Beaver Valley Power Station, Unit Nos. 1 and 2
Docket No. 50-334, License No. DPR-66
Docket No. 50-412, License No. NPF-73
Response to Request for Additional Information regarding a Request for an Amendment to Revise Technical Specification 5.6.3, "Core Operating Limits Report (COLR)" (EPID No. L-2020-LLA-0075)

By letter dated April 26, 2021 (ADAMS Accession No. ML21117A076), Energy Harbor Nuclear Corp. requested Nuclear Regulatory Commission (NRC) approval for a license amendment request (LAR). The proposed change would revise Technical Specification 5.6.3 to allow the use of feedwater venturis that have been normalized to prior leading edge flow meter measurements when calculating reactor thermal power. By email dated September 16, 2021 (ADAMS Accession No. ML21259A164), the NRC staff requested additional information regarding the proposed change. The Energy Harbor Nuclear Corp. response to the September 16, 2021, NRC request is provided in the attachment. The supporting calculation, FEN-CAL-17-0001, Revision 0, "Beaver Valley Units 1 & 2 Leading Edge Flow Meter 72 Hour Out of Service Interval," is provided in the enclosure.

There are no regulatory commitments contained in this submittal. If there are any questions or if additional information is required, please contact Mr. Phil H. Lashley, Manager, Fleet Licensing, at (330) 696-7208.

I declare under penalty of perjury that the foregoing is true and correct. Executed on October 27, 2021.

Sincerely,

Grabnar, John 19072
Site Vice President, Beaver Valley

Response to Request for Additional Information
Page 1 of 4

By letter dated April 26, 2021, (ADAMS Accession No. ML21117A076) Energy Harbor Nuclear Corp. submitted a license amendment request for Nuclear Regulatory Commission (NRC) review and approval. By email dated September 16, 2021, (ADAMS Accession No. ML21259A164) the NRC staff requested additional information to complete its review. Each request for additional information is presented below in bold type and is followed by the Energy Harbor Nuclear Corp. response.

RAI-1

Title 10 of the Code of Federal Regulations (10 CFR) Part 50 Appendix K, "ECCS Evaluation Models," allows for instrumentation uncertainties.

Section 2.1 of your license amendment request states that "The mass flow rate and feedwater temperature are displayed on the local display panel and transmitted to the plant process computer for use in the calorimetric measurement. Alarms are provided in the control rooms to alert operators should the systems require maintenance." What is the contingency plan in the event that the plant process computer fails?

Response:

Plant procedures 1OM-54.4.C1-3, "Daily Heat Balance" and 2OM-54.4.C1, "Daily Heat Balance," provide the step by step instructions for performing the daily power calorimetric for Units 1 and 2 respectively. These procedures include instructions on performing the plant power calorimetric measurement for each of the following: Heat Balance Calculation Using the Plant Computer System, Power Range Channel Gain Adjustments, Venturi Feedwater Flow Indication Manual Daily Heat Balance, Leading Edge Flow Meter (LEFM) Feedwater Flow Indication Manual Daily Heat Balance, and Feedwater Flow Channel Check.

These procedures provide the details for performing the daily heat balance and normalization of the nuclear instrumentation reactor protection setpoints. The procedures require channel checks to confirm instrumentation utilized for the daily heat balance are operating within allowances for deviations between channels. The procedures provide for alternate instrumentation should the primary sources of inputs to the daily heat balance be deemed out of service or unreliable, including equations for performing manual calculations when the plant computer is not available. Should the LEFM be out of service or unreliable, the procedures provide instructions on using the venturi indications along with the appropriate feedwater pressure and temperature inputs to calculate the daily heat balance.

These contingency plans have been in service and will remain in service with a revision to allow remaining at 2900 MWt for up to 72 hours once the LEFM has failed. Once a

LEFM AOT has expired the plants will reduce power to 2859 MWt when operating on a venturi based heat balance. The 72-hour AOT is contingent on the plant remaining above 90 percent rated thermal power (RTP) to prevent possible changes in venturi fouling conditions.

RAI-2

Title 10 of the Code of Federal Regulations (10 CFR) Part 50 Appendix K, "ECCS Evaluation Models" allows for instrumentation uncertainties.

Section 2.3 of your license amendment request, states that in order to avoid a reduction in thermal power when the LEFM systems are nonfunctional, an allowed outage time of 3 days (72 hours) for repairs are an established safety practice in the nuclear power industry.

Section 3.0 of your license amendment states that for Unit 1, the 72-hour change in the upper bounds of the dataset with a 95 percent probability and 95 percent confidence was calculated to be 0.2859 percent. Similarly, the 120-hour change was calculated to be 0.2892 percent.

For Unit 2, the 72-hour change in the upper bounds of the dataset with a 95 percent probability and 95 percent confidence was calculated to be 0.2360 percent. Similarly, the 120-hour change was calculated to be 0.2381 percent.

Please provide the statistical evaluations used to determine the upper bounds of the data set in both Beaver Valley Unit 1 and Unit 2 and demonstrate that the uncertainties observed in the data have been addressed in the analysis.

Response:

The plant-specific instrument uncertainties supporting Beaver Valley Power Station (BVPS) Unit 1 and Unit 2 power uprates were reviewed under separate amendment requests dated December 27, 2000 (ADAMS Accession No. ML003782095). These requests were approved by the NRC staff on July 20, 2001, by Amendment Nos. 239 and 120 to FirstEnergy Operating License Nos. DPR-66 and NPF-73 for BVPS-1 and 2, respectively (ADAMS Accession No. ML011910223). These amendments approved the implementation of the revised thermal design procedure and revisions to the reactor trip system and engineered safety feature actuation system trip setpoints and allowable values. In support of requests associated with amendment numbers 239 and 120, the plant-specific instrument uncertainty information was provided in two Westinghouse Topical Reports. These reports were titled, "Westinghouse Revised Thermal Design Procedure Instrument Uncertainty Methodology for FirstEnergy Nuclear Operating Company Beaver Valley Unit 1," WCAP-15264, Revision 3, December 2000, and "Westinghouse Revised Thermal Design Procedure Instrument Uncertainty Methodology for FirstEnergy Nuclear Operating Company Beaver Valley Unit 2,"

WCAP-15265, Revision 3, December 2000. These topical reports were submitted to the NRC via letter dated December 27, 2000 (ADAMS Accession No. ML003782095), as supplemented by letter dated June 9, 2001 (ADAMS Accession No. ML011640086). The uncertainties for determining the power calorimetric accuracy remain applicable as the instrumentation evaluated in the previously listed reports remain in use or has been replaced with hardware that has equivalent or better accuracy.

The statistical evaluation demonstrates that changes in the data that compare feedwater venturi indications to LEFM indications over a 72-hour period has an insignificant effect on the result of the daily heat balance, as the effect is in the third decimal place whereas the daily heat balance is reported to two decimal places. Likewise, calculations for a 120-hour period confirms that even after 120 hours any change in data remains within the third decimal place when calculating reactor power and thus is not visible to plant operators when adjusting the nuclear instrumentation setpoints. The 120-hour calculations were performed to confirm that the stability of the instrumentation remains acceptable when the venturi indication is normalized.

For both BVPS units, feedwater flow venturis have demonstrated high reliability with only a small degradation in operating accuracy over the period of a fuel cycle due to venturi fouling. This fouling has been estimated to cause a false high-flow measurement of about 0.3 percent over the course of an 18-month fuel cycle, resulting in a higher indicated reactor power level than actual, which is conservative.

BVPS Unit 1 remains within the 0.6 percent power calorimetric uncertainty analysis for the four path Check LEFM system for a small change noted over a 72-hour period and remains within the uncertainty allowance. BVPS Unit 2 is an eight path CheckPlus LEFM with an uncertainty better than the four path Check LEFM and continues to maintain 0.6 percent uncertainty over a 72-hour period.

The statistical analysis for determining the power calorimetric accuracy and data uncertainties based on feedwater fouling is provided in calculation, FEN-CAL-17-0001, Revision 0, "Beaver Valley Units 1 & 2 Leading Edge Flow Meter 72 Hour Out of Service Interval."

In summary, the analysis provided in calculation FEN-CAL-17-001, Revision 0, demonstrates that changes in the results over a 72-hour period remain conservative to 10 CFR 50 Appendix K, "ECCS Evaluation Models" which requires loss-of-coolant accident (LOCA) and emergency core cooling system (ECCS) analyses to assume that the reactor has been operating continuously at a power level of at least 102 percent. For BVPS Unit 1, a margin recovery of 1.4 percent RTP has been approved to allow for 100.6 percent RTP for the Appendix K requirement based on a four path LEFM system. BVPS Unit 2 also has a margin recover of 1.4 percent approved to allow for 100.6 percent RTP for the Appendix K requirement based on an eight path LEFM system. The nuclear instrumentation protection setpoint uncertainties at both BVPS Units 1 and 2 conservatively include a 2 percent daily heat balance uncertainty. Therefore, the

Attachment

L-21-254

Page 4 of 4

nuclear instrumentation protection setpoints remain the same regardless of how the daily heat balance is performed, by either the plant computer system or manual calculations.

FEN-CAL-17-0001

REVISION:

0**OBJECTIVE OR PURPOSE:**

The objective of this calculation is to provide a value for bounding the uncertainty associated with various methods of calculating reactor power with feedwater flow with a 95% probability and 95% confidence level by comparing deviations between feedwater flow and temperature measurements obtained at 10 minute intervals with measurements obtained one, three, and five days later, to determine if the deviations exhibit random or bias behavior. The results are then utilized to support licensing an extended 72 hour outage time for the Leading Edge Flow Meter (LEFM). The LEFM is utilized for more precise measurement of the feedwater flow component of the reactor power calorimetric calculations which was the basis for the Measurement Uncertainty Recapture (MUR) uprate.

SCOPE OF CALCULATION/REVISION:

The scope of this calculation is to address both Beaver Valley Units 1 and 2 through all seasonal time periods in the course of one year, utilizing historical feedwater flow data measured by differential pressure (d/p) venturis, feedwater temperature data measured by Resistance Temperature Detectors (RTDs), and flow and temperature data measured by LEFMs as inputs.

SUMMARY OF RESULTS/CONCLUSIONS:

The results of Attachments 1 and 2 are summarized in the following tables which provide the results of 1, 3 and 5-day time intervals along with the associated number of data points utilized in the final calculation. A data point consists of the difference between a venturi flow measurement and a coincident LEFM flow measurement minus the difference between coincident measurements at another point in time. As such, a data point quantifies how much a venturi measurement deviates from a coincident LEFM measurement over a time interval. The data exhibited a random and consistent uncertainty with respect to data points with 1, 3, or 5-day intervals. Flow results are reported in percent nominal feedwater flow with a 95/95 probability and confidence level. Results for 1, 3, or 5-day intervals are nearly identical. The comparison for 5-days is included to demonstrate that any fouling or other time related changes are not imminent to a 3-day period and will not impact the 3 day values.

Upper bound (average + 95/95 uncertainty) values of percentage feedwater flow comparison of 10-minute data for feedwater flow differences between LEFM and the total loop venturi indicated flow are stated in the tables below. Note that the "Venturi minus LEFM" column contains values that would be used as corrections to normalize subsequent venturi measurements to the last known good LEFM reading, while the 1, 3 and 5-day values are the changes in the differences over time. LEFM flows corresponding to "% RTP of 2900 MWt" column values greater than or equal to 100% were averaged to determine feedwater flow at 100% power. The average was used to convert MPPH values to percent nominal feedwater flow.

Data points were derived from flow and temperature measurements normally logged at 10-minute intervals. Data points for temperature measurements from RTDs and LEFMs were evaluated in a consistent manner to the flow measurements.

LIMITATIONS OR RESTRICTIONS ON CALCULATION APPLICABILITY:

This calculation is applicable only to Beaver Valley Units 1 and 2 Nuclear Power Stations as a basis for operation of up to a three day LEFM Out Of Service (OOS) interval while the plant continues operating at the MUR power level. Plant Technical Specifications and the unit Technical Requirements Manual should be revised to reflect an increase in the allowed outage time of 72-hours from the last known good LEFM reading. The venturi indication when normalized to the last known good LEFM reading is used while the MUR power level is sustained. Should plant power reduce below 90% RTP during the 72-hour outage for the LEFM, plant power must be reduced to the pre-MUR value until such time the LEFM is returned to service.

IMPACT ON OUTPUT DOCUMENTS:

The results of this calculation support a Licensing Amendment Request (LAR) to revise the Beaver Valley Technical Specification (TS) page 5.6-3, and the Licensing Requirements Manual (LRM) 3.3.8 specifying the Leading Edge Flow Meter (LEFM) Allowed Outage Time (AOT).

REVISION:

0**ANALYSIS METHODOLOGY:**

The fundamental objective of this analysis is to compare the data generated by diverse feedwater flow instrumentation, LEFM and venturi, to get an estimate of the stability of the feedwater venturi measurements over a three day time interval when compared or normalized to the LEFM indication of feedwater flow. As the intent of this analysis is to evaluate operation of the plant for up to 72-hours at 100% of Rated Thermal Power (RTP) while the LEFM is out of service, the characteristics at full power are particularly relevant in maintaining the MUR power level of 2900 MWth.

An acceptable approach is to compare reactor power level calculations between those based on LEFM flow, temperature, and feedwater pressure with the total feedwater flow based on installed flow nozzles and the feedwater individual loop RTD temperatures. The objective is to maintain the MUR power level; therefore, the data set is limited to data above 90% reactor power. Extensive data was collected over a one year time frame and inherently includes any seasonal effects. Confirmation of the plant power level was based on first stage turbine pressure and any inconsistencies between the first stage turbine pressure, reactor power calorimetric, feedwater flow by LEFM and venturi measurements was evaluated though additional plant data such as reactor core temperatures for example and the questionable data was either discarded, or discarded and the evaluation reset to assure plant stability for the analysis.

There are two separate and independent single measurements other than primary or secondary calorimetric calculations that can be used to determine baseline Rated Thermal Power (RTP), first stage turbine pressure or the first stage extraction pressure. The first stage turbine pressure, or shell pressure, the pressure after the governor valves at the input to the high-pressure turbine rotor is linear with turbine power, or correspondingly reactor power. Another approach is to use the first stage turbine extraction pressure, which is related to the turbine steam flow graph provided in the thermal kit. The uncertainty of this measure of turbine steam flow is greater than that for the first stage turbine pressure (because turbine extraction pressure is sensitive to more elements in the turbine) and unlike the first stage turbine pressure, does not account for steam flow to the reheater or the auxiliary steam system. The turbine first stage pressure is an independent measurement that represents the turbine load or demand from the reactor for the power necessary to meet the required output. Utilizing data for the last 5 consecutive days at greater than 90% Rated Thermal Power (RTP) with less than 1% power swings anticipated, an evaluation negating intentional power changes for power levels above 90% RTP is used to justify maintaining 100% RTP at the Measurement Uncertainty Recapture (MUR) power rating for 3-days or 72-hours, which provides an additional 48-hours of plant operation prior to reducing plant power compared to current licensing. The currently approved outage time has been established as 1 day or until performance of the next required heat balance (normally 24-hours not accounting for TS 3.0.2 grace period, Reference 9). The associated difference between feedwater flow indications (venturi and LEFM) over this time period is compared to the difference between feedwater flow indications over a 3 and 5-day period. This comparison also is used to identify if there are any biases for any specific method of calculating reactor power or if the data represents a statistically random behavior, references 4, 5, and 6. The same approach is used to compare the individual loop feedwater RTD temperatures to the LEFM temperature.

The calculations performed in Attachments 1 and 2 are based on the Beaver Valley Unit 1 data extracted from the Beaver Valley PI computer system, using Excel version 15.0.4797.1003. The calculations performed in Attachments 3 and 4 are the equivalent calculations based on Beaver Valley Unit 2 data, again extracted from the Beaver Valley PI computer system with the same Excel program. The calculated average flow above 100% RTP was used to determine the actual feedwater flow based on the actual plant conditions in lieu of the rated or best estimate feedwater flows.

**CALCULATION**

CALCULATION NO.:

FEN-CAL-17-0001

REVISION:

0**Outliers**

It is a well-known fact that flow measurements based on differential pressure for venturi or nozzles have a square root dependency which exhibits larger errors at the lower end of their measured flow range. Since the objective here is to maintain full feedwater flow at rated MUR power levels, it would only be necessary to use data at 100% Rated Thermal Power. However, due to minor variations in reactor power based on grid load demands, oscillations in control systems, and other numerous impacts on maintaining a constant power level, the data used for this analysis consist of plant power levels above 90% RTP where reactor power is held relatively constant. Where intentional reactor power levels are manipulated, as in valve testing or other intent power changes, the data points not representative of maintaining constant full power are not included in the calculation.

For those methods that rely primarily on temperature, such as a primary reactor based power level, intended changes in power level for power reductions may exhibit a larger deviation of indicated power than other methods. When it is noted that reactor power is being intentionally decreased, i.e., the final reactor power is below 90% RTP, several data points previous to reaching the 90% RTP point may be removed since this would introduce a recognized bias due to the intentional power move. The actual number of data points removed depends on the rate of power change based on various plant data such as the first stage pressure, feedwater flow, and concurrence with the plant data reviewed. The intentional down power data is observed to be inconsistent with, and has no impact on, the objective of maintaining reactor power at the 100% RTP MUR level and is therefore excluded. The same discussion is applicable to rapid power increases from 90%. To assure plant stability for the data utilized, additional data points have been removed from the analysis until power increases have stabilized. As noted in the attachments additional data has been removed whenever inconsistent plant data are observed for the identified power level.

Seasonal Effects

The evaluation was over a one year period for each of the two Beaver Valley units beginning January 2, 2016 and ending at January 1, 2017, utilizing 52,560 data points per unit. The data showed no evidence of bias in the calculations with regard to seasonal effects. Deviations between the various calculations of reactor power were random throughout the seasons, demonstrating both high and low measurements about the nominal expected value of reactor power. Refer to the histograms provided in the calculation section below for a graphical representation of the data.

Calculations

A data set of reported plant values every 10 minutes between January 2, 2016 and ending at January 1, 2017, utilizing 52,560 data provides more than sufficient data to meet any requirements for obtaining a representative data set as detailed in references 4, 5, and 6. Given the large amount of data and the simplicity of the calculations, an EXCEL spreadsheet is used for the calculations. Data was collected through use of the Beaver Valley PI data base and used for this analysis. The data is checked using logic to ensure that only power levels above 90% RTP are included and to confirm that the data is representative of actual plant power. That is to say, if an instrument loop is Out Of Service (OOS) or the channel exhibits values as though the instrumentation was being calibrated on-line, then the suspect set of data is removed. The resulting data set of nearly 44,000 data points for a 3-day interval exceeding any requirements noted in the references 4, 5, and 6 for an acceptable data set size. A proof of normality of the data set is also evident in the histogram plot below as delineated in References 4, 5, and 6. Note the frequency represents the number of data points at the BIN or percent deviation over time and the normal distribution bell curve is visually used as a check on the normality of the data set.

As a final calculation per references 4 and 5, an upper bounding value of the statistical 95% probability of the data set is generated based on two times the standard deviation of the data set added to the mean average of the data set for each time frame.

**CALCULATION**

CALCULATION NO.:

FEN-CAL-17-0001

REVISION:

0**ASSUMPTIONS:**

No unverified assumptions are made in the development of this calculation.

ACCEPTANCE CRITERIA

The acceptance criterion for this calculation is based on the LEFM and venturi differences over a three-day period that demonstrate essentially the same calculation of feedwater flow, or reactor power. Longer time periods will show evidence of venturi fouling or power changes below 90% power introduces additional error in d/p measurements of the venturi. When comparing the difference of venturi and LEFM indication at a point in time versus the difference of venturi and LEFM indication 1 and 3-days later, the upper bounds of the 95/95 confidence interval of the dataset shall not increase or behave unpredictably.

COMPUTATION

The analysis is calculated as described in the methodology section above. Attachments provide the analysis for Beaver Valley Units 1 and 2. Note that the Attachments each contain 922 pages, therefore only the reactor power, feedwater flow, temperature, and calculated values are attached from the EXCEL file.

The LEFM calculated reactor power level, calculated in percent power, is used to limit the data points to those that are greater than 90% RTP.

The Attachments also calculate the differences between average LEFM and venturi feedwater flows and temperatures. Abrupt or rapid power changes show up at a later time in the secondary method of calculating reactor power levels due to the time lag of the temperature sensitive calorimetric inputs to the calculation of reactor power. Therefore, when the data demonstrates that power level is being intentionally raised or lowered, deviations in the primary and secondary calculations are evidenced and removed to avoid masking the actual deviations between feedwater flow and temperature while maintaining a constant power level at MUR power levels or above 90% RTP.

The LEFM indications for feedwater loops are compared to the total of the feedwater venturi indications from each feedwater loop, where the resulting values are summed and provided in the "SG Total Corrected Flow" column. The difference of these two columns is calculated and provided in the "Venturi Minus LEFM" column.

The differences between "Venturi Minus LEFM" values at one point in time and values from that column 1 day, 3 days, and 5 days later are tabulated in the "MPPH 1 Day", "MPPH 3 Day" and "MPPH 5 Day" columns. These columns are analyzed statistically (EXCEL "Average" and "STDEVP") to determine the upper bounds of the 95/95 confidence interval of the dataset for each time period.

In addition to ignoring data associated with power levels less than 90%, points have been removed manually and identified with highlights for power level changes, instrument out of service, or those readings that are not believable, i.e., one method may be 10 to 20% different than the other two. For data removed due to plant condition reports, notes 1 or 2 are identified in the table.

When the reactor power was maintained above 90% RTP for 3 days, then one data point was available for the 3-day calculation. Likewise, when the reactor power was maintained above 90% for 5-days, then one data point was available for a 5-day evaluation while there were 432 data points available for the 3-day evaluation.

Therefore, 144 data points exist for 1 day, 432 data points for 3 days, and 720 data points over a 5-day period.

**CALCULATION**

CALCULATION NO.:

FEN-CAL-17-0001

REVISION:

0**RESULTS / CONCLUSIONS:**

When comparing a 3 or 5-day period of plant operation above 90% RTP to a 1-day period of plant operation above 90% RTP at 0.2858%, the 95/95 bounding difference for feedwater flow is established for Beaver Valley Unit 1 as 0.2859% flow for 3-day values, and after 5-days produced a difference of 0.2892%, as calculated in the Attachments 1 and 2. This demonstrates the stability of the comparison beyond the 3-day requested extension as evidence that the differences over time are small and are representative of known venture fouling issues.

When comparing a 3 or 5-day period of plant operation above 90% RTP to a 1-day period of plant operation above 90% RTP at 0.2348%, the 95/95 bounding difference for feedwater flow is established for Beaver Valley Unit 2 as 0.2360% flow for 3-day values, and after 5-days produced a difference of 0.2381%, as calculated in the Attachments 3 and 4. This demonstrates the stability of the comparison beyond the 3-day requested extension as evidence that the differences over time are small.

The data exhibits random behavior with a growing bias over time exhibited by the ever-slight increase in the STDVE calculations, attributable to venturi fouling for the 5-day feedwater values beyond the 3-day limit. The data is sufficiently random as the data followed a normal distribution. The number of data points utilized in the calculation is sufficient to allow determination of the 95/95 bounding uncertainty using two standard deviations from the mean for a two-sided statistical application.

Beaver Valley Unit 1

	1 Day		3 Day		5 Day	
	Upper Bound	# of Points	Upper Bound	# of Points	Upper Bound	# of Points
Nominal FW Flow	0.2858%	45,395	0.2859%	44,531	0.2892%	43,961
FW Temperature	0.0597°F	45,591	0.0656°F	45,006	0.0682°F	44,427

Beaver Valley Unit 2

	1 Day		3 Day		5 Day	
	Upper Bound	# of Points	Upper Bound	# of Points	Upper Bound	# of Points
Nominal FW Flow	0.2348%	49,176	0.2360%	47,463	0.2381%	45,743
FW Temperature	0.0414°F	49,255	0.0450°F	47,457	0.0479°F	45,734

For Beaver Valley Unit 1, expressing the change in percentage of nominal feedwater flow, the 3-day change in the upper bounds of the dataset 95/95 confidence interval was calculated at 0.2859% and the 5-day change at 0.2892%. The 5-day value provides support to the conclusions of a time-based deviation in the feedwater flow venturi measurements which appears indicative of feedwater venturi fouling. Note that plant instrumentation provides plant power to two decimal places and the data is consistent through three and nearly identical at three decimal places, one beyond the plant power reported calorimetric data. This difference is within the uncertainty of the feedwater flow of 0.48% per reference 11.

For Beaver Valley Unit 2, expressing the change in percentage of nominal feedwater flow, the 3-day change in the upper bounds of the dataset 95/95 confidence interval was calculated at 0.2360% and the 5-day change at 0.2381%. The 5-day value provides support to the conclusions of a time-based 3-day extension does not increase the deviation between the LEFM and venture measurements to any significant variation in the feedwater flow. Note that plant instrumentation provides plant power to two decimal places and the data is consistent at two decimal places reported in the calorimetric data. This difference is within the uncertainty of the feedwater flow of 0.48% where the Beaver Valley Unit 2 LEFM Check Plus which was licensed at the accuracy of Beaver Valley Unit 1 LEFM per reference 11, and the flow accuracy of the Unit 2 Check Plus is stated as 0.29% in reference 12.

CALCULATION

CALCULATION NO.:

FEN-CAL-17-0001

REVISION:

0

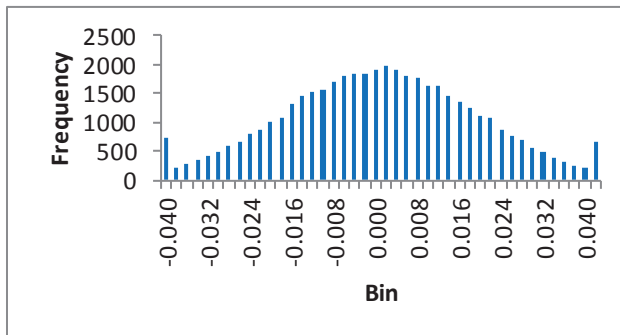

Given the consistent correlation between the LEFM and venturi feedwater flow indication, normalizing the venturi indication to a known-good LEFM indication permits the venturi to be used as input to the calorimetric heat balance calculation for a 72-hour period while the plant remains in a stable state at 100% RTP, above 90%.

For Beaver Valley Unit 1 the sample average difference of ± 0.64 °F between the LEFM and the feedwater RTDs is not significantly different from the uncertainty allowance of the LEFM of ± 0.6 °F (Reference 11). Over a 3-day period the difference did not change significantly (± 0.065 °F with 95% confidence) and would only have affected the calculated reactor power beyond the reported decimal places to the operator. The conclusion is that for the 72 hour OOS LEFM operational interval, the feedwater RTDs can be utilized as an equivalent input to the heat balance in place of the LEFM temperature indication. This conclusion is based on the sampled difference in measurements having an insignificant impact on plant power calculations resulting from the minor change calculated in feedwater enthalpy.

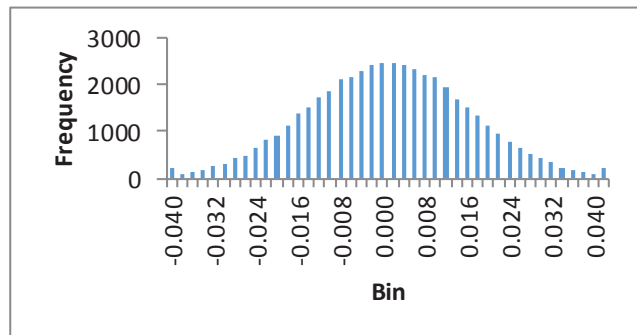

For Beaver Valley Unit 2 the sample average difference of ± 0.098 °F between the LEFM and the feedwater RTDs is less than the uncertainty allowance of the LEFM of ± 0.6 °F (Reference 12). Over a 3-day period the difference did not change significantly (± 0.045 °F with 95% confidence). For the 72-hour OOS, LEFM operational interval, the feedwater RTDs can be utilized as an equivalent input to the heat balance under the same discussions above for Unit 1. This conclusion is again based on the sampled difference in measurements having an insignificant impact on plant power calculations due to the minor change calculated in feedwater enthalpy.

In conclusion, the 3-day difference between utilizing either the normalized venturi or LEFM flows is bounded by the uncertainty licensed for the LEFMs when considering the standard deviation is multiplied by 1.96 to determine a 95/95 probability and confidence level. The temperature differences between the 1 and 3-day temperatures, including the projected 95/95 values, are deemed to be insignificant and will not have any discernable impact on feedwater enthalpy.
