-hour fire-rated barriers. The major openings are discussed below.

There is a 4 ft. x 4 ft. Pipe Chase opening located between Room 314 and Room 115 which runs through the floor and ceiling of Room 236. This opening is required as a flow path for the EVS. Fire suppression systems have been installed in Rooms 314 and 236.

Room 236 is located on Elevation 565'-0" of the Auxiliary Building. There is an opening in the north wall allowing access to the Annulus. A wire door is located in the opening, which is approximately 4 ft. wide x 7 ft. high. The opening is used as a flow path for the EVS.

There is an opening in the west wall of Room 314 allowing access to the Annulus. A wire door is located in the opening, which is approximately 4 ft. wide x 7 ft. high. The opening is used as a flow path for the EVS.

Room 102 has an opening 23" x 8" in size in the north wall 44 that FD-1101 is in. Due to high-rad areas and inaccessibility the damper cannot be inspected or reworked, therefore it is a non-rated opening.

A fire that originates in this fire area will be contained within the fire area. This fire area is enclosed by 3-hour rated concrete walls (except as noted below).

In order to preclude any direct flame/fire communication between ECCS Pump Room 105 (Fire Area AB) and ECCS Pump Room 115 (Fire Area A) through an opening into Room 113A (Fire Area AB), a 3-hour fire-rated door assembly (Door 119A) was installed to protect the opening. Fire Door 119A is held open, in order to accommodate HVAC considerations, by an electromagnetic door holder/closer. Upon actuation of the smoke detection system in either ECCS Pump Room (115 or 105) or Room 113A (located between Rooms 105 and 115), the electromagnetic door holder de-energizes, releasing the door allowing the mechanical door closer to bring the door to a closed position.

In order to preclude any direct flame/fire/smoke communication between the Corridor Room 110 (Fire Area A) and Elevator Machine Room 118 (Fire Area AD) through an opening, a 1-1/2-hour fire-rated door assembly (Door 103) was installed to protect the opening. Fire Door 103 is held open, in order to accommodate tornado depressurization vent considerations, by an electromagnetic door holder/closer. Upon actuation of the smoke detection system in either the Corridor (110) or the Elevator Machine Room (118), the electromagnetic door holder de-energizes, releasing the door allowing the mechanical door closer to bring the door to a closed position.

The Annulus (Rm 127) is divided in half. One half is in Fire Area A, the other in Fire Area AB. There are no fire barriers separating the 2 halves, but, based on the low combustible loading in

FIRE AREA A

the Annulus and the large spatial separation between the combustibles, a fire would not propagate from one half of the Annulus to the other half.

The Annulus is separated from Containment by the steel pressure vessel. Based on the construction and low combustible loading, a fire will not propagate from the Annulus to Containment.

The ceiling of Room 102 contains a non-rated concrete plug between it and Room 300 (Fire Area V). This plug will prevent the spread of a fire from one area to the other.

The west wall of Room 124 contains one non-rated opening. To preclude any direct flame/fire communication with Room 235 (Fire Area G), an automatically actuated water curtain is installed.

The north wall of Room 124 contains two 14 inch pipe penetrations which interface with Auxiliary Feed Pump Rooms 237 (Fire Area E) and 238 (Fire Area F). These penetrations are required in order to avert the consequences of a flooding condition in the Auxiliary Feed Pump Rooms (AFPR's). The lines are open ended in Rooms 237 and 238, extend into Clean Waste Receiver Tank (CWRT) Room 124 and terminate in 14 inch diameter, wafer-style check valves. As shown - on Drawing A-222F, the north wall of CWRT Room 124 is a 3-hour fire rated barrier separating Fire Area A from Fire Areas E and F. The lines are provided to preclude flooding of the AFPR's and subsequent loss of the Auxiliary Feed Pump(s).

The ceiling of Room 110A contains one non-rated opening communicating Area A to Area G. This is a ventilation opening and a hatch area. The ventilation opening is protected by a fire damper and the hatch area is protected by Dura Steel.

There is a 3-hour fire-rated wall separating Rooms 115 and 116 from Rooms 123 and 124 (all within Fire Area A). This wall is used to help separate Train 1 circuits from Train 2 circuits. (See Section 4.6.A.5 for more detail).

The south wall of Room 236 contains one non-rated opening which communicates with Room 235 (Fire Area G). To preclude any direct flame/fire communication with Room 235, an automatically actuated water curtain is installed.

The No. 4 Mechanical Penetration Room (314) is located on Elevation 585'-0" of the Auxiliary Building. There are five non-rated openings in the ceiling of 314. The physical size of the non-rated openings are four 30 in. x 20 in. ducts and one 48 in. diameter duct and are located in the ceiling of Room 314 which communicate Fire Area A with Fire Area DF. Since both fire areas contain fire suppression systems, a fire will not propagate from one area to another.

The east wall of room 314 contains six non-rated openings which communicate with Room 326 (Fire Area II). To preclude any direct flame/fire communication with Room 326 an automatically actuated water curtain is installed.

There are several penetrations which have penetration seals that do not meet the test configurations or penetrations with small annular gaps (too small to seal properly). These non-rated openings have been evaluated and will not allow the propagation of a fire to another fire area.

FIRE AREA A

Rooms 110, 112, 110A have structural steel which does not have a 3-hr fire rating. A detailed analysis shows that the steel will not fail based on the combustible loading in these rooms.

Room 114 has structural steel which does not have a 3-hr fire rating. A detailed analysis shows that the steel will not fail based on the combustible loading in this room.

Rooms 123, 125 and 126 have structural steel which does not have a 3-hr fire rating. A detailed analysis shows that the steel will not fail based on the combustible loading in this room.

Rooms 124, 236 and 314 have structural steel which does not have a 3-hr fire rating. Based on analysis of the combustible loadings and automatic wet-pipe sprinklers in these rooms, the steel will not fail.

4.6.A.4 Fire Detection and Suppression

Fire Area A consists of various rooms and/or plant areas. The following areas have detection:

1. ECCS Pump Room 115, Fire Detection Zone FDZ 115
2. Misc. Waste Monitor Tank and Pump Room 114, Fire Detection Zone FDZ114.
3. Passage 110, Passage 110A, Decontamination Area 112 and Condensate Collection Tank and Pump Room 117A, Fire Detection Zone FDZ 110
4. Clean Waste Receiver Tank Room 124, Fire Detection Zone FDZ 124
5. Cable Chase, Fire Detection Zone FDZ 314
6. No. 2 Mechanical Penetration Room 236, Fire Detection Zone FDZ 236
7. No. 4 mechanical Penetration Room 314, Fire Detection Zone FDZ 314
8. Containment Annulus (East) Room 127E

The following rooms are provided with automatic wet-pipe sprinkler systems:

1. Clean Waste Receiver Tank Room 124
2. No. 2 Mechanical Penetration Room 236
3. No. 4 Mechanical Penetration Room 314

The following barrier penetrations are protected by automatic deluge spraywater curtains:

1. Opening between Room 124 and 235 (Fire Area G)
2. Opening between Room 236 and 235 (Fire Area G)
3. Opening between Room 314 and 326 (Fire Area II)

FIRE AREA A

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on drawings A-221F through A-231F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.A.5 Fire Area A Safe Shutdown Summary

Fire Area A utilizes both Trains for Safe Shutdown depending on the location of the fire. Train 2 is accredited for a fire located in all parts of Rooms 123 and 124 except for the northwest corner of Room 124 where Train 1 is accredited. Train 1 is also accredited for Safe Shutdown if the fire is located in all other rooms in fire A.

Train 1 Safe Shutdown will be accomplished by using HPI, and the PORV for initial depressurization. Train 2 Safe Shutdown will be accomplished by using the Makeup System.

An exemption has been granted for Rooms 123/124 to the extent Appendix R requires separation of redundant Safe Shutdown components by 3-hour rated fire barriers. Specifically, Train 1 circuits in Rooms 123 and 124 are not separated from Train 2 circuits in Room 115 by a complete 3-hour fire-rated barrier.

FIRE AREA A TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates that High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent upstream breakers from tripping on a ground. Additionally coordination for the following 480V AC MCC's is provided:

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA A TABLE 1 NOTES

9. NOT USED
10. An exemption is requested from the provisions of Appendix R Section III.G for not having complete enclosure by a 3-hour barrier. Train 1 cables run along the east wall of 124 into 123 in Cable Trays and the conduits they enter before going embedded in Room 123. Also, Conduits which run along the south wall of 124, the north wall of 123 and the east wall of 124 are separated from Train 2 Raceways (Cable Trays which are located in the northwest corner of Room 124 and the other rooms of Fire Area A) by over 20 ft. with negligible intervening combustibles.
11. MCC F11E may trip due to a lack of coordination in associated circuit breakers. The only Safe Shutdown equipment affected by loss of MCC F11E are HPI Pump 2 Recirc Valve (HP31) (not used) and LPI/HPI Crosstie Valve (DH63) (fail as-is). Safe Shutdown can be achieved in this fire area in spite of the loss of these components.
- MCC F11D may trip due to a lack of coordination in associated circuit breakers. The only Safe Shutdown equipment affected by loss of MCC F11D are CCW Return HDR 2 Valve (CC2649) and 125V DC Battery Charger (DBC2PN). CC2649 will be manually operated and DBC2PN is not required for Safe Shutdown.
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:
- | | |
|----------|----------|
| ICS11A/B | Throttle |
| WC1743 | Open |
| WC1747 | Open |

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action.

FIRE AREA A TABLE 1 NOTES

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. SFAS also provides a level signal for the AFWS level control but either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost.

Due to loss of power to Complimentary Channels, SFAS actuation could operate the following components:

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>

* Don't trip Breaker AC111 which stops P58-1 when shutting down using Train 1.

FIRE AREA A TABLE 1 NOTES

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

15. The AFW Pump Discharge Cross-Connect Valves AF3869, AF3871 are normally closed. These valves could spuriously open thereby diverting feedwater to the opposite non-accredited S/G. The AFW Pump capacities are sufficient for one pump to feed both S/G's. However, to avoid overfilling the idle S/G, close the cross-connect valves. Trip Breaker BE1146 at E11E and close AF3869 for Train 1 Shutdown. Trip Breaker BF1201 at F12A and close AF3871 for Train 2 Shutdown.
16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return Flow

The following manual valves will need to be operated:

MU97	Open	WC119	Open
MU182	Close	WC120	Open

Additionally, the following valves may need to be manually operated:

* See Note 13 for breaker to be tripped

RCS Inventory Control

For Train 1 Shutdown, HPIS Train 1 will be used. The following manual valves will need to be operated: (After 8-Hours)

MU208	Open	HP26	Open
-------	------	------	------

For Train 2 Shutdown, Makeup Train 2 will be used. The following manual valves will need to be operated to transfer MU Recirc to the BWST after aligning MU3971 to the BWST:

MU208	Open	HP1556	Open
HP29	Open	MU203	Closed (after other valves opened)

17. The AFWP flow Control Valves AF6451 and AF6452 are normally open and required to be throttled for Safe Shutdown. A review of the circuits indicates loss of control of these valves. Therefore: for Train 1, fail open AF6452 by depowering the valve at D1P Breaker D1P13 and use ICS038B for SG1 level control. For Train 2, fail open AF6451 by depowering the valve at D2P Breaker D2P13 and use ICS038A for SG2 level control.
18. The AFPT Main Steam Cross-Connect Valves MS106A and MS107A are normally open to provide a steam supply to the opposite train AFW Pump. Since either one of the S/G's could be without level indication and overfilling an S/G could result in damage to the AFW Turbines. If required, for Train 1 Shutdown, trip P14-2 and for Train 2 Shutdown, trip P14-1.
19. The AFPT Main Steam Inlet Valve is normally closed and is required to be open for Safe Shutdown. A review of the circuit in the fire area shows that a fire in this area could prevent the opening of MS106. Therefore, trip Breaker D135 at D1NA and open MS106.

FIRE AREA A TABLE 1 NOTES

20. The CCW Return Header Valves CC2645 and CC2649 are normally open and required to be open to provide cooling to the Seal Return Cooler. For Train 1, open Breaker BE1161 at E11D and open/verify open CC2645. For Train 2, open Breaker BF1161 at F11D open/verify open CC2645 (after 8-hours).
21. The DHR Cooler Isolation Valves CC1467 and CC1469 are normally closed. These valves fail open on loss of air. However, these valves are required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS Cooldown. Before opening CC43, verify CC1467 for Train 1 and CC1469 for Train 2 is closed. When entering DHRS Cooldown, open CC1467 or CC1469 after CC43 is closed.
22. The CCW to Nonessential Inlet Iso Valve CC1495 is normally open. Manual Bypass Valve CC43 will be opened. However, to preclude CCW Pump runout, CC43 has to be closed before CC1467 or CC1469 is open (CCW to DHRS Cooler for Cooldown).
23. One Train of the CCW Line Inlet and Return Isolation Valves CC5095, CC5096, CC5098 and CC5097 is normally open and required to be open to provide cooling for the Letdown Coolers. A review of the circuits indicates that spurious closure is possible. Trip Breakers BE1226 & BE1227 at E12A and open CC5095 and CC5097 for Train 1. Trip Breakers BF1106 & BF1119 at F11A and open CC5096 and CC5098 for Train 2.
24. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A, CF01B before going below 700 psig.
25. Circuit 1PBE1234A provides 480V AC power to MCC E12E which, in turn, supplies the ECCS Room Cooler Fans C31-4 and C31-5, MCC E12E also feeds the HPI Pump 1-1 AC Lube Oil Pump P197-1, the SG 1 Drain Valve MS611, and the HP1 Pump 1-1 Recirculation Line Isolation Valve HP32. Therefore, Circuit 1PBE1234A is to be protected with a 1-hour barrier to preclude the loss of power at MCC E12E.
26. PI-SP12B2 (SG 1-1 outlet pressure indication) does not remain available with power from the NNI-X Automatic Transfer Switch. The Essential Power cable for the normal supply, YBU, is routed outside the fire area; however, when the Train 2 batteries 2P and 2N deplete, YBU is lost and the alternate power source, YAR, is not available due to its non-essential supply. Therefore, no SG 1-1 pressure indication is available following a fire in Room 314, and an interim compensatory measure of an hourly fire watch in Room 314 is in place. Corrective Action 2013-02276-5 tracks the resolution of this issue with the lack of SG 1-1 pressure indication.
27. For a fire in Room 314, Train 1 HPIS flow transmitters and low level instrument cables to the Control Room may be lost, as well as Pressurizer level indication (see Note 35), use Reactor Coolant Pressure and Steam Generator 1 Level indication as an alternate indication for measuring injection flow. See CR 2016-03686 for additional information.
28. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.

FIRE AREA A TABLE 1 NOTES

29. DH Auxiliary Spray Stop Valve (DH2735) and Throttle Valve (DH2736) are normally closed, in series, valves, one of which needs to remain closed to prevent depressurization in DHR Cooldown. Since DH2735 is unaffected by a fire in this area, no action is required.
30. NOT USED
31. NOT USED
32. The Clean Waste Receiver Tanks (T15-1 & 2) are located in Rooms 123 and 124. Due to the low combustibles in these rooms and the automatic wet-pipe sprinkler system in Room 124; T15-1 & 2 will not be damaged by a fire in these rooms.
33. A hot short in Circuit ACV1453C could cause spurious opening of the Clean Waste Primary Demineralizer Inlet Valve (WC1453). Fail closed WC1453 by isolating it and bleeding off the air.
34. NOT USED
35. A fire in Room 314 could disable all Pressurizer level indicators except LRS-RC14 (Pressurizer Level Recorder). However, when the Train 2 batteries 2P and 2N deplete, YBU is lost and the alternate power source, YAR, is not available due to its non-essential supply. Therefore, no Pressurizer level indication is available following a fire in Room 314, and an interim compensatory measure of an hourly fire watch in Room 314 is in place. Corrective Action 2013-02276-5 tracks the resolution of this issue with the lack of Pressurizer level indication. See also Note 27.

The raceways for LRS-RC14 are in the Annulus and are wrapped with 3 hr. fire barrier.

36. TI-RC3B5 is a redundant means of monitoring the same variable (RCS Loop 1 Hot Leg Temperature) as TI-RC3B6. TI-RC3B5 is not affected by a fire in this area.
37. Service water is required to one containment air cooler for Safe Shutdown. The Inlet MOVs SW1366, 1367, and 1368 fail as-is. Outlet Valves SW1356, SW1357 and SW1358 fail open. A loss of air causing the AOV to fail open on the standby cooler could cause insufficient flow to the operating cooler. Spurious closure can occur for any or all of the valves if a fire occurs in Room 314; after the fire is extinguished cooling can be restored manually. Containment air cooling is not required for 2-hours. Procedures provide guidance for placing the Train 1 (or Train 2 for a fire in East side of Room 123 or 124) in service, including opening BE1142 for SW1366 (BF1223 for SW1367), verifying open SW1366 (SW1367) (SW331) then opening SW1356 (SW1357) and SW77 (SW81). In all cases CAC3 will be isolated by SW325 (SW331).
38. Loss of YE2 will cause loss of SFRCS Cabinet C5761A, (SFRCS may actuate; see Note 14).

Loss of YF2 will cause loss of SFRCS Cabinet (C5792A, (SFRCS may actuate; see Note 14).

FIRE AREA A TABLE 1 NOTES

39. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 will therefore be manually operated to place the DHR System in service.
40. NOT USED
41. NOT USED
42. NOT USED
43. Provides Essential CCW to the Makeup Pump Cooler, bypassing CC1460.
44. The Pilot-operated Relief Valve (PORV) RC2A is normally closed and required to operate to reduce pressure when shutting down on Train 1 with HPIS. The PORV is powered from Essential Train 2. The power supply from the Train 2 batteries are not in this area and the control cable (located in the Annulus) is protected with a radiant energy shield. The Train 2 batteries are available for 1-hour when shutting down on Train 1 which is adequate time to reduce RCS pressure below 1600 psig, HPIS can be used for Inventory Control. Therefore, reduce RCS pressure below 1600 psig using the PORV before the end of 1-hour.
45. RC3716 provides control power to the High Pressure Seal Return closing relays for CC4200 and CC4300. Since CC4200 and CC4300 are not required for Safe Shutdown in this area, control power is not required.
46. RCS Loop 1 High Point Vent Valves (RC4608A & B) are normally closed and are required to remain closed in order to prevent uncontrolled blowdown via the High Point Vents. Since these valves are in series and RC4608B is not affected, blowdown will not occur.
47. The Sample Valves RC239A/B and RC4632 or RC200 need to remain closed. A 3 hr. barrier is installed around the control cables for RC200, RC239 and RC239B. The only other way to have flow is to have a 3-phase hot short of the proper alignment on the power cables of one of the valves AND either a second 3-phase hot short of the proper alignment or a hot short of the proper polarity of a cable 3 penetrations away. This is not credible.
48. RCS Loop 2 High Point Vent Valves (RC4610A & B) are normally closed and are required to remain closed in order to prevent blowdown via the High Point Vents. The penetrations for RC4610A & B are approximately 8 ft. apart (P2P5FI & P2C5CI on Drawing E-362). Penetration P2C5CI contains one other cable. 2CV4632A (E56B/47B 125V DC) for the normally closed and de-energized Cold Leg Sample Valve RC4632. Penetration P2P5FI contains approximately 20 other cables; however, only one valve needs to remain closed for the High/Low Pressure Interface.

Spurious operations of both valves requires multiple hot shorts of the right polarity. This is incredible because there is not available power source for RC4610B. Also, the Makeup System is available and capable of maintaining RCS Inventory even if these valves did spuriously open.

FIRE AREA A TABLE 1 NOTES

49. SW Discharge Valves to the Intake Structure (SW2929) & Forebay (SW2931) are two of four SW Discharge Valves (SW2929 through SW2932), one of which is normally open and depowered (controlled administratively) to ensure SWS discharge at all times. The sole concern is that at least one of these valves remains open, thereby assuring a service water flow outlet. Since one of the valves is normally open and depowered, there is no concern associated with the possibility of spurious closure of SW2929 or SW2931 precluding SWS discharge capability.
50. The AFW Pump 1 Discharge to SG 1 Valve AF3870 is normally open and required to be open for Safe Shutdown. A review of the circuit indicates that this valve could spuriously close thereby stopping feedwater flow to SG 1. Therefore, trip Breaker D107 at D1PA and open AF3870.
51. The Decay Heat Removal (DHR) Suction 1 Valve DH1517 is closed during normal operations, but required to be open for DHR Cold Shutdown. A review of the circuits indicates loss of power to DH1517. (Note: If DH1517 spuriously opened, it would not affect Safe Shutdown). Therefore, manually open DH1517.
52. The Decay Heat Pump 1 BWST Suction Valve DH2733 is normally open and required to be closed prior to going into DHR Cooldown. A review of the circuit indicates loss of the valve's control circuit. Therefore, manually close DH2733 and trip Breaker BE1121 at MCC E11A.

Due to the torque/limit switches possibly being bypassed by a hot short, the valve operator may be damaged. If this occurs, procedures instruct plant personnel to remove the operator, replace it with a dedicated spare operator, and then manually close the valve. Since this valve is only needed to go to cold shutdown, GL 86-10 allows repairs to be made.

53. For each 4kV Safe Shutdown component, the ammeter/overcurrent protection cables and the power cables are evaluated to ensure that a fire cannot cause a loss of an entire Safe Shutdown Train (e.g. Essential Switchgear Bus C1 or D1) due to a power cable fault and a simultaneous loss of overcurrent protection on the same accredited scheme.

A trip of an individual load due to a hot short on an ammeter/protection circuit is also evaluated. Train 1 and 2 circuits are both routed in Fire Area A, but do not impact Safe Shutdown for the following reasons:

FIRE AREA AB

4.6.AB.3 Fire Propagation Control

Fire Area AB is located in the Auxiliary Building consisting primarily of the western half of the first 4 levels (545', 555', 565', 585') of the Aux Bldg and the western half of the Containment Annulus, as shown on drawings A-221F through A-223F. The area includes numerous rooms, pipe/cable chases and ventilation openings which prevent further subdivision by 3-hour fire-rated barriers. The major openings are discussed below.

There is an 8 ft. x 10 ft. Pipe Chase opening located between Room 303 and Room 105 which runs through the floor and ceiling of Room 208. This opening is used as a flow path for the Emergency Ventilation System (EVS). Fire suppression systems have been installed in Rooms 303 and 208.

The Room 208 is located on Elevation 565'-0" of the Auxiliary Building. There is an opening in the east wall allowing access to the Annulus. A wire door is located in the opening, which is approximately 4 ft. wide x 7 ft. high. The opening is used as a flow path for the EVS.

There is an opening in the north wall of 303 allowing access to the Annulus. A wire door is located in the opening, which is approximately 4 ft. wide x 7 ft. high. The opening is used as a flow path for the EVS.

A fire that originates in this fire area will be contained in the fire area. This fire area is enclosed by 3-hour rated concrete walls (except as noted below).

In order to preclude any direct flame/fire communication between ECCS Pump Room 105 (Fire Area AB) and ECCS Pump Room 115 (Fire Area A) through an opening into Room 113A (Fire Area AB), a 3-hour fire-rated door assembly (Door 119A) was installed to protect the opening. Fire Door 119A is held open, in order to accommodate HVAC considerations, by an electromagnetic door holder/closer. Upon actuation of the smoke detection system in either ECCS Pump Room (115 or 105) or Room 113A (located between Rooms 105 and 115), the electromagnetic door holder de-energizes, releasing the door allowing the mechanical door closer to bring the door to a closed position.

The Annulus (Rm 127) is divided in half. One half is in Fire Area A, the other in Fire Area AB. There are no fire barriers separating the two halves, but, based on the low combustible loading in the Annulus and the large spatial separation between the combustibles in one half to the other half, a fire would not propagate from one half of the Annulus to the other half.

The Annulus is separated from Containment by the steel pressure vessel. Based on the construction and low combustible loading, a fire will not propagate from the Annulus to Containment.

There is an HVAC duct which penetrates the wall between Room 105 and Stairwell AB3. The penetration does not contain a fire damper due to the physical impossibility of installation. Room 105 and Stairwell AB3 are both in Fire Area AB. Due to the construction of the Ductwork and the low combustible loading in the area, a fire will not propagate from Room 105 to AB3.

There is an equipment removal hatch in the ceiling of Room 113A to Room 227 (Fire Area G). Based on the construction and the low combustible loading, a fire will not propagate from one area to the other.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA AB

There are several penetrations which have penetration seals that do not meet the test configurations or penetrations with small annular gaps (too small to seal properly). These nonrated openings have been evaluated and will not allow the propagation of a fire.

Rooms 113 and 113A have structural steel which does not have a 3-hr fire rating. A detailed analysis shows that the steel will not fail based on the combustible loading in these rooms.

Room 105 has structural steel which does not have a 3-hour fire rating. A detailed analysis shows that only the columns would fail in a fire in Room 105. The bottom 15 ft of the columns will be protected with 3-hour fire-proofing. Rooms 202, 208 and 303 have structural steel which does not have a 3-hr fire rating. Based on analysis of the combustible loadings and automatic wet-pipe sprinklers in these rooms, the steel will not fail.

5.6.AB.4 Fire Detection and Suppression

Fire Area AB consists of various rooms and/or plant areas. The following areas have detection:

1. ECCS Pump Room 105, Fire Detection Zone FDZ 105
2. Decay Heat Cooler Room 113, Fire Detection Zone FDZ 113
3. Hatch Area Room 113A, Fire Detection Zone FDZ 113
4. Pipeway Area Room 202, Fire Detection Zone FDZ 208
5. No. 1 Mechanical Penetration Room 208, Fire Detection Zone, FDZ 208.
6. No. 3 Mechanical Penetration Room 303, Fire Detection Zone, FDZ 303.
7. Annulus Space (West) Room 127W
8. Makeup Pump Room 225

The following rooms are provided with automatic wet-pipe sprinkler systems:

1. No. 1 Mechanical Penetration Room 208
2. No. 3 Mechanical Penetration Room 303
3. Pipeway Area Room 202

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawings A-221F through A-231F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

FIRE AREA AB

4.6.AB.5 Fire Area Safe Shutdown Summary

Train 2 will be used for Safe Shutdown in Fire Area AB. Safe Shutdown will be accomplished using the High Pressure Injection System (HPIS) along with the Pressurizer Vent Path (RC200 and RC239A) for Reactor Coolant System Inventory Control, the Makeup and Purification System (MUPS) for a Letdown path and HPIS Seal Injection for RCP Seal Cooling. The RCP seals will be restaged using flow through the RCP Seal Return line.

Detailed Analysis

SAFE SHUTDOWN ANALYSIS

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA AB

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA AB

9. NOT USED
10. An evaluation has shown that ECCS Pump Room Cooler Fans C31-1 through -5 are not required for SSD. An exemption is no longer required from the provisions of Appendix R III.G.3 to have full area suppression where credit is taken for an Alternate Shutdown capability. (Use of portable ventilation for ECCS Pump Room 115 is not required.)
11. MCC F11E may trip due to a lack of coordination in associated circuit breakers. The only Safe Shutdown equipment affected by loss of MCC F11E are HPI Pump 2 Recirc Valve (HP31) and LPI/HPI Crosstie Valve (DH63). Safe Shutdown can be achieved in this fire area in spite of the loss of power to these components. HP31 is normally open, fails as-is and is required open for Shutdown. DH63 will be manually closed.
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:
- | | |
|--------|----------|
| ICS11A | Throttle |
| WC1743 | Open |
| WC1747 | Open |

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level set-point is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication. (See Note 12).

Due to lose of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531	CS Iso Vlv	Open	Stop P56-1, -2

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

15. NOT USED
16. RCP Seal integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA AB

RCP Seal Return Flow. The following manual valves will need to be operated:

MU97	Open	WC119	Open
MU182	Close	WC120	Open

RCP Seal Injection from the HPI System with RCS Letdown via the Makeup System. The following valves may need to be manually operated:

HP27	Open	MU11	Align to CWRT
MU02B	Open MU02B & Trip BE1172 at E11B	MU208	Open
MU04	Open MU04 & Trip BE2259 at E22B	MU214	Close
MU10A	Open	MU216	Throttle

17. NOT USED
18. To prevent spurious operation, Valves DH09A, DH9B, DH7A, and DH7B have been depowered.
19. NOT USED
20. NOT USED
21. MCC F11D may trip due to a lack of coordination in associated circuit breakers. The only Safe Shutdown equipment affected by loss of MCC F11D are Backup Battery Charger (DBC2PN) and CCW Return Header 2 Valve (CC2649). Safe Shutdown can be achieved in this fire area in spite of the loss of these components.
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01B before going below 700 psig.
23. NOT USED
24. CCW is provided to the Makeup Pump Cooler, by passing CC1460.
25. Although DH12 is a High/Low Interface component, Valve DH11 is in series and has no circuits that pass through this fire area. Failure of these circuits could result in the inability to open DH12 as required to initiate Decay Heat Removal when going from Hot Shutdown to Cold Shutdown. Bypass Valves DH21 and DH23, which are located outside of this fire area, will be opened.
26. The DHR Cooler 1-2 Isolation Valve CC1469 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened.

FIRE AREA AB

(NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).

27. Failure of Circuit 2CBF1129G could affect operation of DH1518. Trip Breaker BF1129 at F11C and manually open DH1518 if required.

Failure of these circuits could prevent remote operation of DH2734 and a hot short in Circuits 2CBF1134D, E, & G, could cause spurious operation. Trip Breaker BF1134 at F11C and manually operate DH2734 if required. Due to the torque/limit switches possibly being bypassed by a hot short, the valve operator may be damaged. If this occurs, procedures instruct plant personnel to remove the operator, replace it with a dedicated spare operator, and then manually close the valve. Since this valve is only needed to go to cold shutdown, GL 86-10 allows repairs to be made.

A hot short in Circuit 2CBF1195C or 2CBF1195D could cause spurious opening of DH63. Trip Breaker BF1189 at F11A (de-energizes F11E) and manually operate DH63 if required (See Note 11).

Cooler E27-2 is a mechanical component located in an area with very low combustible loading.

28. There are two concerns for Valve RC11 associated with this fire area:

- 1) Spurious closure would isolated the power operated Relief Valve (RC2A) and impair the ability to provide Makeup to the RCS Inventory using the HPI system. If this occurs, then use the Pressurizer Vent Path (RC200 and RC239A).
- 2) RC11 is a High/Low Pressure Interface Valve. Since it is in series with normally closed Valve RC2A, which is unaffected by a fire in this fire area, RC11 is not a concern.

29. TI-RC3A6 is a redundant means of monitoring the same variable (RCS Loop 2 Hot Leg Temperature) as TI-RC3A5. No circuits for TI-RC3A6 pass through this fire area. The power supply for TI-RC3A6 is C5755G which is not affected by a fire in this fire area.

30. RC4608B is not a concern because RC4608A is in series and not affected by a fire in this area.

31. To prevent spurious operation, valve HP31 has been de-energized.

32. Failure of Circuit ACV1453C could affect the ability to close WC1453 in the normal manner. Fail close WC1453 by venting off its air supply.

33. Coolers E26-1 and 2 are passive mechanical components in areas of very low combustible loading.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: AC

TRAIN ACCREDITED FOR SHUTDOWN: 2

4.6.AC.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM No.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT2)	DETECTION Y/N	SUPPRESSION MAN/AUTO
A1	BWST PIPE TRENCH	400	N	MAN
A2	PWST TRENCH	400	N	MAN

.....

4.6.AC.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA AC

The following components are located in fire area AC.

See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
DHRS	2	DH07A	MOV	BWST ISO VLV A
	1	DH07B	MOV	BWST ISO VLV B
SFAS	1/2	LT1525A	LT	BWST Level Transmitter
	1/2	LT1525B	LT	BWST Level Transmitter
	1/2	LT1525C	LT	BWST Level Transmitter
	1/2	LT1525D	LT	BWST Level Transmitter

FIRE AREA AC

4.6.AC.3 Fire Propagation Control

The north, south and east walls are below grade and backed up by backfill. The south and east wall area a minimum 1 ft. thick concrete with all penetration seals to meet a 3-hour rating: There is negligible combustible material in the vicinity of the trenches for a fire to propagate past the metal plate into the trench.

The combustible loading is due to incidentals and grease associated with 2 motor-operated valves. All cables are routed in steel conduit. A 1 inch schedule 160 pipeline for hydrogen supply to the Makeup Tank is routed through this area. This line is installed to Seismic Class I requirements and has no valves located in this area. Therefore, the hydrogen and cable insulation are not considered in the combustible loading.

4.6.AC.4 Fire Detection and Suppression

There is no automatic fire detection located in the Pipe Trenches. Manual fire suppression equipment is provided for this area by fire extinguishers located as shown on Drawings A-221F through A-230F and Hose House (HH) 11 located within 90 feet of the trenches. In the event of a fire, smoke would be vented through the hatch-type door in the roof.

4.6.AC.5 Fire Area Safe Shutdown Summary

Train 2 will be used for Safe Shutdown in Fire Area AC. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and MUPS Seal Injection for RCP Seal Cooling.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA AC TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection, and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 54-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates that High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent upstream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA AC TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:
- | | |
|--------|----------|
| ICS11A | Throttle |
| WC1743 | Open |
| WC1747 | Open |

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-2	CS Iso Vlv LPI Pump 2	Open On	Stop P56-1, -2 Stop P42-2 from the CR after blocking SFAS

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWs.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

15. NOT USED
16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	WC119	Open
MU182	Close	WC120	Open

FIRE AREA AC TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

CC1410	Open	MU11	Direct Flow to CWRT
MU01B	Open	MU214	Close
MU02B	Open	MU216	Throttle
MU10A	Open		

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU203 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A, DH9B, DH7A, and DH7B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01B before going below 700 psig.
23. NOT USED
24. Essential CCW is provided to the Makeup Pump Cooler, by passing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-2 Isolation Valve CC1469 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).

27. NOT USED
28. NOT USED
29. NOT USED

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA AD

4.6.AD.1 Fire Area Description

<u>Room No.</u>	<u>Description</u>	<u>Combustible Loading</u>	<u>Detection</u>	<u>Suppression</u>
118	Elevator Mach Rm	3,304 Btu/ft ²	Y	Man
AB2	Aux Bldg Stairwell (East)	400 Btu/ft ²	N	Man
EL3	Aux Bldg Elevator (RACA)	400 Btu/ft ²	N	Man

4.6.AD.2 Safe Shutdown Equipment In Fire Area AD

There are no Safe Shutdown components or cables in this fire area.

4.6.AD.3 Fire Propagation Control

Fire Area AD is located in the Auxiliary Building and consists primarily of one elevator shaft (with its Machine Room) and one stairwell (Elevations 545' to 613') as shown on Drawings A-221F through A-224F.

A fire that originates in this fire area will be contained in the fire area. This fire area is enclosed by a minimum of 2-hour fire-rated walls and ceilings.

This fire area contains no Safe Shutdown equipment and therefore provides the equivalent of 3-hour separation between fire areas containing Safe Shutdown equipment. That is, a fire in one Safe Shutdown area would have to breach one 2-hour wall to enter the Stairwell/Elevator Shaft and then breach another 2-hour wall to spread to another Safe Shutdown fire area. Based on the low combustible loading in this fire area and the low combustible loadings or automatic suppression in surrounding fire areas, it is highly unlikely for a fire to breach one of the 2-hour fire barriers, let alone 2 fire barriers.

The fire barriers are primarily 12 inch concrete block walls with minimum 10 inch thick poured concrete ceilings.

In order to preclude any direct flame/fire/smoke communication between the Corridor Room 110 (Fire Area A) and Elevator Machine Room 118 (Fire Area AD) through an opening, a 1-1/2-hour fire-rated door assembly (Door 103) was installed to protect the opening. Fire Door 103 is held open, in order to accommodate tornado depressurization vent considerations, by an electromagnetic door holder/closer. Upon actuation of the smoke detection system in either the Corridor (110) or the Elevator Machine Room (118), the electromagnetic door holder de-energizes, releasing the door allowing the mechanical door closer to bring the door to a closed position.

4.6.AD.4 Fire Detection and Suppression

Fire Area AD consists of Rooms 118, AB2 & EL3. The following area has detection:

1. Elevator Machine Room 118, Fire Detection Zone FDZ-118

Room AB2 & EL3 do not have detection in this fire area.

There is no automatic suppression in this fire area.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA AD

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawings A-221F through A-229F.

In the event of a fire, smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.AD.5 Fire Area AD Safe Shutdown Summary

Since there are no Safe Shutdown components or cables in this fire area, a fire in this area will not affect Safe Shutdown.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: B

TRAIN ACCREDITED FOR SHUTDOWN: 2

4.6.B.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM No.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT2)	DETECTION Y/N	SUPPRESSION MAN/AUTO
100	EQUIPMENT & PIPE CHASE	76,391	Y	MAN
101	PIPE TUNNEL	1,060	Y	MAN

4.6.B.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA B

The following components are located in fire area B.

See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
ESSPWR	1	E12E	MCC	480VAC MCC
	2	F11E	MCC	480VAC MCC

FIRE AREA B

4.6.B.3 Fire Propagation Control

Fire Area B is located at elevation 545 west end of the Auxiliary Building.

A fire that originates in this fire area will be contained in the fire area. This fire area is enclosed by 3-hour fire-rated ceiling and walls.

4.6.B.4 Fire Detection and Suppression

Fire Area B consists of two rooms covered by Fire Detection Zone FDZ 101. Manual fire suppression equipment is provided for this fire area. Fire Extinguishers and Hose Stations (HS) are shown on Drawings A-221F through A-231F.

In the event of a fire, smoke venting will be accomplished in accordance with the Pre-Fire Plan.

4.6.B.5 Fire Area Safe Shutdown Summary

Train 2 will be used for Safe Shutdown in Fire Area B. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, MUPS for a Letdown path and MUPS Seal Injection for RCP Seal Cooling.

LEGEND

H - required for hot standby C - required for cold shutdown H/L - High/Low interface B - valve maintains boundary isolation N/A - not affected

FIRE AREA B TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent upstream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA B TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. F11E will be de-energized. See Note 29.
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11A	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30 minutes are available to complete the manual action.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication. (See Note 12).

Due to loss of power to Train 1, Channels 1 and 3, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-2	CS Iso Vlv LPI Pump 2	Open On	Stop P56-1, -2 Stop P42-2 from the CR after blocking SFAS

MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, fire trip Breaker BF1201 at F12A.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

FIRE AREA B TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

CC1410	Open	MU10A	Open
MU01B	Open	MU11	Direct Flow to CWRT
MU02B	Open		

RCS Inventory Control

After transferring the Makeup Suction to the BWST, MU203 will be manually closed after opening MU208, HP29, and HP1556 to provide MUPS Recirc to the BWST rather than the MU Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A, DH9B, DH7A, and DH7B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01B before going below 700 psig.
23. NOT USED
24. Essential CCW to the Makeup Pump Cooler, by passing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-2 Isolation Valve CC1469 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).
27. DH63 would spuriously open following a hot short in Circuits 2CBF1195C or 2CBF1195D. To preclude this, Procedure DB-OP-02501 will include instructions to close/verify closed DH63 and open fused disconnect switch BF1189 at MCC F11A for a fire in this area (See Note 29).
28. NOT USED

FIRE AREA B TABLE 1 NOTES

29. Open Fused Disconnect Switch BF1189 at MCC F11A to de-energize MCC F11E and Valve DH63. MCC F11E provides power to DH63 and HP31. DH63 will be manually closed (see Note 27) and HP31 is not required for Shutdown.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BD

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: BD

TRAIN ACCREDITED FOR SHUTDOWN: 2

4.6.BD.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM NO.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT2)	DETECTION Y/N	SUPPRESSION MAN/AUTO
050	SCREEN WASH PUMP ROOM	17,200	N	Man
054	STAIRWAY	400	N	Man

4.6.BD.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA BD

The following components are located in fire area BD.
See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
HVAC	1	HV0531A	DMPR	AIR IN LVR FOR B/U SW PUMP
	1	HV0532A	DMPR	AIR IN LVR FOR B/U SW PUMP
	1	C100	FAN	TRAV SCR AREA EXH FAN (B/U SW PUMP)
SWS	1/2	P180	PUMP	BACKUP SW PUMP

FIRE AREA BD

4.6.BD.3 Fire Propagation Control

Fire Area BD is located in the Intake Structure as shown on Drawing A-230F.

A fire that originates in this fire area will be contained in this fire area. This fire area is separated from other fire areas by 3-hour fire-rated barriers.

4.6.BD.4 Fire Detection and Suppression

There is no automatic fire detection located in this area.

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawing A-230F.

In the event of a fire, smoke venting is accomplished in accordance with the Pre-Fire Plans.

4.6.BD.5 Fire Area Safe Shutdown Summary

Train 2 will be used for Safe Shutdown in Fire Area BD. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and MUPS Seal Injection for RCP Seal Cooling.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BD TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA BD TABLE 1 NOTES

9. NOT USED

| WC1743 | Open |
| WC1747 | Open |

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Train 1 Channels 1 and 3, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-2	CS Iso Vlv LPI Pump 2	Open On	Stop P56-1, -2 Stop P42-2 from the CR after blocking SFAS

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

FIRE AREA BD TABLE 1 NOTES

Additionally, the following valve may need to be manually operated:

CC1410	Open	MU10A	Open
MU01B	Open	MU11	Direct Flow to CWRT
MU02B	Open		

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU203 will be manually closed after opening MU208, HP29, and HP1556 to provide MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been depowered.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01B before going below 700 psig.
23. NOT USED
24. Essential CCW is provided to the Makeup Pumps, thereby passing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-2 Isolation Valve CC1469 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BE

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: BE

TRAIN ACCREDITED FOR SHUTDOWN: 2

4.6.BE.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM NO.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT2)	DETECTION Y/N	SUPPRESSION MAN/AUTO
051	DIESEL FIRE PUMP ROOM	8,625	Y	MAN
055	DIESEL FIRE PMP TNK ENCL	741,576	N	MAN

4.6.BE.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA BE

The following components are located in fire area BE.
See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
ESSPWR	1	E12C	MCC	480VAC MCC
	1	E12D	MCC	480V AC MCC

FIRE AREA BE

4.6.BE.3 Fire Propagation Control

Fire Area BE is located in the Intake Structure as shown on Drawing A-230F.

A fire that originates in this fire area will be contained in this fire area. This fire area is separated from other fire areas by 3-hour fire-rated barriers (except as noted below).

The west wall of Room 51 contains 1 non-rated opening. To preclude any direct flame/fire communication with Room 52A (Fire Area BF), an automatic wet-pipe sprinkler (fed from Room 52) is located in the opening.

The south wall of Room 51 contains 1 fire damper which was not certified for closure against air flow. This arrangement has been tested and found acceptable.

The Diesel Fire Pump is located on a concrete stand which is surrounded by a 6 inch concrete curb to contain any leakage of fuel or lubricating oil.

The Fire Pump Diesel Oil Day Tank (T47) is surrounded by a 1 foot high concrete curb to contain any leakage of fuel.

4.6.BE.4 Fire Detection and Suppression

Fire Area BE consists of 2 rooms. Room 51 is covered by Detection Zone FDZ 51.

Room 51 is provided with a manual wet-pipe sprinkler system which utilizes fusible sprinklers. Actuation is accomplished by opening FP215 located in Room 53 (Fire Area BG).

Manual fire suppression equipment is provided for this fire area. Fire Extinguishers and Hose Stations (HS) are shown on Drawing A-230F.

In the event of a fire, smoke venting is accomplished in accordance with the Pre-Fire Plans.

4.6.BE.5 Fire Area Safe Shutdown Summary

Train 2 will be used for Safe Shutdown in Fire Area BE. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, for a Letdown path and Seal Injection for RCP Seal Cooling.

FIRE AREA BE TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BE TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11A	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Train 1, Channels 1 and 3, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-2	CS Iso Vlv LPI Pump 2	Open On	Stop P56-1, -2 Stop P42-2 from the CR after blocking SFAS

MU66C	RCP 1-1 Seal Inj Vlv	Closed	Open MU66C
MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

FIRE AREA BE TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

CC1410	Open	MU10A	Open
MU01B	Open	MU11	Direct Flow to CWRT
MU02B	Open		

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU203 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01B before going below 700 psig.
23. NOT USED
24. Essential CCW is provided to the Makeup Pump Cooler, bypassing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-2 Isolation Valve CC1469 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).

FIRE AREA BF

4.6.BF.3 Fire Propagation Control

Fire Area BF is located in the Intake Structure as shown on Drawing A-230F.

A fire that originates in this fire area will be contained in this fire area. This fire area is separated from other fire areas by 3-hour fire-rated barriers (except as noted below).

The east wall of Room 52A contains 1 non-rated opening. To preclude any direct flame/fire communication with Room 51 (Fire Area BE), an automatic wet-pipe sprinkler (fed from Room 52) is located in the opening.

The north wall of Room 52 contains 1 fire damper which was not certified for closure against air flow. This arrangement has been tested and found acceptable.

4.6.BF.4 Fire Detection and Suppression

Fire Area BF consists of 2 rooms. Room 52 is covered by Detection Zone FDZ 52 and is provided with an automatic wet-pipe sprinkler system.

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawing A-230F.

In the event of a fire, smoke venting is accomplished in accordance with the Pre-Fire Plans.

4.6.BF.5 Fire Area Safe Shutdown Summary

Train 1 will be used for Safe Shutdown in Fire Area BF. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and Seal Injection for RCP Seal Cooling. The Backup Service Water Pumps will be used instead of Service Water Pump 1 or 3.

C - required for cold shutdown

H/L - High/Low interface

B - valve maintains boundary isolation

N/A - not affected

FIRE AREA BF TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA BF TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:
- | | |
|--------|----------|
| ICS11B | Throttle |
| WC1743 | Open |
| WC1747 | Open |

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level set-point is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-1	CS Iso Vlv LPI Pump 1	Open On	Stop P56-1, -2 Stop P42-1 from the CR after blocking SFAS

MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3869 is manually closed, first trip Breaker BE1146 at E11E.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

FIRE AREA BF TABLE 1 NOTES

The following valves may also need to be operated manually:

CC1409	Open	MU10A	Open
MU01A	Open	MU11	Align to CWRT
MU02B	Open		

RCS Inventory Control

After transferring the Makeup Suction to the BWST, MU206 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A before going below 700 psig.
23. NOT USED
24. Essential CCW has been provided to the Makeup Pump Cooler, by passing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-1 Isolation Valve CC1467 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).
27. The Backup Service Water Pump (P180) will be used instead of Service Water Pump P3-1, or 3. Bus C2 and Bus A will be aligned in accordance with the Plant procedure for loss of Service Water. Open Breaker AACC2 at Bus C2 to isolate Bus A. Since Pump P180 is not located in the Service Water Pump Room, HV0531A, HV0532A, C99-1, and C99-2 are not needed.

FIRE AREA BF TABLE 1 NOTES

SW45 will be closed manually since a hot short may damage SW1399 in this fire area. Although the circuits for SW2929 and SW2931 pass through this fire area, a discharge path for SWS is assured because SW2929, SW2930, SW2931, or SW2932 is always open and depowered.

28. Operators will manually start fan C100.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BG

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: BG

TRAIN ACCREDITED FOR SHUTDOWN: 1

4.6.BG.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM NO.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT2)	DETECTION Y/N	SUPPRESSION MAN/AUTO
053	SERVICE WTR VALVE ROOM	11,678	Y	MAN
053A	PIPE TUNL-H2O TRMT BLDG	14,114	N	MAN
250	PIPE TUNNEL	23,074	N	MAN
251	VALVE ROOM	1,032	N	MAN

4.6.BG.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA BG

The following components are located in fire area BG.

See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
SWS	2	SW1395	MOV	TPCW HX IN HEADER ISO VLV
	1	SW1399	MOV	TPCW HX IN HEADER ISO VLV
	1	SW2929	MOV	SW TO INT STRU VLV
	2	SW2930	MOV	SW TO INT FOREBAY VLV

	2	SW2932	MOV	SW TO COLLECT BASIN VLV
	1	SW45	MAN	TPCW HX ISO VLV
	2	SW46	MAN	TPCW HX ISO VLV

FIRE AREA BG

4.6.BG.3 Fire Propagation Control

Fire Area BG is located in the Intake Structure and Service Water Tunnel as shown on Drawings A-222F, A-223F and A-230F.

This fire area is separated from other fire areas by 3-hour fire-rated barriers (except as noted below).

The door between Room 334 (Fire Area II) and Room 251 (Fire Area BG) is not a fire door. Based on the sprinkler system in Room 334, the low combustible loading and the construction for the door, a fire will not spread from one fire area to the other.

The north wall of Room 53A to Room 15 (Fire Area BH) is an Appendix A fire barrier and is not taken credit for, as Safe Shutdown.

4.6.BG.4 Fire Detection and Suppression

Fire Detection is provided in the Service Water Valve Room 53 (Fire Detection Zone FDZ 53)

Manual fire suppression equipment is provided for in this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawings A-222F, A-223F and A-230F.

In the event of a fire, isolation and smoke venting is accomplished in accordance with the Pre-Fire Plans.

4.6.BG.5 Fire Area Safe Shutdown Summary

Train 1 will be used for Safe Shutdown in Fire Area BG. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, for a Letdown path and Seal Injection for RCP Seal Cooling. Analysis shows that for a fire in combined Fire Areas BG and BH, Safe Shutdown is not impacted. Shutdown is the same as for this fire area.

FIRE AREA BG TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BG TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11B	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-1	CS Iso Vlv LPI Pump 1	Open On	Stop P56-1, -2 Stop P42-1 from the CR after blocking SFAS

MU66A	RCP 2-1 Seal Inj Vlv	Closed	Open MU66A
MU66B	RCP 2-2 Seal Inj Vlv	Closed	Open MU66B
MU66C	RCP 1-1 Seal Inj Vlv	Closed	Open MU66C
MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3869 is manually closed, first trip Breaker BE1146 at E11E.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection & Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

FIRE AREA BG TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

CC1409	Open	MU10A	Open
MU01A	Open	MU11	Align to CWRT
MU02B	Open		

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU206 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A before going below 700 psig.
23. NOT USED
24. Essential CCW is provided to the Makeup Pump Cooler, by-passing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-1 Isolation Valve CC1467 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).
27. Although the circuits for SW2929 and SW2931 pass through this fire area, a discharge path for SWS is assured because one or the other is always open and depowered.
28. The circuits for Valve SW1399 and the valve itself may be affected by a fire in this area. Service Water flow to the TPCW Heat Exchangers will be terminated by manually closing Valves SW54, SW55 and SW56 which are located outside this fire area.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BH

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: BH

TRAIN ACCREDITED FOR SHUTDOWN: 1/2

4.6.BH.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM NO.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT2)	DETECTION Y/N	SUPPRESSION MAN/AUTO
010	SAMPLE LABORATORY	36,000	N	MAN
011	SUBSTATION	81,082	Y	MAN
012	CHEMICAL STORAGE ROOM	24,000	Y	MAN
012A	CONTROL ROOM	400	N	MAN
013	CHLORINATION ROOM	10,895	Y	MAN
015	FILTER ROOM	6,045	Y	MAN

.....

4.6.BH.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA BH

The following components are located in fire area BH.
See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
NONE				

FIRE AREA BH

4.6.BH.3 Fire Propagation Control

Fire Area BH is the Water Treatment Building, as shown on Drawing A-231F.

A fire that originates in this fire area will be contained in the fire area.

This fire area's walls are exterior walls except for one small portion of the South wall which separates this fire area from Fire Area BG. This wall is an Appendix A barrier and is not taken credit for in the Safe Shutdown analysis.

There is a drain located under Door 111 which separates Fire Area BH from BG. A portion of this drain is provided with a steel cover under Door 111 to prevent the spread of a fire under the door.

The major combustible in this fire area is the Substation located in Room 11. The interior wall and floor to Room 11 are 2-hour fire-rated walls/floor which separate Room 11 from the rest of Fire Area BH.

Also, the walls and floors of Room 12 and 13 (Chemical Storage Room and Chlorination Room) are provided with 2-hour fire-rated walls which separate these two rooms from the rest of Fire Area BH to reduce the consequences of a fire involving chemicals.

4.6.BH.4 Fire Detection and Suppression

The Motor-Driven Fire Pump and Jockey Fire Pump are located in this fire area. The Diesel-Driven Fire Pump is located outside this area and is available to provide fire suppression.

Fire Area BH consists of various rooms. The following areas have detection:

1.	Substation Room 11	Alarms on Panel C5401
2.	Chemical Storage Room 12	Alarms on Panel C5401
3.	Chlorination Room 13	Alarms on Panel C5401
4.	Filter Room 15	Partial Coverage Alarms on Panel C5401

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawing A-231F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.BH.5 Fire Area BH Safe Shutdown Summary

Both Train 1 and 2 are available for Safe Shutdown in Fire Area BH. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and Seal Injection for RCP Seal Cooling.

If a fire spreads from this fire area to Fire Area BG, Shutdown using Train 1 in accordance with Fire Area BG. Analysis shows a fire in both areas at the same time will not affect Safe Shutdown.

FIRE AREA BH TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA BH TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11A/B	Throttle	WC1743	Open
MU38	Open	WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.
13. SFAS will not actuate, since neither Train of power to SFAS is affected.
14. Response to SFRCS initiation due to loss of Off-Site Power (LOOP) is in accordance with DB-OP-02000. Both Trains of SFRCS are available.
15. NOT USED
16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

Additionally, the following valves may need to be manually operated:

CC1410	Open	MU03	Open
MU01A	Open	MU10A	Open
MU01B	Open	MU11	Direct Flow to CWRT
MU02A	Open	MU66A-D	Open
MU02B	Open		

CS Inventory Control

After transferring the Makeup suction to the BWST, MU203 (Train 2) or MU206 (Train 1) will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

FIRE AREA BH TABLE 1 NOTES

- 17. NOT USED
- 18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
- 19. NOT USED
- 20. NOT USED
- 21. NOT USED
- 22. NOT USED
- 23. NOT USED
- 24. Essential CCW is provided to the Makeup Pump Cooler, by-passing CC1460.
- 25. NOT USED
- 26. The DHR Cooler 1-1(1-2) Isolation Valve CC1467 (CC1469) is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: BM

TRAIN ACCREDITED FOR SHUTDOWN: 2

4.6.BM.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM NO.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT ²)	DETECTION Y/N	SUPPRESSION MAN/AUTO
A3	DIESEL OIL ...PUMPHOUSE	400	Y	MAN

.....

4.6.BM.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA BM

The following components are located in fire area BM.
See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
EDG	1	P8-1	PUMP	DO XFER PUMP 1

.....

FIRE AREA BM

4.6.BM.3 Fire Propagation Control

Fire Area BM is located approximately 250 ft. northwest of the Power Block and consists of the Diesel Oil Pumphouse and Diesel Oil Storage Tank (T45) as shown on Drawing A-231F.

The Diesel Oil Storage Tank is surrounded by a dike (the pumphouse is part of the dike) with a capacity in excess of the tank.

There is no other structure in proximity to this area and, therefore, a fire in this area would not spread to other fire areas.

4.6.BM.4 Fire Detection and Suppression

The Diesel Oil Pumphouse is provided with automatic fire detection.

Manual fire suppression equipment is provided for this area. Fire extinguisher locations are shown on A-231F.

The Yard hydrant and Hose House 18 provide backup suppression.

The Pumphouse can be ventilated using portable fans. The tank is outside and requires no smoke venting.

4.6.BM.5 Fire Area Safe Shutdown Summary

Train 2 will be used for Safe Shutdown in Fire Area BM. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, Letdown and Seal Injection for RCP Seal Cooling.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BM TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) is provided and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BM TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11A/B	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level set-point is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-2	CS Iso Vlv LPI Pump 2	Open On	Stop P56-1, -2 Stop P42-2 from the CR after blocking SFAS
P42-1 P56-2	LPI Pump 1 CS Pump 2	On On	Trip Bkr AC112 at C1 Stop P56-2 from the CR after Blocking SFAS
P56-1 P58-2	CS Pump 1 HPI Pump 2	On On	Trip Bkr BE111 at E1 Stop P58-2 from the CR after blocking SFAS
P58-1 CC1407A, B	HPI Pump 1 CCW Out Iso Vlv	On Closed	Trip Bkr AC111 at C1 Open CC1407A, B and Trip Bkr BE1173 at E11B & BF1158 at F11B

MU59B	RCP 2-2 Seal Rtn Vlv	Closed	Open MU59B and Trip BE1175 at E11B

FIRE AREA BM TABLE 1 NOTES

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
MU59C	RCP 1-1 Seal Rtn Vlv	Closed	Open MU59C and Trip BE1177 at E11B
MU59D	RCP 1-2 Seal Rtn Vlv	Closed	Open MU59D and Trip BE1178 at E11B
MU66A	RCP 2-1 Seal Inj Vlv	Closed	Open MU66A
MU66B	RCP 2-2 Seal Inj Vlv	Closed	Open MU66B
MU66C	RCP 1-1 Seal Inj Vlv	Closed	Open MU66C
MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

15. NOT USED
16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

FIRE AREA BM TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

CC1410	Open	MU10A	Open
MU01B	Open	MU11	Direct flow to CWRT
MU02B	Open		

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU203 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01B before going below 700 psig.
23. NOT USED
24. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
25. The DHR Cooler 1-2 Isolation Valve CC1469 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: BN

TRAIN ACCREDITED FOR SHUTDOWN: 1

4.6.BN.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM NO.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT2)	DETECTION Y/N	SUPPRESSION MAN/AUTO
A4	EMERG DIESEL WK TANKS	3,863,179	N	MAN

4.6.BN.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA BN

The following components are located in fire area BN.
See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
EDG	1	P195-1	PUMP	EDG FUEL OIL TRANSFER PUMP 1
	2	P195-2	PUMP	EDG FUEL OIL TRANSFER PUMP 2
	1	T153-1	TANK	EDG FUEL OIL TANK 1-1
	2	T153-2	TANK	EDG FUEL OIL TANK 1-2

FIRE AREA BN

4.6.BN.3 Fire Propagation Control

Fire Area BN is located in the Yard approximately 500 ft. northwest of the Power Block. It consists of the two Emergency Diesel Generator Fuel Oil Storage Tanks which are installed outdoors, above grade level, and are protected by a truncated pyramid of structural backfill to a minimum depth of 4 ft.-6 in. Both tanks are vented to the atmosphere through gooseneck vent pipes which are provided with flame arresters. Each tank contains one Seismic I electric motor-driven submersible supply pump. Access to the pumps is through a 48-inch manway on top of each tank.

The use of vented tanks with flame arresters and the protection provided by the structural backfill reduces the probability of a fire originating in this area. In addition, if a fire did originate in this area, its distance (500 ft.) from the Power Block reduces the effects of such a fire on any other equipment required for Safe Shutdown.

4.6.BN.4 Fire Detection and Suppression

There is no automatic fire detection in the tanks.

Manual fire suppression is provided for this area by Yard hydrants and Hose Houses 14 and 15.

There is no need for smoke venting in this area since it is completely outdoors.

4.6.BN.5 Fire Area Safe Shutdown Summary

Train 1 will be used for Safe Shutdown in Fire Area BN. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and Seal Injection for RCP Seal Cooling.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA BN TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA BN TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11A/B	Throttle
WC1743	Open
WC1747	Open

CC1695 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-1	CS Iso Vlv LPI Pump 1	Open On	Stop P56-1, -2 Stop P42-1 from the CR after blocking SFAS

MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3869 is manually closed, first trip Breaker BE1146 at E11E.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

FIRE AREA BN TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

CC1409	Open	MU10A	Open
MU01A	Open	MU11	Direct Flow to CWRT
MU02B	Open		

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU206 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A before going below 700 psig.
23. NOT USED
24. Essential CCW is provided to the Makeup Pump Cooler, by-passing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-1 Isolation Valve CC1467 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).
27. Fuel oil can be transferred from the Oil Storage Tank (T45) using the Oil Transfer Pump P8-1 after connecting the flexible hose. EDG Fuel Oil Tank 1 (T153-1) and EDG Fuel Oil Transfer Pump 1 (P195-1) would then not be used.

FIRE AREA CA

4.6.CA.1 Fire Area Description

Fire area CA consists of the Containment Access Facility (CAF), which is a multi-purpose, four-story building, containing general offices as well as radiation protection briefing areas and dress-out spaces that are to be used prior to entry into Containment; as well as to directly access the Missile Shield Passageway (MSP) for entry into the Auxiliary Building. The CAF also provides an additional exit way from the MSP at elevation 603'.

4.6.CA.2 Safe Shutdown Equipment In Area CA

There is no safe shutdown equipment or cable in the fire area.

4.6.CA.3 Fire Propagation Control

Fire area CA is located adjacent to the south wall of the Auxiliary Building and the south and west walls of the Personnel Shop Facility (PSF) passageway (fire area PS). The west wall of fire area CA is adjacent to the Low Level Radwaste Storage Facility (fire area RW).

Fire area CA is separated from the walls of the Auxiliary Building, Personnel Shop Facility passageway, and the Low Level Radwaste Storage Facility by fire rated walls of the CAF.

4.6.CA.4 Fire Detection and Suppression

The CAF has an alarm panel that transmits alarms and trouble signals to the main control room.

All floors in the building are provided with fixed sprinklers.

4.6.CA.5 Fire Area CA Safe Shutdown Summary

There are no Safe Shutdown components or cables in this fire area. Therefore, safe Shutdown is not affected by a fire in this area.

FIRE HAZARDS ANALYSIS

4.6.CC.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA CC

The following components are located in fire area CC.
See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
SFAS	1/2	PT2003	PT	CTMT VESSEL PRESS XMTR

.....

FIRE AREA CC

4.6.CC.3 Fire Propagation Control

Fire Area CC is located in the Auxiliary Building consisting primarily of the southeast portion of the 603' elevation, as shown on Drawing A-224F.

A fire that originates in this fire area will be contained in the fire area. This fire area is enclosed by 3-hour rated concrete walls (except as noted below).

The concrete block walls enclosing the stairwells and elevator shafts (Fire Area UU and AD) are rated for 2-hours. Based on the construction arrangement and low combustible loadings, a fire will not propagate from one fire area to another. See Fire Areas AD and UU for details.

There are several penetrations which have penetration seals that do not meet the test configurations or penetrations with small annular gaps (too small to seal properly). These non-rated openings have been evaluated and will not allow the propagation of a fire.

4.6.CC.4 Fire Detection and Suppression

Fire Area CC consists of various rooms. The following areas have detection:

1. Corridor, Room 411, Fire Detection Zone FDZ 412A
2. Corridor, Room 412, Fire Detection Zone FDZ 412A
3. Corridor, Room 412A, Fire Detection Zone FDZ 412A
4. Trace Analysis Lab, Room 413, Fire Detection Zone FDZ 412A
5. Corridor, Room 415, Fire Detection Zone FDZ 412A
6. Decon Shower, Room 417, Fire Detection Zone FDZ 412A
I&C Hot Shop, Room 419, Fire Detection Zone FDZ 412A
7. I&C Hot Shop, Room 420, Fire Detection Zone FDZ 412A
I&C Hot Shop, Room 420A, Fire Detection Zone FDZ 412A
8. Chemistry/RP Storage Area, Room 421, Fire Detection Zone FDZ 412A
9. Chem. Oil Testing Lab, Room 423, Fire Detection Zone FDZ 412A
10. Chem Lab, Room 424, Fire Detection Zone FDZ 412A
11. Chem Lab, Room 424B, Fire Detection Zone FDZ 412A
12. Counting Room, Room 424C, Fire Detection Zone FDZ 412A
13. Personnel Lock Area, Room 426, Fire Detection Zone FDZ 412A
14. Decon Shower, Room 417A, Fire Detection Zone FDZ 412A
15. Decon Shower, Room 418, Fire Detection Zone FDZ 412A

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawing A-224F.

In the event of a fire, isolation and smoke venting will be in accordance with the Pre-Fire Plans.

4.6.CC.5 Fire Area Safe Shutdown Summary

Train 2 will be used for Safe Shutdown in Fire Area CC. Safe Shutdown will be accomplished using the High Pressure Injection System (HPIS) along with the Power-Operated Relief Valve (RC2A) for Reactor Coolant System Inventory Control, the Makeup and Purification System (MUPS) for a Letdown path and the HPIS Seal Injection for RCP Seal Cooling. The RCP seals will be restaged using flow through the RCP Seal Return line.

FIRE AREA CC TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA CC TABLE 1 NOTES

9. NOT USED

10. The DHR Cooler 1-1 Isolation Valve CC1469 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS Cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467(CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467(CC1469).

11. The CCW Return Header 2 Valve CC2649 is normally closed and required to be open to provide cooling for Seal Return. A review of the circuits indicates spurious closure and loss of control power. Therefore, trip Breaker BF1161 at MCC F11D.

12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11A	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

In this fire area WC1747 may also fail due to loss of RC1761.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level set-point is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531	CS Iso Vlv	Open	Stop P56-1, -2

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in

FIRE AREA CC TABLE 1 NOTES

the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

Inventory Control will be maintained using HPIS Train 2 and Depressurizing using the PORV. Pressurizer level can be controlled by throttling on HPO2A or 02B as required.

Upon restoration of seal injection, RCP Seal Flow will be used to restage the seals draining to the Clean Waste Receiver Tanks.

The following valves may need to be operated:

MU10A	Open	WC119	Open
MU11	Direct flow to CWRT	WC120	Open
MU97	Close	WC1453	Close
MU182	Close	WC3560	Open

In addition, RCP Seal Cooling will be accomplished by Seal Injection and Letdown.

The following valves may need to be operated:

CC1410	Open	MU04	Open
HP27	Open	MU208	Open
MU01B	Open	MU214	Close
MU02B	Open	MU216	Throttle

17. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01B before going below 700 psig.
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. AFPT 2 Governor Control Valve ICS038B is normally open on the high speed stops and required to be operable for Safe Shutdown. Loss of power supply (CDF-12A-1) causes the valve to fail as-is open. The AFPT 2 will operate at normal speed and Auxiliary Feedwater will be controlled by using AFWP 2 Flow Control Valve AF6451 (SG-2 level).
20. NOT USED
21. NOT USED
22. To prevent spurious operation, valve HP31 has been de-energized.
23. Pressurizer Vapor Sample Valves RC239A & B and Cold Leg SG-2 Sample Valve RC4632 are normally closed and are required to be closed to prevent RCS Depressurization. A review of the circuit indicates that spurious actuation of the valves is not possible. Also, RC200 is available to prevent RCS Depressurization.

FIRE AREA CC TABLE 1 NOTES

24. Valves RC4608A & B are in series and 4 shorts would be required to repower both valves. See E-52B sht 71A & B. Such an occurrence is not credible. The one inch lines include a restricting orifice sized to limit the flow to within the Makeup System capacity.
25. Essential CCW is provided to the Makeup Pump which provides a bypass around CC1460.
26. LPI/HPI Cross-Connect Valve DH63 is normally closed and required to be closed for DHR cooldown. A review of the circuit indicates spurious opening is possible. Transfer control on CDF-11D to local and close/verify closed DH63 prior to using DHR. Due to the torque/limit switches possibly being bypassed by a hot short, the valve operator may be damaged. If this occurs, procedures instruct plant personnel to remove the operator, replace it with a dedicated spare operator and then manually close the valve. Since this valve is only needed to go to cold shutdown, GL 86-10 allows repairs to be made.
27. NOT USED
28. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
29. NOT USED
30. Although DH2736 may be affected by a fire in this area, DH2735 remains available to function as the boundary isolation valve.
31. Due to lack of breaker coordination, MCC F11B may be lost for a fault in the power cable for Valve CS1531. The following Safe Shutdown equipment is powered from MCC F11B:

MS107A	Not required for Shutdown
CC1407B	Manually operated
CC1411B	Manually operated
DH07A	Normally open, fail as-is, Shutdown position is "open" Breaker is also maintained in the open position

FIRE AREA D

4.6.D.3 Fire Propagation Control

Fire Area D is comprised of the entire Containment, as shown on Drawing A-221F through A-229F.

A fire that originates in this fire area will be contained in this fire area.

This fire area is separated from Fire Areas A and AB (the East and West halves of the Annulus) by the steel pressure vessel. Based on the low combustible loading and the design of the pressure vessel, a fire will not spread from one side of the pressure vessel to the other.

There are several non-rated penetrations through the pressure vessel. These penetrations include the Equipment Hatch Personnel Air Lock, the Emergency Air Lock, the Transfer Tubes, Electrical Penetrations, and Piping Penetrations. Based on the design of these penetrations and the low combustible loadings, a fire will not propagate through one of these openings.

Other than cable insulation, the major combustible is the lube oil in the Reactor Coolant Pump Motors. The Reactor Coolant Pumps are provided with siesmically designed lube oil collection systems to collect any leakage from the RCP Motors, thereby reducing the potential for the oil to leak from one of the motors and start a fire.

4.6.D.4 Fire Detection and Suppression

Fire Area D consists of various rooms and/or areas. The following areas have detection.

1. Core Flooding Tank Area Room 214, Fire Detection Zone FDZ 214
2. Letdown Cooler Area Room 215, Fire Detection Zone FDZ 215
3. Steam Generator Area (West D-Ring) Room 216, Fire Detection Zones FDZ RCP-1, FDZ RCP-2
4. Steam Generator Area (East D-Ring) Room 218, Fire Detection Zones FDZ RCP-3, FDZ RCP-4, FDZ PSV-1
5. Incore Instrument Trench Area Room 220, Fire Detection Zone FDZ 220
6. Hatch Area Room 317, Fire Detection Zone FDZ 317
7. Passage Room 410, Fire Detection Zone FDZ 410
8. Pressurizer Valve Room, Room 580 Fire Detection Zone FDZ 410

Manual Fire Suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawings A-221F through A-229F.

A 2½ hose connection is available on the Service Water System in containment that could be used for fire fighting. Three separate connections are provided on the 603' Elev, near the Personnel Hatch, so that one will usually be available.

FIRE AREA D

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.D.5 Fire Area D Safe Shutdown Summary

In general, separation of Safe Shutdown and Associated Circuits of redundant trains is prevalent throughout most of Containment. For the most part, Train 1 circuits enter Containment from the West and Train 2 circuits primarily from the East. Consequently, Train 1 Safe Shutdown and Associated Circuits are basically confined to the West side of Containment while Train 2 circuits are primarily found in the East side. The few exceptions stem from a few Train 1 Safe Shutdown circuits that were routed into the predominantly Train 2 East penetration area.

Since the location of a fire could be on either the east or west side of Containment, and since Containment will not be immediately accessible, the following method was used to demonstrate compliance with Appendix R:

1. High/Low Interface valves and cables were evaluated.
 - a. The PORV (RC2A) and Block Valve RC11 are separated by less than 20 ft. but dedicated conduit is used up to the electrical penetrations which are separated by more than 20 ft. Safe Shutdown does not require opening the PORV, and if it did open spuriously, there is physical separation for the circuits for RC11. It is considered incredible for a fire in the vicinity of the two valves to open the PORV due to the lack of a hot short power source; therefore, the installation of a radiant energy shield is not required.
 - b. Letdown is isolated by manually closing MU03 outside of Containment.
 - c. Decay Heat Suction Valves DH11 & 12 are closed and depowered.
 - d. At least one steam generator primary High Point Vent valve will remain closed due to separation.
 - e. Adequate time is available to manually isolate 3/4" sample and 1" vent paths to the Quench Tanks.
2. A minimum set of Safe Shutdown equipment was developed assuming the Makeup Pumps were used for inventory control and after 8-hours: Letdown, Seal Injection from MUPS, and Seal Return.

<u>SYSTEM</u>	<u>TRN</u>	<u>COMPONENT</u>	<u>DESCRIPTION</u>

RCS	1	RC11	PORV Block Valve
	2	RC200	Pzr Smpl CTMT Vnt HDR Valve
	2	RC2A	Pressurizer PORV

Safe Shutdown can be achieved with either train of the above equipment.

An exemption is requested for the lack of separation of cables and equipment and associated non-safety circuits by a horizontal separation of more than 20 ft. with no intervening combustibles or fire hazards as required per Section III.G.2 of Appendix R for non-inerted containments. The justification is provided in the notes for the CAC fans.

H - required for hot standby

C - required for cold shutdown

H/L - High/Low interface

B - valve maintains boundary isolation

N/A - not affected

FIRE AREA D TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent upstream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA D TABLE 1 NOTES

9. NOT USED
10. An exemption is requested from the provisions of Appendix R, III.G.2, for separation of cables and equipment and associated non-safety circuits of redundant trains by a horizontal distance of more than 20 ft. with no intervening combustibles or fire hazards.
11. MCC E11B may trip due to a lack of coordination in associated circuit breakers. The following Safe Shutdown equipment powered from MCC E11B will be manually operated, if required:

CF01B	DH2735
CC1407A	MU02A & B
CC1411A	MU59A-D
DH12 (de-energized)	MCC YE2

12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11A/B	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components:

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-1, -2	CS Iso Vlv LPI Pump 1, 2	Open On	Stop P56-1, -2 Stop P42-1, -2 from CR after blocking SFAS

MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3869 is manually closed, first trip Breaker BE1146 at E11E.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

15. NOT USED

16. RCP Inventory Control and RCP Seal Integrity are maintained by re-establishing Seal Return, Seal Injection and RCS Letdown.

RCP Seal Return, Seal Injection and Letdown Flow (after 8 hours). The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA D TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

MU02B	Trip Breaker BE1172 at E11B & open MU02B	MU10A MU11	Open Direct flow to CWRT
-------	---	---------------	-----------------------------

RCS Inventory Control

After transferring Makeup Suction to the BWST, MU203 (Train 2) or MU206 (Train 1) will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank or Clean Waste System to conserve water.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. YE2/YF2 associated circuits are not coordinated. This results in loss of YE2/YF2. The loss of this panel will cause a Reactor Trip via ARTS, which is acceptable.
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A, and CF01B before going below 700 psig.
23. The circuits for the Steam Generator Vent Valves RC4608A & B (SG1) and RC4610A & B (SG2) are routed in individual conduits up to the containment penetrations where the cables are exposed. The penetrations for RC4608A & B are separated by more than 20 ft. The penetrations for RC4610A & B are approximately 8 ft. apart (P2P5FI & P2C5CI on Drawing E-362).

Penetration P2C5CI contains one other cable, 2CV4632A (E56B/47B 125V DC) for the normally closed and de-energized Cold Leg Sample Valve RC4632 which is also a dedicated conduit 39296A. Penetration P2P5FI contains approximately 20 other cables; however, only one valve needs to remain closed for the High/Low Pressure Interface. The details of the penetration boxes are shown on Drawings E376 and E378B and include covers which act like the conduit.

Spurious operation of both valves in a train requires multiple hot shorts of the right polarity, for Train 1, this is incredible due to separation. For Train 2, this is incredible because there is not available power source for RC4610B. Also, the Makeup System is available and capable of maintaining RCS Inventory even if these valves did spuriously open.

24. The power and control cables for the PORV (RC2A) were routed in dedicated conduit (with no other cables) and repowered to Train 2 (E52B/13). The power and control cables for the PORV block Valve (RC11, Train 1) were also routed in dedicated conduit

FIRE AREA D TABLE 1 NOTES

which approaches the PORV and other Train 1 equipment and conduits within 20 ft. However, there is no other power source in the conduit or at the components which could credibly hot short and cause spurious operation. The Train 1 & 2 penetration boxes are widely separated by over 100 ft. and metal enclosed (E-376). There is no credible fire which could impair both boxes at the same time. Within the penetration, the PORV power cables are exposed and in close proximity to other train 2 circuits (See E-530).

In the unlikely event that a fire in or around the penetration did cause a spuriously PORV opening, the Block Valve would remain operable. Spurious closure of the PORV Block Valve is of no consequence for Safe Shutdown.

25. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.
26. Decay Heat Suction Valves DH11 & DH12 are normally closed and required to be closed for High/Low Interface until going into DHR, at which time DH11 and DH12 are open and the valves depowered under normal plant operations. Generic Letter 86-10 states that for a high-low interface MOV, a hot short needs to be considered on all three phases in the proper sequence. The power cables (three-phase 480V) for DH11 and DH12 are routed in individual dedicated conduits in Containment until the conduits reach the Penetration Boxes. The Penetration Boxes are separated by over 100 ft. For a fire in Containment to damage both power cables such that each receive an internal hot short of the proper voltage and polarity without grounding is highly unlikely. Hence, a breach of this interface is not a concern. To go into DHR, manually open Bypass Valves DH21 & DH23 for Cold Shutdown.
27. Valves RC200, RC239A, RC239B and RC4632 may be affected by a fire in this area. Manual Valve RC147 (located in Containment, outside the D-Rings) will be closed to provide a High/Low Pressure Interface. This manual action need not be taken for 8-hours because the Quench Tank has sufficient capacity to hold the discharge from this line for at least 8-hours. The Makeup System is available and capable of maintaining RCS inventory with these valves open.
28. Essential CCW is provided to the Makeup Pumps, bypassing CC1460.
29. NOT USED
30. The DHR Cooler 1-1(1-2) Isolation Valve CC1467(CC1469) is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467(CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467(CC1469).

FIRE AREA D TABLE 1 NOTES

31. Failure of Circuit 1CBE1155D may result in spurious opening of DH2735. However, DH2736 is unaffected by a fire in this area and remains available for a High/Low Pressure Boundary Interface.
32. The following instrumentation may be lost, but in each case, there is redundant instrumentation available which is unaffected:

<u>INSTRUMENT LOST</u>	<u>TRAIN</u>	<u>REDUNDANT INSTRUMENT</u>
NI-5874C	1	NI-5874A
NI-NI1	2	NI-5875A
NI-NI2	1	NI-5874A

TI-RC4A2	2	TI-RC4A4
TI-RC4B2	1	TI-RC4B4

33. Level Indicators LI-SP09A1 and LI-SP09B1 remain available to monitor the level of each steam generator.
34. NOT USED
35. Letdown coolers 1 and 2 (E25-1 and E25-2) are passive mechanical components in an area with low combustible loading.
36. The Reactor Coolant System Code Safety Valves (RC13A and RC13B) are passive mechanical components in an area with low combustible loading.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: DD

TRAIN ACCREDITED FOR SHUTDOWN: 1

4.6.DD.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM NO.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT ²)	DETECTION Y/N	SUPPRESSION MAN/AUTO
422A	CABLE SPREADING ROOM	129,035	Y	AUTO

.....

4.6.DD.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA DD

The following components are located in fire area DD.
See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
--------	-------	-----------	------	-------------

NONE

.....

FIRE AREA DD

4.6.DD.3 Fire Propagation Control

Fire Area DD is the Cable Spreading Room (Room 422A), as shown on Drawing A-224F.

A fire that originates in this fire area will be contained in the fire area.

The floors, walls and ceilings are reinforced concrete or 12 inch concrete block construction having a fire resistance rating of 3-hours.

Not all of the structural steel in Room 422A is adequately fire-proofed. Analysis was performed which demonstrates that the structural steel in this area will not fail in a fire, based on the type of combustible loading (mainly cables) and the automatic wet-pipe sprinkler system.

4.6.DD.4 Fire Detection and Suppression

Fire Area DD is provided with an automatic fire detection system (FDZ 422A).

Fire Area DD is provided with a dual feed automatic wet-pipe sprinkler system.

Manual fire suppression equipment is provided for this area. Fire extinguishers and Hose Stations (HS) are shown on Drawing A-224F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.DD.5 Fire Area DD Safe Shutdown Summary

Train 1 will be used for Safe Shutdown in Fire Area DD. Safe Shutdown will be accomplished from the Auxiliary Shutdown Panel using the Makeup and Purification System (MUPS) for Reactor Coolant System inventory control, a Letdown path, and Seal Injection for RCP Seal Cooling. The RCP seals will be restaged using flow through the RCP Seal Return line.

LEGEND

H - required for hot standby

C - required for cold shutdown

H/L - High/Low interface

B - valve maintains boundary isolation

N/A - not affected

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA DD TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, partial suppression, and exemption request.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the three-phase motor-operated component are the same, spurious operation is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals, the minimum requirements of NRC IEN 84-09 are met).

(This note cannot be referenced for control circuits susceptible to maloperation due to shorts, opens, or grounds or to High/Low Interface valves where multiple faults are considered).
6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1 and Motor Control Centers (supplied from E1 & F1) which will prevent upstream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA DD TABLE 1 NOTES

9. NOT USED
10. RCP Seal Integrity is maintained by re-establishing Seal Return, Seal Injection and Letdown. Inventory Control will be maintained using Makeup Train 1 and Letdown.
11. MUPS is assured for SSD; therefore this component is not needed for SSD.
12. The AFW Pump 1 Discharge to SG 2 Valve AF3869 is normally closed. This valve could spuriously open and will need to be manually closed to prevent overfilling SG-2, after operating the LOCAL/REMOTE disconnect switch in CDE11E.
13. The AFW Pump 1 Discharge to SG 1 Valve AF3870 is normally open and required to be open for Safe Shutdown. This valve could spuriously close thereby stopping flow to SG 1. Therefore, Trip Breaker D107 at D1PA and open AF3870.
14. AFW Pump 2 Discharge to SG 1 Valve AF3871 is normally closed. This valve could spuriously open. AFW Pump 2 Discharge to SG 2 Valve AF3872 is normally open and AFPT 2 P14-2 could start on SFRCS actuation. In order to avoid overfilling either steam generator, trip the throttle valve on AFPT 2.
15. The AFW to SG 1 Isolation Valve AF608 is normally open and required to be open for Safe Shutdown. The Control Circuit is normally isolated by a separate control switch in the Control Room. A review of the circuits shows, with the circuit isolated, spurious closure would require two hot shorts which is not considered credible. Therefore, no actions are required.
16. The AFWP 1 Flow Control Valve AF6452 is open and required to modulate for Safe Shutdown. A review of the circuit in this fire area shows that the potential exists for loss of control to this valve. Therefore, fail open this valve by depowering the valve at D1P (Breaker D1P3) and use ICS038B via manual control at the ASP to control SG 1 level. A review of the circuit for AFPT 1 Steam Admin Valve ICS038B shows that manual control of ICS038B can be regained at the ASP by transferring control at the ASP.
17. The AFPT Main Steam Inlet Valve MS106 is normally closed and is required to be open for Safe Shutdown. A review of the circuit in the fire area shows that a fire in this area could prevent the opening of or spuriously close MS106. Therefore, trip Breaker D135 at D1NA and open MS106.
18. The AFPT 1-2 Main Steam Cross-Connect Valve MS107A is normally open to provide a steam supply to AFPT 1-2. For a fire in this area, no credit is taken for AFPT 1-2 and the steam output from SG 1-1 is such that it's capacity is sufficient to run the AFW Pump Turbine 1-1 even with flow through MS107A. During cooldown at lower temperatures, the flow diversion could effect AFPT Pump 1 capacity. With the throttle valve for AFPT 1-2 tripped, steam flow past MS107A will be insignificant. Therefore, no action is required.

FIRE AREA DD TABLE 1 NOTES

The AFPT 1-1 Main Steam Cross-Connect Valve MS106A is normally open to provide a steam supply to AFPT 1-1 for a fire in this area. No credit is taken for SG 2, since any steam from SG 2 to AFPT 1-1 will not affect the operation of AFPT 1-1 and AFPT 1-2 is tripped to prevent overfilling SG 2. Therefore, no action is required.

19. The AFWP Turbine 1 Steam Admission Valve MS5889A is an air-operated valve which is normally closed and required to be open for Safe Shutdown. Review of the circuit indicates a hot short can prevent the valve from opening. Fail open the valve by isolating and venting the air off the valve.
20. Containment Air Cooler Fan C1-1 is required for Safe Shutdown. A review of the circuit indicates that the potential exists for loss of control as well as spurious stopping of Fan C1-1, for a fire in this area. The control circuits can be isolated by manually placing the disconnect switch in Cabinet CDE12A-1 in the LOCAL position. CAC Fan C1-1 can be manually started in slow speed by placing the control switch on the BE1401 door in the SLOW position.
21. A review of the circuits shows that spurious operation (either open or closed) and loss of control is possible. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control
For restoring Letdown, trip Breaker BF1227 at F12A and open CC1409.
22. The CCW Inlet Isolation Valves CC1411A, B and Outlet Isolation Valves CC1407A, B are normally open and required to be open for Safe Shutdown to restore Letdown. A review of the circuits shows that spurious closure is possible. For restoring Letdown, trip the respective breakers and open/verify open CC1407A, B, and CC1411A, B.
23. The CCW Return Header 1 Valve CC2645 is normally open and required to be open to provide cooling to the Seal Return Coolers. A review of the circuits shows that spurious closure is possible. Open Breaker BE1161 at E11D and open/verify open CC2645.
24. The DHR Cooler 1-1 Isolation Valve CC1467 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown (See Note 26).
25. Not Used
26. The CCW to Nonessential Isolation Valve CC1495 is normally opened and required to be open for Seal Return. A review of the circuits indicates that a hot short may cause this valve to remain open. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened when the DHR coolers are not in service. (NOTE: Verify CC1467(CC1469) is closed before opening CC43 and that CC42 (manual isolation valve) and CC43 are closed before opening CC1467(CC1469).
27. The CCW Line 1 Inlet and Return Isolation Valves CC5095 and CC5097 are normally open and required to be open to provide cooling for Letdown Coolers. A review of the

FIRE AREA DD TABLE 1 NOTES

circuits indicates that spurious closure is possible. Trip breakers BE1226 and BE1227 at E12A and manually open CC5095 and CC5097.

28. CCW Pump P43-1 is aligned to CCW Train 1 and is required to be operable for Safe Shutdown. Based on a review of the circuits, control of the pump can be regained locally after operation of disconnect switch at C1 Bus.
29. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A, CF01B before going below 700 psig.
30. The Control Room Emergency Ventilation System (CREVS) is required to be operable to maintain Control Room habitability. If CREVS is lost, the operators can evacuate the Control Room for a fire in this area and shut down the plant from outside the Control Room.
31. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication. (See Note 12).

Due to loss of power to Train 1, (Ch 1/3), Train 2 (Ch 2/4), and loss of SFAS prefabricated cables, SFAS could actuate. This actuation could operate the following components:

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530,1531	CS Iso Vlv	Open	Stop P56-1, 2
P42-2	LPI Pump 2	On	Trip Bkr AD112 at D1

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
MU59D	RCP 1-2 Seal Rtn Vlv	Closed	Open MU59D and Trip BE1178 at E11B
MU66A	RCP 2-1 Seal Inj Vlv	Closed	Open MU66A
MU66B	RCP 2-2 Seal Inj Vlv	Closed	Open MU66B
MU66C	RCP 1-1 Seal Inj Vlv	Closed	Open MU66C
MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

32. The LPI Line 1 Valve DH01B is normally open and is required to be open for Cold Shutdown. The control circuit is normally isolated by an isolation switch in the Control Room and a review of the circuits show with the circuit isolated, spurious closure is not possible. However, control and indication can be maintained by operating Disconnect Switch CDE-11A which will provide control and indication at local controller.
33. NOT USED
34. To prevent spurious operation of Valves DH09A, DH7A, and DH7B are deenergized.
35. The DH Normal Suction Valves DH11 and DH12 are normally closed and depowered during plant operation. A review of the circuits indicates loss of control power is possible. Since the DHR System is only required operable for Cold Shutdown, manually open Inlet Isolation Valves (DH11 & 12) or Bypass Valves DH21 & DH23.
36. The Decay Heat Removal (DHR) Suction 1 Valve DH1517 is closed during normal operation but required open for DHR Cold Shutdown. A review of the circuits indicates the Disconnect Switch at CDE-11D will regain local control at NVDH1517. Transfer Disconnect Switch to local. (NOTE: DH2733 should be verified closed prior to opening DH1517).
37. The Decay Heat Pump 1 BWST Suction Valve DH2733 is normally open but required to be closed prior to going into DHR cooldown. A review of the circuits indicates control of the valve may be lost. Therefore, trip Breaker BE1121 at MCC E11A and close DH2733. Due to the torque/limit switches possibly being bypassed by a hot short, the valve operator may be damaged. If this occurs, procedures instruct plant personnel to remove the operator, replace it with a dedicated spare operator, and then manually close the valve. Since this valve is only needed to go to cold shutdown, GL 86-10 allows repairs to be made.
38. DH Auxiliary Spray Stop Valve (DH2735) and Throttle Valve (DH2736) are normally closed and one of them is to be closed when starting DHR Cooldown, to prevent Pressurizer Quenching. A review of the circuits indicates that 2 hot shorts (1 per valve) are required for both valves to spuriously open. This is not a credible event. (NOTE: If Aux Spray is required, local control can be regained by transferring the Disconnect Switches (CDE-11B-1 for DH2735 and CDF-11A-2 for DH2736) to local and using Local Switches NVDH2735 and NVDH2736).
39. The LPI/HPI Crosstie Valve DH64 is normally closed and is required closed for DHR Cooldown. A review of the circuit indicates spurious opening is possible. Transfer

FIRE AREA DD TABLE 1 NOTES

control on CDE-11E to local and verify DH64 is closed prior to use of DHR. Due to the torque/limit switches possibly being bypassed by a hot short, the valve operator may be damaged. If this occurs, procedures instruct plant personnel to remove the operator, replace it with a dedicated spare operator and then manually close the valve. Since this valve is only needed to go to cold shutdown, GL 86-10 allows repairs to be made.

40. DHR Pump 1 P42-1 is required to be operable for cooldown to Cold Shutdown. A review of the circuit indicated the pump could spuriously start or be made inoperable. However, local control can be regained by transferring the Disconnect Switches to local at C1 and using the local controller to start the pump.
41. Letdown Cooler Inlet Valve MU02B is normally open and needed open to restore Letdown. A review of the circuits indicates that control power is lost in this fire area but can be regained locally by transferring the disconnect switch to local. Transfer Disconnect Switch on CDE-11B-1 to local and control MU02B at MCC E11B.
42. The EDG 1 Air Start Solenoid Valves DA1147A/B are normally closed and are required to open to provide starting air to the air motors. A review of the circuits indicates the circuits can be disconnected from the Cable Spread Area and Control Room. Disconnect and repower the circuits using the disconnect switch at C3621 and start diesel locally.
43. Emergency Diesel Generator 1 is normally stopped and is required to run due to Loss of Offsite Power. Disconnects and redundant fuses are installed to allow isolation at CSR or CTRL Room. Disconnect and repower the circuits using the disconnect at C3621. Operate the Diesel locally.
44. Essential Power supplies C1 and E1 are required to be operable for Safe Shutdown. A review of the circuits indicates that not all of the circuits can be isolated from the Cable Spread Room or Control Room. The Ammeter circuit for E1 is from a current transformer. A short or open on this circuit will not affect E1 (loss of indication only). Disconnect Control Room circuits by locally operating disconnect switch at C1 and E1.
45. Neutron Flux Monitoring Cabinet (Ch 1)(C4808) is required to provide Source Range Indication for a fire in the Control/Cable Spread Room.

Monitor source range indication at C4808 (Room 402).
46. Control Cabinets C5759C, CC5763A, C5799, and C5760D provide power to NNI Instrumentation. However, redundant NNI Instrumentation is available at the Auxiliary Shutdown Panel (C3630).
47. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS:

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow

FIRE AREA DD TABLE 1 NOTES

Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW Flow to the accredited steam generator may be required.

48. Reactor Protection System Panel and Source Range Monitoring NI-NI2 and NI-5874A are required to be operable to monitor source range flux. A failure of the circuits would disable monitoring capability in the Control Room. Monitor Source Range at C4808 (NI-5874C)(See Note 45).
49. The Low Voltage Switchgear Room 429 HVAC Damper HV5305A & B are normally closed and required to be open for Safe Shutdown. A review of the circuits indicates loss of power to the dampers is possible. Analysis shows that only 1 damper has to be opened manually after 1-hour. Open HV5305B.
50. Atmospheric Vent Valve ICS11B is normally closed and is required to be throttled for Safe Shutdown. A circuit failure or loss of air can disable the remote operation of this valve. SFRCS actuation will ensure the valve remains closed until local manual action is taken. The Main Steam Safety Line Valves will provide a steam release path until local manual control for ICS11B is achieved. Manually operate ICS11B in Room 500.
51. The Main Steam Isolation Valves (MSIV) MS100 and MS101 are normally open and required to be closed for Safe Shutdown. Each MSIV has 5 separate solenoids which need to be open for the MSIV to remain open. A review of the circuits for the solenoid shows that a credible number of hot shorts to [reopen or] keep the MSIV's open is not possible. Closing the MSIV's in the Control Room before leaving and de-energizing YE2 and YF2 by opening Breakers BE1180 on E11B and BF1101 on F11A, or its upstream supply, (de-energizing Ch 3/4 of SFRCS) (See Note 47) to de-energize the solenoid valves will close MS100 and MS101.
52. In order to reduce water to the Clean Waste Receiver Tanks, align Makeup Pump P37-1 Recirc to the BWST. Manually open HP29, and HP1556 and then open MU208 and close MU206.
53. Seal Injection, Seal Return and Letdown (including lineup to Clean Waste Receiver Tanks) are required for Safe Shutdown for a fire in this area. A review of the circuits for the following valves indicate manual operation is required:

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA DD TABLE 1 NOTES

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>ACTION</u>
MU10A	Mxd Bed 1-1 LtDn In Vlv	Trip Bkr BE2262 at E22B & Open MU10A

WC3560	Degasifier Bypass Valve	Open

54. The Makeup Pump 1 (P37-1) and its Lube Oil Pumps P-371B & D are required to be available for Safe Shutdown for a fire in this area. A review of the circuits indicates that control of the pumps can be regained locally after transferring the disconnects. Operate the pumps locally. (NOTE: Since Lube Oil Pump P-371B is available, Lube Oil Pump P-371C is not required.)
55. Makeup Flow Indicators FI-6435 are used to monitor makeup flow. A review of the circuits indicates that FI-6425 and FI-6435 may not work. Monitor Pressurizer Level via LI-RC14-1 at the ASP as an indirect means of measuring makeup flow.
56. Pressurizer Level, Pressurizer Pressure, SG1-1 Startup Level, SG 1-1 Pressure Indication, RCS Loop 1 Pressure, and SG 2 Startup Level and SG 2 Pressure Indication will be monitored at the Auxiliary Shutdown Panel (ASP). The SG 1 Level and Pressure indicators on the ASP are used to read the SG 2 Level and Pressure by transferring the two-position selector switch on the ASP from SG 1 to SG 2. The cable/connector for the SG 2 pressure signal is manually connected to the selector switch only during unit shutdown (for testing) or during a fire event to ensure that channel separation is maintained. This type of repair is similar to the repair for Hot and Cold Leg Temperature instrumentation documented in the NRC SER (Ref. 2.5.R).
57. RCS Loop 1 Hot and Cold Leg Temperatures and RCS Loop 2 Hot and Cold Leg Temperatures will be monitored locally using a portable instrument. Acceptability of this repair is documented in the NRC SER (Ref. 2.5.R).

FIRE AREA DD TABLE 1 NOTES

58. The Pilot-Operated Relief Valve (PORV) RC2A is normally closed and is required to remain closed to preclude RCS Blowdown to the Pressurizer Quench Tank. Review of the circuits shows that a fire-induced failure of cables for the PORV could result in the inadvertent spurious opening of the valve.

The PORV Block Valve RC11 is normally open and is required closed for Shutdown purposes in the event the PORV spuriously opens. Therefore, in the event of a fire in the Cable Spreading Room or Control Room, Valve RC11 should be closed by means of the Control Switch HIS-RC11 (C5705) prior to evacuating the Control Room. Afterwards, the circuits need to be isolated from the influence of a fire by operating a Disconnect Switch at CDE-16B, thus ensuring control and indication at MCC E16B.

59. Valves RC200, RC239A, RC239B, and RC4632 may be affected by a fire in this area. Manual Valve RC147 (located in Containment, outside the D-Ring) will be closed to provide a High/Low Pressure Interface. This manual action need not be taken for 8-hours because the Quench Tank has sufficient capacity to hold the discharge from this line for at least 8-hours. Even if this flow path were opened, no unrecoverable condition would result because the restricting orifice is sized such that one Makeup Pump could easily handle the flow.

60. RCS Loop 1 and Loop 2 High Point Vent Valves (RC4608A, B and RC4610A, B respectively) are normally closed and are required to remain closed in order to prevent uncontrolled blowdown via the High Point Vents. Each pair of valves per loop are in series and both would be required to open for blowdown to the containment atmosphere to occur.

Fire damage to the D cable for Valves RC4608A and RC4610A cannot spuriously open the respective valve due to the open control switch in the Control Room. Hence, fire damage to these cables is inconsequential with regards to breach of a High/Low Pressure Interface.

In order for spurious actuation of Valves RC4608A, B or RC4610A, B to occur, 2 concurrent hot shorts of the proper polarity without grounding to the C cable would be required. Since these valves are aligned in series, an inadvertent breach of a High/Low Pressure Interface could only occur in the event of 4 specific concurrent hot shorts of the proper polarity. Such an occurrence is not credible. Loss of control power to C5799 will cause loss of power to RC4608A, B which cannot cause spurious opening of the valves.

Hence, fire damage of the cables for RC4608A, B and RC4610A, B is concluded not to be a concern from the point of view of breaching a High/Low Pressure Interface.

61. Either SWS Pump P3-1 or P3-3, whichever is aligned to Train 1 SWS at the time of the fire, is required for Safe Shutdown. A review of the circuits shows that control can be regained locally by Disconnecting the Control Room circuits (DSA and DSB Switch at C1) and controlling the pump locally. (NOTE: For P3-3, also transfer disconnect at CD and reclose Breaker ACD4. The trip function of this breaker may be disabled.
62. Containment Air Cooler (CAC) 1 SW Inlet and Outlet Valves (SW1366 and SW1356) are required to be open to provide containment cooling. A review of the circuits indicates

FIRE AREA DD TABLE 1 NOTES

spurious operation and loss of control power is possible for a fire in this area. Therefore, open Breaker BE1142 at E11C and open/verify open SW1366. Open SW1356 by isolating and bleeding off the air to the valve.

63. AFP1 Suction Valve SW1382 is normally closed and is required to be closed until the Condensate Storage Tanks are low and then opened to supply water to the S/G's. Transfer control to the ASP. Due to the torque/limit switches possibly being bypassed by a hot short, the valve may be damaged such that the valve can not be opened. If this occurs, procedures instruct plant personnel to provide an additional source of water from the Fire Water System. Since this valve is only needed to go to cold shutdown, GL 86-10 allows repairs to be made.
64. SW Nonessential Isolation Valve SW1399 may be opened under normal operation and this flowpath is required to be closed for Safe Shutdown to avoid SWP3-1 or P3-3 flow diversion. A review of the circuits indicates a fire in this area can disable control power and possibly damage SW1399 (Ref. 2.7.F). Close TPCW valves SW54, 55 and 56.
65. SW Discharge Valves to the Intake Structure (SW2929) and Forebay (SW2931) are 2 of 4 SW Discharge Valves SW2929 through SW2932, 1 of which is normally open and depowered (controlled administratively) to ensure SWS Discharge at all times.

The sole concern is that at least 1 of these valves remains open, thereby assuring a service water flow outlet. Since 1 of the valves is normally open and depowered, there is no concern associated with the possibility of spurious closure of SW2929 or SW2931 precluding SWS Discharge capability.
66. Essential CCW is provided to the Makeup Pumps, bypassing CC1460.
67. YE2 associated circuits are not coordinated. This results in loss of YE2. Loss of this panel will cause a Reactor Trip via ARTS which is acceptable.
68. The Letdown Block Orifice Isolation Valve MU04 is normally open and is required to be open to restore Letdown. A review of the circuit indicates spurious closure of this valve is possible. Therefore, trip Breaker BE2259 at E22B and verify open/open MU04.
69. NOT USED
70. SW Flow CCHX 1 Iso Valve SW1424 is normally open and required to be open for Safe Shutdown. Spurious closure of the valve is not possible due to control scheme design (see MOD 87-1315).
71. Letdown Cooler Inlet Iso Valves MU01A, B are normally open and required to be open after restoring Seal Injection (Note MU02B will be used to maintain High/Low Interface). A review of the circuits indicates spurious closure of the valves is possible. For restoring Letdown, trip Breaker BF1237 at F12A and open MU01A. (Note: Verify that MU01B is closed if CC1410 is closed).
72. Normally closed manual Valve SW325 maintains isolation for CAC 3.
73. Spurious opening of MU6420, MU32 Bypass Valve, could result in Makeup Pump 1

FIRE AREA DD TABLE 1 NOTES

runout. Direct diagnostic indication of Makeup Pump 1 runout is via pump discharge pressure indicator MU25A, locally at the pump. Maintaining a minimum pressure of 2260 psig assures a pump flow of less than 250 gpm and no pump runout condition (Ref. 2.6.O).

74. Spurious operation of the Motor Driven Feed Pump (MDFP) P241 is possible due to hot shorts on control cables in this fire area. Manual Operator Action to close locked valve FW6398 shall be taken to preclude overfill of the credited Steam Generator.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: DF

TRAIN ACCREDITED FOR SHUTDOWN: 1

4.6.DF.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM NO.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT2)	DETECTION Y/N	SUPPRESSION MAN/AUTO
427	NO.2 ELEC PENETRATION RM	49,447	Y	AUTO

4.6.DF.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA DF

The following components are located in fire area DF.

See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
ESSPWR	2	C4602	PNL	NEUTRON FLUX MON. CABINET (CH.2)
	2	CDF-11A-1	PNL	CONTROL DISCONNECT TRANSFER SWITCH
	2	F11A	MCC	480VAC MCC
	2	YF2	PNL	240/120VAC MCC

FIRE AREA DF

4.6.DF.3 Fire Propagation Control

Fire Area DF is located in the Auxiliary Building consisting of Room 427 (elev 603) as shown on Drawing A-224F.

A fire that originates in this fire area will be contained in the fire area. This fire area is enclosed by 3-hour rated concrete (except as noted below).

There are four Emergency Ventilation System ducts and one Containment Purge duct which pass through this fire area. The ductwork does not have a fire damper installed in the floor (to Fire Area A) or ceiling (to Fire Area EE). The duct-work does not have any opening in Room 427. Based on the combustible loadings, automatic wet-pipe sprinkler system and construction of the ductwork, a fire will not propagate from one fire area to another.

There are non-rated openings in the wall separating fire area DF and X. These non-rated openings have been evaluated and will not allow the propagation of a fire.

Room 427 has structural steel which does not have a 3-hour fire rating. Based on analysis of the combustible loadings and automatic wet-pipe sprinklers in the room, the steel will not fail.

4.6.DF.4 Fire Detection and Suppression

Fire Area DF consists of Room 427 which has a fire detection system, Fire Detection Zone FDZ 427 and an automatic wet-pipe sprinkler system.

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawing A-224F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.DF.5 Fire Area Safe Shutdown Summary

Train 1 will be used for Safe Shutdown in Fire Area DF. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and Seal Injection for RCP Seal Cooling.

LEGEND

H - required for hot standby

C - required for cold shutdown

H/L - High/Low interface

B - valve maintains boundary isolation

N/A - not affected

FIRE AREA DF TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA DF TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. Valves RC4610A & B are in series and 4 shorts would be required to repower both valves. See E-52B sht 71A & B. Such an occurrence is not credible. The one inch lines include a restricting orifice sized to limit the flow to within the Makeup System capacity.
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11B	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level set-point is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to lose of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-1	CS Iso Vlv LPI Pump 1	Open On	Stop P56-1, -2 Stop P42-1 from the CR after blocking SFAS

MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

Trip Breaker BE1146 at E11B before closing AF3871 and trip Breaker D135 at D1NA before manually opening MS106.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

FIRE AREA DF TABLE 1 NOTES

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

CC5095	Trip Bkr BE1226 at	MU182	Close
	E12A & open CC5095	MU214	Close
CC5097	Trip Bkr BE1227 at	MU216	Throttle
	E12A & open CC5097	WC119	Open
MU97	Open	WC120	Open

The following valves may also need to be operated manually:

CC1409	Open	MU02B	Open
MU01A	Trip Bkr BF1237 at	MU10A	Open
	F12A & open MU01A	MU11	Align to CWRT

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU206 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A, before going below 700 psig. In addition, if action were required to deenergize MCC F11A (located in the fire area), Breaker BF115 on MCC F1 could be tripped to deenergize the MCC. All equipment powered via MCC F11A is Train 2 equipment and therefore not required for this fire area.
23. NOT USED
24. Essential CCW is provided to the Makeup Pump Cooler, by-passing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-1 Isolation Valve CC1467 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

FIRE AREA DF TABLE 1 NOTES

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).

27. AF3871 may spuriously open or close upon a hot short to its control circuits. AF3871 may not be able to be opened or closed upon an open circuit. This is of no consequence, however, unless AFWP 2 is in use. Since this is a Train 1 Shutdown area, AFWP 2 is not used for SSD. AF3871 may spuriously actuate due to a loss of power to SFRCS Actuation Channel 2. If this occurs, AFWP 2 will be tripped (See Note 14).
28. Loss of power to PAMS Panels C5763A & C5799 would result in loss of PI6365B, TI-RC3B5, and TI-RC3B6. PI-RC2B4 is available for RCS Pressure Indication and TI-RC3B2 is available for RCS Temperature Indication.
29. A review of EWD E-52B, Sheet 11, showed that a fire-induced failure of the circuits for the Pressurizer Vent Header Valve RC200 could not result in the spurious opening of the valve.

A breach of the Pressurizer Vent Header High/Low Pressure Interface can only occur in the event of a 3-phase-to-phase uninterrupted hot short of the proper polarity of the Power Cable (2PBF1285J) for Valve RC200 (which is only possible at Containment Penetration P2P5FX) in conjunction with, at a minimum, one additional uninterrupted hot short to cables for either Valve RC239A, B or RC4632. The probability of such an occurrence (4 hot shorts) is extremely low.

30. Although P371C may be affected by a fire in this area, the MUP 1 Main Lube Oil Pump (P371B) remains available to provide lubrication for the Makeup Pump.
31. DH Aux Spray Valve DH2736 is normally closed and required to be closed when going into DHRS to prevent depressurization if DH2735 is also open. A review of the circuits indicates that DH2736 could spuriously open. Since DH2735 is not affected by a fire in this area, no action is required.
32. YBU is the normal power supply for C5759C and is not required for shutdown in this area as other indicators are available.
33. Normally closed manual Valve SW325 maintains isolation for CAC 3.
34. Spurious opening of MU6420, MU32 Bypass Valve, could result in Makeup Pump 1 runout. Direct diagnostic indication of Makeup Pump 1 runout is available in the Control Room via Makeup Flow Indicators, FI-6425 and FI-6435.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: DG

TRAIN ACCREDITED FOR SHUTDOWN: 2

4.6.DG.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM No.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT ²)	DETECTION Y/N	SUPPRESSION MAN/AUTO
402	NO. 1 ELEC PENETRATION RM	24,767	Y	AUTO

4.6.DG.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA DG

The following components are located in fire area DG.
See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION
ESSPWR	1	C4808	PNL	NEUTRON FLUX MON. CABINET (CH. 1)
	1	E11E	MCC	480VAC MCC
	1	E16B	MCC	480VAC MCC
	1	RC4801	PNL	DC CONT PWR TO RC4801 (MU6405, MU6407)
NI	1	NI-5874C	IND	LOCAL SOURCE RANGE IND

FIRE AREA DG

4.6.DG.3 Fire Propagation Control

Fire Area DG is located in the Auxiliary Building consisting of Room 402 (elevation 603) as shown on Drawing A-224F.

A fire that originates in this fire area will be contained in the fire area. This fire area is enclosed by 3-hour rated concrete (except as noted below).

Room 402 has structural steel which does not have a 3-hour fire rating. Based on analysis of the combustible loadings and automatic wet-pipe sprinklers in the room, the steel will not fail.

4.6.DG.4 Fire Detection and Suppression

Fire Area DG consists of Room 402 which has a fire detection system (Fire Detection Zone FDZ 402) and an automatic wet-pipe sprinkler system.

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawing A-224F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.DG.5 Fire Area Safe Shutdown Summary

Train 2 will be used for Safe Shutdown in Fire Area DG. Safe Shutdown will be accomplished using the High Pressure Injection System (HPIS) along with the Pressurizer Sample/Vent Header for Reactor Coolant System Inventory Control, the Makeup and Purification System for a Letdown path and HPI Seal injection for RCP Seal Cooling.

B - valve maintains boundary isolation

N/A - not affected

FIRE AREA DG TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates that High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent upstream breakers from tripping on a ground.

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11A	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 HP02A, B	CS Iso Vlv HPI 2 Disch Iso Vlv	Open Open	Stop P56-1, -2 Operate from the CR after blocking SFAS

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

HP27	Open	MU214	Close
MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU208	Open	WC120	Open

FIRE AREA DG TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

CC1410	Open	MU10A	Open
MU01B	Open	MU11	Direct flow to CWRT
MU02B	Open		

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01B before going below 700 psig.
23. NOT USED
24. Essential CCW is provided CCW to the Makeup Pump Cooler, by-passing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-2 Isolation Valve CC1469 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).
27. AF3869 may spuriously open or close upon a hot short to its control circuits. AF3869 may not be able to be opened or closed upon an open circuit. This is of no consequence, however, unless AFWP 1 is in use. Since this is a Train 2 Shutdown area, AFWP 1 is not used for SSD. AF3869 may spuriously actuate due to a loss of power to SFRCS actuation Channel 1. If this occurs, AFWP 1 will be tripped (See Note 14).
28. Spurious closure and/or failure to close is possible for RC11. RC200 in conjunction with RC239A will be used for Depressurization to allow HPI. RC2A is available as the High/Low Pressure Interface.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA DG TABLE 1 NOTES

29. RC4608B is in series with normally closed Valve RC4608A. RC4608A is relied upon as the High/Low Pressure Interface since RC4608A has no circuits or power supply in this fire area.

FIRE AREA DH

4.6.DH.3 Fire Propagation Control

Fire Area DH is located in the Auxiliary Building consisting of the Main Steam Area (elev 643') as shown on Drawings A-226F and A-227F.

A fire that originates in this fire area will be contained in this fire area. This fire area is enclosed by 3-hour rated concrete floors and walls (except external walls as noted below).

The Pressure Doors 601 and 602 are not UL listed (separate Fire Area DH from Fire Area HH) fire doors. Based on the low combustible loading and construction of the doors, a fire will not propagate from one fire area to the other.

The Floor Hatch (Door 607) between Room 600 (Fire Area DH) and Room 500 (Fire Area EE) is not a UL listed door. Based on the low combustible loadings and construction of this hatch, a fire will not propagate from one fire area to the other.

The Containment Exhaust Duct penetrates the floor of Room 600 (Fire Area DH) into Room 500 (Fire Area EE). Based on the low combustible loadings and construction of the ductwork, a fire will not propagate from one fire area to the other (See Reference for details).

The Train 1 Safe Shutdown equipment (Steam Generator Safeties and Atmospheric Vent Valve) is separated from the Train 2 Safe Shutdown equipment (Steam Generator Safeties and Atmospheric Vent Valve) by over 200 ft. horizontal distance with minimal intervening combustible. Therefore, a fire would not spread from one train of equipment to the other train.

4.6.DH.4 Fire Detection and Suppression

There is no automatic fire detection in this fire area.

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawings A-226F and A-227F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.DH.5 Fire Area Safe Shutdown Summary

Trains 1 and 2 are accredited for Safe Shutdown in Fire Area DH due to presence of both Trains of Main Steam Safety Valves as well as circuits for both Trains of the Control Room Emergency Ventilation System and the Atmospheric Vent Valves are in this fire area. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and Seal Injection for RCP Seal Cooling.

Manual actions may also be required to close the appropriate valve(s) or trip the appropriate Auxiliary Feedwater (AFW) Pump Turbine to terminate AFW Flow to the steam generator associated with the nonaccredited Train.

FIRE AREA DH TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent upstream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA DH TABLE 1 NOTES

9. NOT USED
10. The separation of cables and equipment and associated nonsafety circuits of redundant trains are separated by a horizontal distance of more than 200 ft. with no intervening combustibles or fire hazards.
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:
- | | |
|----------|-----------|
| ICS11A/B | Throttle* |
| WC1743 | Open |
| WC1747 | Open |

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action.

* These valves are manually repositioned by personnel standing outside Fire Area DH by remote mechanical actions. Therefore, entry into the fire area is not required for manual operation.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components:

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B)

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

If AF3869 is manually closed, first trip Breaker BE1146 at E11E.

15. NOT USED
16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

FIRE AREA DH TABLE 1 NOTES

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

Additionally, the following valves may need to be manually operated:

CC1410	Open	MU02B	Open
CC2645	Open	MU10A	Open
CC2649	Open	MU11	Align to CWRT
MU01B	Open		

RCS Inventory Control

Either Train of MUPS is available for RCS Inventory Control. After transferring Makeup Suction to the BWST, MU203 (Train 2) or MU206 (Train 1) will be manually closed after opening HP29, HP1556 and MU208 to route MUPS Recirc to the BWST rather than the Makeup Tank or Clean Waste System to conserve water.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A and CF01B before going below 700 psig.
23. The DHR Cooler Isolation Valves CC1467 and CC1469 are normally closed. These valves fail open on loss of air. However, these valves are required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS Cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467(CC1469).
24. There are no Train 1 CREVS cables in Room 602. For a fire in Room 602, Train 1 is used for Shutdown.

FIRE AREA DH TABLE 1 NOTES

Circuit 2CBF1132B could be affected by a fire in this area, disabling SW2928. CREVS Train 1 and SW2927 can be used if SW2928 is not available.

- 25. NOT USED
- 26. Decay Heat Suction Valves DH11 & 12 are normally closed and depowered at all times. Manual Bypass Valves DH21 & 23 are opened for Cold Shutdown.
- 27. NOT USED
- 28. Essential CCW is provided to the Makeup Pumps, bypassing CC1460.
- 29. NOT USED
- 30. Failure of Circuit 1PD135A would result in inability to remotely operate MS106; therefore, manually operate MS106. Failure of Circuit 2PBF1124A or 2CBF1124B would result in inability to remotely operate MS107; therefore, trip Breaker BF1124 at F11A and manually operated MS107.

FIRE AREA DUCT

4.6.DUCT.1 Fire Area Description

Fire Area DUCT is made up of several conduit Duct Banks used to route cables to various parts of the plant. These Duct Banks are located below grade.

4.6.DUCT.2 Safe Shutdown Equipment In Fire Area DUCT

There is no Safe Shutdown equipment located in this area. All Safe Shutdown cables are located in conduits surrounded by concrete.

4.6.DUCT.3 Fire Propagation Control

Fire Area DUCT is made up of several Duct Banks that are used to connect various areas of the plant. These Duct Banks are made up of either steel or PVC conduits surrounded by concrete. Each conduit is separated from surrounding conduits by at least 2 inches of concrete. The Duct Banks are below grade and surrounded by earth except at the ends where they terminate. Therefore, a fire in any one conduit would, at best, only damage the cables in that conduit.

4.6.DUCT.4 Fire Detection and Suppression

There is no fire detection or automatic suppression in the Duct Banks.

4.6.DUCT.5 Fire Area DUCT Safe Shutdown Summary

Fire Area DUCT is made up of several Duct Banks with multiple conduits in each Duct Bank. Based on the design of the Duct Banks, a fire could not damage more than the cables in one conduit. This will limit loss of equipment to only one Train and a small portion of that Train. Therefore, Safe Shutdown can be accomplished using existing plant procedures and no detailed Safe Shutdown analysis is required.

SWS	1	SW1382	MOV	AFP 1 SUCT VLV FROM SW

FIRE AREA E

4.6.E.3 Fire Propagation Control

Fire Area E is located in the Auxiliary Building (below the Heater Bay) consisting of Room 237 (elev 565') as shown on Drawing A-222F and A-223F.

A fire that originates in this fire area will be contained in the fire area. This fire area is enclosed by 3-hour rated concrete barriers (except as noted below).

The south wall of Room 237 contains a 14-inch pipe penetration which interfaces with Room 124 (Fire Area A). This penetration is required in order to avert the consequences of a flooding condition in Room 237. The line is open ended in Room 237 and extends into Room 124 where it terminates in a 14-inch water-style check valve. Based on the construction and low combustible loadings, a fire will not propagate from one fire area to another.

There are two ventilation openings in the ceiling of Room 237 (floor of Room 326, Fire Area II). These openings are not provided with fire dampers. Analysis shows that these openings will not affect Safe Shutdown.

Flood Door 215 separates Room 237 from Room 238 (Fire Area F) and is not a UL listed fire door. Based on the construction of the door and the low combustible loadings, a fire will not propagate from one fire area to the other.

There are penetrations which have penetration seals that do not meet the tested configurations. These non-rated openings have been evaluated and will not allow the propagation of a fire.

Room 237 has structural steel which does not have a 3-hour fire rating. A detailed analysis shows that the steel will not fail based on the combustible loading in the room.

4.6.E.4 Fire Detection and Suppression

Fire Area E consists of Room 237 which has fire detection (Fire Detection Zone 237).

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawings A-222F and A-223F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.E.5 Fire Area Safe Shutdown Summary

Train 2 will be used for Safe Shutdown in Fire Area E. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and Seal Injection for RCP Seal Cooling.

FIRE AREA E TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent upstream breakers from tripping on a ground.

E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA E TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11A	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level set-point is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

If AF3871 is manually closed, first trip Breaker BF1201 at F12A.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

Additionally, the following valves may need to be manually operated:

CC1410	Open	MU10A	Open
MU01B	Open	MU11	Direct flow to CWRT
MU02B	Open		

FIRE AREA E TABLE 1 NOTES

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU203 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01B before going below 700 psig.
23. NOT USED
24. Essential CCW is provided to the Makeup Pump Cooler, bypassing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 will therefore be manually operated to place the DHR System in service.
26. The DHR Cooler 1-2 Isolation Valve CC1469 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is airoperated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469)).
27. AF3869 may spuriously open or close upon a hot short to its control circuits. AF3869 may not be able to be opened or closed following an open circuit. Valves MS106 and MS106A will be closed to stop AFWP 1 and prevent feeding the unaccredited steam generator.
28. MS106A may spuriously close; this is of no consequence since its purpose is to supply steam to AFWP 1 (P14-1) and AFWP 1 is not used for SSD in this fire area. If SFRCS spuriously starts AFWP 1 due to loss of power to SFRCS actuation Channel 1, MS106 and MS106A will be manually closed (and Breaker D135 at D1NA and BE1271 at E12B tripped) to stop AFWP 1 and prevent feeding the unaccredited steam generator.
29. For components that are relied upon for Safe Shutdown, the ammeter/over-current protection cables and the power cables are free of fire damage. This ensures that a fire

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA E TABLE 1 NOTES

cannot cause a loss of an entire Safe Shutdown Train (e.g. Essential Switchgear Bus C1 or D1) due to a power cable fault and a simultaneous loss of overcurrent protection on the same scheme. These circuits do not impact Safe Shutdown for the following reasons:

<u>System</u>	<u>Component</u>	<u>Power Cable</u>	<u>AM & 50/51 Cable Justification</u>
CCWS	P43-3	1PAC108A Outside Fire Area	1CAC108B Not Req'd for Train 2 SSD

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA EE

4.6.EE.3 Fire Propagation Control

Fire Area EE is located in the Auxiliary Building, consisting of the Auxiliary Building Ventilation Equipment Area (Fan Alley) (elev 623') as shown on Drawing A-225F.

A fire that originates in this fire area will be contained in this fire area.

This fire area is enclosed by 3-hour rated concrete barriers (except as noted below).

The Floor Hatch (Door 607) between Room 500 (Fire Area EE) and Room 600 (Fire Area DH) is not a UL listed door. Based on the low combustible loadings and construction of the hatch, a fire will not propagate from one fire area to the other.

The Containment Purge Duct penetrates the ceiling of Room 500 (fire Area EE) into Room 600 (Fire Area DH) and the floor of Room 500 into Room 303PC (Fire Area AB).

Based on the low combustible loadings and construction of the ductwork, (no opening in Room 500), a fire will not propagate from one fire area to the other.

There are four Emergency Ventilation System Ducts and one Containment Purge Duct which pass through the floor of Room 501 (Fire Area EE) from Room 427 (Fire Area DF). The ductwork does not have a fire damper installed at the floor. Based on the low combustible loadings, automatic wet-pipe sprinkler system and construction of the ductwork, a fire will not propagate from one fire area to another.

Room 500 has structural steel which has fire-proofing that does not conform with the UL details for a 3-hour fire rating. A detailed analysis shows that the steel will not fail based on the combustible loading in this room.

Room 501 has structural steel which has fire-proofing that does not conform with the UL details for a 3-hour fire rating. Based on analysis of the combustible loadings and the automatic wet-pipe sprinklers in this room, the steel will not fail.

Door 517 in Room 501 has had its latch removed and is held closed by two blow-out fasteners. This was to provide a vent path for postulated high energy line breaks. Based on automatic wet-pipe sprinkler protection, low combustible loading, a fire will not spread to Room 514 (Fire Area II).

Room 515 has structural steel which does not have a 3-hour fire rating. The steel supports the ceiling which is not a fire barrier, but has Safe Shutdown conduits embedded in the concrete.

A detailed analysis shows that the steel will not fail based on the combustible loading analysis of the room.

4.6.EE.4 Fire Detection and Suppression

Fire Area EE consists of several rooms. The following areas have fire detection:

1. Radwaste & Fuel Handling HVAC Area, Room 500, Fire Detection Zone FDZ 500

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA EE

2. Radwaste Exhaust Fan Room, Room 501, Fire Detection Zone FDZ 501
3. Purge Exhaust Equipment Room, Room 515, Fire Detection Zone FDZ 515

Room 501 is provided with an automatic wet-pipe sprinkler system

Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations (HS) are shown on Drawing A-225F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.EE.5 Fire Area Safe Shutdown Summary

Train 1 will be used for Safe Shutdown in Fire Area EE. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and Seal Injection for RCP Seal Cooling. The Motor-Driven Feed Pump will be used to supply Auxiliary Feedwater to Steam Generator 1.

FIRE AREA EE TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA EE TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:
- | | |
|--------|------|
| WC1743 | Open |
| WC1747 | Open |

CC1495 also fails closed on loss of air. Manual Solenoid Valve CC42 and Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output Channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-1	CS Iso Vlv LPI Pump 1	Open On	Stop P56-1, -2 Stop P42-1 from the CR after blocking SFAS

MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

15. NOT USED

16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA EE TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

CC2645	Trip Bkr BE1161 at E11D and open CC2645	CC1409 MU01A	Open Open
CC5095	Trip Bkr BE1226 at E12A and open CC5095	MU01B MU10A	Open Open
CC5097	Trip Bkr BE1227 at E12A and open CC5097	MU11	Align to CWRT

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU206 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B have been deenergized.
19. NOT USED
20. NOT USED
21. YE2/YF2 associated circuits are not coordinated. This results in loss of YE2/YF2. The loss of this panel will cause a reactor trip via ARTS which is acceptable.
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A before going below 700 psig.
23. Circuit 1PBE1617A is an alternate feed to Y3. The primary feed is still available.
24. Essential CCW is provided to the Makeup Pump Cooler, bypassing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 will therefore be manually operated to place the DHR System in service.
26. The DHR Cooler 1-1 Isolation Valve CC1467 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467(CC1469) is closed before opening CC43 and that CC42 and CC43 are closed before opening CC1467(CC1469).

27. For this fire area, the Motor-Driven Feed Pump will be used to supply feedwater to Steam Generator SG 1-1. The Motor-Driven Feed Pump will take suction from the Condensate Storage tanks. In order to prevent overfilling Steam Generator SG 1-2, trip

FIRE AREA EE TABLE 1 NOTES

Auxiliary Feedwater Pumps P14-1 and P14-2 and close Manual Valve FW6397 Motor-Driven Feed Pump to SG 2 Discharge Isolation Valve (Flow Control Valve FW6459 could fail open due to loss of power).

Spurious actuation of the SFRCS feed-only-good SG signal from the pressure sensors or actuation of SFRCS as a result of loss of the unaccredited Train 2 power to SFRCS can be rectified by tripping the AFW Pumps P14-1 and P14-2. Operation of the Motor-Driven Feed Pump is not adversely affected by SFRCS actuation.

28. The only SSD equipment powered from E16A or E16B are the PORV Block Valve, RC11 and the Inverter Y3. Since the PORV (RC2A) is available as a High/Low Pressure Interface, loss of power to RC11 is of no concern. Loss of Y3 causes SFAS to initiate, but SFAS initiation is assumed in Appendix R analysis (See Note 13).
29. NOT USED
30. Circuit 1PBE1616A is an alternate feed to Y1. The primary feed is still available.
31. The CCW Surge Tank is a metal tank filled with water and there is very low combustible loading in the area of the tank.
32. The solenoid valve for ICS11B is normally energized so that the valve positioner can control the valve. A hot short to this circuit would result in the solenoid remaining energized. An open circuit would result in loss of air to the air operator. ICS11B would then remain closed, but would be unable to be opened from the Control Room. This is the same effect as a loss of Instrument Air. Procedure OP-02501 addresses manual operation of ICS11B for this fire area.
33. NOT USED
34. RC239A is in series with RC200 and is not affected by a fire in this fire area. It can be relied upon for the High/Low Pressure Interface.
35. Opening Breaker HBBB at Bus B and repowering Buses D2, F7, and F71 will be required before placing the Motor-Driven Feed Pump in service.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: EF

4.6.EF.1 Fire Area Description

Fire area EF consists of the Emergency Feedwater Facility (EFWF), which is a reinforced concrete structure with an integral Emergency Water Storage Tank (EWST). The EFWF is a separate building, located west of the Auxiliary Building, and contains the major equipment for the Emergency Feedwater System (EFWS).

4.6.EF.2 Safe Shutdown Systems In Fire Area EF

There are no Safe Shutdown components or cables in this fire area.

4.6.EF.3 Fire Propagation Control

This fire area is inside of a robustly constructed concrete building, comprised primarily of 36 inch poured concrete walls with a minimum 24 inch thick poured concrete roof. The Diesel Fuel Oil Tank Room (Room 461) and Battery Room (Room 462) are each separated from the rest of the rooms by 3-hour rated walls, floors, and penetration seals. The outside doors are not fire-rated.

This fire area is a separate building from the power block, and therefore provides the equivalent of 3-hour separation between fire areas containing safe shutdown equipment.

4.6.EF.4 Fire Detection and Suppression

Fire area EF consists of five (5) rooms on three different elevations. The entire fire area has fire detection capability. An automatic sprinkler system covers this entire fire area except the Electrical Equipment Room (Room 460) and Battery Room (Room 462). Manual fire suppression equipment is provided for this fire area. Fire extinguishers and Hose Stations are shown on drawing A-232F.

4.6.EF.5 Fire Area Safe Shutdown Summary

There are no safe shutdown components or cables in this fire area. Therefore, safe shutdown is not affected by a fire in this area.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE HAZARDS ANALYSIS

FIRE AREA EVALUATION

FIRE AREA: F

TRAIN ACCREDITED FOR SHUTDOWN: 1

4.6.F.1 FIRE AREA DESCRIPTION

Room numbers and fire protection features for this fire area are as follows:

ROOM No.	ROOM DESCRIPTION	COMBUSTIBLE LOADING (BTU/FT2)	DETECTION Y/N	SUPPRESSION MAN/AUTO
238	AUX FEED PUMP 1-2 ROOM	13,542	Y	MAN

4.6.F.2 SAFE SHUTDOWN SYSTEMS IN FIRE AREA F

The following components are located in fire area F.

See Appendix B-2 for a list of circuits / cables in this fire area.

SYSTEM	TRAIN	COMPONENT	TYPE	DESCRIPTION

HVAC	2	C73-2	FAN	AFP RM VENT FAN 2

FIRE AREA F

4.6.F.3 Fire Propagation Control

Fire Area F is located in the Auxiliary Building (below the Heater Bay) consisting of Room 238 (elev 565') as shown on Drawing A-222F and A-223F.

A fire that originates in this fire area will be contained in the fire area. This fire area is enclosed by 3-hour rated concrete barriers (except as noted below).

The south wall of Room 238 contains a 14-inch pipe penetration which interfaces with Room 124 (Fire Area A). This penetration is required in order to avert the consequences of a flooding condition in Room 238. The line is open ended in Room 238 and extends into Room 124 where it terminates in a 14-inch water-style check valve. Based on the construction and low combustible loadings, a fire will not propagate from one fire area to another.

There are two ventilation openings in the ceiling of Room 238 (floor of Room 326, Fire Area II). These openings are not provided with fire dampers. Analysis shows that these openings will not affect Safe Shutdown.

Flood Door 215 separates Room 238 from Room 237 (Fire Area E) and is not a UL listed fire door. Based on the construction of the door and the low combustible loadings, a fire will not propagate from one fire area to the other.

There are penetrations which have penetration seals that do not meet the tested configurations. These non-rated openings have been evaluated and will not allow the propagation of a fire.

Room 238 has structural steel which does not have a 3-hour fire rating. A detailed analysis shows that the steel will not fail based on the combustible loading in the room.

4.6.F.4 Fire Detection and Suppression

Fire Area F consists of Room 238 which has fire detection (Fire Detection Zone 238).

Manual fire suppression equipment is provided for this fire area. Fire extinguish and Hose Stations (HS) are shown on Drawings A-222F and A-223F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.F.5 Fire Area Safe Shutdown Summary

Train 1 will be used for Safe Shutdown in Fire Area F. Safe Shutdown will be accomplished using the Makeup and Purification System (MUPS) for Reactor Coolant System Inventory Control, a Letdown path and Seal Injection for RCP Seal Cooling.

H/L - High/Low interface

B - valve maintains boundary isolation

N/A - not affected

FIRE AREA F TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent upstream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA F TABLE 1 NOTES

9. NOT USED
10. NOT USED
11. NOT USED
12. Due to loss of Instrument Air, the following valves must be manually operated for Safe Shutdown:

ICS11B	Throttle
WC1743	Open
WC1747	Open

CC1495 also fails closed on loss of air. Manual Bypass Valve CC43 will be operated.

At least 30-minutes are available to complete the manual action unless otherwise noted.

13. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Complimentary Channels, SFAS could actuate. This actuation could operate the following components.

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530, 1531 P42-1	CS Iso Vlv LPI Pump 1	Open On	Stop P56-1, -2 Stop P42-1 from the CR after blocking SFAS
P42-2 P56-1	LPI Pump 2 CS Pump 1	On On	Trip Bkr AD112 at D1 Stop P56-1 from the CR after blocking SFAS

MU02A	RC Lt Dn Cooler Out	Closed	Open MU02A and Trip BE1171 at E11B
MU03	RC Lt Dn Cooler Out	Closed	Open MU03
MU38	RCP Seal Rtn Isol	Closed	Open MU38
MU59A	RCP 2-1 Seal Rtn Vlv	Closed	Open MU59A and Trip BE1174 at E11B

FIRE AREA F TABLE 1 NOTES

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
MU59B	RCP 2-2 Seal Rtn Vlv	Closed	Open MU59B and Trip BE1175 at E11B
MU59C	RCP 1-1 Seal Rtn Vlv	Closed	Open MU59C and Trip BE1177 at E11B
MU59D	RCP 1-2 Seal Rtn Vlv	Closed	Open MU59D and Trip BE1178 at E11B
MU66A	RCP 2-1 Seal Inj Vlv	Closed	Open MU66A
MU66B	RCP 2-2 Seal Inj Vlv	Closed	Open MU66B
MU66C	RCP 1-1 Seal Inj Vlv	Closed	Open MU66C
MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D

14. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS.

The steam generator level control and steam generator level indication for the nonaccredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B).

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW flow to the accredited steam generator may be required.

Trip the following breakers before operating the following valves:

<u>Valve</u>	<u>Breaker</u>
MS107	BF1124 at F11A
MS107A	BF1188 at F11B

15. NOT USED
16. RCP Seal Integrity is maintained by prompt restoration of seal cooling, or by performing a plant cooldown to below 350 degrees F as discussed in section 3.6.3. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control.

RCP Seal Return, Seal Injection and Letdown Flow

The following manual valves will need to be operated:

MU97	Open	MU216	Throttle
MU182	Close	WC119	Open
MU214	Close	WC120	Open

FIRE AREA F TABLE 1 NOTES

Additionally, the following valves may need to be manually operated:

CC1409	Open	MU10A	Open
MU01A	Open	MU11	Align to CWRT
MU02B	Open		

RCS Inventory Control

After transferring the Makeup suction to the BWST, MU206 will be manually closed after opening MU208, HP29, and HP1556 to route MUPS Recirc to the BWST rather than the Makeup Tank.

17. NOT USED
18. To prevent spurious operation, Valves DH09A and DH09B are deenergized.
19. NOT USED
20. NOT USED
21. NOT USED
22. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A before going below 700 psig.
23. NOT USED
24. Essential CCW has been provided to the Makeup Pump Cooler, bypassing CC1460.
25. Valves DH11 and DH12 are depowered. Bypass Valves DH21 and DH23 can be manually operated to place the DHR System in service.
26. The DHR Cooler 1-1 Isolation Valve CC1467 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS cooldown.

The CCW to Nonessential Isolation Valve CC1495 is normally opened. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened. (NOTE: Verify CC1467(CC1469) is closed before opening CC43 and that CC43 is closed before opening CC1467 (CC1469).

FIRE AREA FF

4.6.FF.3 Fire Propagation Control

Fire Area FF consists of the Control Room complex and is located in the Auxiliary Building (EI 623') as shown on drawing A-225F.

A fire that originates in this fire area will be contained in the fire area.

The floors, walls and ceilings are reinforced concrete or concrete block having a fire resistance rating of 3-hours (except as noted below).

The block walls into the elevator shaft (Fire Area UU) do not meet a tested configuration. Based on the low combustible loading and the construction of the block walls, a fire will not propagate from one fire area to the other.

Door 509 (separating II from FF) is not a UL fire Door. This door is a steel double door, used as part of the pressure boundary for the Control Room and was built to UL standards for a fire door. Based on the door's design and construction and the low combustible loading in the area, a fire will not propagate from one fire area to the other.

The structural steel fireproofing in rooms 502, 505, and 510 is not installed in accordance with the UL design in that the attachments (e.g. conduit supports) are not adequately fire-proofed. These rooms are provided with a noncombustible suspended acoustic tile ceiling below the structural steel. Based on the minor deficiencies in the fire-proofing, the low combustible loading and the barrier provided by the ceiling tiles, a fire in this area will not cause failure of the structural steel.

The Control Room (Room 505) and Control Cabinet Room (502) are separated from Rooms 503 (Operator Study Room), 504 (Control Room Kitchen), 509 (Control Room Passage), 510 (Computer Room), 511 (Shift Supervisor's Office), 512 (Administrative Assistant's Office), and 513 (Toilet) by 1-hour fire-rated walls.

There are several small penetrations which do not conform to tested configurations. Based on the construction and low fire loadings, a fire will not pass through these penetrations.

The Control Room is protected from and does not contain high-energy equipment such as switchgear, power transformers, rotating equipment, or potential sources of missiles or pipe whip. The separation distance between redundant Class 1E equipment and circuits internal to the control board is discussed in section 8 of the USAR.

Analog signal isolation devices, with individual power supplies, are provided between the sensing channel and the logic channel. Digital signal isolation devices are provided between the logic channel trip bistables and the output modules of the actuation channel.

Physical separation between redundant channels of the RPS is accomplished by locating each redundant channel in a separate cabinet assembly. The cabinet assembly provides physical protection of the cabinet internal equipment from external hazards such as missiles and fire. All openings between the Cable Spreading Room and RPS cabinets through which RPS cables pass, are sealed to prevent the passage of fire, smoke and fumes. These seals are silicone foam base.

FIRE AREA FF

Internal to the RPS cabinets, the separation of redundant channels is maintained by isolation device circuits. The isolation device circuits have been tested and analyzed to protect against short circuits, open circuits, grounds, and the application of AC or DC potential.

The isolation device circuits include the isolation device, internal wiring, an field wiring connection terminal strips. The isolation device is an isolation amplifier for analog signals and a relay for digital signals. The isolation device circuit internal wiring and field connection terminal strips have the same characteristics (flame retardancy, maximum operating temperature, dielectric strength) as the wiring and terminal strips used internally within the cabinets for 1E service.

5.FF.4 Fire Detection and Suppression

Fire Area FF consists of various rooms. The following rooms have detection.

1. Control Cabinet Room 502 with detectors in Panels C5715, C5716, C5717 and C5718, Fire Detection Zone FDZ 505
2. Operator Study Room, Room 503, Fire Detection Zone FDZ 505
3. Kitchen, Room 504, Fire Detection Zone FDZ 505
4. Control Room, Room 505, Fire Detection Zone FDZ 505
5. Toilet, Room 506, Fire Detection Zone FDZ 505
6. Shift Supervisor's Office, Room 507, Fire Detection Zone FDZ 505
7. Shift Manager's Office, Room 511, Fire Detection Zone FDZ 505
8. Computer Room, 510 (one below floor), Fire Detection Zone FDZ 505
9. Shift Supervisor Administrative Assistant's Office, Room 512, Fire Detection Zone FDZ 505
10. Toilet, Room 513, Fire Detection Zone FDZ 505

Manual fire suppression equipment is provided for this area. Fire extinguishers and Hose Stations (HS) are shown on Drawing A-225F.

In the event of a fire, isolation and smoke venting will be accomplished in accordance with the Pre-Fire Plans.

4.6.FF.5 Fire Area FF Safe Shutdown Summary

Train 1 will be used for Safe Shutdown in Fire Area FF. Safe Shutdown will be accomplished from the Auxiliary Shutdown Panel using the Makeup and Purification System (MUPS) for Reactor Coolant System inventory control, a Letdown path, and Seal Injection for RCP Seal Cooling. The RCP seals will be restaged using flow through the RCP Seal Return line.

Davis-Besse Unit 1 Fire Hazard Analysis Report

FIRE AREA FF TABLE 1 NOTES

1. 1-hour fire wrap provided with room detection and suppression. An asterisk indicates the circuit is embedded and adequate separation exists with detection and suppression or low combustible loadings.
2. 20 ft. horizontal separation between redundant trains with suppression, detection, and no significant intervening combustibles or fire hazards, or separation by an equivalent distance around a fire retardant barrier.
3. 3-hour fire wrap provided (or a radiant energy shield inside Containment, as noted).
4. 20 ft. separation, detection and room suppression.
5. The circuit is not required for Safe Shutdown for one of the following reasons:
 - a. The circuit provides indicating lights only.
 - b. The normal, failed, and desired SSD positions of the component are the same; spurious operation of three-phase power circuits is incredible.
 - c. The solenoid/relay and isolating contact(s) is (are) outside the fire area and spurious operation due to a hot short on one side of the circuit and a simultaneous ground on the other is considered incredible.
 - d. The power supply is not needed for Safe Shutdown to operate the component.
 - e. Failure of the low level instrument cable will not prevent SSD (e.g. SFAS analog inputs, SFRCS pressure switches, AFW modulating valve digital signals; the minimum requirements of NRC IEN 84-09 are met).

(This note is not referenced for control circuits susceptible to maloperation due to a single short, open, or ground or for power and control circuits for High/Low Pressure Interface valves).

6. Associated circuit coordination exists, see Appendix C-3. An asterisk indicates that it is assumed that the Associated Circuits related to MOV's are considered to have no impact since they are not expected to be in operation. Spurious operation of the valve coincident with a short on the power cable is not considered credible.

A double asterisk indicates High Impedance Ground Fault protection for the 480V AC Switchgear (E1 & F1) and Motor Control Centers (supplied from E1 & F1) which will prevent up-stream breakers from tripping on a ground.

E11A	E12A	E15	F11A	F12B	F15
E11C	E12B	E16A	F11C	F12C	F16A
E11D	E14		F12A	F14	

7. This backup component is not needed for SSD in this fire area.
8. NOT USED

FIRE AREA FF TABLE 1 NOTES

9. NOT USED
10. RCP Seal Integrity is maintained by re-establishing Seal Return, Seal Injection and Letdown. Inventory Control will be maintained using Makeup Train 1 and Letdown.
11. MUPS is assured for SSD. Therefore, this component is not needed for SSD.
12. The AFW Pump 1 Discharge to SG2 Valve AF3869 is normally closed. This valve could spuriously open and may not be able to be manually closed (Ref. 2.7.F) thereby supplying Feedwater to SG2. The AFW Pump capacity is sufficient to provide flow to both SG's. However, to avoid overfilling SG2 which is not utilized for Shutdown in this area, AF599 needs to be closed.
13. The AFW Pump 1 Discharge to SG1 Valve AF3870 is normally open and required to be open for Safe Shutdown. This valve could spuriously close thereby stopping flow to SG1. Therefore, Trip Breaker D107 at D1PA and open AF3870.
14. The AFW Pump 2 Discharge to SG1 Valve AF3871 is normally closed. This valve could spuriously open. AFW Pump 2 Discharge to SG2 Valve AF3872 is normally open and AFPT 2 P14-2 could start on SFRCS actuation. In order to avoid overfilling either steam generator, trip the throttle valve on AFPT 2.
15. The AFW to SG 1 Isolation Valve AF608 is normally open and required to be open for Safe Shutdown. The Control Circuit is normally isolated by a separate control switch in the Control Room. A review of the circuits shows, with the circuit isolated, spurious closure would require two hot shorts which is not considered credible. Therefore, no actions are required.
16. The AFWP 1 Flow Control Valve AF6452 is open and required to modulate for Safe Shutdown. A review of the circuit in this fire area shows that the potential exists for loss of control to this valve. Therefore, fail open this valve by depowering the valve at D1P breaker and use ICS038B via manual control at the ASP to control SG 1 level. A review of the circuit for AFPT 1 Governor Control Valve ICS038B shows that manual control of ICS038B can be regained at the ASP.
17. The AFPT Main Steam Inlet Valve MS106 is normally closed and is required to be open for Safe Shutdown. A review of the circuit in the fire area shows that a fire in this area could prevent the opening of or spuriously close MS106. Therefore, open Breaker D135 at D1NA and open MS106.
18. The AFPT 1-2 Main Steam Cross-Connect Valve MS107A is normally open to provide a steam supply to AFPT 1-2 for a fire in this area. No credit is taken for AFPT 1-2 and the steam output from SG1-1 is such that the capacity is sufficient to run the AFW Pump Turbine 1-1 even with flow through MS107A. During cooldown at lower temperatures, the flow diversion could effect AFP Pump 1 capacity. With the throttle valve for AFPT 1-2 tripped, steam flow by MS107A will be insignificant. Therefore, no action is required.

The AFPT 1-1 Main Steam Cross-Connect Valve MS106A is normally open to provide a steam supply to AFPT 1-1 for a fire in this area. No credit is taken for SG 2, since any

FIRE AREA FF TABLE 1 NOTES

steam from SG 2 to AFPT 1-1 will not affect the operation of AFPT 1-1 AFPT 1-2 is tripped to prevent overfilling SG 2. Therefore, no action is required.

19. The AFWP Turbine 1 Steam Admission Valve MS5889A is an air-operated valve which is normally closed and required to be open for Safe Shutdown. Review of the circuit indicates a hot short can prevent the valve from opening. Fail open the valve by isolating and venting the air off the valve.
20. Containment Air Cooler Fan C1-1 is required for Safe Shutdown. A review of the circuit indicates that the potential exists for loss of control as well as spurious stopping of Fan C1-1, for a fire in this area. The control circuits can be isolated by manually placing the disconnect switch in Cabinet CDE12A-1 in the LOCAL position. CAC Fan C1-1 can be manually started in slow speed by placing the control switch on the BE1401 door in the SLOW position.
21. A review of the circuits shows that spurious operation (either open or closed) and loss of control is possible. RCS Inventory control is maintained by a controlled plant cooldown if letdown is not available. Although RCP seal injection and letdown are not required for safe shutdown, they are detailed in the FHAR because availability of these systems simplifies safe shutdown and results in enhanced plant control. For restoring Letdown, trip breaker and open CC1409.
22. The CCW Inlet Isolation Valves CC1411A, B and Outlet Isolation Valves CC1407A, B are normally open and required to be open for Safe Shutdown to restore Letdown. A review of the circuits shows that spurious closure is possible. For restoring Letdown, trip the respective breakers and open/verify open CC1407A, B, and CC1411A, B.
23. The CCW Return Header Valve CC2645 is normally open and required to be open for Safe Shutdown to restore the Seal Return Coolers. A review of the circuits shows that spurious closure is possible. Therefore, open breaker for CC2645 and open/verify open CC2645.
24. The DHR Cooler 1-1 Iso Valve CC1467 is normally closed. This valve fails open on loss of air. However, this valve is required to be closed when CCW is aligned to the Seal Return Coolers and opened for DHRS Cooldown (See Note 26).
25. Not Used
26. The CCW to Nonessential Isolation Valve CC1495 is normally opened and required to be open for Seal Return. A review of the circuits indicates that a hot short may cause this valve to remain open. CC1495 is air-operated and fails closed on loss of air. Manual bypass Valve CC43 will be opened when the DHR coolers are not in service. (NOTE: Verify CC1467 (CC1469) is closed before opening CC43 and that CC42 (manual isolation valve) and CC43 are closed before opening CC1467 (CC1469).
27. The CCW Line 1 Inlet and Return Isolation Valves CC5095 and CC5097 are normally open and required to be open for provide cooling for Letdown Coolers. A review of the circuits indicates that spurious closure is possible. Trip breaker and manually open CC5095 and CC5097.

FIRE AREA FF TABLE 1 NOTES

28. CCW Pump P43-1 is aligned to CCW Train 1 and is required to be operable for Safe Shutdown. Based on a review of the circuits, control of the pump can be regained locally after operation of Disconnect Switches at C1 Bus.
29. The Core Flood Isolation Valves CF01A, B are normally open and are required to be closed when cooling down before going below 700 psig. A review of the circuits indicates loss of control power to the valves. Breakers BF1120 at F11A and BE1162 at E11B are normally open; manual action may be required to close CF01A and CF01B before going below 700 psig.
30. The Control Room Emergency Ventilation System (CREVS) is required to be operable to maintain Control Room habitability. If CREVS is lost, the operators can evacuate the Control Room for a fire in this area and shut down the plant from outside the Control Room.
31. Shorts, opens, or grounds in SFAS Analog inputs cannot cause a change of state of the SFAS logic channels. All inputs are isolated so hot shorts will not affect the logic. Either a high or low SG level setpoint is adequate for SSD. SFAS actuated components will not change state unless both actuation output channels (Ch 1/3 or Ch 2/4) or the air supply (where needed) is lost. NNI provides SG level indication.

Due to loss of power to Train 1, (Ch 1/3), Train 2 (Ch 2/4, and loss of SFAS Cabinets, SFAS could actuate. This actuation could operate the following components:

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>EFFECT</u>	<u>ACTION</u>
CS1530,1531	CS Iso Vlv	Open	Stop P56-1
P56-1, 2	CS Pump 1, 2	On	Open Bkr P56-1, 2

MU66C	RCP 1-1 Seal Inj Vlv	Closed	Open MU66C
MU66D	RCP 1-2 Seal Inj Vlv	Closed	Open MU66D
MU02A	RC Lt Dn Cooler Out	Closed	Open MU02A
MU03	RC Lt Dn Cooler Out	Closed	Close then Open MU03
MU38	RCP Seal Rtn Isol	Closed	Open MU38

32. The LPI Line 1 Valve DH01B is normally open and is required to be open for Cold Shutdown. A review of the circuits shows that 3 hot shorts are required to spuriously close the valve. Two of the hot shorts are on the Isolation Switch, while the other hot short is on the Control Switch. This is not a credible event; hence, spurious closure is not possible. However, if required, control and indication can be maintained by

FIRE AREA FF TABLE 1 NOTES

operating the disconnect Switch at CDE-11A, which will provide control and indication at Local Controller.

33. NOT USED
34. To prevent spurious operation, Valves DH09A, DH9B, DH7A, and DH7B are deenergized.
35. The DH Normal Suction Valves DH11 and DH12 are normally closed and depowered during plant operation. A review of the circuits indicates loss of control power is possible. Since the DHR System is only required operable for Cold Shutdown, open Inlet Isolation Valves (DH11, 12) Bypass Valves DH21 and DH23.
36. The Decay Heat Removal (DHR) Suction 1 Valve DH1517 is closed during normal operation but required open for DHR Cold Shutdown. A review of the circuits indicates the Disconnect Switch at CDE-11D will regain local control. Transfer Disconnect Switch to local. (NOTE: DH2733 should be verified closed prior to opening DH1517).
37. The Decay Heat Pump 1 BWST Suction Valves DH2733 is normally open but required to be closed prior to going into DHR Cooldown. A review of the circuits indicates control of the valve may be lost. Therefore, trip Breaker BE1121 at MCC E11A and close DH2733. Due to the torque/limit switches possibly being bypassed by a hot short, the valve operator may be damaged. If this occurs, procedures instruct plant personnel to remove the operator, replace it with a dedicated spare operator and then manually close the valve. Since this valve is only needed to go to cold shutdown, GL 86-10 allows repairs to be made.
38. DH Auxiliary Spray Stop Valve (DH2735) and Throttle Valve (DH2736) are normally closed and one of them is to be closed when starting DHR Cooldown, to prevent Pressurizer Quenching. A review of the circuits indicates that 2 hot shorts are required for both valves to spuriously open. This is not a credible event. (NOTE: If Aux Spray is required, local control can be regained by transferring the Disconnect Switches (CDE-11B-1 for DH2735 and CDF-11A-2 for DH2736) to local and using Local Switches NVDH2735 and NVDH2736.)
39. The LPI/HPI Crosstie Valve DH64 is normally closed and is required to be closed for DHR cooldown. A review of the circuit indicates spurious opening is possible. Transfer control on CDE-11E to local and verify DH64 is closed prior to using DHR. Due to the torque/limit switches possibly being bypassed by a hot short, the valve operator may be damaged. If this occurs, procedures instruct plant personnel to remove the operator, replace it with a dedicated spare operator and then manually close the valve. Since this valve is only needed to go to cold shutdown, GL 86-10 allows repairs to be made.
40. DHR Pump P42-1 is required to be operable for cooldown to Cold Shutdown. A review of the circuit indicated the pump could spuriously start or be made inoperable. However, local control can be regained by transferring the Disconnect Switches to local at C1 and using the local controller to start the pump.
41. Letdown Cooler Inlet Valve MU02B is normally open and is needed open to restore Letdown. A review of the circuits indicates that control power is lost in the Control

FIRE AREA FF TABLE 1 NOTES

Room, but can be regained locally by transferring the Disconnect Switch to local. Transfer Disconnect Switch on CDE-11B-1 to local and control MU02B at MCC E11B.

42. The EDG 1 Air Start Solenoid Valves DA1147A/B are normally closed and are required to open to provide starting air to the air motors. A review of the circuits indicates the circuits can be disconnected from the Cable Spread Area and Control Room. Redundant fuses are installed to allow repowering. Disconnect and repower the circuits using the Disconnect Switch at C3621 and start diesel locally.
43. Emergency Diesel Generator 1 is normally stopped and is required to run due to Loss of Offsite Power. Disconnect and repower the circuits using the disconnect at C3621. Operate the Diesel locally. Disconnect and redundant fuses are installed to provide isolation at CSR and Control Room.
44. Essential Power supplies C1 and E1 are required to be operable for Safe Shutdown. Switches are installed to allow isolation from CSR and Control Room. The Ammeter circuit for E1 is from a current transformer. A short or open on this circuit will not affect E1 (loss of indication only). Disconnect Control Room circuits by locally operating disconnect switch at C1 and E1.
45. Neutron Flux Monitoring Cabinet (Chi 1) (C4808) is required to provide Source Range Indication for a fire in the Control/Cable Spread Room. Monitor source range indication at C4808 (Room 402).
46. Control Cabinets C5759C, C5760D and C5799 provide power to NNI Instrumentation. However, redundant NNI Instrumentation is available at the Auxiliary Shutdown Panel (C3630).
47. A loss of power to all four reactor coolant pumps will result in actuation of both Trains of the AFWS:

The steam generator level control and steam generator level indication for the non-accredited train may also be lost.

Spurious SFRCS signals in the nonaccredited train may result in opening AFWP Discharge Valve to the opposite steam generator (AF3869/AF3871) and/or AFW Flow Control Valve (AF6451/AF6452) which could then open the AFPT Steam Admission Valve (MS5889A/MS5889B). Due to spurious signal, isolation of AFW to the SG 1 is possible; Auxiliary Feedwater manual actions already identify/provide for this event.

Manual actions to close the appropriate valve(s) or trip the appropriate AFPT to terminate AFW flow to the steam generator associated with the nonaccredited train while maintaining AFW Flow to the accredited steam generator may be required.

48. Reactor Protection System Panel and Source Range Monitoring NI-NI2 and NI-5874A are required to be operable to monitor source range flux. A failure of the circuits would disable monitoring capability in the Control Room. Monitor Source Range at C4808 (NI-5874C) (See Note 45).
49. NOT USED

FIRE AREA FF TABLE 1 NOTES

50. Atmospheric Vent Valve ICS11B is normally closed and is required to be throttled for Safe Shutdown. A circuit failure or loss of air can disable the remote operation of this valve. SFRCS actuation will ensure the valve remains closed until local manual action is taken. The main steam line safeties will provide a steam release path until local manual control for ICS11B is achieved. Manually operate ICS11B in Room 500.
51. The Main Steam Isolation Valves (MSIV) MS100 and MS101 are normally open and required to be closed for Safe Shutdown. Each MSIV has 5 separate solenoids which need to be open for the MSIV to remain open. A review of the circuits for the solenoid shows that a credible number of hot shorts to keep the MSIV's open is not possible. Closing the MSIV's in the Control Room before leaving or de-energizing YE2 AND YF2 by opening Breakers BE1180 on E11B and BF1101 on F11A or its upstream supply, (de-energizing Ch 3/4 of SFRCS) (See Note 47) to de-energize the solenoid valves will close MS100 and MS101.
52. In order to reduce water to the Clean Waste Receiver Tanks, align Makeup Pump 37-1 Recirc to the BWST. Manually open MU208, HP29, and HP1556 and then close MU206.
53. Seal Injection, Seal Return and Letdown (including lineup to Clean Waste Receiver Tanks) are required for Safe Shutdown for a fire in this area. A review of the circuits for the following valves indicate manual operation is required:

<u>COMPONENT</u>	<u>DESCRIPTION</u>	<u>ACTION</u>
MU10A	Mxd Bed 1-1 LtDn In Vlv	On
MU11	Letdown to Radwaste 3-Way-Vlv	Align CWRT
MU19	Seal Inj Inlet Iso Vlv	Close MU214 and Throttle MU216

MU6421	Makeup CTMT Iso Valve	Verify Close
MU6422	Makeup CTMT Iso Vlv	Verify Open
WC119	Cln Wst Tk In Iso Vlv	Open
WC120	Cln Wst Tk In Iso Vlv	Open
WC1453	Cln Wste Pri Demin Inlet Vlv	Close
WC1743	Cln Wste Recvr Tk Iso Vlv	Open
WC1747	Cln Wste Recvr Tk Iso Vlv	Open
WC3560	Degasifier Bypass Valve	Open

54. The Makeup Pump 1 (P37-1) and its Lube Oil Pumps P-371B & D are required to be available for Safe Shutdown for a fire in this area. A review of the circuits indicates that control of the pumps can be regained locally after transferring the disconnects. Operate

FIRE AREA FF TABLE 1 NOTES

the pumps locally. (NOTE: Since Lube Oil Pump P-371B is available, Lube Oil Pump P-371C is not required.)

55. Makeup Flow Indicators FI-6425 and FI-6435 are used to monitor makeup flow. A review of the circuits indicates that FI-6425 and FI-6435 may not work. Monitor Pressurizer Level via LI-RC14-1 at the ASP as an indirect means of measuring makeup flow.
56. Pressurizer Level, SG 1-1 Startup Level, SG 1-1 Pressure Indication, RCS Loop 1 Pressure, and SG 2 Startup Level and SG 2 Pressure Indication will be monitored at the Auxiliary Shutdown Panel (ASP). The SG 1 Level and Pressure indicators on the ASP are used to read the SG 2 Level and Pressure by transferring the two-position selector switch on the ASP from SG 1 to SG 2. The cable/connector for the SG 2 pressure signal is manually connected to the selector switch only during unit shutdown (for testing) or during a fire event to ensure that channel separation is maintained. This type of repair is similar to the repair for Hot and Cold Leg Temperature instrumentation documented in the NRC SER (Ref. 2.5.R).
57. RCS Loop 1 Hot and Cold Leg Temperatures and RCS Loop 2 Hot and Cold Leg Temperatures will be monitored locally using a portable instrument. Acceptability of this repair is documented in the NRC SER (Ref. 2.5.R).
58. The Pilot-Operated Relief Valve (PORV) RC2A is normally closed and is required to remain closed to preclude RCS Blowdown to the Pressurizer Quench Tank. Review of the circuits shows that a fire-induced failure of cables for the PORV could result in the inadvertent spurious opening of the valve.

The PORV Block Valve RC11 is normally open and is required closed for Shutdown purposes in the event the PORV spuriously opens. Therefore, in the event of a fire in the Cable Spreading Room or Control Room, Valve RC11 should be closed by means of the Control Switch HIS-RC11 (C5705) prior to evacuating the Control Room. Afterwards, the circuits need to be isolated from the influence of a fire by operating a Disconnect Switch at CDE-16B, thus ensuring control and indication at MCC E16B.

59. Valves RC200, RC239A, RC239B and RC4632 may be affected by a fire in this area. Manual Valve RC147 (located in Containment, outside the D-Ring) will be closed to provide a High/Low Pressure Interface. This manual action need not be taken for 8-hours because the Quench Tank has sufficient capacity to hold the discharge from this line for at least 8-hours. Even if this flow path were opened, no unrecoverable condition would result because the restricting orifice is sized such that one Makeup Pump could easily handle the flow.
60. Valves RC4608A, B and RC4610A, B are in series and 4 shorts would be required to repower both valves. See E-52B sht 71A & B. Such an occurrence is not credible. The one inch lines include a restricting orifice sized to limit the flow to within the makeup system capacity.
61. Either SWS Pump P3-1 or P3-3, whichever is aligned to Train 1 SWS at the time of the fire, is required for Safe Shutdown. A review of the circuits shows that control can be regained locally by Disconnecting the Control Room circuits (DSA Switch at C1) and

FIRE AREA FF TABLE 1 NOTES

controlling the pump locally. (NOTE: For P3-3, also transfer disconnect at CD and reclose Breaker ACD4. The trip function of this breaker may be disabled).

62. Containment Air Cooler (CAC) 1 SW Inlet and Outlet Valves (SW1366, SW1356) are required to be open to provide containment cooling. A review of the circuits indicates spurious operation and loss of control power is possible for a fire in this area. Therefore, open the breaker [at E11C (SW1366)] and then open/verify open SW1366. Open SW1356 by isolating and bleeding off the air to the valve.
63. AFP 1 Suction Valve SW1382 is normally closed and is required to be closed until the Condensate tanks are low and then opened to supply water to the S/G's. Transfer control to the ASP. Due to the torque/limit switches possibly being bypassed by a hot short, the valve may be damaged such that the valve can not be opened. If this occurs, procedures instruct plant personnel to provide an additional source of water from the Fire Water System. Since this valve is only needed to go to cold shutdown, GL 86-10 allows repairs to be made.
64. SW Nonessential Isolation Valve SW1399 may be opened under normal operation and this flowpath is required to be closed for Safe Shutdown to avoid SWP1-3 or P3-3 flow diversion. A review of the circuits indicates a fire in this area can disable control power and possibly damage SW1399 (Ref. 2.7.F). Close TPCW valves SW54, 55 and 56.
65. SW Discharge Valves to the Intake Structure (SW2929) and Forebay (SW2931) are 2 of 4 SW Discharge Valves SW2929 through SW2932, 1 of which is normally open and depowered (controlled administratively) to ensure SWS Discharge at all times.

The sole concern is that at least one of these valves remains open, thereby assuring a service water flow outlet. Since one of the valves is normally open and depowered, there is no concern associated with the possibility of spurious closure of SW2929 or SW2931 precluding SWS Discharge capability.
66. Essential CCW is provided to the Makeup Pumps, bypassing CC1460.
67. YE2 associated circuits are not coordinated. This results in loss of YE2. Loss of this panel will cause a reactor trip via ARTS which is acceptable.
68. The Letdown block Orifice Isolation Valve MU04 is normally open and is required to be open to restore Letdown. A review of the circuit indicates spurious closure of this valve is possible. Therefore, verify open MU04.
69. NOT USED
70. SW Flow CCHX 1 Iso Valve SW1424 is normally open and required to be open for Safe Shutdown.
71. Letdown Cooler Inlet Iso Valves MU01A, B are normally open and required to be open after restoring Seal Injection (Note MU02B will be used to maintain High/Low Interface). A review of the circuits indicates spurious closure of the valves is possible. For restoring Letdown, trip breaker and open MU01A. (Note: Verify that MU01B is closed if CC1410 is closed).

FIRE AREA FF TABLE 1 NOTES

- 72. Normally closed manual Valve SW325 maintains isolation for CAC 3.
- 73. Spurious opening of MU6420, MU32 Bypass Valve, could result in Makeup Pump 1 runout. Direct diagnostic indication of Makeup Pump 1 runout is via pump discharge pressure indicator MU25A, locally at the pump. Maintaining a minimum pressure of 2260 psig assures a pump flow of less than 250 gpm and no pump runout condition. (Ref 2.6.O).
- 74. Spurious operation of the Motor Driven Feed Pump (MDFP) P241 is possible due to hot shorts on control cables in this fire area. Manual Operator Action to close locked valve FW6398 shall be taken to preclude overfill of the credited Steam Generator.
