d. Maintaining, to the extent practical, the ability to perform required functions (even if not meeting MODE 1, 2, 3, and 4 OPERABILITY requirements) with systems assumed to function during an event.

In the event of an accident during shutdown, this LCO ensures the capability to support systems necessary to avoid immediate difficulty, assuming either a loss of all offsite power or a loss of all onsite diesel generator (DG) power.

The AC sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

One offsite circuit capable of supplying the onsite Class 1E power distribution subsystem(s) of LCO 3.8.10, "Distribution Systems - Shutdown," ensures that all required loads are powered from offsite power. An OPERABLE DG, associated with a distribution system train required to be OPERABLE by LCO 3.8.10, ensures a diverse power source is available to provide electrical power support, assuming a loss of the offsite circuit. Together, OPERABILITY of the required offsite circuit and DG ensures the availability of sufficient AC sources to operate the unit in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents ~~[involving handling recently irradiated fuel]~~). 2

The qualified offsite circuit must be capable of providing three phases of AC power, maintaining rated frequency and voltage, and accepting required loads during an accident, while connected to the Engineered Safety Feature (ESF) bus(es). Qualified offsite circuits are those that are described in the FSAR and are part of the licensing basis for the unit. 1

U

BASES

LCO (continued)

~~[Offsite circuit #1 consists of Safeguards Transformer B, which is supplied from Switchyard Bus B, and is fed through breaker 52-3 powering the ESF transformer XNBO1, which, in turn, powers the #1 ESF bus through its normal feeder breaker. The second offsite circuit consists of the Startup Transformer, which is normally fed from the Switchyard Bus A, and is fed through breaker PA 0201 powering the ESF transformer, which, in turn, powers the #2 ESF bus through its normal feeder breaker.]~~ 2

Insert 1

degraded or

The DG must be capable of starting, accelerating to rated speed and voltage, connecting to its respective ESF bus on detection of bus undervoltage, and accepting required loads. This sequence must be accomplished within ~~[~~10~~]~~ seconds. The DG must be capable of accepting required loads within the assumed loading sequence intervals, and must continue to operate until offsite power can be restored to the ESF buses. These capabilities are required to be met from a variety of initial conditions such as DG in standby with the engine hot and DG in standby at ambient conditions. 1 2

Proper sequencing of loads, including tripping of nonessential loads, is a required function for DG OPERABILITY.

~~[In addition, proper sequencer operation is an integral part of offsite circuit OPERABILITY since its inoperability impacts on the ability to start and maintain energized loads required OPERABLE by LCO 3.8.10.]~~ 3

~~It is acceptable for trains to be cross tied during shutdown conditions, allowing a single offsite power circuit to supply all required trains.~~ 1

APPLICABILITY

The AC sources required to be OPERABLE in MODES 5 and 6 and during movement of ~~[recently]~~ irradiated fuel assemblies provide assurance that: 2

a. Systems to provide adequate coolant inventory makeup are available for the irradiated fuel assemblies,

b. Systems needed to mitigate a fuel handling accident ~~[involving handling [recently] irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~ are available, 2

c. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available, and

2

Insert 1

An offsite circuit consists of a unit startup transformer and the associated circuit path, including non-ESF buses, up to and including the feeder breaker to the respective unit 4.16 kV ESF bus. Alternately, when the unit startup transformer is unavailable, the associated offsite circuit may be supplied from the opposite unit startup transformer via the associated non-ESF buses. The Unit 2 startup transformer may only be utilized as a qualified offsite AC source to Unit 1 provided it is not supplying power to a Unit 2 bus while operating in MODE 1, 2, 3, or 4. The Unit 2 startup transformer may supply power to ESF buses of both units when both units are in MODE 5 or 6 or defueled. | R1

BASES

APPLICABILITY (continued)

d. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition or refueling condition.

The AC power requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.1.

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

A.1

An offsite circuit would be considered inoperable if it were not available to one required ESF train. Although two trains may be required by LCO 3.8.10, the remaining train with offsite power available may be capable of supporting sufficient required features to allow continuation of ~~[recently]~~ irradiated fuel movement. By the allowance of the option to declare required features inoperable, with no offsite power available, appropriate restrictions will be implemented in accordance with the affected required features LCO's ACTIONS. (2)

A.2.1, A.2.2, A.2.3, B.1, B.2, and B.3

With the offsite circuit not available to all required trains, the option would still exist to declare all required features inoperable. Since this option may involve undesired administrative efforts, the allowance for sufficiently conservative actions is made. With the required DG inoperable, the minimum required diversity of AC power sources is not available. It is, therefore, required to suspend movement of ~~[recently]~~ irradiated fuel assemblies, and operations involving positive reactivity additions that could result in loss of required SDM (MODE 5) or boron concentration (MODE 6). Suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum SDM or refueling boron concentration. This may result in an overall reduction in RCS boron (2)

BASES

ACTIONS (continued)

concentration, but provides acceptable margin to maintaining subcritical operation. Introduction of temperature changes including temperature increases when operating with a positive ~~MTC~~ must also be evaluated to ensure they do not result in a loss of required SDM.

moderator temperature coefficient

4

Suspension of these activities does not preclude completion of actions to establish a safe conservative condition. These actions minimize the probability or the occurrence of postulated events. It is further required to immediately initiate action to restore the required AC sources and to continue this action until restoration is accomplished in order to provide the necessary AC power to the unit safety systems.

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required AC electrical power sources should be completed as quickly as possible in order to minimize the time during which the unit safety systems may be without sufficient power.

Pursuant to LCO 3.0.6, the Distribution System's ACTIONS are not entered even if all AC sources to it are inoperable, resulting in de-energization. Therefore, the Required Actions of Condition A are modified by a Note to indicate that when Condition A is entered with no AC power to any required ESF bus, the ACTIONS for LCO 3.8.10 must be immediately entered. This Note allows Condition A to provide requirements for the loss of the offsite circuit, whether or not a train is de-energized. LCO 3.8.10 provides the appropriate restrictions for the situation involving a de-energized train.

SURVEILLANCE REQUIREMENTS

SR 3.8.2.1

SR 3.8.2.1 requires the SRs from LCO 3.8.1 that are necessary for ensuring the OPERABILITY of the AC sources in other than MODES 1, 2, 3, and 4. SR 3.8.1.8 is not required to be met since only one offsite circuit is required to be OPERABLE. SR 3.8.1.~~12~~ and SR 3.8.1.~~19~~ are not required to be met because the ESF actuation signal is not required to be OPERABLE. SR 3.8.1.~~17~~ is not required to be met because the required OPERABLE DG~~(s)~~ is not required to undergo periods of being synchronized to the offsite circuit. SR 3.8.1.~~20~~ is excepted because starting independence is not required ~~with DG(s) that are~~ not required to be OPERABLE.

11

15

18

17

5

1

1

for the DG that is

BASES

SURVEILLANCE REQUIREMENTS (continued)

This SR is modified by a Note. The reason for the Note is to preclude requiring the OPERABLE DG~~(s)~~ from being paralleled with the offsite power network or otherwise rendered inoperable during performance of SRs, and to preclude deenergizing a required 4160 V ESF bus or disconnecting a required offsite circuit during performance of SRs. With limited AC Sources available, a single event could compromise both the required circuit and the DG. It is the intent that these SRs must still be capable of being met, but actual performance is not required during periods when the DG and offsite circuit is required to be OPERABLE. Refer to the corresponding Bases for LCO 3.8.1 for a discussion of each SR. 1

REFERENCES None.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.2 AC Sources - Shutdown

BASES

BACKGROUND

A description of the AC sources is provided in the Bases for LCO 3.8.1, "AC Sources - Operating."

APPLICABLE SAFETY ANALYSES

The OPERABILITY of the minimum AC sources during MODES 5 and 6 and during movement of ~~[recently]~~ irradiated fuel assemblies ensures that: (2)

a. The unit can be maintained in the shutdown or refueling condition for extended periods,

b. Sufficient instrumentation and control capability is available for monitoring and maintaining the unit status, and

c. Adequate AC electrical power is provided to mitigate events postulated during shutdown, such as a fuel handling accident ~~[involving handling recently irradiated fuel. Due to radioactive decay, AC electrical power is only required to mitigate fuel handling accidents involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~. (2)

In general, when the unit is shut down, the Technical Specifications requirements ensure that the unit has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. The rationale for this is based on the fact that many Design Basis Accidents (DBAs) that are analyzed in MODES 1, 2, 3, and 4 have no specific analyses in MODES 5 and 6. Worst case bounding events are deemed not credible in MODES 5 and 6 because the energy contained within the reactor pressure boundary, reactor coolant temperature and pressure, and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and in minimal consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCO for required systems.

During MODES 1, 2, 3, and 4, various deviations from the analysis assumptions and design requirements are allowed within the Required Actions. This allowance is in recognition that certain testing and maintenance activities must be conducted provided an acceptable level of risk is not exceeded. During MODES 5 and 6, performance of a

BASES

APPLICABLE SAFETY ANALYSES (continued)

significant number of required testing and maintenance activities is also required. In MODES 5 and 6, the activities are ~~generally~~ planned and administratively controlled. Relaxations from MODE 1, 2, 3, and 4 LCO requirements are acceptable during shutdown modes based on: 1

a. The fact that time in an outage is limited. This is a risk prudent goal as well as a utility economic consideration.

b. Requiring appropriate compensatory measures for certain conditions. These may include administrative controls, reliance on systems that do not necessarily meet typical design requirements applied to systems credited in operating MODE analyses, or both.

c. Prudent utility consideration of the risk associated with multiple activities that could affect multiple systems.

d. Maintaining, to the extent practical, the ability to perform required functions (even if not meeting MODE 1, 2, 3, and 4 OPERABILITY requirements) with systems assumed to function during an event.

In the event of an accident during shutdown, this LCO ensures the capability to support systems necessary to avoid immediate difficulty, assuming either a loss of all offsite power or a loss of all onsite diesel generator (DG) power.

The AC sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

One offsite circuit capable of supplying the onsite Class 1E power distribution subsystem(s) of LCO 3.8.10, "Distribution Systems - Shutdown," ensures that all required loads are powered from offsite power. An OPERABLE DG, associated with a distribution system train required to be OPERABLE by LCO 3.8.10, ensures a diverse power source is available to provide electrical power support, assuming a loss of the offsite circuit. Together, OPERABILITY of the required offsite circuit and DG ensures the availability of sufficient AC sources to operate the unit in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents ~~[involving handling recently irradiated fuel]~~). 2

The qualified offsite circuit must be capable of providing three phases of AC power, maintaining rated frequency and voltage, and accepting required loads during an accident, while connected to the Engineered Safety Feature (ESF) bus(es). Qualified offsite circuits are those that are described in the FSAR and are part of the licensing basis for the unit. 1

degraded or

The DG must be capable of starting, accelerating to rated speed and voltage, connecting to its respective ESF bus on detection of bus undervoltage, and accepting required loads. This sequence must be accomplished within ~~[~~10~~]~~ seconds. The DG must be capable of accepting required loads within the assumed loading sequence intervals, and must continue to operate until offsite power can be restored to the ESF buses. These capabilities are required to be met from a variety of initial conditions such as DG in standby with the engine hot and DG in standby at ambient conditions. 1 2

Proper sequencing of loads, including tripping of nonessential loads, is a required function for DG OPERABILITY.

~~[In addition, proper sequencer operation is an integral part of offsite circuit OPERABILITY since its inoperability impacts on the ability to start and maintain energized loads required OPERABLE by LCO 3.8.10.]~~ 3

~~It is acceptable for trains to be cross tied during shutdown conditions, allowing a single offsite power circuit to supply all required trains.~~ 1

APPLICABILITY

The AC sources required to be OPERABLE in MODES 5 and 6 and during movement of ~~[recently]~~ irradiated fuel assemblies provide assurance that: 2

a. Systems to provide adequate coolant inventory makeup are available for the irradiated fuel assemblies,

b. Systems needed to mitigate a fuel handling accident ~~[involving handling [recently] irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~ are available, 2

c. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available, and

2

Insert 1

An offsite circuit consists of a unit startup transformer and the associated circuit path, including non-ESF buses, up to and including the feeder breaker to the respective unit 4.16 kV ESF bus. Alternately, when the unit startup transformer is unavailable, the associated offsite circuit may be supplied from the opposite unit startup transformer via the associated non-ESF buses. The Unit 1 startup transformer may only be utilized as a qualified offsite AC source to Unit 2 provided it is not supplying power to a Unit 1 bus while operating in MODE 1, 2, 3, or 4. The Unit 1 startup transformer may supply power to ESF buses of both units when both units are in MODE 5 or 6 or defueled. |R1

BASES

APPLICABILITY (continued)

d. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition or refueling condition.

The AC power requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.1.

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

A.1

An offsite circuit would be considered inoperable if it were not available to one required ESF train. Although two trains may be required by LCO 3.8.10, the remaining train with offsite power available may be capable of supporting sufficient required features to allow continuation of ~~[recently]~~ irradiated fuel movement. By the allowance of the option to declare required features inoperable, with no offsite power available, appropriate restrictions will be implemented in accordance with the affected required features LCO's ACTIONS. (2)

A.2.1, A.2.2, A.2.3, B.1, B.2, and B.3

With the offsite circuit not available to all required trains, the option would still exist to declare all required features inoperable. Since this option may involve undesired administrative efforts, the allowance for sufficiently conservative actions is made. With the required DG inoperable, the minimum required diversity of AC power sources is not available. It is, therefore, required to suspend movement of ~~[recently]~~ irradiated fuel assemblies, and operations involving positive reactivity additions that could result in loss of required SDM (MODE 5) or boron concentration (MODE 6). Suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum SDM or refueling boron concentration. This may result in an overall reduction in RCS boron (2)

BASES

ACTIONS (continued)

concentration, but provides acceptable margin to maintaining subcritical operation. Introduction of temperature changes including temperature increases when operating with a positive ~~MTC~~ must also be evaluated to ensure they do not result in a loss of required SDM.

moderator temperature coefficient

4

Suspension of these activities does not preclude completion of actions to establish a safe conservative condition. These actions minimize the probability or the occurrence of postulated events. It is further required to immediately initiate action to restore the required AC sources and to continue this action until restoration is accomplished in order to provide the necessary AC power to the unit safety systems.

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required AC electrical power sources should be completed as quickly as possible in order to minimize the time during which the unit safety systems may be without sufficient power.

Pursuant to LCO 3.0.6, the Distribution System's ACTIONS are not entered even if all AC sources to it are inoperable, resulting in de-energization. Therefore, the Required Actions of Condition A are modified by a Note to indicate that when Condition A is entered with no AC power to any required ESF bus, the ACTIONS for LCO 3.8.10 must be immediately entered. This Note allows Condition A to provide requirements for the loss of the offsite circuit, whether or not a train is de-energized. LCO 3.8.10 provides the appropriate restrictions for the situation involving a de-energized train.

SURVEILLANCE REQUIREMENTS

SR 3.8.2.1

SR 3.8.2.1 requires the SRs from LCO 3.8.1 that are necessary for ensuring the OPERABILITY of the AC sources in other than MODES 1, 2, 3, and 4. SR 3.8.1.8 is not required to be met since only one offsite circuit is required to be OPERABLE. SR 3.8.1.~~12~~ and SR 3.8.1.~~19~~ are not required to be met because the ESF actuation signal is not required to be OPERABLE. SR 3.8.1.~~17~~ is not required to be met because the required OPERABLE DG~~(s)~~ is not required to undergo periods of being synchronized to the offsite circuit. SR 3.8.1.~~20~~ is excepted because starting independence is not required ~~with DG(s) that are~~ not required to be OPERABLE.

e. With two of the above required diesel generators inoperable, demonstrate the OPERABILITY of two offsite A.C. circuits by performing Surveillance Requirement 4.8.1.1.1.a within 1 hour and at least once per 8 hours thereafter; restore one of the inoperable diesel generators to OPERABLE status within 2 hours or be in the at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN. Following restoration of one diesel generator unit, follow ACTION Statement b. with the time requirement of that ACTION Statement based on the time of initial loss of the remaining inoperable diesel generator.

f. With one Unit 1 startup transformer (1A or 1B) inoperable and with a Unit 2 startup transformer (2A or 2B) connected to the same A or B offsite power circuit and administratively available to both units, then should Unit 2 require the use of the startup transformer administratively available to both units, Unit 1 shall demonstrate the OPERABILITY of the remaining A.C. sources by performing Surveillance Requirement 4.8.1.1.1.a within 1 hour and at least once per 8 hours thereafter. Restore the inoperable startup transformer to OPERABLE status within 72 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours.

g. LCO 3.0.4.b is not applicable to diesel generators.

SURVEILLANCE REQUIREMENTS

4.8.1.1.1 Each of the above required independent circuits between the offsite transmission network and the onsite Class 1E distribution system shall be:

a. Determined OPERABLE in accordance with the Surveillance Frequency Control Program by verifying correct breaker alignments, indicated power availability; and

b. Demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program by transferring (manually and automatically) unit power supply from the auxiliary transformer to the startup transformer.

4.8.1.1.2 Each diesel generator shall be demonstrated OPERABLE:

SR 3.8.3.1 a. In accordance with the Surveillance Frequency Control Program by:

See ITS 3.8.1

1. Verifying fuel level in the engine-mounted fuel tank,

SR 3.8.3.1 2. Verifying the fuel level in the fuel storage tank,

See ITS 3.8.1

3. Verifying the fuel transfer pump can be started and transfers fuel from the storage system to the engine-mounted tank,

Add proposed SR 3.8.3.2

M01

ELECTRICAL POWER SYSTEMS

SURVEILLANCE REQUIREMENTS (continued)

See ITS 3.8.1

4. Verifying the diesel starts from ambient condition and accelerates to approximately 900 rpm in less than or equal to 10 seconds**. The generator voltage and frequency shall be 4160 ± 420 volts and 60 ± 1.2 Hz within 10 seconds after the start signal**. The diesel generator shall be started for this test by using one of the following signals:

   a) Manual/Local

   b) Simulated loss-of-offsite power by itself.

   c) Simulated loss-of-offsite power in conjunction with an ESF actuation test signal.

   d) An ESF actuation test signal by itself.

5. Verifying the generator is synchronized, loaded to greater than or equal to 3500 kW in accordance with the manufacturer's recommendations and operates within a load band of 3300 to 3500 kW*** for at least an additional 60 minutes, and

6. Verifying the diesel generator is aligned to provide standby power to the associated emergency busses.

SR 3.8.3.5

b. ~~By removing~~ Check for and remove accumulated water:

See ITS 3.8.1

1. From the engine-mounted fuel tank in accordance with the Surveillance Frequency Control Program and after each occasion when the diesel is operated for greater than 1 hour, and

SR 3.8.3.5

2. From ~~the~~ each fuel oil storage tank in accordance with the Surveillance Frequency Control Program.

See ITS 3.8.1

** The diesel generator start (10 sec.) from ambient conditions shall be performed in accordance with the Surveillance Frequency Control Program in these surveillance tests. All other diesel generator starts for the purposes of this surveillance testing may be preceded by an engine prelube period and may also include warmup procedures (e.g., gradual acceleration) as recommended by the manufacturer so that mechanical stress and wear on the diesel generator is minimized.

*** The indicated load band is meant as guidance to avoid routine overloading. Variations in loads in excess of the band due to changing bus loads shall not invalidate this test.

NOTE

Enter the ACTION of LCO 3.8.2.2, “A.C. Distribution - Shutdown,” with one required train de-energized as a result of inoperable offsite circuit.

With less than the above minimum required A.C. electrical power sources OPERABLE, immediately suspend all operations involving CORE ALTERATIONS, operations involving positive reactivity additions that could result in loss of required SHUTDOWN MARGIN or boron concentration, movement of irradiated fuel, or crane operation with loads over the fuel storage pool. In addition, when in MODE 5 with the reactor coolant loops not filled, or in MODE 6 with the water level less than 23 feet above the top of irradiated fuel assemblies seated within the reactor vessel, immediately initiate corrective action to restore the required sources to OPERABLE status as soon as possible.

See ITS 3.8.2

SURVEILLANCE REQUIREMENTS

4.8.1.2.1 The above required A.C. electrical power sources shall be demonstrated OPERABLE by the performance of each of the Surveillance Requirements of 4.8.1.1.1 and 4.8.1.1.2 except for requirement 4.8.1.1.2a.5.

See ITS 3.8.2

ACTION: (Continued)

d. With two of the required offsite A.C. circuits inoperable:

1. Within 12 hours from discovery of two offsite circuits inoperable concurrent with inoperability of redundant required feature(s), declare required feature(s) inoperable when its redundant required feature(s) is inoperable.

2. Restore one of the inoperable offsite sources to OPERABLE status within 24 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within the next 6 hours.

3. Following restoration of one offsite source, follow ACTION a with the time requirement of that ACTION based on the time of the initial loss of the remaining inoperable offsite A.C. circuit.

e. With two of the above required diesel generators inoperable, demonstrate the OPERABILITY of two offsite A.C. circuits by performing Surveillance Requirement 4.8.1.1.1.a within 1 hour and at least once per 8 hours thereafter; restore one of the inoperable diesel generators to OPERABLE status within 2 hours or be in the at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN. Following restoration of one diesel generator unit, follow ACTION Statement b. with the time requirement of that ACTION Statement based on the time of initial loss of the remaining inoperable diesel generator.

f. With one Unit 2 startup transformer (2A or 2B) inoperable and with a Unit 1 startup transformer (1A or 1B) connected to the same A or B offsite power circuit and administratively available to both units, then should Unit 1 require the use of the startup transformer administratively available to both units, Unit 2 shall demonstrate the operability of the remaining A.C. sources by performing Surveillance Requirement 4.8.1.1.1a. within 1 hour and at least once per 8 hours thereafter. Restore the inoperable startup transformer to OPERABLE status within 72 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours.

g. LCO 3.0.4.b is not applicable to diesel generators.

SURVEILLANCE REQUIREMENTS

4.8.1.1.1 Each of the above required independent circuits between the offsite transmission network and the onsite Class 1E distribution system shall be:

a. Determined OPERABLE in accordance with the Surveillance Frequency Control Program by verifying correct breaker alignments, indicated power availability; and

b. Demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program by transferring (manually and automatically) unit power supply from the normal circuit to the alternate circuit.

4.8.1.1.2 Each diesel generator shall be demonstrated OPERABLE:

SR 3.8.3.1

a. In accordance with the Surveillance Frequency Control Program by:

See ITS 3.8.1

ELECTRICAL POWER SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

1. Verifying fuel level in the engine-mounted fuel tank,

See ITS 3.8.1

SR 3.8.3.1

2. Verifying the fuel level in the fuel storage tank,

3. Verifying the fuel transfer pump can be started and transfers fuel from the storage system to the engine-mounted tank,

4. Verifying the diesel starts from ambient condition and accelerates to approximately 900 rpm in less than or equal to 10 seconds**. The generator voltage and frequency shall be 4160 ± 420 volts and 60 ± 1.2 Hz within 10 seconds after the start signal**. The diesel generator shall be started for this test by using one of the following signals:

   a) Manual/Local.

   b) Simulated loss-of-offsite power by itself.

   c) Simulated loss-of-offsite power in conjunction with an ESF actuation test signal.

   d) An ESF actuation test signal by itself.

5. Verifying the generator is synchronized, loaded to greater than or equal to 3685 kW in accordance with the manufacturer's recommendations, and operates within a load band of 3450 to 3685 kW*** for at least an additional 60 minutes, and

6. Verifying the diesel generator is aligned to provide standby power to the associated emergency busses.

Check for and remove

SR 3.8.3.5

b. ~~By removing~~ accumulated water:

See ITS 3.8.1

1. From the engine-mounted fuel tank in accordance with the Surveillance Frequency Control Program and after each occasion when the diesel is operated for greater than 1 hour, and

SR 3.8.3.5

each fuel oil

2. From ~~the~~ storage tank in accordance with the Surveillance Frequency Control Program.

See ITS 3.8.1

** The diesel generator start (10 sec.) from ambient conditions shall be performed in accordance with the Surveillance Frequency Control Program in these surveillance tests. All other diesel generator starts for purposes of this surveillance testing may be preceded by an engine prelube period and may also include warmup procedures (e.g., gradual acceleration) as recommended by the manufacturer so that mechanical stress and wear on the diesel generator is minimized.

*** The indicated load band is meant as guidance to avoid routine overloading. Variations in loads in excess of the band due to changing bus loads shall not invalidate this test.

Add proposed SR 3.8.3.2

DISCUSSION OF CHANGES
ITS 3.8.3, DIESEL FUEL OIL, LUBE OIL, AND STARTING AIR

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS LCOs 3.8.1.1 and 3.8.1.2 state the requirements for the AC Sources during operating and shutdown conditions, respectively. These requirements are used to form the LCO and Applicability for the ITS diesel fuel oil Specification. ITS LCO 3.8.3, "Diesel Fuel Oil, Lube Oil, and Starting Air," states that the stored diesel fuel oil, lube oil, and starting air subsystem shall be within limits for each required DG. The Applicability for this requirement is when the associated DG is required to be OPERABLE. This changes the CTS by combining the requirements for diesel fuel oil and diesel lube oil and starting air subsystem into one Specification.

This change is acceptable because the current requirements are translated into ITS form with no technical changes. The additional requirements for DG lube oil and starting air subsystem are discussed in DOC M01. Diesel fuel oil, lube oil and starting air subsystem are a support system for each DG. The CTS and ITS maintain this relationship between the DGs and the Diesel Fuel Oil System, DG Lube oil System and Starting Air Subsystem. This change is designated as administrative because it does not result in a technical change to the CTS.

A03 CTS 3.8.1.1 and 3.8.1.2 Actions, in part, provide requirements to be taken for each inoperable DG. ITS 3.8.3 ACTIONS include an explicit Note that states, "Separate Condition entry is allowed for each DG." This Note provides instructions for the proper application of the ACTIONS for ITS compliance. This changes the CTS by providing explicit direction for using the ACTIONS when diesel fuel oil and diesel lube oil and starting air subsystem parameters for a DG are not within limits.

This change is acceptable because the addition of the Note reflects the CTS allowance to take appropriate Actions for each DG. This change is designated as administrative since it does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 The CTS does not provide any requirements for DG lube oil or starting air pressure. ITS LCO 3.8.3, in part, requires lube oil and starting air to be within limits for each required DG with associated Required Actions and Completion times when outside these limits. ITS SR 3.8.3.2 requires verification that the lube oil inventory is ≥ a 7-day supply for each DG. ITS SR 3.8.3.4 requires verification that required air start receiver bank pressure is ≥ 135 psig for each Unit 1 DG and

≥ 129 psig for each Unit 2 DG. ITS 3.8.3 ACTIONS B and E provide Required Actions if the required DG lube oil inventory is not within limits or the required starting air receiver bank pressure is not within limits respectively. This changes the CTS by adding limits for lube oil inventory and starting air, which Surveillance Requirements to verify the limits are being maintained and explicit ACTIONS for when the limits are not met.

The purpose of ITS 3.8.3 is to provide appropriate limits, ACTIONS, and Surveillances for diesel fuel oil, lube oil, and the air start subsystems because these subsystems support the operation of the standby AC power sources (DGs). The purpose of ITS SR 3.8.3.2 is to provide the appropriate limits for stored lube oil volume. ITS 3.8.3 ACTION B provides an explicit Required Action and Completion Time for restoring stored lube oil volume to within limits. The purpose of ITS SR 3.8.3.4 is to provide the appropriate limits for the DG starting air subsystem. ITS 3.8.3 ACTIONS E provides explicit Required Action and Completion Time for restoring starting air pressures to within limits. If a Required Action and associated Completion Time is not met or one or more DGs with lube oil inventory or required starting air receiver bank pressure not within limits for reasons other than addressed by Conditions B or E, ITS 3.8.3 ACTION F requires the associated DG to be declared inoperable immediately. This change is designated as more restrictive because explicit requirements are included in the Technical Specifications for lube oil inventory and starting air subsystems.

M02 **Unit 1 only:** CTS 3.8.1.1.b.2 and 3.8.1.2.b.2 require, for each DG set, the fuel oil storage system to contain a minimum of 19,000 gallons of fuel oil. ITS SR 3.8.3.1 requires a combined fuel inventory in the fuel oil storage tanks of ≥ a 7 day supply (See LA01 for discussion of relocating fuel oil volume value to the ITS Bases). The ITS Bases for SR 3.8.3.1 indicates that the fuel oil volume equivalent to a 7 day supply is 38,000 gallons. This changes the CTS by requiring more fuel oil volume be available to a DG to ensure at least 7 days of fuel oil is available to a DG.

The purpose of the ISTS minimum fuel oil storage requirement is to ensure that there is an adequate inventory of fuel oil in the storage tanks to support each DG's operation for 7 days at post accident load conditions. PSL Unit 1 is designed and licensed with a combined fuel oil storage inventory between two storage tanks to ensure one DG can operate for 7 days at post accident load conditions. These two fuel oil storage tanks are designed to supply each DG. Excess fuel oil in the Unit 2 fuel oil storage tanks can also be provided to support the Unit 1 DGs via a fuel transfer crosstie line between the unit’s storage tanks. A fuel oil level of 38,000 gallons is calculated in accordance with Regulatory Guide 1.137 and ANSI N195-1976 and takes into consideration a consumption of 36,107 gallons (7 days post-accident minus the usable day tank inventory), unusable storage tank volume, and assumed instrument tolerance.

This change is designated as more restrictive because the minimum fuel oil storage volume required to be maintained for a DG is increased from the value in CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.8.1.1.b.2 and CTS 3.8.1.2.b.2 require a separate fuel storage system containing a minimum volume of 19,000 gallons of fuel in each fuel storage tank for Unit 1 and 42,500 gallons in each fuel storage tank for Unit 2. Unit 1 ITS SR 3.8.3.1 requires verifying a combined fuel inventory in the fuel oil storage tanks is ≥ a 7-day supply (38,000 gals) when the diesel generator sets are required to be OPERABLE (See Discussion of Change M02 for change to fuel oil volume). Unit 2 ITS SR 3.8.3.1 requires, in part, verifying that each fuel oil storage tank contains ≥ a 7-day supply of fuel oil (42,500 gals) when the associated diesel generator is required to be OPERABLE. This changes the CTS by moving the specific values for the fuel oil inventory to the Bases and clarifying the Unit 1 fuel storage requirement to meet the 7 day criteria.

The removal of these details from the Technical Specifications is acceptable because this type of information is not necessary to provide adequate protection of public health and safety. The purpose of CTS 3.8.1.1.b.2 and CTS 3.8.1.2.b.2 is to ensure that the DGs have sufficient fuel oil to perform their safety function when the DGs are required to be OPERABLE. ITS SR 3.8.3.1 will continue to ensure that sufficient fuel is contained in the fuel oil storage system for the DGs to perform their intended safety function when the DGs are required to be OPERABLE. In addition, this change is acceptable because these type of details will be adequately controlled in the Technical Specification Bases. Changes to the Bases are controlled by the Technical Specification Control Program in Chapter 5. The program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as less restrictive removal of detail change because details are being moved from the Technical Specifications to the ITS Bases

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* CTS 3.8.1.1 and CTS 3.8.1.2 do not provide explicit compensatory actions if the volume of fuel oil in a storage tank is less than the specified limit. Thus, if the minimum required volume is not met, the associated DG must be declared inoperable and the actions of CTS 3.8.1.1 or CTS 3.8.1.2 must be entered, as appropriate. ITS 3.8.3 ACTION A allows for not declaring the associated DG inoperable as long as the volume of stored fuel oil is greater than a 6 day supply. ITS 3.8.3 Required Action A.1 allows 48 hours to restore the fuel oil volume to within limits. If this Required Action and associated Completion Time is not met or if the fuel oil storage tank volume is < a 6-day supply, the associated DG(s) must be declared inoperable immediately, as required by ITS 3.8.3 ACTION F. For Unit 1, this would require declaring both DGs inoperable because the Unit 1 DGs rely on a combined fuel oil inventory volume in the fuel oil storage tanks (See Discussion of Change

M02). This changes the CTS by allowing the DGs to not be declared inoperable with the fuel oil less than a 7-day supply as long as the associated DG(s) has enough fuel oil for 6 days of operation at post accident load.

The purpose of ITS 3.8.3 ACTION A is to allow time to restore the stored diesel fuel oil volume to within the specified limit for a given DG. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to a degraded condition in order to minimize risk associated with continued operation while providing time to restore inventory. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features including the capacity and capability of remaining systems or features, reasonable time for repairs or replacement, and the low probability of a DBA occurring during the repair period. The addition of ITS 3.8.3 ACTION A will allow each DG to not be declared inoperable with the associated stored diesel fuel oil volume not within the specified Surveillance limit as long as the DG has enough fuel oil for 6 days of operation at post accident load. In this Condition, the 7 day fuel oil supply for the DG is not available. However, the Condition is restricted to fuel oil volume that maintains at least a 6 day supply. These circumstances may be caused by events such as full load operation required after an inadvertent start while at minimum required fuel oil level, or feed and bleed operations, which may be necessary due to increasing particulate levels or any number of other oil quality degradations. This restriction allows sufficient time for obtaining the requisite replacement volume and performing the analyses required prior to addition of fuel oil to the tank. A period of 48 hours is considered sufficient to complete restoration of the required volume prior to declaring the associated DG(s) inoperable. This period is acceptable based on the remaining capacity (> 6 days), the fact that procedures will be initiated to obtain replenishment, and the low probability of an event during this brief period. This change is designated as less restrictive since less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 4.8.1.1.2.c requires, in part, to verify fuel oil properties of new and stored fuel oil are tested in accordance with and maintained within limits specified in the Diesel Fuel Oil Testing Program. CTS 6.8.4.n provides requirements for new fuel oil properties and fuel oil total particulates. CTS 3.8.1.1 and CTS 3.8.1.2 do not provide explicit compensatory actions if the new fuel oil properties or fuel oil total particulates are not within the limits specified in the Diesel Fuel Oil Testing Program. Thus, if the fuel oil properties are not met, the associated DG must be declared inoperable and the actions of CTS 3.8.1.1 or CTS 3.8.1.2 must be entered, as appropriate. ITS SR 3.8.3.3 also requires verification that new and stored fuel oil properties are tested and maintained within limits, as specified in the Diesel Fuel Oil Testing Program. This includes a stored fuel oil total particulate limit and new fuel oil properties. ITS 3.8.3 ACTION C specifies the compensatory actions for one or more DGs with stored fuel oil total particulates not within limits. ITS 3.8.3 ACTION D specifies the compensatory actions for one or more DGs with new fuel oil properties not within limits. If a Required Action and associated Completion Time is not met or one or more DGs with new and stored fuel oil properties not within limits for reasons other than addressed by Conditions C or D, ITS 3.8.3 ACTION F requires the associated DG to be declared inoperable immediately. This

changes the CTS by allowing the DGs to not be declared inoperable with fuel oil total particulates or new fuel oil properties not within the specified Surveillance limits unless the applicable ITS 3.8.3 ACTIONS cannot be completed within the required Completion Time.

The purpose of CTS 4.8.1.1.2.c (ITS SR 3.8.3.3) is to provide the appropriate limits for stored and new fuel oil properties. ITS 3.8.3 ACTIONS C and D provide explicit Required Actions and Completion Times for restoring both total particulates and stored fuel oil properties (affected by the addition of new fuel oil whose properties are not within limits) to within limits. ITS 3.8.3 ACTION C is entered when the acceptance criterion of total particulate concentration specified in ITS 5.5.10 is not met. Normally, trending of particulate levels allows sufficient time to correct high particulate levels prior to reaching the limit of acceptability. Poor sample procedures, contaminated sampling equipment, and errors in laboratory analysis can produce failures that do not follow a trend. Since the presence of particulates does not necessarily result in a failure of the fuel oil to burn properly in the diesel engine, particulate concentration is unlikely to change significantly between Surveillance Frequency intervals, and proper engine performance has been recently demonstrated (within 31 days), it is prudent to allow a brief period prior to declaring the associated DG inoperable. The 7 day Completion Time allows for further evaluation, re-sampling and re-analysis of the DG fuel oil. ITS 3.8.3 ACTION D is entered because of failure to meet the requirements specified in ITS 5.5.10.b. With the new fuel oil properties defined in the Bases for ITS SR 3.8.3.3 not within the required limits, a period of 30 days is allowed for restoring the stored fuel oil properties. This period provides sufficient time to test the stored fuel oil to determine that the new fuel oil did not cause the stored fuel oil to be outside of the required limits, or to restore the stored fuel oil properties to within limits. This restoration may involve feed and bleed procedures, filtering, or combinations of these procedures. Even if a DG start and load was required during this time interval and the stored fuel oil properties were outside limits, there is a high likelihood that the DG would still be capable of performing its intended function. ITS 3.8.3 ACTION F covers the condition when a Required Action and associated Completion Time of any ITS 3.8.3 ACTIONS could not be met, or if one or more DGs with diesel fuel oil, lube oil, or starting air subsystem is not within limits for reasons other than Condition A, B, C, D, or E. The allowances are considered acceptable since a relatively short time is allowed to exist with DG parameters not within limits

This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a design basis accident occurring during the repair period. The fuel oil properties must be restored within limits within 30 days and the fuel oil total particulates must be stored in 7 days. In this condition, the DG fuel oil is degraded but remains capable of supporting the DG OPERABILITY. The ITS

requirements are consistent with the ISTS wording for these requirements. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.3 Diesel Fuel Oil, Lube Oil, and Starting Air

BASES

BACKGROUND

~~Each diesel generator (DG) is~~ provided with a ~~storage tank~~ having a fuel oil capacity sufficient to operate ~~that diesel~~ for a period of ~~[~~7~~]~~ days, while the DG is supplying ~~maximum~~ post loss of coolant accident load demand as discussed in the FSAR, Section ~~[~~9.5.4.2~~]~~ (Ref. 1) ~~[~~and Regulatory Guide 1.137 (Ref. 2)~~]~~. The ~~maximum~~ load demand is calculated using the assumption that ~~at least two~~ DG~~s~~ ~~are~~ available. This onsite fuel oil capacity is sufficient to operate the DG~~s~~ for longer than the time to replenish the onsite supply from outside sources.

Fuel oil is transferred from storage tank to day tank by ~~either of two~~ transfer pump~~s~~ associated with each storage tank. Redundancy of pumps and piping precludes the failure of one pump, or the rupture of any pipe, valve, or tank to result in the loss of more than one DG. All ~~outside tanks, pumps, and piping are~~ located underground.

For proper operation of the standby DGs, it is necessary to ensure the proper quality of the fuel oil. Regulatory Guide 1.137 (Ref. 2) addresses the recommended fuel oil practices as supplemented by ANSI N195-1976 (Ref. 3). The fuel oil properties governed by these SRs are the water and sediment content, the kinematic viscosity, specific gravity (or API gravity), and impurity level.

The DG lubrication system is designed to provide sufficient lubrication to permit proper operation of its associated DG ~~under all~~ loading conditions. The system is required to circulate the lube oil to the ~~diesel engine~~ working surfaces and to remove excess heat generated by friction during operation. Each engine oil sump contains an inventory capable of supporting ~~a minimum of [7] days of~~ operation. ~~[~~The onsite storage in addition to ~~the~~ engine oil sump is sufficient to ensure ~~[~~7~~]~~ days of continuous operation.~~]~~ This supply is sufficient ~~supply~~ to allow the operator to replenish lube oil from outside sources.

Each DG has an air start system with adequate capacity for five ~~successive~~ start ~~attempts~~ on the DG without recharging the air start receiver(s).

1

INSERT 1

Sufficient onsite fuel oil storage is provided to support 7 days of DG operation for one DG at post accident load conditions. Onsite fuel oil storage inventory includes the volume of both Unit 1 fuel oil storage tanks and excess fuel in the Unit 2 fuel oil storage tanks. Fuel oil transfer capability is provided between the storage tanks to ensure at least one DG has a 7-day supply of fuel.

BASES

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 4), and in the FSAR, Chapter ~~[~~15~~]~~ (Ref. 5), assume Engineered Safety Feature (ESF) systems are OPERABLE. The DGs are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to ESF systems so that fuel, Reactor Coolant System and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for LCO Section 3.2, Power Distribution Limits; Section 3.4, Reactor Coolant System (RCS); and Section 3.6, Containment Systems.

Since diesel fuel oil, lube oil, and the air start subsystems support the operation of the standby AC power sources, they satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Stored diesel fuel oil is required to have sufficient supply for ~~[~~7~~]~~ days ~~of full~~ load operation. ~~It is~~ also required to meet specific standards for quality. Additionally, sufficient lubricating oil supply must be available to ensure the capability to operate at full load for ~~[~~7~~]~~ days. This requirement, in conjunction with an ability to obtain replacement supplies within ~~[~~7~~]~~ days, supports the availability of DGs required to shut down the reactor and to maintain it in a safe condition for an anticipated operational occurrence (AOO) or a postulated DBA with loss of offsite power. DG day tank fuel requirements, as well as transfer capability from the storage tank to the day tank, are addressed in LCO 3.8.1, "AC Sources - Operating," and LCO 3.8.2, "AC Sources - Shutdown."

The starting air system is required to have a minimum capacity for five ~~successive~~ DG start~~attempts~~ without recharging the air start receivers.

APPLICABILITY

The AC sources (LCO 3.8.1 and LCO 3.8.2) are required to ensure the availability of the required power to shut down the reactor and maintain it in a safe shutdown condition after an AOO or a postulated DBA. Since stored diesel fuel oil, lube oil, and starting air subsystems support LCO 3.8.1 and LCO 3.8.2, stored diesel fuel oil, lube oil and starting air are required to be within limits when the associated DG is required to be OPERABLE.

ACTIONS

The ACTIONS Table is modified by a Note indicating that separate Condition entry is allowed for each DG. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable DG subsystem. Complying with the Required Actions for one inoperable DG subsystem may allow for continued operation, and subsequent inoperable DG subsystem(s) are governed by separate Condition entry and application of associated Required Actions.

BASES

ACTIONS (continued)

A.1

In this Condition, ~~the~~ [~~7~~] day ~~fuel oil supply~~ for a DG is not available. However, the Condition is restricted to fuel oil level reductions, that maintain at least a [~~6~~] day ~~supply~~. The fuel oil ~~level~~ equivalent to a [~~6~~] day supply is [~~28,285~~] gallons. These circumstances may be caused by events such as full load operation required after an inadvertent start while at minimum required level; or feed and bleed operations, which may be necessitated by increasing particulate levels or any number of other oil quality degradations. This restriction allows sufficient time for obtaining the requisite replacement volume and performing the analyses required prior to addition of fuel oil to the tank. A period of 48 hours is considered sufficient to complete restoration of the required level prior to declaring the DG inoperable. This period is acceptable based on the remaining ~~capacity~~ (≥ [~~6~~] days), the fact that procedures will be initiated to obtain replenishment, and the low probability of an event during this brief period.

a

combined fuel oil inventory in the fuel oil storage tanks

to support either DG

volume

5

2

32,572

combined onsite fuel oil storage tank inventory

2

1

If the combined fuel oil inventory in the fuel oil storage tanks is < 6 days or a combined inventory of 7 days is not restored within 48 hours, both DGs must be declared inoperable per Required Action F.1.

5

B.1

In this Condition, the [~~7~~] day lube oil inventory i.e., sufficient lubricating oil to support [~~7~~] days of continuous DG operation at ~~full~~ load conditions is not available. However, the Condition is restricted to lube oil volume reductions that maintain at least a [~~6~~] day supply. The lube oil inventory equivalent to a [~~6~~] day supply is [~~425~~] gallons. This restriction allows sufficient time to obtain the requisite replacement volume. A period of 48 hours is considered sufficient to complete restoration of the required volume prior to declaring the DG inoperable. This period is acceptable based on the remaining capacity (> [~~6~~] days), the low rate of usage, the fact that procedures will be initiated to obtain replenishment, and the low probability of an event during this brief period.

onsite (500 gallons)

1

post accident

428

2

C.1

This Condition is entered as a result of a failure to meet the acceptance criterion of SR 3.8.3.5. Normally, trending of particulate levels allows sufficient time to correct high particulate levels prior to reaching the limit of acceptability. Poor sample procedures (bottom sampling), contaminated sampling equipment, and errors in laboratory analysis can produce failures that do not follow a trend. Since the presence of particulates does not mean failure of the fuel oil to burn properly in the diesel engine, and particulate concentration is unlikely to change

BASES

ACTIONS (continued)

significantly between Surveillance Frequency intervals, and proper engine performance has been recently demonstrated (within 31 days), it is prudent to allow a brief period prior to declaring the associated DG inoperable. The 7 day Completion Time allows for further evaluation, resampling, and re-analysis of the DG fuel oil.

D.1

With the new fuel oil properties defined in the Bases for SR 3.8.3.4 not within the required limits, a period of 30 days is allowed for restoring the stored fuel oil properties. This period provides sufficient time to test the stored fuel oil to determine that the new fuel oil, when mixed with previously stored fuel oil, remains acceptable, or restore the stored fuel oil properties. This restoration may involve feed and bleed procedures, filtering, or combinations of these procedures. Even if a DG start and load was required during this time interval and the fuel oil properties were outside limits, there is a high likelihood that the DG would still be capable of performing its intended function.

E.1

required

135

With starting air receiver pressure < ~~[225]~~ psig, sufficient capacity for five successive DG start attempts does not exist. However, as long as the receiver pressure is > ~~[125]~~ psig, there is adequate capacity for at least one start attempt, and the DG can be considered OPERABLE while the air receiver pressure is restored to the required limit. A period of 48 hours is considered sufficient to complete restoration to the required pressure prior to declaring the DG inoperable. This period is acceptable based on the remaining air start capacity, the fact that most DG starts are accomplished on the first attempt, and the low probability of an event during this brief period.

85

1

2

F.1

With a Required Action and associated Completion Time not met, or one or more DGs with diesel fuel oil, lube oil, or starting air subsystem not within limits for reasons other than addressed by Conditions A through E, the associated DG may be incapable of performing its intended function and must be immediately declared inoperable.

post accident load conditions. Implicit in this SR is the requirement to verify the capability to transfer the fuel oil from the other onsite storage tanks to the DG day tank

BASES

SURVEILLANCE REQUIREMENTS

SR 3.8.3.1

volume

one

combined onsite

This SR provides verification that there is an adequate inventory of fuel oil in the storage tanks to support ~~each~~ DG's operation for [7] days at ~~full load~~. The fuel oil ~~level~~ equivalent to a [7] day supply is [~~33,~~38,000] gallons when calculated in accordance with References 2 and 3. The required fuel storage volume is determined using the most limiting energy content of the stored fuel. Using the known correlation of diesel fuel oil absolute specific gravity or API gravity to energy content, the required diesel generator output, and the corresponding fuel consumption rate, the onsite fuel storage volume required for [7] days of operation can be determined. SR 3.8.3.3 requires new fuel to be tested to verify that the absolute specific gravity or API gravity is within the range assumed in the diesel fuel oil consumption calculations. The [7] day period is sufficient time to place the unit in a safe shutdown condition and to bring in replenishment fuel from an offsite location.

38,000

The calculated value takes into consideration a consumption of 36,107 gallons (7 days post-accident minus the usable day tank inventory), unusable storage tank volume, and assumed instrument tolerance.

2 1 5 2 2

[~~The 31 day Frequency is adequate to ensure that a sufficient supply of fuel oil is available, since low level alarms are provided and unit operators would be aware of any large uses of fuel oil during this period.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

] 2 4 2

SR 3.8.3.2

onsite

post accident

This Surveillance ensures that sufficient lube oil inventory is available to support at least [7] days of ~~full~~ load operation for each DG. The lube oil inventory equivalent to a [7] day supply is [500] gallons and is based on the DG manufacturer consumption values for the run time of the DG. Implicit in this SR is the requirement to verify the capability to transfer the lube oil from its storage location to the DG, when the DG lube oil ~~sump does~~ not hold adequate inventory for [7] days of full load operation without the level reaching the manufacturer recommended minimum level.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[A 31 day Frequency is adequate to ensure that a sufficient lube oil supply is onsite, since DG starts and run time are closely monitored by the unit staff.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

SR 3.8.3.3

The tests listed below are a means of determining whether new fuel oil is of the appropriate grade and has not been contaminated with substances that would have an immediate, detrimental impact on diesel engine combustion. If results from these tests are within acceptable limits, the fuel oil may be added to the storage tanks without concern for contaminating the entire volume of fuel oil in the storage tanks. These tests are to be conducted prior to adding the new fuel to the storage tank(s), but in no case is the time between receipt of new fuel and conducting the tests to exceed 31 days. The tests, limits, and applicable ASTM Standards are as follows:

a. Sample the new fuel oil in accordance with ASTM D4057-~~[ ]~~ (Ref. 6),

b. Verify in accordance with the tests specified in ASTM D975-~~[ ]~~ (Ref. 6) that the sample has an absolute specific gravity at 60/60°F of ≥ 0.83 and ≤ 0.89, or an API gravity at 60°F of ≥ 27° and ≤ 39° when tested in accordance with ASTM D1298-~~[ ]~~ (Ref. 6), a kinematic viscosity at 40°C of ≥ 1.9 centistokes and ≤ 4.1 centistokes, and a flash point ≥ 125°F, and

c. Verify that the new fuel oil has a clear and bright appearance with proper color when tested in accordance with ASTM D4176-~~[ ]~~ or a water and sediment content within limits when tested in accordance with ~~[~~ASTM D2709-~~[ ]]~~ (Ref. 6).

BASES

SURVEILLANCE REQUIREMENTS (continued)

Failure to meet any of the above limits is cause for rejecting the new fuel oil, but does not represent a failure to meet the LCO concern since the fuel oil is not added to the storage tanks.

Within 31 days following the initial new fuel oil sample, the fuel oil is analyzed to establish that the other properties specified in Table 1 of ASTM D975-~~[ ]~~ (Ref. 7) are met for new fuel oil when tested in accordance with ASTM D975-~~[ ]~~ (Ref. 6), except that the analysis for sulfur may be performed in accordance with ASTM D~~1552-[ ]~~, ASTM D2622-~~[ ]~~, or ASTM D~~4294-[ ] (Ref. 6)~~. The 31 day period is acceptable because the fuel oil properties of interest, even if they were not within stated limits, would not have an immediate effect on DG operation. This Surveillance ensures the availability of high quality fuel oil for the DGs.

06

2
1

Fuel oil degradation during long term storage shows up as an increase in particulate, due mostly to oxidation. The presence of particulate does not mean the fuel oil will not burn properly in a diesel engine. The particulate can cause fouling of filters and fuel oil injection equipment, however, which can cause engine failure.

Particulate concentrations should be determined in accordance with ASTM D~~5452-[ ] (Ref. 6)~~. This method involves a gravimetric determination of total particulate concentration in the fuel oil and has a limit of 10 mg/l. It is acceptable to obtain a field sample for subsequent laboratory testing in lieu of field testing. ~~[For those designs in which the~~ total stored fuel oil volume ~~is~~ contained in two or more interconnected tanks~~, each tank must be~~ considered and tested separately.~~]~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

SR 3.8.3.5

Microbiological fouling is a major cause of fuel oil degradation. There are numerous bacteria that can grow in fuel oil and cause fouling, but all must have a water environment in order to survive. Removal of water from the fuel storage tanks eliminates the necessary environment for bacterial survival. This is the most effective means of controlling microbiological fouling. In addition, it eliminates the potential for water entrainment in the fuel oil during DG operation. Water may come from any of several sources, including condensation, ground water, rain water, and contaminated fuel oil, and from breakdown of the fuel oil by bacteria. Frequent checking for and removal of accumulated water minimizes fouling and provides data regarding the watertight integrity of the fuel oil system. ~~[The Surveillance Frequency of 31 days is established by Regulatory Guide 1.137 (Ref. 2). This SR is for preventative maintenance.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

The presence of water does not necessarily represent failure of this SR provided the accumulated water is removed during performance of the Surveillance.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.3 Diesel Fuel Oil, Lube Oil, and Starting Air

BASES

BACKGROUND

Each diesel generator (DG) is provided with a storage tank having a fuel oil capacity sufficient to operate that diesel for a period of ~~[~~7~~]~~ days, while the DG is supplying ~~maximum~~ post ~~loss of coolant~~ accident load demand as discussed in the FSAR, Section ~~[~~9.5.4.2~~]~~ (Ref. 1) ~~[~~and Regulatory Guide 1.137 (Ref. 2)~~]~~. The ~~maximum~~ load demand is calculated using the assumption that ~~at least two~~ DG~~s~~ ~~are~~ available. This onsite fuel oil capacity is sufficient to operate the DG~~s~~ for longer than the time to replenish the onsite supply from outside sources.

Fuel oil is transferred from storage tank to day tank by ~~either of two~~ transfer pump~~s~~ associated with each storage tank. Redundancy of pumps and piping precludes the failure of one pump, or the rupture of any pipe, valve, or tank to result in the loss of more than one DG. All ~~outside tanks, pumps, and piping are~~ located underground.

For proper operation of the standby DGs, it is necessary to ensure the proper quality of the fuel oil. Regulatory Guide 1.137 (Ref. 2) addresses the recommended fuel oil practices as supplemented by ANSI N195-1976 (Ref. 3). The fuel oil properties governed by these SRs are the water and sediment content, the kinematic viscosity, specific gravity (or API gravity), and impurity level.

The DG lubrication system is designed to provide sufficient lubrication to permit proper operation of its associated DG ~~under all~~ loading conditions. The system is required to circulate the lube oil to the ~~diesel engine~~ working surfaces and to remove excess heat generated by friction during operation. Each engine oil sump contains an inventory capable of supporting ~~a minimum of [7] days of~~ operation. ~~[~~The onsite storage in addition to ~~the~~ engine oil sump is sufficient to ensure ~~[~~7~~]~~ days of continuous operation.~~]~~ This supply is sufficient ~~supply~~ to allow the operator to replenish lube oil from outside sources.

Each DG has an air start system with adequate capacity for five ~~successive~~ start ~~attempts~~ on the DG without recharging the air start receiver(s).

BASES

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter [6] (Ref. 4), and in the FSAR, Chapter [15] (Ref. 5), assume Engineered Safety Feature (ESF) systems are OPERABLE. The DGs are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to ESF systems so that fuel, Reactor Coolant System and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for LCO Section 3.2, Power Distribution Limits; Section 3.4, Reactor Coolant System (RCS); and Section 3.6, Containment Systems.

Since diesel fuel oil, lube oil, and the air start subsystems support the operation of the standby AC power sources, they satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Stored diesel fuel oil is required to have sufficient supply for [7] days of full load operation. It is also required to meet specific standards for quality. Additionally, sufficient lubricating oil supply must be available to ensure the capability to operate at full load for [7] days. This requirement, in conjunction with an ability to obtain replacement supplies within [7] days, supports the availability of DGs required to shut down the reactor and to maintain it in a safe condition for an anticipated operational occurrence (AOO) or a postulated DBA with loss of offsite power. DG day tank fuel requirements, as well as transfer capability from the storage tank to the day tank, are addressed in LCO 3.8.1, "AC Sources - Operating," and LCO 3.8.2, "AC Sources - Shutdown."

The starting air system is required to have a minimum capacity for five successive DG start attempts without recharging the air start receivers.

APPLICABILITY

The AC sources (LCO 3.8.1 and LCO 3.8.2) are required to ensure the availability of the required power to shut down the reactor and maintain it in a safe shutdown condition after an AOO or a postulated DBA. Since stored diesel fuel oil, lube oil, and starting air subsystems support LCO 3.8.1 and LCO 3.8.2, stored diesel fuel oil, lube oil and starting air are required to be within limits when the associated DG is required to be OPERABLE.

ACTIONS

The ACTIONS Table is modified by a Note indicating that separate Condition entry is allowed for each DG. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable DG subsystem. Complying with the Required Actions for one inoperable DG subsystem may allow for continued operation, and subsequent inoperable DG subsystem(s) are governed by separate Condition entry and application of associated Required Actions.

BASES

ACTIONS (continued)

A.1

In this Condition, the [7] day fuel oil supply for a DG (42,500) is not available. However, the Condition is restricted to fuel oil level reductions, that maintain at least a [6] day supply. The fuel oil level equivalent to a [6] day supply is 36,429 [~~28,285~~] gallons. These circumstances may be caused by events such as full load operation required after an inadvertent start while at minimum required level; or feed and bleed operations, which may be necessitated by increasing particulate levels or any number of other oil quality degradations. This restriction allows sufficient time for obtaining the requisite replacement volume and performing the analyses required prior to addition of fuel oil to the tank. A period of 48 hours is considered sufficient to complete restoration of the required level prior to declaring the DG inoperable. This period is acceptable based on the remaining capacity (≥ [6] days), the fact that procedures will be initiated to obtain replenishment, and the low probability of an event during this brief period. (1) (2) (2)

B.1

In this Condition, the [7] day lube oil inventory onsite (500 gallons) i.e., sufficient lubricating oil to support [7] days of continuous DG operation at ~~full~~ post accident load conditions is not available. However, the Condition is restricted to lube oil volume reductions that maintain at least a [6] day supply. The lube oil inventory equivalent to a [6] day supply is 428 [~~425~~] gallons. This restriction allows sufficient time to obtain the requisite replacement volume. A period of 48 hours is considered sufficient to complete restoration of the required volume prior to declaring the DG inoperable. This period is acceptable based on the remaining capacity (> [6] days), the low rate of usage, the fact that procedures will be initiated to obtain replenishment, and the low probability of an event during this brief period. (1) (2)

C.1

This Condition is entered as a result of a failure to meet the acceptance criterion of SR 3.8.3.5. Normally, trending of particulate levels allows sufficient time to correct high particulate levels prior to reaching the limit of acceptability. Poor sample procedures (bottom sampling), contaminated sampling equipment, and errors in laboratory analysis can produce failures that do not follow a trend. Since the presence of particulates does not mean failure of the fuel oil to burn properly in the diesel engine, and particulate concentration is unlikely to change

BASES

ACTIONS (continued)

significantly between Surveillance Frequency intervals, and proper engine performance has been recently demonstrated (within 31 days), it is prudent to allow a brief period prior to declaring the associated DG inoperable. The 7 day Completion Time allows for further evaluation, resampling, and re-analysis of the DG fuel oil.

D.1

With the new fuel oil properties defined in the Bases for SR 3.8.3.4 not within the required limits, a period of 30 days is allowed for restoring the stored fuel oil properties. This period provides sufficient time to test the stored fuel oil to determine that the new fuel oil, when mixed with previously stored fuel oil, remains acceptable, or restore the stored fuel oil properties. This restoration may involve feed and bleed procedures, filtering, or combinations of these procedures. Even if a DG start and load was required during this time interval and the fuel oil properties were outside limits, there is a high likelihood that the DG would still be capable of performing its intended function.

E.1

required

129

With starting air receiver pressure < ~~[225]~~ psig, sufficient capacity for five successive DG start attempts does not exist. However, as long as the receiver pressure is > ~~[125]~~ psig, there is adequate capacity for at least one start attempt, and the DG can be considered OPERABLE while the air receiver pressure is restored to the required limit. A period of 48 hours is considered sufficient to complete restoration to the required pressure prior to declaring the DG inoperable. This period is acceptable based on the remaining air start capacity, the fact that most DG starts are accomplished on the first attempt, and the low probability of an event during this brief period.

85

2

F.1

With a Required Action and associated Completion Time not met, or one or more DGs with diesel fuel oil, lube oil, or starting air subsystem not within limits for reasons other than addressed by Conditions A through E, the associated DG may be incapable of performing its intended function and must be immediately declared inoperable.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.8.3.1

This SR provides verification that there is an adequate inventory of fuel oil in the storage tanks to support each DG's operation for [7] days at full load. The fuel oil level equivalent to a [7] day supply is [33,000] gallons when calculated in accordance with References 2 and 3. The required fuel storage volume is determined using the most limiting energy content of the stored fuel. Using the known correlation of diesel fuel oil absolute specific gravity or API gravity to energy content, the required diesel generator output, and the corresponding fuel consumption rate, the onsite fuel storage volume required for [7] days of operation can be determined. SR 3.8.3.3 requires new fuel to be tested to verify that the absolute specific gravity or API gravity is within the range assumed in the diesel fuel oil consumption calculations. The [7] day period is sufficient time to place the unit in a safe shutdown condition and to bring in replenishment fuel from an offsite location.

post-accident load conditions

42,500

The calculated value takes into consideration a consumption of 40,671 gallons (7 days post-accident minus the usable day tank inventory), unusable storage tank volume, and assumed instrument tolerance.

2 1 5 2 2

[The 31 day Frequency is adequate to ensure that a sufficient supply of fuel oil is available, since low level alarms are provided and unit operators would be aware of any large uses of fuel oil during this period.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

REVIEWER'S NOTE

Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

]

2 4 2

SR 3.8.3.2

This Surveillance ensures that sufficient lube oil inventory is available to support at least [7] days of full load operation for each DG. The lube oil inventory equivalent to a [7] day supply is [500] gallons and is based on the DG manufacturer consumption values for the run time of the DG. Implicit in this SR is the requirement to verify the capability to transfer the lube oil from its storage location to the DG, when the DG lube oil sump does not hold adequate inventory for [7] days of full load operation without the level reaching the manufacturer recommended minimum level.

onsite

post-accident

sumps do

1 2 1 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[A 31 day Frequency is adequate to ensure that a sufficient lube oil supply is onsite, since DG starts and run time are closely monitored by the unit staff.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

SR 3.8.3.3

The tests listed below are a means of determining whether new fuel oil is of the appropriate grade and has not been contaminated with substances that would have an immediate, detrimental impact on diesel engine combustion. If results from these tests are within acceptable limits, the fuel oil may be added to the storage tanks without concern for contaminating the entire volume of fuel oil in the storage tanks. These tests are to be conducted prior to adding the new fuel to the storage tank(s), but in no case is the time between receipt of new fuel and conducting the tests to exceed 31 days. The tests, limits, and applicable ASTM Standards are as follows:

a. Sample the new fuel oil in accordance with ASTM D4057-~~[ ]~~ (Ref. 6),

b. Verify in accordance with the tests specified in ASTM D975-~~[ ]~~ (Ref. 6) that the sample has an absolute specific gravity at 60/60°F of ≥ 0.83 and ≤ 0.89, or an API gravity at 60°F of ≥ 27° and ≤ 39° when tested in accordance with ASTM D1298-~~[ ]~~ (Ref. 6), a kinematic viscosity at 40°C of ≥ 1.9 centistokes and ≤ 4.1 centistokes, and a flash point ≥ 125°F, and

c. Verify that the new fuel oil has a clear and bright appearance with proper color when tested in accordance with ASTM D4176-~~[ ]~~ or a water and sediment content within limits when tested in accordance with ~~[~~ASTM D2709-~~[ ]]~~ (Ref. 6).

BASES

SURVEILLANCE REQUIREMENTS (continued)

Failure to meet any of the above limits is cause for rejecting the new fuel oil, but does not represent a failure to meet the LCO concern since the fuel oil is not added to the storage tanks.

Within 31 days following the initial new fuel oil sample, the fuel oil is analyzed to establish that the other properties specified in Table 1 of ASTM D975-~~[ ]~~ (Ref. 7) are met for new fuel oil when tested in accordance with ASTM D975-~~[ ]~~ (Ref. 6), except that the analysis for sulfur may be performed in accordance with ASTM D~~1552-[ ]~~, ASTM D2622-~~[ ]~~, or ASTM D~~4294-[ ] (Ref. 6)~~. The 31 day period is acceptable because the fuel oil properties of interest, even if they were not within stated limits, would not have an immediate effect on DG operation. This Surveillance ensures the availability of high quality fuel oil for the DGs.

Fuel oil degradation during long term storage shows up as an increase in particulate, due mostly to oxidation. The presence of particulate does not mean the fuel oil will not burn properly in a diesel engine. The particulate can cause fouling of filters and fuel oil injection equipment, however, which can cause engine failure.

Particulate concentrations should be determined in accordance with ASTM D~~5452-[ ] (Ref. 6)~~. This method involves a gravimetric determination of total particulate concentration in the fuel oil and has a limit of 10 mg/l. It is acceptable to obtain a field sample for subsequent laboratory testing in lieu of field testing. ~~[For those designs in which the~~ total stored fuel oil volume ~~is~~ contained in two or more interconnected tanks~~, each tank must be~~ considered and tested separately.~~]~~

SURVEILLANCE REQUIREMENTS (continued)

~~[The 31 day Frequency takes into account the capacity, capability, redundancy, and diversity of the AC sources and other indications available in the control room, including alarms, to alert the operator to below normal air start pressure.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

SR 3.8.3.5

Microbiological fouling is a major cause of fuel oil degradation. There are numerous bacteria that can grow in fuel oil and cause fouling, but all must have a water environment in order to survive. Removal of water from the fuel storage tanks eliminates the necessary environment for bacterial survival. This is the most effective means of controlling microbiological fouling. In addition, it eliminates the potential for water entrainment in the fuel oil during DG operation. Water may come from any of several sources, including condensation, ground water, rain water, and contaminated fuel oil, and from breakdown of the fuel oil by bacteria. Frequent checking for and removal of accumulated water minimizes fouling and provides data regarding the watertight integrity of the fuel oil system. ~~[The Surveillance Frequency of 31 days is established by Regulatory Guide 1.137 (Ref. 2). This SR is for preventative maintenance.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~ 4 2

The presence of water does not necessarily represent failure of this SR provided the accumulated water is removed during performance of the Surveillance.

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.3 BASES, DIESEL FUEL OIL, LUBE OIL, AND STARTING AIR

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. Editorial grammar changes to the Bases have been made to enhance clarity.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. Changes are made to clarify the 7 day fuel oil storage volume requirement.

(3) With any Category B parameter not within its allowable value, declare the battery inoperable.

DISCUSSION OF CHANGES
ITS 3.8.4, DC SOURCES - OPERATING

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS LCO 3.8.2.3 and Unit 2 CTS LCO 3.8.2.1 Action b state, “With one of the required full capacity chargers inoperable, demonstrate the OPERABILITY of its associated battery bank by performing Surveillance Requirement 4.8.2.3.2.a.1 within one hour, and at least once per 8 hours thereafter.” ITS LCO 3.8.4 Condition A requires, in part, with the required battery charger on one subsystem inoperable, that the required inoperable charger must be restored to OPERABLE status within 72 hours. Refer to DOC L01 for discussion related to less restrictive actions. This changes the CTS by adding a requirement to restore the required charger to Operable status.

The purpose of ITS 3.8.4 Required Actions is to provide the appropriate actions to be taken when a charger becomes inoperable. This change is acceptable because the additional requirements are appropriate to ensure the battery is returned to a condition that it can provide the required safety functions. The ITS requirements are consistent with the ISTS wording for this requirement. This change is designated as more restrictive because it adds an additional required action to restore a required battery charger within 72 hours.

M02 Unit 1 CTS 4.8.2.3.2.e and Unit 2 4.8.2.1.e allow the performance discharge test to be performed in lieu of the battery service test. ITS SR 3.8.4.3 Note 1 provides a similar allowance but requires the performance discharge test to be a modified performance discharge test to be used in lieu of the battery services test. This changes the CTS by requiring a more restrictive type of performance discharge test to be performed in lieu of the battery service test.

The purpose of allowing a performance discharge test in lieu of a battery service test is to eliminate the need to perform two separate tests, thus minimizing the time the battery is unavailable to perform its related electrical support function.

This change is necessary because the normal performance discharge test is inadequate to satisfy the battery service test requirements. A modified discharge test is a test of the battery capacity and its ability to provide a high rate, short duration load (usually the highest rate of the duty cycle) and is described in IEEE 450, “IEEE Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications.” The modified performance discharge test combines the greater of both the peak duty cycle load values of the service test with the load values and duration of the

performance capacity test. This will often confirm the battery's ability to meet the critical period of the load duty cycle, in addition to determining its percentage of rated capacity. Initial conditions for the modified performance discharge test should be identical to those specified for a service test. It may consist of just two rates; for instance the one minute rate for the battery or the largest current load of the duty cycle, followed by the test rate employed for the performance test, both of which envelope the duty cycle of the service test. Since the ampere-hours removed by a one minute discharge represents a very small portion of the battery capacity, the test rate can be changed to that for the performance test without compromising the results of the performance discharge test. The battery terminal voltage for the modified performance discharge test must remain above the minimum battery terminal voltage specified in the battery service test for the duration of time equal to that of the service test. The ITS requirements are consistent with the ISTS wording for this requirement. This change is designated as more restrictive because it requires a more restrictive allowance than CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS LCO 3.8.2.3 and Unit 2 CTS LCO 3.8.2.1 state, in part, that the DC electrical sources shall be OPERABLE and lists the details of what constitutes a DC electrical power source. ITS LCO 3.8.4 requires the Train A and Train B DC electrical power subsystems to be OPERABLE. This changes the CTS by moving the details of the components of the DC Sources (battery and charger) from the CTS to the ITS Bases.

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirements for the DC electrical power subsystems. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Control Program in Chapter 5. The program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information related to system design is being removed from the Technical Specifications.

LA02 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS surveillance requirement 4.8.2.3.2.a.2 and Unit 2 surveillance requirement 4.8.2.1.a.2 state that each 125 volt battery bank and charger shall be demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program with total battery terminal voltage greater than or equal to 129 volts on float charge. ITS SR 3.8.4.1 requires verification that battery terminal voltage is greater than or equal to “the minimum established float voltage.” This changes the CTS by moving the battery terminal voltage requirements from the specifications to the ITS Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The Technical Specifications still retain the surveillance requirement to verify battery terminal voltage is ≥ the minimum established float voltage. The minimum establish float voltage for the PSL batteries is 2.20 Vpc as specified by the battery manufacturer and equates to 132 V for a 60 cell battery. As such, the 129 volts is changed to 132 V in the ITS Bases to reflect the minimum float voltage specified by the battery manufacturer. This change is acceptable because the removed information will be adequately controlled in the Technical Specification Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Section 5 of the Technical Specifications. This program provides for the evaluation of Bases changes in accordance with 10 CFR 50.59 to ensure the Bases are properly controlled. The ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 (Category 4 – Relaxation of Required Action) Unit 1 CTS 3.8.2.3 and Unit 2 CTS 3.8.2.1 Action b in part states with one of the required full capacity chargers inoperable, demonstrate the OPERABILITY of its associated battery bank by performing Surveillance Requirement 4.8.2.3.2.a.1 (Unit 1) and Surveillance Requirement 4.8.2.1.a.1 (Unit 2) within 1 hour. The requirement goes on to state that the action requires the applicable Surveillance Requirement to be performed once per 8 hours thereafter and if any Category A limit in Table 3.8-1 is not met, declare the battery inoperable. ITS LCO 3.8.4 Condition A states, in part, with one required battery charger on one train inoperable, restore battery terminal voltage to greater than or equal to the minimum established float voltage within 2 hours (Required Action A.1). Required Action A.2 states a verification of float current of ≤ 2 amps is required once per 12 hours. This changes the CTS by allowing the battery terminal voltage to be restored to the minimum established float voltage with float current to be ≤ 2 amps instead of declaring the battery inoperable based on individual cell parameters.

The purpose of ITS Required Actions is to allow appropriate remedial actions with appropriate time limitations prior to restoring an inoperable battery charger to OPERABLE status. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a design basis accident occurring during the repair period. This change establishes the appropriate actions to be taken with the required battery charger inoperable. The current requirement specifies that all Category A parameters listed in Table 3.8-1

be within limits. The battery charger affect on the associated battery is directly related to the terminal voltage and the charging current in a float condition and not necessarily individual battery cell parameters. With a charger with the capability of restoring the minimum float voltage and less than 2 amps of charging current, the battery can continue to perform its safety related support function and should be considered OPERABLE. Twelve hours is acceptable for the verification of the charging current because it provides a limited time and the required charger must be returned to OPERABLE within 72 hours (Refer to DOC M02 for discussion of restoring the required battery charger). The ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS surveillance requirement 4.8.2.3.2.c.4 and Unit 2 surveillance requirement 4.8.2.1.c.4 state that the battery charger will supply at least 300 amps at 140 volts for at least 6 hours. ITS SR 3.8.4.2 provides an alternative test method that allows a verification of each battery charger can recharge the battery to the fully charged state within 12 hours while supplying the largest combined demands of the various continuous steady state loads, after a battery discharge to the bounding design basis event discharge state. This changes the CTS by allowing an alternate test that is not currently allowed. | R1

The purpose of Unit 1 CTS 4.8.2.3.2.c.4 and Unit 2 surveillance requirement 4.8.2.1.a.2 is to verify the required 125 V DC battery chargers can recharge their respective batteries following a loss of offsite power event. This change is acceptable because the relaxed Surveillance Requirement acceptance criteria are adequate to verify that the equipment used to meet the LCO can perform its required functions. The alternate test provides an acceptable method for determining charger capability by actually recharging a discharged battery within 12 hours while supplying required loads. The ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L03 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.8.2.3.2.d and Unit 2 4.8.2.1.d state that battery capacity is verified by subjecting the battery to a service test. ITS SR 3.8.4.3 requires a service test to be performed to verify the battery capacity with a modifying Note 2. Note 2 that modifies the SR states “This Surveillance shall not normally be performed in MODE 1, 2, 3, or 4. However, portions of the Surveillance may be performed to reestablish OPERABILITY provided an assessment determines the safety of the plant is maintained or enhanced. Credit may be taken for unplanned events that satisfy this SR.” This changes the CTS by allowing portions of the SR to be performed in MODES 1, 2, 3, or 4 and allowing credit for unplanned events.

The purpose of ITS SR 3.8.4.3 Note 2 is to allow portions of the requirement to be performed to ensure OPERABILITY of the batteries. These portions of the SR may only be performed in MODE 1, 2, 3, or 4 if the safety of the plant is maintained or enhanced. This change is acceptable because the relaxed Surveillance Requirement acceptance criteria are adequate to verify that the

equipment used to meet the LCO can perform its required functions. The change allows the performance of portions of the SR in MODE 1, 2, 3, or 4 provided plant safety is maintained or enhanced. Normally, the SR is conducted when the battery is not required to be OPERABLE. Under limited conditions, battery OPERABILITY may have to be demonstrated with the plant operating. Verification of battery OPERABILITY under these conditions is infrequent and the plant's safety is always maintained or enhanced by the performance of this requirement. The ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.4, DC SOURCES - OPERATING

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. The bracketed ISTS 3.8.4 ACTION B has been deleted since it is not necessary. ISTS 3.8.4 ACTION C (ITS 3.8.4 ACTION B) covers the condition of an inoperable battery. Due to this deletion, the subsequent ACTIONS have been arranged in sequence.

4. Changed the word “One” to “Required” in ISTS 3.8.4 Condition A since there are two DC electrical power system chargers per DC electrical power subsystem and only one is required for each subsystem.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.4 DC Sources - Operating

BASES

BACKGROUND

The station DC electrical power system provides the AC emergency power system with control power. It also provides both motive and control power to selected safety related equipment and preferred AC ~~vital~~ bus power (via inverters). As required by 10 CFR 50, Appendix A, GDC 17 (Ref. 1), the DC electrical power system is designed to have sufficient independence, redundancy, and testability to perform its safety functions, assuming a single failure. The DC electrical power system also conforms to the recommendations of ~~Regulatory~~ Guide ~~1.~~6 (Ref. 2) and IEEE-308 (Ref. 3).

The ~~[~~125~~/250]~~ VDC electrical power system consists of two independent and redundant safety related Class 1E DC electrical power subsystems (~~[~~Train A and Train B~~]~~). Each subsystem consists of ~~[two]~~ 125 VDC batter~~ies~~ ~~[(each battery [50]% capacity)],~~ ~~the associated~~ battery charger~~(s)~~ for each battery, and all the associated control equipment and interconnecting cabling.

~~[The 250 VDC source is obtained by use of the two 125 VDC batteries connected in series. Additionally there is [one] spare battery~~ charger ~~per subsystem, which provides backup service in the event that the preferred battery charger is out of service~~. If the ~~spare~~ battery charger is substituted ~~for one of the preferred battery chargers, then~~ the requirements of independence and redundancy between subsystems are maintained.~~]~~

During normal operation, the ~~[~~125~~/250]~~ VDC load is powered from the battery chargers with the batteries floating on the system. In case of loss of normal power to ~~the battery charger,~~ the DC load is automatically powered from the station batteries.

The ~~[~~Train A and Train B~~]~~ DC electrical power subsystems provide the control power for its associated Class 1E AC power load group, ~~[~~4.16~~]~~ kV switchgear, and ~~[~~480~~]~~ V load centers. The DC electrical power subsystems also provide DC electrical power to the inverters, which in turn power the AC ~~vital buses~~.

The DC power distribution system is described in more detail in the Bases for LCO 3.8.9, "Distributions System Operating," and for LCO 3.8.10, "Distribution Systems - Shutdown."

System

BASES

BACKGROUND (continued)

Each 125~~/250~~ VDC battery is separately housed in a ventilated room ~~apart from its charger and distribution centers~~. Each subsystem is located in an area separated physically and electrically from the other subsystem to ensure that a single failure in one subsystem does not cause a failure in a redundant subsystem. ~~[~~There is no sharing between redundant Class 1E subsystems, such as batteries, battery chargers, or distribution panels.~~]~~

Each battery has adequate storage capacity to meet the duty cycle(s) discussed in the FSAR, Chapter ~~[~~8~~]~~ (Ref 4). The battery is designed with additional capacity above that required by the design duty cycle to allow for temperature variations and other factors.

The batteries for Train A and Train B DC electrical power subsystems are sized to produce required capacity at 80% of nameplate rating, corresponding to warranted capacity at end of life cycles and the 100% design demand. The minimum design voltage limit ~~is [105/210] V.~~

The battery cells are of flooded lead acid construction with a nominal specific gravity of ~~[~~1.215~~]~~. This specific gravity corresponds to an open circuit battery voltage of approximately ~~120~~ V for a ~~[58]~~ cell battery (i.e., cell voltage of ~~[2.065]~~ volts per cell (Vpc)). The open circuit voltage is the voltage maintained when there is no charging or discharging. ~~Once fully charged with its open circuit voltage ≥ [2.065] Vpc, the battery cell will maintain its capacity for [30] days without further charging per manufacturer's instructions.~~ Optimal long term performance however, is obtained by maintaining a float voltage ~~[~~2.20 to 2.25~~]~~ Vpc. This provides adequate over-potential, which limits the formation of lead sulfate and self discharge. The nominal float voltage of ~~[2.22]~~ Vpc corresponds to a total float voltage output of ~~[128.8]~~ V for a ~~[58]~~ cell battery ~~as discussed in the FSAR, Chapter [8] (Ref. 4)~~.

Each Train A and Train B DC electrical power subsystem battery charger has ample power output capacity for the steady state operation of connected loads required during normal operation, while at the same time maintaining its battery bank fully charged. Each battery charger also has sufficient excess capacity to restore the battery from the design minimum charge to its fully charged state within ~~[24]~~ hours while supplying normal steady state loads ~~discussed in the FSAR, Chapter [8] (Ref. 4)~~.

BASES

BACKGROUND (continued)

The battery charger is normally in the float-charge mode. Float-charge is the condition in which the charger is supplying the connected loads and the battery cells are receiving adequate current to optimally charge the battery. This assures the internal losses of a battery are overcome and the battery is maintained in a fully charged state.

When desired, the charger can be placed in the equalize mode. The equalize mode is at a higher voltage than the float mode and charging current is correspondingly higher. The battery charger is operated in the equalize mode after a battery discharge or for routine maintenance. Following a battery discharge, the battery recharge characteristic accepts current at the current limit of the battery charger (if the discharge was significant, e.g., following a battery service test) until the battery terminal voltage approaches the charger voltage setpoint. Charging current then reduces exponentially during the remainder of the recharge cycle. Lead-calcium batteries have recharge efficiencies of greater than 95%, so once at least 105% of the ampere-hours discharged have been returned, the battery capacity would be restored to the same condition as it was prior to the discharge. This can be monitored by direct observation of the exponentially decaying charging current or by evaluating the amp-hours discharged from the battery and amp-hours returned to the battery.

Battery parameters are described in further detail in the Bases for LCO 3.8.6, "Battery Parameters."

1

APPLICABLE SAFETY ANALYSES

U

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 5) and Chapter ~~[~~15~~]~~ (Ref. 6), assume that Engineered Safety Feature (ESF) systems are OPERABLE. The DC electrical power system provides normal and emergency DC electrical power for the DGs, emergency auxiliaries, and control and switching during all MODES of operation.

2 1

The OPERABILITY of the DC sources is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This includes maintaining the DC sources OPERABLE during accident conditions in the event of:

a. An assumed loss of all offsite AC power or all onsite AC power and

b. A worst-case single failure.

The DC sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The DC electrical power subsystems, each subsystem consisting of ~~[two]~~ batteries battery charger ~~[for each battery]~~ and the corresponding control equipment and interconnecting cabling supplying power to the associated bus within the subsystem are required to be OPERABLE to ensure the availability of the required power to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA. Loss of any DC electrical power subsystem does not prevent the minimum safety function from being performed (Ref. 4).

An OPERABLE DC electrical power subsystem requires ~~all required~~ batteries and ~~respective~~ chargers to be operating and connected to the associated DC bus(es).

APPLICABILITY

The DC electrical power sources are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure safe unit operation and to ensure that:

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients and

b. Adequate core cooling is provided, and containment integrity and other vital functions are maintained in the event of a postulated DBA.

The DC electrical power requirements for MODES 5 and 6 are addressed in the Bases for LCO 3.8.5, "DC Sources - Shutdown."

ACTIONS

A.1, A.2, and A.3

Condition A represents one subsystem with one ~~[or two]~~ battery chargers inoperable (e.g., the voltage limit of SR 3.8.4.1 is not maintained). The ACTIONS provide a tiered response that focuses on returning the battery to the fully charged state and restoring a fully qualified charger to OPERABLE status in a reasonable time period. Required Action A.1 requires that the battery terminal voltage be restored to greater than or equal to the minimum established float voltage within 2 hours. This time provides for returning the inoperable charger to OPERABLE status or providing an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage. Restoring the battery terminal voltage to greater than or equal to the minimum established float voltage provides good assurance that, within ~~[~~12~~]~~ hours, the battery will be restored to its fully charged condition (Required Action A.2) from any discharge that might have occurred due to the charger inoperability.

BASES

ACTIONS (continued)

~~REVIEWER'S NOTE~~

~~A plant that cannot meet the 12 hour Completion Time due to an inherent battery charging characteristic can propose an alternate time equal to 2 hours plus the time experienced to accomplish the exponential charging current portion of the battery charge profile following the service test (SR 3.8.4.3).~~ 3

A discharged battery having terminal voltage of at least the minimum established float voltage indicates that the battery is on the exponential charging current portion (the second part) of its recharge cycle. The time to return a battery to its fully charged state under this condition is simply a function of the amount of the previous discharge and the recharge characteristic of the battery. Thus there is good assurance of fully recharging the battery within ~~[~~12~~]~~ hours, avoiding a premature shutdown with its own attendant risk. 2

If established battery terminal float voltage cannot be restored to greater than or equal to the minimum established float voltage within 2 hours, and the charger is not operating in the current-limiting mode, a faulty charger is indicated. A faulty charger that is incapable of maintaining established battery terminal float voltage does not provide assurance that it can revert to and operate properly in the current limit mode that is necessary during the recovery period following a battery discharge event that the DC system is designed for.

If the charger is operating in the current limit mode after 2 hours that is an indication that the battery is partially discharged and its capacity margins will be reduced. The time to return the battery to its fully charged condition in this case is a function of the battery charger capacity, the amount of loads on the associated DC system, the amount of the previous discharge, and the recharge characteristic of the battery. The charge time can be extensive, and there is not adequate assurance that it can be recharged within ~~[~~12~~]~~ hours (Required Action A.2). 2

Required Action A.2 requires that the battery float current be verified as less than or equal to ~~[~~2~~]~~ amps. This indicates that, if the battery had been discharged as the result of the inoperable battery charger, it is now fully capable of supplying the maximum expected load requirement. The ~~[~~2~~]~~ amp value is based on returning the battery to ~~[~~95~~]~~% charge and assumes a ~~[~~5~~]~~% design margin for the battery. If at the expiration of the initial ~~[~~12~~]~~ hour period the battery float current is not less than or equal to ~~[~~2~~]~~ amps this indicates there may be additional battery problems and the battery must be declared inoperable. 2

BASES

ACTIONS (continued)

~~REVIEWER'S NOTE~~
~~Any licensee wishing to adopt Completion Time greater than 72 hours for Required Action A.3 will need to demonstrate that the longer Completion Time is appropriate for the plant in accordance with the guidance in Regulatory Guide (RG) 1.177, "An Approach for Plant-Specific, Risk-Informed Decision Making: Technical Specifications", and RG 1.174, "An Approach for Using Probabilistic Risk Assessment in Risk-Informed Decisions on Plant-Specific Changes to the Licensing Basis." Alternatively, a 7 day Completion Time can be justified by an acceptable method, such as a regulatory commitment that an alternate means to charge the batteries will be available that is capable of being supplied power from a power source that is independent of the offsite power supply. Otherwise, the 72 hour Completion Time must be adopted.~~

3

Required Action A.3 limits the restoration time for the inoperable battery charger to ~~[~~72~~]~~ hours. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ This action is applicable if an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage has been used ~~(e.g., balance of plant non-Class 1E battery charger)~~. The ~~[~~72~~]~~ hour Completion Time reflects a reasonable time to effect restoration of the qualified battery charger to OPERABLE status.

2

~~B.1~~

5

~~REVIEWER'S NOTE'S~~
~~1. The 2 hour Completion Times of Required Actions B.1 and C.1 are in brackets. Any licensee wishing to request a longer Completion Time will need to demonstrate that the longer Completion Time is appropriate for the plant in accordance with the guidance in RG 1.177 and 1.174.~~

~~2. Condition B is included if Required Action B.1 (one [or two] batter[y][ies on one subsystem] inoperable) and Required Action C.1 (one DC electrical power subsystem inoperable for reasons other than Condition A [or B]) would have different Completion Times. If the plant design supports different Completion Times when a battery is inoperable but the charger is OPERABLE, then Condition B is used. If not, Condition B is deleted and only Condition C is used.~~

3

1

BASES

ACTIONS (continued)

~~Condition B represents one subsystem with one [or two] batter[y][ies] inoperable. With one [or two] batter[y][ies] inoperable, the DC bus is being supplied by the OPERABLE battery charger[s]. Any event that results in a loss of the AC bus supporting the battery charger[s] will also result in loss of DC to that subsystem. Recovery of the AC bus, especially if it is due to a loss of offsite power, will be hampered by the fact that many of the components necessary for the recovery (e.g., diesel generator control and field flash, AC load shed and diesel generator output circuit breakers, etc.) likely rely upon the batter[y][ies]. In addition the energization transients of any DC loads that are beyond the capability of the battery charger[s] and normally require the assistance of the batter[y][ies] will not be able to be brought online. The [2] hour limit allows sufficient time to effect restoration of an inoperable battery given that the majority of the conditions that lead to battery inoperability (e.g., loss of battery charger, battery cell voltage less than [2.07] V, etc.) are identified in Specifications 3.8.4, 3.8.5, and 3.8.6 together with additional specific Completion Times. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 2

~~C~~.1

B

Condition ~~C~~ represents one subsystem with a loss of ability to completely respond to an event, and a potential loss of ability to remain energized during normal operation. It is therefore, imperative that the operator's attention focus on stabilizing the unit, minimizing the potential for complete loss of DC power to the affected subsystem. The 2 hour limit is consistent with the allowed time for an inoperable DC distribution subsystem. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 5 2

If one of the required DC electrical power subsystems is inoperable for reasons other than Condition A ~~or B~~ (e.g., inoperable battery charger and associated inoperable battery), the remaining DC electrical power subsystem has the capacity to support a safe shutdown and to mitigate an accident condition. Since a subsequent worst case single failure could, however, result in the loss of the minimum necessary DC electrical subsystems to mitigate a worst case accident, continued power operation should not exceed 2 hours. The 2 hour Completion Time is based on Regulatory Guide 1.93 (Ref. 7) and reflects a reasonable time to assess unit status as a function of the inoperable DC electrical power subsystem and, if the DC electrical power subsystem is not restored to OPERABLE status, to prepare to effect an orderly and safe unit shutdown. 5

BASES

ACTIONS (continued)

~~D~~.1 and ~~D~~.2

C

5

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

3

If the inoperable DC electrical power subsystem cannot be restored to OPERABLE status within the required Completion Time, the unit must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 8). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

C

Required Action ~~D~~.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

5

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

ACTIONS (continued)

topical report, CE NPSD-1186-A

The Completion Time to bring the unit to MODE ~~5~~ 4 is consistent with ~~the time required in Regulatory Guide 1.93~~ (Ref. ~~7~~ 8). 5 1

SURVEILLANCE REQUIREMENTS

SR 3.8.4.1

Verifying battery terminal voltage while on float charge for the batteries helps to ensure the effectiveness of the battery chargers, which support the ability of the batteries to perform their intended function. Float charge is the condition in which the charger is supplying the continuous charge required to overcome the internal losses of a battery and maintain the battery in a fully charged state while supplying the continuous steady state loads of the associated DC subsystem. On float charge, battery cells will receive adequate current to optimally charge the battery. The voltage requirements are based on the nominal design voltage of the battery and are consistent with the minimum float voltage established by the battery manufacturer (~~[~~2.20~~]~~ Vpc times the number of connected cells or ~~[127.6]~~ 132 V for a ~~58~~ 60 cell battery at the battery terminals). This voltage maintains the battery plates in a condition that supports maintaining the grid life. ~~[The 7 day Frequency is consistent with manufacturer recommendations.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. 1 2

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~ 3 2

SR 3.8.4.2

Safety

This SR verifies the design capacity of the battery chargers. According to ~~Regulatory~~ Guide ~~1.~~32 (Ref. 9), the battery charger supply is recommended to be based on the largest combined demands of the various steady state loads and the charging capacity to restore the battery from the design minimum charge state to the fully charged state, irrespective of the status of the unit during these demand occurrences. The minimum required amperes and duration ensures that these requirements can be satisfied. 1

BASES

SURVEILLANCE REQUIREMENTS (continued)

300
140 V
6

This SR provides two options. One option requires that each battery charger be capable of supplying ~~[400]~~ amps at ~~the minimum established float voltage~~ for ~~[8]~~ hours. The ampere requirements are based on the output rating of the chargers. The voltage requirements are based on the charger voltage level after a response to a loss of AC power. The time period is sufficient for the charger temperature to have stabilized and to have been maintained for at least ~~[~~2~~]~~ hours. 1 2

The other option requires that each battery charger be capable of recharging the battery after a service test coincident with supplying the largest coincident demands of the various continuous steady state loads (irrespective of the status of the plant during which these demands occur). This level of loading may not normally be available following the battery service test and will need to be supplemented with additional loads. The duration for this test may be longer than the charger sizing criteria since the battery recharge is affected by float voltage, temperature, and the exponential decay in charging current. The battery is recharged when the measured charging current is ≤ ~~[~~2~~]~~ amps.

~~[The Surveillance Frequency of 18 months is acceptable, given the unit conditions required to perform the test and the other administrative controls existing to ensure adequate charger performance during these [18 month] intervals. In addition, this Frequency is intended to be consistent with expected fuel cycle lengths.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 3 2

SR 3.8.4.3

A battery service test is a special test of the battery capability, as found, to satisfy the design requirements (battery duty cycle) of the DC electrical power system. The discharge rate and test length should correspond to the design duty cycle requirements as specified in Reference 4.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[The Surveillance Frequency of [18 months] is consistent with the recommendations of Regulatory Guide 1.32 (Ref. 9) and Regulatory Guide 1.129 (Ref. 10), which state that the battery service test should be performed during refueling operations, or at some other outage, with intervals between tests not to exceed [18 months].~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
]~~

This SR is modified by two Notes. Note 1 allows the performance of a modified performance discharge test in lieu of a service test.

The reason for Note 2 is that performing the Surveillance would perturb the electrical distribution system and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 ~~or 2~~ is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed partial Surveillance, a successful partial Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the partial Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when portions of the Surveillance are performed in MODE 1 ~~or~~2. Risk insights or deterministic methods may be used for the assessment. Credit may be taken for unplanned events that satisfy this SR.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.4 DC Sources - Operating

BASES

BACKGROUND

The station DC electrical power system provides the AC emergency power system with control power. It also provides both motive and control power to selected safety related equipment and preferred AC ~~vital~~ bus power (via inverters). As required by 10 CFR 50, Appendix A, GDC 17 (Ref. 1), the DC electrical power system is designed to have sufficient independence, redundancy, and testability to perform its safety functions, assuming a single failure. The DC electrical power system also conforms to the recommendations of Regulatory Guide 1.6 (Ref. 2) and IEEE-308 (Ref. 3).

The ~~[~~125~~/250]~~ VDC electrical power system consists of two independent and redundant safety related Class 1E DC electrical power subsystems (~~[~~Train A and Train B~~]~~). Each subsystem consists of ~~[two]~~ 125 VDC batter~~ies~~ ~~[(each battery [50]% capacity)],~~ ~~the associated~~ battery charger~~(s)~~ for each battery, and all the associated control equipment and interconnecting cabling.

~~[The 250 VDC source is obtained by use of the two 125 VDC batteries connected in series. Additionally there is [one] spare battery~~ charger ~~per subsystem, which provides backup service in the event that the preferred battery charger is out of service~~. If the ~~spare~~ battery charger is substituted ~~for one of the preferred battery chargers, then~~ the requirements of independence and redundancy between subsystems are maintained.~~]~~

During normal operation, the ~~[~~125~~/250]~~ VDC load is powered from the battery chargers with the batteries floating on the system. In case of loss of normal power to ~~the battery charger,~~ the DC load is automatically powered from the station batteries.

The ~~[~~Train A and Train B~~]~~ DC electrical power subsystems provide the control power for its associated Class 1E AC power load group, ~~[~~4.16~~]~~ kV switchgear, and ~~[~~480~~]~~ V load centers. The DC electrical power subsystems also provide DC electrical power to the inverters, which in turn power the AC ~~vital buses~~.

The DC power distribution system is described in more detail in the Bases for LCO 3.8.9, "Distributions System Operating," and for LCO 3.8.10, "Distribution Systems - Shutdown."

System

BASES

BACKGROUND (continued)

Each 125~~/250~~ VDC battery is separately housed in a ventilated room ~~apart from its charger and distribution centers~~. Each subsystem is located in an area separated physically and electrically from the other subsystem to ensure that a single failure in one subsystem does not cause a failure in a redundant subsystem. ~~[~~There is no sharing between redundant Class 1E subsystems, such as batteries, battery chargers, or distribution panels.~~]~~

Each battery has adequate storage capacity to meet the duty cycle(s) discussed in the FSAR, Chapter ~~[~~8~~]~~ (Ref 4). The battery is designed with additional capacity above that required by the design duty cycle to allow for temperature variations and other factors.

The batteries for Train A and Train B DC electrical power subsystems are sized to produce required capacity at 80% of nameplate rating, corresponding to warranted capacity at end of life cycles and the 100% design demand. The minimum design voltage limit ~~is [105/210] V.~~

of 105 V is bounded by the minimum calculated DC System voltage required to support the DC loads.

The battery cells are of flooded lead acid construction with a nominal specific gravity of ~~[~~1.215~~]~~. This specific gravity corresponds to an open circuit battery voltage of approximately ~~[~~120 V for a ~~[~~58~~]~~ cell battery (i.e., cell voltage of ~~[~~2.065~~]~~ volts per cell (Vpc)). The open circuit voltage is the voltage maintained when there is no charging or discharging. ~~Once fully charged with its open circuit voltage ≥ [2.065] Vpc, the battery cell will maintain its capacity for [30] days without further charging per manufacturer's instructions.~~ Optimal long term performance however, is obtained by maintaining a float voltage ~~[~~2.20 to 2.25~~]~~ Vpc. This provides adequate over-potential, which limits the formation of lead sulfate and self discharge. The nominal float voltage of ~~[2.22]~~ Vpc corresponds to a total float voltage output of ~~[128.8]~~ V for a ~~[58]~~ cell battery ~~as discussed in the FSAR, Chapter [8] (Ref. 4)~~.

Each Train A and Train B DC electrical power subsystem battery charger has ample power output capacity for the steady state operation of connected loads required during normal operation, while at the same time maintaining its battery bank fully charged. Each battery charger also has sufficient excess capacity to restore the battery from the design minimum charge to its fully charged state within ~~[~~24~~]~~ hours while supplying normal steady state loads ~~discussed in the FSAR, Chapter [8] (Ref. 4)~~.

BASES

BACKGROUND (continued)

The battery charger is normally in the float-charge mode. Float-charge is the condition in which the charger is supplying the connected loads and the battery cells are receiving adequate current to optimally charge the battery. This assures the internal losses of a battery are overcome and the battery is maintained in a fully charged state.

When desired, the charger can be placed in the equalize mode. The equalize mode is at a higher voltage than the float mode and charging current is correspondingly higher. The battery charger is operated in the equalize mode after a battery discharge or for routine maintenance. Following a battery discharge, the battery recharge characteristic accepts current at the current limit of the battery charger (if the discharge was significant, e.g., following a battery service test) until the battery terminal voltage approaches the charger voltage setpoint. Charging current then reduces exponentially during the remainder of the recharge cycle. Lead-calcium batteries have recharge efficiencies of greater than 95%, so once at least 105% of the ampere-hours discharged have been returned, the battery capacity would be restored to the same condition as it was prior to the discharge. This can be monitored by direct observation of the exponentially decaying charging current or by evaluating the amp-hours discharged from the battery and amp-hours returned to the battery.

Battery parameters are described in further detail in the Bases for LCO 3.8.6, "Battery Parameters."

1

APPLICABLE SAFETY ANALYSES

U

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 5) and Chapter ~~[~~15~~]~~ (Ref. 6), assume that Engineered Safety Feature (ESF) systems are OPERABLE. The DC electrical power system provides normal and emergency DC electrical power for the DGs, emergency auxiliaries, and control and switching during all MODES of operation.

2 1

The OPERABILITY of the DC sources is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This includes maintaining the DC sources OPERABLE during accident conditions in the event of:

a. An assumed loss of all offsite AC power or all onsite AC power and

b. A worst-case single failure.

The DC sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The DC electrical power subsystems, each subsystem consisting of ~~[two]~~ batteries battery charger ~~[for each battery]~~ and the corresponding control equipment and interconnecting cabling supplying power to the associated bus within the subsystem are required to be OPERABLE to ensure the availability of the required power to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA. Loss of any DC electrical power subsystem does not prevent the minimum safety function from being performed (Ref. 4).

An OPERABLE DC electrical power subsystem requires ~~all required~~ batteries and ~~respective~~ chargers to be operating and connected to the associated DC bus(es).

APPLICABILITY

The DC electrical power sources are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure safe unit operation and to ensure that:

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients and

b. Adequate core cooling is provided, and containment integrity and other vital functions are maintained in the event of a postulated DBA.

The DC electrical power requirements for MODES 5 and 6 are addressed in the Bases for LCO 3.8.5, "DC Sources - Shutdown."

ACTIONS

A.1, A.2, and A.3

Condition A represents one subsystem with one ~~[or two]~~ battery chargers inoperable (e.g., the voltage limit of SR 3.8.4.1 is not maintained). The ACTIONS provide a tiered response that focuses on returning the battery to the fully charged state and restoring a fully qualified charger to OPERABLE status in a reasonable time period. Required Action A.1 requires that the battery terminal voltage be restored to greater than or equal to the minimum established float voltage within 2 hours. This time provides for returning the inoperable charger to OPERABLE status or providing an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage. Restoring the battery terminal voltage to greater than or equal to the minimum established float voltage provides good assurance that, within ~~[~~12~~]~~ hours, the battery will be restored to its fully charged condition (Required Action A.2) from any discharge that might have occurred due to the charger inoperability.

BASES

ACTIONS (continued)

~~REVIEWER'S NOTE~~

~~A plant that cannot meet the 12 hour Completion Time due to an inherent battery charging characteristic can propose an alternate time equal to 2 hours plus the time experienced to accomplish the exponential charging current portion of the battery charge profile following the service test (SR 3.8.4.3).~~ 3

A discharged battery having terminal voltage of at least the minimum established float voltage indicates that the battery is on the exponential charging current portion (the second part) of its recharge cycle. The time to return a battery to its fully charged state under this condition is simply a function of the amount of the previous discharge and the recharge characteristic of the battery. Thus there is good assurance of fully recharging the battery within ~~[~~12~~]~~ hours, avoiding a premature shutdown with its own attendant risk. 2

If established battery terminal float voltage cannot be restored to greater than or equal to the minimum established float voltage within 2 hours, and the charger is not operating in the current-limiting mode, a faulty charger is indicated. A faulty charger that is incapable of maintaining established battery terminal float voltage does not provide assurance that it can revert to and operate properly in the current limit mode that is necessary during the recovery period following a battery discharge event that the DC system is designed for.

If the charger is operating in the current limit mode after 2 hours that is an indication that the battery is partially discharged and its capacity margins will be reduced. The time to return the battery to its fully charged condition in this case is a function of the battery charger capacity, the amount of loads on the associated DC system, the amount of the previous discharge, and the recharge characteristic of the battery. The charge time can be extensive, and there is not adequate assurance that it can be recharged within ~~[~~12~~]~~ hours (Required Action A.2). 2

Required Action A.2 requires that the battery float current be verified as less than or equal to ~~[~~2~~]~~ amps. This indicates that, if the battery had been discharged as the result of the inoperable battery charger, it is now fully capable of supplying the maximum expected load requirement. The ~~[~~2~~]~~ amp value is based on returning the battery to ~~[~~95~~]~~% charge and assumes a ~~[~~5~~]~~% design margin for the battery. If at the expiration of the initial ~~[~~12~~]~~ hour period the battery float current is not less than or equal to ~~[~~2~~]~~ amps this indicates there may be additional battery problems and the battery must be declared inoperable. 2

BASES

ACTIONS (continued)

~~REVIEWER'S NOTE~~

~~Any licensee wishing to adopt Completion Time greater than 72 hours for Required Action A.3 will need to demonstrate that the longer Completion Time is appropriate for the plant in accordance with the guidance in Regulatory Guide (RG) 1.177, "An Approach for Plant-Specific, Risk-Informed Decision Making: Technical Specifications", and RG 1.174, "An Approach for Using Probabilistic Risk Assessment in Risk-Informed Decisions on Plant-Specific Changes to the Licensing Basis." Alternatively, a 7 day Completion Time can be justified by an acceptable method, such as a regulatory commitment that an alternate means to charge the batteries will be available that is capable of being supplied power from a power source that is independent of the offsite power supply. Otherwise, the 72 hour Completion Time must be adopted.~~

3

Required Action A.3 limits the restoration time for the inoperable battery charger to ~~[~~72~~]~~ hours. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ This action is applicable if an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage has been used ~~(e.g., balance of plant non-Class 1E battery charger)~~. The ~~[~~72~~]~~ hour Completion Time reflects a reasonable time to effect restoration of the qualified battery charger to OPERABLE status.

2

~~B.1~~

5

~~REVIEWER'S NOTE'S~~

~~1. The 2 hour Completion Times of Required Actions B.1 and C.1 are in brackets. Any licensee wishing to request a longer Completion Time will need to demonstrate that the longer Completion Time is appropriate for the plant in accordance with the guidance in RG 1.177 and 1.174.~~

~~2. Condition B is included if Required Action B.1 (one [or two] batter[y][ies on one subsystem] inoperable) and Required Action C.1 (one DC electrical power subsystem inoperable for reasons other than Condition A [or B]) would have different Completion Times. If the plant design supports different Completion Times when a battery is inoperable but the charger is OPERABLE, then Condition B is used. If not, Condition B is deleted and only Condition C is used.~~

3

BASES

ACTIONS (continued)

~~Condition B represents one subsystem with one [or two] batter[y][ies] inoperable. With one [or two] batter[y][ies] inoperable, the DC bus is being supplied by the OPERABLE battery charger[s]. Any event that results in a loss of the AC bus supporting the battery charger[s] will also result in loss of DC to that subsystem. Recovery of the AC bus, especially if it is due to a loss of offsite power, will be hampered by the fact that many of the components necessary for the recovery (e.g., diesel generator control and field flash, AC load shed and diesel generator output circuit breakers, etc.) likely rely upon the batter[y][ies]. In addition the energization transients of any DC loads that are beyond the capability of the battery charger[s] and normally require the assistance of the batter[y][ies] will not be able to be brought online. The [2] hour limit allows sufficient time to effect restoration of an inoperable battery given that the majority of the conditions that lead to battery inoperability (e.g., loss of battery charger, battery cell voltage less than [2.07] V, etc.) are identified in Specifications 3.8.4, 3.8.5, and 3.8.6 together with additional specific Completion Times. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 2

~~C~~.1

B

Condition ~~C~~ represents one subsystem with a loss of ability to completely respond to an event, and a potential loss of ability to remain energized during normal operation. It is therefore, imperative that the operator's attention focus on stabilizing the unit, minimizing the potential for complete loss of DC power to the affected subsystem. The 2 hour limit is consistent with the allowed time for an inoperable DC distribution subsystem. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 5 2

If one of the required DC electrical power subsystems is inoperable for reasons other than Condition A ~~or B~~ (e.g., inoperable battery charger and associated inoperable battery), the remaining DC electrical power subsystem has the capacity to support a safe shutdown and to mitigate an accident condition. Since a subsequent worst case single failure could, however, result in the loss of the minimum necessary DC electrical subsystems to mitigate a worst case accident, continued power operation should not exceed 2 hours. The 2 hour Completion Time is based on Regulatory Guide 1.93 (Ref. 7) and reflects a reasonable time to assess unit status as a function of the inoperable DC electrical power subsystem and, if the DC electrical power subsystem is not restored to OPERABLE status, to prepare to effect an orderly and safe unit shutdown. 5

BASES

ACTIONS (continued)

~~D~~.1 and ~~D~~.2

C

5

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

3

If the inoperable DC electrical power subsystem cannot be restored to OPERABLE status within the required Completion Time, the unit must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 8). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

C

Required Action ~~D~~.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

5

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

ACTIONS (continued)

The Completion Time to bring the unit to MODE ~~5~~ is consistent with ~~the time required in Regulatory Guide 1.93~~ (Ref. ~~7~~).

SURVEILLANCE REQUIREMENTS

SR 3.8.4.1

Verifying battery terminal voltage while on float charge for the batteries helps to ensure the effectiveness of the battery chargers, which support the ability of the batteries to perform their intended function. Float charge is the condition in which the charger is supplying the continuous charge required to overcome the internal losses of a battery and maintain the battery in a fully charged state while supplying the continuous steady state loads of the associated DC subsystem. On float charge, battery cells will receive adequate current to optimally charge the battery. The voltage requirements are based on the nominal design voltage of the battery and are consistent with the minimum float voltage established by the battery manufacturer (~~[~~2.20~~]~~ Vpc times the number of connected cells or ~~[127.6]~~ V for a ~~58~~ cell battery at the battery terminals). This voltage maintains the battery plates in a condition that supports maintaining the grid life. ~~[The 7 day Frequency is consistent with manufacturer recommendations.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

SR 3.8.4.2

This SR verifies the design capacity of the battery chargers. According to Regulatory Guide 1.32 (Ref. 9), the battery charger supply is recommended to be based on the largest combined demands of the various steady state loads and the charging capacity to restore the battery from the design minimum charge state to the fully charged state, irrespective of the status of the unit during these demand occurrences. The minimum required amperes and duration ensures that these requirements can be satisfied.

BASES

SURVEILLANCE REQUIREMENTS (continued)

This SR provides two options. One option requires that each battery charger be capable of supplying ~~[400]~~ 300 amps at ~~the minimum established float voltage~~ 140 V for ~~[8]~~ 6 hours. The ampere requirements are based on the output rating of the chargers. The voltage requirements are based on the charger voltage level after a response to a loss of AC power. The time period is sufficient for the charger temperature to have stabilized and to have been maintained for at least ~~[~~2~~]~~ hours. 1 2

The other option requires that each battery charger be capable of recharging the battery after a service test coincident with supplying the largest coincident demands of the various continuous steady state loads (irrespective of the status of the plant during which these demands occur). This level of loading may not normally be available following the battery service test and will need to be supplemented with additional loads. The duration for this test may be longer than the charger sizing criteria since the battery recharge is affected by float voltage, temperature, and the exponential decay in charging current. The battery is recharged when the measured charging current is ≤ ~~[~~2~~]~~ amps.

~~[The Surveillance Frequency of 18 months is acceptable, given the unit conditions required to perform the test and the other administrative controls existing to ensure adequate charger performance during these [18 month] intervals. In addition, this Frequency is intended to be consistent with expected fuel cycle lengths.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------~~ 3
~~]~~ 2

SR 3.8.4.3

A battery service test is a special test of the battery capability, as found, to satisfy the design requirements (battery duty cycle) of the DC electrical power system. The discharge rate and test length should correspond to the design duty cycle requirements as specified in Reference 4.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[The Surveillance Frequency of [18 months] is consistent with the recommendations of Regulatory Guide 1.32 (Ref. 9) and Regulatory Guide 1.129 (Ref. 10), which state that the battery service test should be performed during refueling operations, or at some other outage, with intervals between tests not to exceed [18 months].~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

This SR is modified by two Notes. Note 1 allows the performance of a modified performance discharge test in lieu of a service test.

The reason for Note 2 is that performing the Surveillance would perturb the electrical distribution system and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 ~~or 2~~ is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed partial Surveillance, a successful partial Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the partial Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when portions of the Surveillance are performed in MODE 1 ~~or 2~~. Risk insights or deterministic methods may be used for the assessment. Credit may be taken for unplanned events that satisfy this SR.

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.4 BASES, DC SOURCES - OPERATING

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.
2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.
3. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.
4. These battery design values have been deleted because they are more specific than necessary and are not required to provide sufficient background for this Specification.
5. Changes have been made to be consistent with changes made to the Specifications.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.8.4, DC SOURCES - OPERATING

DISCUSSION OF CHANGES
ITS 3.8.5, DC SOURCES - SHUTDOWN

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.8.2.4 and Unit 2 CTS 3.8.2.2 are applicable in MODES 5 and 6. ITS 3.8.5 is applicable in MODES 5 and 6 and during movement of irradiated fuel assemblies. A Note has been added to the ACTIONS which states that LCO 3.0.3 is not applicable. This changes the CTS by adding the Applicability of during movement of irradiated fuel assemblies and adds the Note to the ACTIONS stating that LCO 3.0.3 is not applicable.

This change is acceptable because the proposed requirements are necessary to ensure the DC electrical power sources are OPERABLE to support equipment required to be OPERABLE during movement of irradiated fuel assemblies. Movement of fuel normally occurs during MODES 5 and 6, however, it can also occur outside of containment in other plant MODES (MODES 1, 2, 3, and 4) or other conditions (i.e., reactor defueled). This Specification is needed to ensure the appropriate DC electrical power source requirements are specified during fuel handling and ensure the appropriate actions are taken (i.e., stop fuel movement) when the minimum electrical supplies are not available (See Unit 1 DOC L01 and Unit 2 DOCs L03 and L04 for the changes to the Required Actions). This change adds a clarification Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODES 5 or 6, LCO 3.0.3 is not applicable and would not specify any action. If moving irradiated fuel assemblies while in MODES 1, 2, 3, or 4, the fuel movement is independent of reactor operations and the inability to suspend movement in accordance with the ITS 3.8.5 Required Actions would not be sufficient reason to require a reactor shutdown. This Note has been added for clarification and is necessary since defaulting to LCO 3.0.3 would require the reactor to be shutdown but would not require suspension of activities with a potential for releasing radioactive materials. This change is designated as more restrictive because the ITS requires the equipment to be OPERABLE during movement of irradiated fuel assemblies both inside and outside of the containment in conditions other than MODES 5 and 6.

RELOCATED SPECIFICATIONS

None

DISCUSSION OF CHANGES
ITS 3.8.5, DC SOURCES - SHUTDOWN

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.8.2.4 states, in part, 1 - 125-volt battery bank and charger supplying the DC bus. Unit 2 CTS 3.8.2.2 requires a minimum of one 125 volt battery and a full capacity charger. ITS LCO 3.8.5 requires one DC electrical power subsystem to be OPERABLE. This changes the CTS by moving the details of the DC electrical power subsystems from the CTS to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the OPERABILITY requirements for electrical power trains. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Control Program in Chapter 5. The program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 **Unit 1 only:** *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.8.2.4 ACTION requires the establishment of containment integrity within 8 hours with less than the minimum complement of DC sources OPERABLE. ITS 3.8.5 ACTION A requires suspending movement of irradiated fuel assemblies, suspending operations involving a positive reactivity addition that could result in the loss of required SDM or boron concentration, and the initiation of action to restore required DC electrical power sources to OPERABLE status. This changes the CTS by replacing the existing Required Action to restore containment integrity with Actions that will prevent a fuel handling accident from occurring and Actions that will ensure the reactor remains subcritical.

The purpose of the CTS 3.8.2.4 Action is to isolate the containment to minimize any release from the plant if an event were to occur during shutdown conditions with no DC Sources OPERABLE. This change is acceptable because the ITS Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The proposed Required Actions require the suspension of movement of irradiated fuel assemblies, suspension of operations involving positive reactivity additions that could result in the loss of required SDM or boron concentration, and the initiation of actions to restore required DC electrical power subsystem to OPERABLE status. Suspending the movement of irradiated fuel assemblies will prevent a fuel handling accident from occurring and suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit will ensure the reactor remains subcritical. The requirement to initiate action to restore the required DC electrical power subsystem to OPERABLE status will

ensure the plant is placed in compliance with the LCO in an expeditious manner. The proposed actions will also minimize the potential for any accident releases outside of the containment and are considered acceptable in lieu of the current action to restore containment integrity within 8 hours. The actions may be considered somewhat more restrictive since immediate action is required, however, is classified as less restrictive since the current actions to restore containment integrity have been deleted. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 7 - Relaxation Of Surveillance Frequency)* Unit 1 CTS 4.8.2.4.2 and Unit 2 CTS 4.8.2.2 require the demonstration of the OPERABILITY of the 125 VDC battery banks and chargers in accordance with the Surveillance Requirements of Unit 1 CTS 4.8.2.3.2 and Unit 2 CTS 4.8.2.1. ITS SR 3.8.5.1 requires SR 3.8.4.1, SR 3.8.4.2, and SR 3.8.4.3 to be applicable. However, a Note has been added that states ITS SR 3.8.4.2 and SR 3.8.4.3 do not have to be performed. This changes the CTS by allowing certain SRs not to be performed.

The purpose of the ITS SR 3.8.5.1 Note is to ensure that required equipment is not made inoperable by testing when the equipment is the only OPERABLE equipment available to support unit operations. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. ITS SR 3.8.4.3 is the battery capacity test. ITS SR 3.8.4.2 is a battery charger capacity test. The performance of these SRs involves tests that would cause the only required OPERABLE DC electrical power subsystem components to be rendered inoperable. This condition presents a significant risk if an event were to occur during test performance. In an effort to address this concern, ITS SR 3.8.5.1 has a Note that excludes performance requirements of any Surveillance that would require the required OPERABLE DC electrical power subsystem components to be rendered inoperable. This allowance does not take exception to the requirement for the DC electrical power subsystem to be capable of performing the particular function, but just to the requirement to demonstrate that capability while the required DC source of power is being relied on to support meeting the LCO. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L03 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* Unit 2 CTS 3.8.2.2 Action b states, in part, “with the required battery bank inoperable, within 8 hours, depressurize and vent the Reactor Coolant System through a 3.58 square inch vent. ITS 3.8.5 does not include a required action for depressurizing and venting the Reactor Coolant System. This changes the CTS by removing the requirement to depressurize and vent the Reactor Coolant System within 8 hours with the required battery bank inoperable.

The purpose of minimum DC electrical power subsystem technical specification required actions is to establish mitigating actions with appropriate time limitations to restore the minimum required DC electrical power subsystem. This change is acceptable because CTS 3.4.9.3 provides the operability requirements,

mitigating actions, and time limitations for low temperature overpressure protection (LTOP) systems. CTS 3.4.9.3 Action a.1 requires depressurization and venting of the Reactor Coolant System when the LTOP System is inoperable for any reason including the loss of DC power to required LTOP components. ITS 3.4.12 retains the required CTS ACTION. Refer to ITS 3.4.12 Discussion of Changes for changes to CTS 3.4.9.3 actions. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L04 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* Unit 2 CTS 3.8.2.2 Action b in part states with the required full capacity charger inoperable, demonstrate the OPERABILITY of its associated battery bank. ITS LCO 3.8.5 does not include Actions for an inoperable required battery charger for plants that require only one DC electrical power subsystem to be OPERABLE during shutdown conditions. This changes CTS by removing the CTS ACTIONS associated with a required full capacity charger inoperable.

The purpose of the ITS 3.8.5 Required Actions is to allow appropriate remedial actions with appropriate time limitations to restore a required inoperable DC electrical power subsystem to OPERABLE status. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk while providing time to restore inoperable features. This change establishes the appropriate actions to be taken with an inoperable required DC electrical power subsystem for the PSL Unit 2 design. The proposed Required Actions require the suspension of movement of irradiated fuel assemblies, suspension of operations involving positive reactivity additions that could result in the loss of required SDM or boron concentration, and the initiation of actions to restore required DC electrical power subsystem to OPERABLE status. Suspending the movement of irradiated fuel assemblies will prevent a fuel handling accident from occurring and suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit will ensure the reactor remains subcritical. The requirement to initiate action to restore the required DC electrical power subsystem to OPERABLE status will ensure the plant is placed in compliance with the LCO in an expeditious manner. The ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L05 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* Unit 2 CTS 3.8.2.2 ACTION states, in part, “With the required battery bank inoperable, immediately suspend all operations involving CORE ALTERATIONS,...” ITS 3.8.5 ACTIONS do not include the requirement to suspend CORE ALTERATIONS. This changes the CTS by removing the Required Action to suspend all operations involving CORE ALTERATIONS. R1

The purpose of the CTS 3.8.2.2 ACTION is to minimize the possibility of an event that may require the electrical power source to mitigate the consequences of a design basis event. CORE ALTERATIONS is defined in CTS 1.9, in part, as "the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity, within the reactor vessel with the head

removed and fuel in the vessel." Core Alterations only occur when the reactor vessel head is removed - it only applies in MODE 6. There is only one accident considered during MODE 6 that involves a Core Alteration - a fuel handling accident. According to UFSAR Section 15.7.4.1.2, a fuel handling accident is initiated by the dropping of an irradiated fuel assembly either in the containment or in the fuel handling building. Suspension of CORE ALTERATIONS, except for suspension of movement of irradiated fuel, will not prevent or impair the mitigation of a fuel handling accident. ITS 3.8.5 retains the requirement to suspend movement of irradiated fuel assemblies as Required Action A.1 (for an inoperable DC electrical power subsystem). R1

Deleting the reference to “CORE ALTERATIONS” is acceptable because the only CORE ALTERATION analyzed in the safety analysis that is potentially affected by an inoperable DC electrical power subsystem is covered by the ITS Required Actions. Additionally, CORE ALTERATIONS that may be capable of damaging a fuel assembly prior to the 72 hour decay period is improbable because of the physical time required to perform plant shutdown, cooldown, depressurize the Reactor Coolant System (RCS), and the additional operations required to expose irradiated fuel in the reactor vessel (e.g., containment entry, removal of vessel head, removal of vessel internals, etc.) is greater than 72 hours. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.5, DC SOURCES - SHUTDOWN

1. The bracketed optional ISTS LCO 3.8.5 and "Reviewers Note" have been deleted since the current licensing basis only requires one DC electrical power subsystem to be OPERABLE. ISTS 3.8.5 ACTION A has been deleted since only one required DC electrical power train is specified in the LCO. This allowance is only acceptable if the first option of the LCO is used. The subsequent Condition and Required Actions have been renumbered and modified, as applicable.

2. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.5 DC Sources - Shutdown

BASES

BACKGROUND

A description of the DC sources is provided in the Bases for LCO 3.8.4, "DC Sources - Operating."

APPLICABLE SAFETY ANALYSES

U

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 1) and Chapter ~~[~~15~~]~~ (Ref. 2), assume that Engineered Safety Feature (ESF) systems are OPERABLE. The DC electrical power system provides normal and emergency DC electrical power for the DGs, emergency auxiliaries, and control and switching during all MODES of operation. 1 2

The OPERABILITY of the DC subsystems is consistent with the initial assumptions of the accident analyses and the requirements for the supported systems' OPERABILITY.

The OPERABILITY of the minimum DC electrical power sources during MODES 5 and 6 and during movement of ~~[recently]~~ irradiated fuel assemblies ensures that: 2

a. The unit can be maintained in the shutdown or refueling condition for extended periods,

b. Sufficient instrumentation and control capability is available for monitoring and maintaining the unit status, and

c. Adequate DC electrical power is provided to mitigate events postulated during shutdown, such as a fuel handling accident ~~[involving handling recently irradiated fuel~~. ~~Due to radioactive decay, DC electrical power is only required to mitigate fuel handling accidents involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)].~~ 2

In general, when the unit is shut down, the Technical Specifications requirements ensure that the unit has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. The rationale for this is based on the fact that many DBAs that are

BASES

APPLICABLE SAFETY ANALYSES (continued)

analyzed in MODES [1, 2, 3, and 4] have no specific analyses in MODES [5 and 6] because the energy contained within the reactor pressure boundary, reactor coolant temperature and pressure, and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and in minimal consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCO for required systems. 2

The shutdown Technical Specification requirements are designed to ensure that the unit has the capability to mitigate the consequences of certain postulated accidents. Worst case DBAs which are analyzed for operating MODES are generally viewed not to be a significant concern during shutdown MODES due to the lower energies involved. The Technical Specifications therefore require a lesser complement of electrical equipment to be available during shutdown than is required during operating MODES. More recent work completed on the potential risks associated with shutdown, however, have found significant risk associated with certain shutdown evolutions. As a result, in addition to the requirements established in the Technical Specifications, the industry has adopted NUMARC 91-06, "Guidelines for Industry Actions to Assess Shutdown Management," as an Industry initiative to manage shutdown tasks and associated electrical support to maintain risk at an acceptable low level. This may require the availability of additional equipment beyond that required by the shutdown Technical Specifications.

The DC sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The DC electrical power subsystem[s, [each required] [the required] subsystem] consisting of [two] batter[ies], one battery charger per battery, and the corresponding control equipment and interconnecting cabling within the subsystem, [are] [is] required to be OPERABLE to support [required] [one] subsystem[s] of distribution systems required [OPERABLE by LCO 3.8.10, "Distribution Systems - Shutdown."] This ensures the availability of sufficient DC electrical power sources to operate the unit in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents [involving handling recently irradiated fuel]).

one
y
required
2
1
2

BASES

APPLICABILITY

The DC electrical power sources required to be OPERABLE in MODES 5 and 6, and during movement of ~~[recently]~~ irradiated fuel assemblies provide assurance that: (2)

a. Required features needed to mitigate a fuel handling ~~[involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~ accident are available, (2)

b. Required features necessary to mitigate the effects of events that can lead to core damage during shutdown are available, and

c. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition or refueling condition.

The DC electrical power requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.4.

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

~~A.1, A.2, and A.3~~ (3)

~~REVIEWER'S NOTE~~

~~ACTION A is included only when plant-specific implementation of LCO 3.8.5 includes the potential to require both subsystems of the DC System to be OPERABLE. If plant-specific implementation results in LCO 3.8.5 requiring only one subsystem of the DC System to be OPERABLE, then ACTION A is omitted and ACTION B is renumbered as ACTION A.~~ (4)

~~Condition A represents one subsystem with one [or two] battery chargers inoperable (e.g., the voltage limit of SR 3.8.4.1 is not maintained). The ACTIONS provide a tiered response that focuses on returning the battery to the fully charged state and restoring a fully qualified charger to OPERABLE status in a reasonable time period. Required Action A.1 requires that the battery terminal voltage be restored to greater than or~~ (3)

BASES

ACTIONS (continued)

equal to the minimum established float voltage within 2 hours. This time provides for returning the inoperable charger to OPERABLE status or providing an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage. Restoring the battery terminal voltage to greater than or equal to the minimum established float voltage provides good assurance that, within [12] hours, the battery will be restored to its fully charged condition (Required Action A.2) from any discharge that might have occurred due to the charger inoperability.

---REVIEWER'S NOTE---
A plant that cannot meet the 12 hour Completion Time due to an inherent battery charging characteristic can propose an alternate time equal to 2 hours plus the time experienced to accomplish the exponential charging current portion of the battery charge profile following the service test (SR 3.8.4.3).

A discharged battery having terminal voltage of at least the minimum established float voltage indicates that the battery is on the exponential charging current portion (the second part) of its recharge cycle. The time to return a battery to its fully charged state under this condition is simply a function of the amount of the previous discharge and the recharge characteristic of the battery. Thus there is good assurance of fully recharging the battery within [12] hours, avoiding a premature shutdown with its own attendant risk. 3

If established battery terminal float voltage cannot be restored to greater than or equal to the minimum established float voltage within 2 hours, and the charger is not operating in the current-limiting modes, a faulty charger is indicated. A faulty charger that is incapable of maintaining established battery terminal float voltage does not provide assurance that it can revert to and operate properly in the current limit modes that is necessary during the recovery period following a battery discharge event that the DC system is designed for.

If the charger is operating in the current limit mode after 2 hours that is an indication that the battery is partially discharged and its capacity margins will be reduced. The time to return the battery to its fully charged condition in this case is a function of the battery charger capacity, the amount of loads on the associated DC system, the amount of the previous discharge, and the recharge characteristic of the battery. The charge time can be extensive, and there is not adequate assurance that it can be recharged within [12] hours (Required Action A.2).

BASES

ACTIONS (continued)

~~Required Action A.2 requires that the battery float current be verified as less than or equal to [2] amps. This indicates that, if the battery had been discharged as the result of the inoperable battery charger, it has now been fully recharged. If at the expiration of the initial [12] hour period the battery float current is not less than or equal to [2] amps this indicates there may be additional battery problems and the battery must be declared inoperable.~~

~~----------REVIEWER'S NOTE----------~~
~~Any licensee wishing to adopt a Completion Time greater than 72 hours for Required Action A.3 will need to demonstrate that the Completion Time is appropriate for the plant in accordance with the guidance in Regulatory Guide (RG) 1.177, "An Approach for Plant-Specific, Risk-Informed Decision Making: Technical Specifications." Otherwise, the 72 hour Completion Time must be adopted.~~
~~----------~~

~~Required Action A.3 limits the restoration time for the inoperable battery charger to [72] hours. This action is applicable if an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage has been used (e.g., balance of plant non-Class 1E battery charger). The [72] hour Completion Time reflects a reasonable time to effect restoration of the qualified battery charger to OPERABLE status.~~

3

A.1, A.2, and A.3

~~B.1, B.2.1, B.2.2, and B.2.3~~

With the required DC electrical power subsystem inoperable, the minimum required DC electrical power source is not available. Therefore, suspension of

3

~~[If two subsystems are required by LCO 3.8.10, the remaining subsystem with DC power available may be capable of supporting sufficient systems to allow continuation of [recently] irradiated fuel movement]. By allowing the option to declare required features inoperable with the associated DC power source(s) inoperable, appropriate restrictions will be implemented in accordance with the affected required features LCO ACTIONS. In many instances this option may involve undesired administrative efforts. Therefore, the allowance for sufficiently conservative actions is made (i.e., to suspend~~ movement of ~~[recently]~~ irradiated fuel assemblies, and operations involving positive reactivity additions~~)~~ that could result in loss of required SDM (MODE 5) or boron concentration (MODE 6)~~.~~ Suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit is required to assure continued safety operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than ~~that~~ what

2

3

2

is required

1

5

St. Lucie – Unit 1

1

BASES

ACTIONS (continued)

would be required in the RCS for minimum SDM or refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation. Introduction of temperature changes including temperature increases when operating with a positive MTC must also be evaluated to ensure they do not result in a loss of required SDM.

Suspension of these activities shall not preclude completion of actions to establish a safe conservative condition. These actions minimize probability of the occurrence of postulated events. It is further required to immediately initiate action to restore the required DC electrical power subsystem~~[s]~~ and to continue this action until restoration is accomplished in order to provide the necessary DC electrical power to the unit safety systems. (2)

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required DC electrical power subsystem~~s~~ should be completed as quickly as possible in order to minimize the time during which the unit safety systems may be without sufficient power. (1)

SURVEILLANCE REQUIREMENTS

SR 3.8.5.1

SR 3.8.5.1 states that Surveillances required by SR 3.8.4.1 through SR 3.8.4.3 are applicable in these MODES. See the corresponding Bases for LCO 3.8.4 for a discussion of each SR.

This SR is modified by a Note. The reason for the Note is to preclude requiring the OPERABLE DC sources from being discharged below their capability to provide the required power supply or otherwise rendered inoperable during the performance of SRs. It is the intent that these SRs must still be capable of being met, but actual performance is not required.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.5 DC Sources - Shutdown

BASES

BACKGROUND

A description of the DC sources is provided in the Bases for LCO 3.8.4, "DC Sources - Operating."

APPLICABLE SAFETY ANALYSES

U

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 1) and Chapter ~~[~~15~~]~~ (Ref. 2), assume that Engineered Safety Feature (ESF) systems are OPERABLE. The DC electrical power system provides normal and emergency DC electrical power for the DGs, emergency auxiliaries, and control and switching during all MODES of operation. 1 2

The OPERABILITY of the DC subsystems is consistent with the initial assumptions of the accident analyses and the requirements for the supported systems' OPERABILITY.

The OPERABILITY of the minimum DC electrical power sources during MODES 5 and 6 and during movement of ~~[recently]~~ irradiated fuel assemblies ensures that: 2

a. The unit can be maintained in the shutdown or refueling condition for extended periods,

b. Sufficient instrumentation and control capability is available for monitoring and maintaining the unit status, and

c. Adequate DC electrical power is provided to mitigate events postulated during shutdown, such as a fuel handling accident ~~[involving handling recently irradiated fuel~~. ~~Due to radioactive decay, DC electrical power is only required to mitigate fuel handling accidents involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)].~~ 2

In general, when the unit is shut down, the Technical Specifications requirements ensure that the unit has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. The rationale for this is based on the fact that many DBAs that are

BASES

APPLICABLE SAFETY ANALYSES (continued)

analyzed in MODES [1, 2, 3, and 4] have no specific analyses in MODES [5 and 6] because the energy contained within the reactor pressure boundary, reactor coolant temperature and pressure, and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and in minimal consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCO for required systems. 2

The shutdown Technical Specification requirements are designed to ensure that the unit has the capability to mitigate the consequences of certain postulated accidents. Worst case DBAs which are analyzed for operating MODES are generally viewed not to be a significant concern during shutdown MODES due to the lower energies involved. The Technical Specifications therefore require a lesser complement of electrical equipment to be available during shutdown than is required during operating MODES. More recent work completed on the potential risks associated with shutdown, however, have found significant risk associated with certain shutdown evolutions. As a result, in addition to the requirements established in the Technical Specifications, the industry has adopted NUMARC 91-06, "Guidelines for Industry Actions to Assess Shutdown Management," as an Industry initiative to manage shutdown tasks and associated electrical support to maintain risk at an acceptable low level. This may require the availability of additional equipment beyond that required by the shutdown Technical Specifications.

The DC sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The DC electrical power subsystem[s, [each required] [the required] subsystem] consisting of [two] batter[ies], one battery charger per battery, and the corresponding control equipment and interconnecting cabling within the subsystem, [are] [is] required to be OPERABLE to support [required] [one] subsystem[s] of distribution systems required [OPERABLE by LCO 3.8.10, "Distribution Systems - Shutdown."] This ensures the availability of sufficient DC electrical power sources to operate the unit in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents [involving handling recently irradiated fuel]).

one
y
required
2
1
2

BASES

APPLICABILITY

The DC electrical power sources required to be OPERABLE in MODES 5 and 6, and during movement of ~~[recently]~~ irradiated fuel assemblies provide assurance that: (2)

a. Required features needed to mitigate a fuel handling ~~[involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~ accident are available, (2)

b. Required features necessary to mitigate the effects of events that can lead to core damage during shutdown are available, and

c. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition or refueling condition.

The DC electrical power requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.4.

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

~~A.1, A.2, and A.3~~ (3)

~~REVIEWER'S NOTE~~

~~ACTION A is included only when plant-specific implementation of LCO 3.8.5 includes the potential to require both subsystems of the DC System to be OPERABLE. If plant-specific implementation results in LCO 3.8.5 requiring only one subsystem of the DC System to be OPERABLE, then ACTION A is omitted and ACTION B is renumbered as ACTION A.~~ (4)

~~Condition A represents one subsystem with one [or two] battery chargers inoperable (e.g., the voltage limit of SR 3.8.4.1 is not maintained). The ACTIONS provide a tiered response that focuses on returning the battery to the fully charged state and restoring a fully qualified charger to OPERABLE status in a reasonable time period. Required Action A.1 requires that the battery terminal voltage be restored to greater than or~~ (3)

BASES

ACTIONS (continued)

~~equal to the minimum established float voltage within 2 hours. This time provides for returning the inoperable charger to OPERABLE status or providing an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage. Restoring the battery terminal voltage to greater than or equal to the minimum established float voltage provides good assurance that, within [12] hours, the battery will be restored to its fully charged condition (Required Action A.2) from any discharge that might have occurred due to the charger inoperability.~~

~~REVIEWER'S NOTE~~
~~A plant that cannot meet the 12 hour Completion Time due to an inherent battery charging characteristic can propose an alternate time equal to 2 hours plus the time experienced to accomplish the exponential charging current portion of the battery charge profile following the service test (SR 3.8.4.3).~~

~~A discharged battery having terminal voltage of at least the minimum established float voltage indicates that the battery is on the exponential charging current portion (the second part) of its recharge cycle. The time to return a battery to its fully charged state under this condition is simply a function of the amount of the previous discharge and the recharge characteristic of the battery. Thus there is good assurance of fully recharging the battery within [12] hours, avoiding a premature shutdown with its own attendant risk.~~ 3

~~If established battery terminal float voltage cannot be restored to greater than or equal to the minimum established float voltage within 2 hours, and the charger is not operating in the current-limiting modes, a faulty charger is indicated. A faulty charger that is incapable of maintaining established battery terminal float voltage does not provide assurance that it can revert to and operate properly in the current limit modes that is necessary during the recovery period following a battery discharge event that the DC system is designed for.~~

~~If the charger is operating in the current limit mode after 2 hours that is an indication that the battery is partially discharged and its capacity margins will be reduced. The time to return the battery to its fully charged condition in this case is a function of the battery charger capacity, the amount of loads on the associated DC system, the amount of the previous discharge, and the recharge characteristic of the battery. The charge time can be extensive, and there is not adequate assurance that it can be recharged within [12] hours (Required Action A.2).~~

BASES

ACTIONS (continued)

~~Required Action A.2 requires that the battery float current be verified as less than or equal to [2] amps. This indicates that, if the battery had been discharged as the result of the inoperable battery charger, it has now been fully recharged. If at the expiration of the initial [12] hour period the battery float current is not less than or equal to [2] amps this indicates there may be additional battery problems and the battery must be declared inoperable.~~

~~----------REVIEWER'S NOTE----------~~
~~Any licensee wishing to adopt a Completion Time greater than 72 hours for Required Action A.3 will need to demonstrate that the Completion Time is appropriate for the plant in accordance with the guidance in Regulatory Guide (RG) 1.177, "An Approach for Plant-Specific, Risk-Informed Decision Making: Technical Specifications." Otherwise, the 72 hour Completion Time must be adopted.~~
~~----------~~

~~Required Action A.3 limits the restoration time for the inoperable battery charger to [72] hours. This action is applicable if an alternate means of restoring battery terminal voltage to greater than or equal to the minimum established float voltage has been used (e.g., balance of plant non-Class 1E battery charger). The [72] hour Completion Time reflects a reasonable time to effect restoration of the qualified battery charger to OPERABLE status.~~

3

A.1, A.2, and A.3

~~B.1, B.2.1, B.2.2, and B.2.3~~

With the required DC electrical power subsystem inoperable, the minimum required DC electrical power source is not available. Therefore, suspension of

3

~~[If two subsystems are required by LCO 3.8.10, the remaining subsystem with DC power available may be capable of supporting sufficient systems to allow continuation of [recently] irradiated fuel movement]. By allowing the option to declare required features inoperable with the associated DC power source(s) inoperable, appropriate restrictions will be implemented in accordance with the affected required features LCO ACTIONS. In many instances this option may involve undesired administrative efforts. Therefore, the allowance for sufficiently conservative actions is made (i.e., to suspend~~ movement of ~~[recently]~~ irradiated fuel assemblies, and operations involving positive reactivity additions~~)~~ that could result in loss of required SDM (MODE 5) or boron concentration (MODE 6)~~.~~ Suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit is required to assure continued safety operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than ~~that~~ what

2

3

2

is required

1

5

St. Lucie – Unit 2

1

BASES

ACTIONS (continued)

would be required in the RCS for minimum SDM or refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation. Introduction of temperature changes including temperature increases when operating with a positive MTC must also be evaluated to ensure they do not result in a loss of required SDM.

Suspension of these activities shall not preclude completion of actions to establish a safe conservative condition. These actions minimize probability of the occurrence of postulated events. It is further required to immediately initiate action to restore the required DC electrical power subsystem~~[s]~~ and to continue this action until restoration is accomplished in order to provide the necessary DC electrical power to the unit safety systems. (2)

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required DC electrical power subsystem~~s~~ should be completed as quickly as possible in order to minimize the time during which the unit safety systems may be without sufficient power. (1)

SURVEILLANCE REQUIREMENTS

SR 3.8.5.1

SR 3.8.5.1 states that Surveillances required by SR 3.8.4.1 through SR 3.8.4.3 are applicable in these MODES. See the corresponding Bases for LCO 3.8.4 for a discussion of each SR.

This SR is modified by a Note. The reason for the Note is to preclude requiring the OPERABLE DC sources from being discharged below their capability to provide the required power supply or otherwise rendered inoperable during the performance of SRs. It is the intent that these SRs must still be capable of being met, but actual performance is not required.

LIMITING CONDITION FOR OPERATION

Add proposed LCO 3.8.6

A02

LCO 3.8.6

3.8.2.3 As a minimum the following D.C. electrical sources shall be OPERABLE:

a. 125-volt D.C. bus No. 1A, 125-volt Battery bank No. 1A and a full capacity charger.

b. 125-volt D.C. bus No. 1B, 125-volt Battery bank No. 1B and a full capacity charger.

See ITS 3.8.4

See ITS 3.8.9

Applicability

APPLICABILITY: ~~MODES 1, 2, 3 and 4.~~

When associated DC electrical power subsystems are required to be OPERABLE.

A02

See ITS 3.8.9

ACTION:

a. With one of the required battery banks or busses inoperable, restore the inoperable battery bank or bus to OPERABLE status within 2 hours or be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

See ITS 3.8.4

b. With one of the required full capacity chargers inoperable, demonstrate the OPERABILITY of its associated battery banks by performing Surveillance Requirement 4.8.2.3.2.a.1 within 1 hour, and at least once per 8 hours thereafter. If any Category A limit in Table 4.8-2 is not met, declare the battery inoperable.

Add proposed ACTIONS A, B, C, D, E and F.

L01

SURVEILLANCE REQUIREMENTS

4.8.2.3.1 Each D.C. bus train shall be determined OPERABLE and energized in accordance with the Surveillance Frequency Control Program by verifying indicated power availability.

See ITS 3.8.9

4.8.2.3.2 Each 125-volt battery bank and charger shall be demonstrated OPERABLE:

See ITS 3.8.4

a. In accordance with the Surveillance Frequency Control Program by verifying that:

SR 3.8.6.1
SR 3.8.6.2

1. The parameters in Table 4.8-2 meet the Category A limits, and

2. The total battery terminal voltage is greater than or equal to 129-volts on float charge.

See ITS 3.8.4

ELECTRICAL POWER SYSTEMS

2. ~~The cell-to-cell and terminal connections are clean, tight, and coated with anti-corrosion material,~~

3. ~~Battery cell inter-connection resistance values are maintained at the values below:~~

~~Battery Inter-Connection Measurement Limits~~		
~~Battery Inter-Connection Type~~	~~Maximum Individual Inter-Connection Resistance~~	~~Maximum Average Inter-Connection Resistance [Battery Bank*]~~
~~Inter-Cell~~	~~≤ 150 x 10-6 ohms~~	~~≤ 50 x 10-6 ohms~~
~~Inter-Tier~~	~~≤ 200 x 10-6 ohms~~	
~~Inter-Rack~~	~~≤ 200 x 10-6 ohms~~	
~~Output Terminal~~	~~≤ 150 x 10-6 ohms~~	

L03

~~* The battery bank average interconnection resistance limit is the average of all inter-cell, inter-tier, inter-rack and output terminal connection resistance measurements for all series connections in the battery string~~

~~and,~~

4. The battery charger will supply at least 300 amperes at 140 volts for at least 6 hours.

See ITS 3.8.4

ELECTRICAL POWER SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

See ITS 3.8.4

d. In accordance with the Surveillance Frequency Control Program, during shutdown, by verifying that the battery capacity is adequate to supply and maintain in OPERABLE status all of the actual or simulated emergency loads for the design duty cycle when the battery is subjected to a battery service test.

Add proposed SR 3.8.6.6 NOTE

SR 3.8.6.6

e. In accordance with the Surveillance Frequency Control Program~~, during shutdown,~~ by verifying that the battery capacity is at least 80% of the manufacturer's rating when subjected to a performance discharge test. This performance discharge test may be performed in lieu of the battery service test required by Surveillance Requirement 4.8.2.1d.

L04

L05

or a modified performance discharge test

SR 3.8.6.6

f. Annual performance discharge tests of battery capacity shall be given to any battery that shows signs of degradation or has reached 85% of the service life expected for the application. ~~Degradation is indicated when the battery capacity drops more than 10% of rated capacity from its average on previous performance tests, or is below 90% of the manufacturer's rating.~~

See ITS 3.8.4

SHUTDOWN

LIMITING CONDITION FOR OPERATION

Add proposed LCO 3.8.6

A02

3.8.2.2 As a minimum, one 125-volt battery bank and a full capacity charger shall be OPERABLE.

See ITS 3.8.5

Applicability **APPLICABILITY**: ~~MODES 5 and 6.~~

When associated DC electrical power subsystems are required to be OPERABLE.

A02

ACTION:

a. With the required battery bank inoperable, immediately suspend all operations involving CORE ALTERATIONS, operations involving positive reactivity additions that could result in loss of required SHUTDOWN MARGIN or boron concentration, or movement of irradiated fuel; initiate corrective action to restore the required battery bank to OPERABLE status as soon as possible, and within 8 hours, depressurize and vent the Reactor Coolant System through a 3.58 square inch vent.

b. With the required full capacity charger inoperable, demonstrate the OPERABILITY of its associated battery banks by performing Surveillance Requirement 4.8.2.1a.1. within 1 hour, and at least once per 8 hours thereafter. If any Category A limit in Table 4.8-2 is not met, declare the battery inoperable.

See ITS 3.8.5

Add proposed ACTIONS A, B, C, D, E and F.

SR 3.8.6.2
SR 3.8.6.3
SR 3.8.6.4
SR 3.8.6.5
SR 3.8.6.6

4.8.2.2 The above required 125-volt battery bank and charger shall be demonstrated OPERABLE per Surveillance Requirement 4.8.2.1.

DISCUSSION OF CHANGES
ITS 3.8.6, BATTERY PARAMETERS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.8.2.3 and Unit 2 CTS 3.8.2.1 are applicable during MODES 1, 2, 3, and 4. Unit 1 CTS 3.8.2.4 and Unit 2 CTS 3.8.2.2 are applicable during MODES 5 and 6. ITS LCO 3.8.6 requires the battery parameters for the Train A and Train B DC electrical power subsystem batteries to be within limits when the associated DC electrical power subsystems are required to be OPERABLE. This changes the CTS by combining the requirements for the DC electrical subsystem battery parameters into one Specification and replacing the actual MODES with the phrase "When associated DC electrical power subsystems are required to be OPERABLE."

The purpose of ITS 3.8.6 is to provide battery parameter requirements for safety related batteries. This change combines Unit 1 CTS 3.8.2.3 and 3.8.2.4 and Unit 2 CTS 3.8.2.1 and 3.8.2.2 requirements for the DC electrical power subsystem battery parameters into one Specification. There are no technical changes as a result of this change since it converts the requirements into the format of the ITS. The proposed LCO states that the required battery's parameters shall be within limits. The proposed Applicability ensures the battery parameter requirements are met when the associated battery is required to be OPERABLE. Any technical changes to the battery parameters are discussed in a Discussion of Change specifically associated with that change. Any changes to the LCO and Applicability of the DC electrical power subsystem batteries are discussed in the Discussion of Changes for ITS 3.8.4 and 3.8.5. This change is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 4.8.2.3.2.b.3 and Unit 2 4.8.2.1.b.3 require, in part, verifying the average electrolyte temperature of 10% of connected cells above

50°F. ITS SR 3.8.6.4 requires, in part, verification that each required battery pilot cell temperature is greater than or equal to minimum established design limits. The pilot cell temperature for the minimum established design limits is moved to the technical specification Bases. This changes the CTS by moving the specified temperature value for this SR to the Bases.

The removal of these details related to battery electrolyte temperature limits from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety and the removed information will be adequately controlled in the ITS Bases. The Technical Specification Bases Control Program in Chapter 5 controls changes to the Bases. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications. Furthermore, the battery and its preventive maintenance and monitoring program are under the regulatory requirements of 10 CFR 50.65. This relocation will continue to assure that the battery is maintained at current levels of performance, and that operators appropriately focus on monitoring the battery parameters for degradation.

LA02 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 4.8.2.3.2.f and Unit 2 CTS 4.8.2.1.f require the performance of a battery performance test. The Surveillance requires a more frequent performance if the battery shows signs of "degradation" or has reached 85% of the service life expected for the application. The CTS further states that degradation is indicated when the battery capacity drops more than 10% from its capacity on previous performance tests or is below 90% of the manufacturer's rating. ITS SR 3.8.6.6 requires verification of the battery capacity when subjected to a performance discharge test or a modified performance discharge test. The Surveillance is also required more frequently when the battery shows degradation or has reached 85% of the expected life, but the definition of what constitutes "degradation" is not included. This changes the CTS by moving the detail on how degradation is determined from the CTS to the ITS Bases.

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS SR 3.8.6.6 retains the requirement to verify the battery capacity when subjected to a performance discharge test or a modified performance discharge test. The Surveillance also requires more frequent performance when the battery shows degradation or has reached 85% of the expected life. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. The Technical Specification Bases Control Program in Chapter 5 controls changes to the Bases. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA03 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 4.8.2.3.2.b.1 and Unit 2 CTS 4.8.2.1.b require verification that battery electrolyte level is greater than the minimum level indication mark, and less than or equal to ¼ inch above maximum level indication mark for the safety related batteries. ITS SR 3.8.6.3 requires a similar Surveillance and specifies the acceptance criteria as "greater than or equal to the minimum established design limits." The minimum established design limits for battery electrolyte level will be placed in the technical specification Bases. This changes the CTS by moving the design detail for this SR from CTS to the Bases. | R1 | R1

The removal of these details related to Surveillance Requirement limits from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. This Category B value of CTS Table 4.8-2 represent appropriate monitoring levels and appropriate preventive maintenance levels for long-term battery quality and extended battery life. Removing this design detail to the Bases is acceptable because these battery parameter values will continue to be controlled at their current level and the removed information will be adequately controlled in the ITS Bases. The Technical Specification Bases Control Program in Chapter 5 controls changes to the Bases. This program provides for the evaluation of changes to ensure the Bases are properly controlled. Furthermore, the battery and its preventive maintenance and monitoring program are under the regulatory requirements of 10 CFR 50.65. This relocation will continue to assure that the battery is maintained at current levels of performance, and that operators appropriately focus on monitoring the battery parameters for degradation. This change is designated as a less restrictive removal of detail change because the Surveillance limits are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.8.2.3 and 3.8.2.4 and Unit 2 CTS 3.8.2.1 and 3.8.2.2 provide ACTIONS and associated Completion Times for when a DC electrical power subsystem battery is inoperable due to battery parameters not within limits. In addition, CTS Table 4.8.2 provide in the form of Notes (1), (2), and (3), ACTIONS and associated Completions Times when Category A or Category B parameter limits or allowable values are exceeded. In lieu of these current Actions under these conditions, ITS 3.8.6 ACTIONS provide compensatory Required Actions and associated Completion Times when battery parameters are not within limits. This changes the CTS by replacing the current ACTIONS with new compensatory ACTIONS for battery parameters not within limits.

The purpose of Unit 1 CTS 3.8.2.3 and 3.8.2.4 and Unit 2 CTS 3.8.2.1 and 3.8.2.2 ACTIONS is to provide a finite period for continued operation when a safety related battery is inoperable due to battery parameters not within limits. ITS 3.8.6 ACTIONS also allow a certain amount of time to restore battery parameters to within limits before declaring the associated battery inoperable. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions to minimize risk associated with continued operation while providing time to correct

degraded conditions. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features including the capacity and capability of remaining systems or features, time for repairs or replacement, and the low probability of a DBA occurring during the Completion Time. ACTIONS have been added to allow a short time period to restore battery parameters to within limits. The Note to the ACTIONS clarifies that separate Condition entry is allowed for each battery. This is acceptable since the Required Actions for each Condition provide appropriate compensatory actions for each battery parameter not within limits. Complying with the Required Actions for one inoperable battery may allow for continued operation, and a subsequent inoperable battery is governed by separate Condition entry and application of associated Required Actions. ITS 3.8.6 ACTION A covers the condition of one battery with one or more battery cells float voltage less than the specified limit and requires the performance of SR 3.8.4.1 within 2 hours, the performance of SR 3.8.6.1 within 2 hours, and restoration of the affected cell voltage to within limits within 24 hours. ITS 3.8.6 ACTION B covers the condition of one battery with float current not within the specified limit and requires the performance of SR 3.8.4.1 within 2 hours and restoration of the battery float current to within limits within 12 hours. ITS 3.8.6 ACTION C covers the condition of one battery with one or more cells electrolyte level less than minimum established design limits and requires the restoration of electrolyte level to above top of plates within 8 hours, verification that there is no evidence of leakage within 12 hours, and restoration of electrolyte level to greater than or equal to the minimum established design limits within 31 days. ITS 3.8.6 ACTION C NOTE requires Required Action C.2 to be completed if electrolyte level was below the top of plates. With electrolyte level below the top of the plates there is a potential for dryout and plate degradation; therefore, this Note requires verification of no evidence of leakage even if the level is increased above the top of the plates allowing the Condition to be exited. ITS 3.8.6 Required Action C.1 NOTE states that Required Actions C.1 and C.2 are only applicable if electrolyte level was below the top of the plates allowing 31 days to restore electrolyte level to greater than or equal to the minimum established design level. ITS 3.8.6 ACTION D covers the condition of one battery with pilot cell electrolyte temperature less than the minimum established design limits and requires the restoration of battery pilot cell temperature to greater than or equal to minimum established design limits within 12 hours. ITS 3.8.6 ACTION E covers the condition of two batteries with battery parameters not within limits and requires restoration of the battery parameters for one battery to within limits in 2 hours. ITS 3.8.6 ACTION F covers the conditions when a Required Action and associated Completion Time of any of the above ACTIONS cannot be met, if one or both batteries with one or more battery cells float voltage and float current are not within limits, or SR 3.8.6.6 is not met, and requires the immediate declaration that the associated battery is inoperable. The allowances are considered acceptable since only a short time is allowed to exist with battery parameters not within limits. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 7 – Relaxation of Surveillance Frequency)* Unit 1 CTS 4.8.2.3.2.b and Unit 2 CTS 4.8.2.1.b require the performance of several Surveillances within 7 days after a battery discharge (battery terminal voltage below 110 volts), or battery overcharge (battery terminal voltage above 150 volts). ITS 3.8.6 does not

require these Surveillances to be performed after a battery discharge or overcharge. (See DOC L03 for the discussion on deleting the battery inspection requirements from CTS. See DOC L10 for the discussion on replacing the requirement to verify the battery cell specific gravity within limits to a requirement to verify battery float current within limits.) This changes the CTS by not including a specific Surveillance Requirement to perform these tests after a discharge or overcharge.

The purpose of the Unit 1 CTS 4.8.2.3.2.b and Unit 2 CTS 4.8.2.1.b Frequency is to ensure the batteries remain OPERABLE after a severe battery discharge or overcharge. This change is acceptable because the proposed Surveillance Requirement Frequency continues to ensure an acceptable level of equipment reliability. ITS SR 3.8.6.1 requires verification that each battery float current is ≤ 2 amps at a periodic frequency in accordance with the Surveillance Frequency Control Program. The float current requirements are based on the float current indicative of a charged battery. Therefore, this Surveillance will detect a discharge condition of the battery. In addition, ITS 5.5.14, "Battery Monitoring and Maintenance Program," requires a program for battery maintenance based on the recommendations of IEEE 450. The requirement to perform these battery preventative maintenance activities are consistent with IEEE 450, and as such, will be maintained in the plant procedures implementing ITS 5.5.14. This change is designated as less restrictive because Surveillances will be performed less frequently under ITS than under CTS.

L03 *(Category 5 – Deletion of Surveillance Requirement)* Unit 1 CTS 4.8.2.3.2.b.2 and Unit 2 CTS 4.8.2.1.b.2 require verification that there is no visible corrosion at either terminals or connectors. Unit 1 CTS 4.8.2.3.2.c and Unit 2 CTS 4.8.2.1.c, in part, require verification that the cells, cell plates and battery racks show no visual indication of physical damage or abnormal deterioration, the cell-to-cell and terminal connections are clean, tight and coated with anti-corrosion material, and battery cell interconnection resistance values are maintained with defined limits. ITS 3.8.6 does not include these requirements for battery inspections, the removal of visible corrosion, and the verification that the battery-to-battery and terminal connections are clean, tight, and coated with anti-corrosion material. This changes the CTS by deleting the explicit battery requirements from the Technical Specifications.

The purpose of Unit 1 CTS 4.8.2.3.2.b.2 and CTS 4.8.2.3.2.c and Unit 2 CTS 4.8.2.1.b.2 and CTS 4.8.2.1.c is to ensure that proper preventative maintenance activities are performed on the safety related batteries. In accordance with ITS SR 3.0.1, when any SR is not met, the LCO is not met. This is based on the premise that SRs represent the minimum acceptable requirements for OPERABILITY of the required equipment. However, the failure to meet these specific Surveillances does not necessarily mean that the equipment is not capable of performing its safety function. When the batteries are capable of meeting ITS SR 3.8.4.1, the battery terminal voltage verification and ITS SR 3.8.4.3, the battery capacity test, they are considered to be able to meet their safety function. The Surveillances that are proposed to be deleted are considered preventative maintenance activities and are not considered the minimum acceptable requirements for OPERABILITY of the batteries. This change is acceptable because the SR requirements proposed in ITS 3.8.4

continue to ensure that the batteries are maintained consistent with the safety analyses and licensing basis. In addition, ITS 5.5.14, "Battery Monitoring and Maintenance Program," requires a program for battery maintenance based on the recommendations of IEEE 450. The requirement to perform these battery preventative maintenance activities are consistent with IEEE 450, and as such, will be maintained in plant procedures implementing ITS 5.5.14. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

L04 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS surveillance requirement 4.8.2.3.2.e and Unit 2 CTS surveillance requirement 4.8.2.1.e require the performance of discharge tests verifying battery capacity in accordance with the Surveillance Frequency Control Program during shutdown. ITS SR 3.8.6.6, in part, requires the verification of battery capacity when subjected to a performance discharge test. A Note modifies the ITS SR. The Note states “This Surveillance shall not be performed in MODE 1, 2, 3, or 4. However, portions of the Surveillance may be performed to reestablish OPERABILITY provided an assessment determines the safety of the plant is maintained or enhanced. Credit may be taken for unplanned events that satisfy this SR". This changes the CTS by allowing portions of the surveillance to be performed in MODES 1, 2, 3, or 4 (to confirm OPERABILITY) when an assessment determines safe plant operation can be maintained. | R1

The purpose of the CTS requirement to perform the required surveillance during shutdown conditions is to assure plant safety. The ITS SR note allows the SR to be conducted during power operation but only if the performance of the SR does not reduce plant safety. The proposed change is acceptable because it continues to adequately verify that the equipment used to meet the LCO can perform its required functions while assuring the plant is operated safely. The allowance to perform the SR in MODE 1, 2, 3, or 4 is accompanied by the requirement to assess the impact on safety prior to performing the SR. The requirement to assess the impact on the safe operation of the plant provides additional assurance that plant safety will not be decreased. Thus, the proposed ITS relaxation for performing this SR at power is balanced by the additional requirement to assure safe plant operation. The proposed ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L05 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.8.2.3.2.e and Unit 2 CTS 4.8.2.1.e require the performance of a battery performance discharge test on the batteries. ITS SR 3.8.6.6 requires the performance of a performance discharge test or a modified performance discharge test. This changes the CTS by adding the allowance to perform a modified performance discharge test instead of the performance discharge test.

The purpose of Unit 1 CTS 4.8.2.3.2.e and Unit 2 CTS 4.8.2.1.e is to determine overall battery degradation due to age and usage. A performance test, as defined in IEEE 450, is a constant-current or constant-power capacity test made on a battery after it has been in service, to detect any change in the capacity. A modified performance test, as defined in IEEE 450, is a test, in the "as found"

condition, of battery capacity and the ability of the battery to satisfy the duty cycle. Both tests, performance discharge test or modified performance discharge test, monitor the battery capacity. IEEE 450, as endorsed by RG 1.129-2007, states that a modified performance test is a test of battery capacity using a constant current, modified by increasing the current to bound the currents in the duty cycle. Deviations from the constant-current test, which increase the current, are acceptable. IEEE 450 also states that a modified performance test can be used in lieu of a service test and/or a performance test at any time. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are acceptable for verification that the equipment used to meet the LCO can perform its required functions. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L06 *(Category 7 – Relaxation of Surveillance Frequency)* Unit 1 CTS 4.8.2.3.2.f and Unit 2 CTS 4.8.2.1.f require an increased Frequency from that in Unit 1 CTS 4.8.2.3.2.e and Unit 1 CTS 4.8.2.1.e for battery performance tests if the battery shows signs of degradation or has reached 85% of its expected service life. ITS SR 3.8.6.6 provides two Frequencies when a battery has reached 85% of its expected service life based on whether the battery's remaining capacity is less than 100% or not. If the battery's remaining capacity is less than 100% of the manufactures rating, the required discharge test is performed every 12 months (annually). If the battery's remaining capacity is greater than or equal to 100% of the manufacturer's rating, then the required discharge test is performed every 24 months. This changes the CTS by relaxing the Frequency of required discharge tests when the battery has reached 85% of its expected service life.

The purpose of Unit 1 CTS 4.8.2.3.2.f and Unit 2 CTS 4.8.2.1.f is to verify the battery capacity is acceptable on batteries that show signs of degradation or have reached 85% of the service life. ITS 3.8.6.6 provides an alternative Frequency if the battery that has reached 85% of its service life but has not shown signs of degradation and has a capacity of greater than or equal to 100% of the manufacture's rating. This relaxed frequency is acceptable because the battery has not shown signs of degradation, retains greater than or equal to the manufacturer's rated capacity, and is being tested at a more frequent periodicity than a battery that has not reached 85% of the service life expected. Also, IEEE 450 states that if the battery has reached 85% of service life, delivers a capacity of 100% or greater of the manufacturer's rated capacity, and has shown no signs of degradation, performance testing at two-year intervals is acceptable until the battery shows signs of degradation. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L07 *(Category 5 – Deletion of Surveillance Requirement)* Unit 1 CTS 4.8.2.3.2.a.1 and Unit 2 CTS 4.8.2.1.a.1 require verifying the parameters in Table 4.8-1a meet Category A limits in accordance with the Surveillance Frequency Control Program. CTS Table 4.8-2 Category A contains the parameter 'Electrolyte Level' with the limit for each designated pilot cell set at "> Minimum level indication mark, and ≤ 1/4" above maximum level indication mark." Unit 1 CTS 4.8.2.3.2.b.1 and Unit 2 CTS 4.8.2.1.a.1 require verifying the parameters in Table 4.8-2 meet Category B limits in accordance with the Surveillance Frequency Control

Program. CTS Table 4.8-2 Category B contains the parameter 'Electrolyte Level' with the limit for each connected cell set at "> Minimum level indication mark, and ≤ 1/4" above maximum level indication mark." In addition, the Category B electrolyte level Allowable Value for each connected cell (which includes the pilot cells) is above the top of plates, and not overflowing. ITS SR 3.8.6.3 requires verifying each battery connected cell electrolyte level is greater than or equal to minimum established design limits in accordance with the Surveillance Frequency Control Program. This changes the CTS by deleting the requirement to verify the pilot cells electrolyte level is within limits.

The purpose of CTS Category A limit on pilot cell electrolyte level and its related Frequency is to represent appropriate monitoring levels and appropriate preventive maintenance levels for long-term battery quality and extended battery life. The definition of Limiting Condition for Operation (LCO) presented in 10 CFR 50.36 states that LCOs are "the lowest functional capability or performance levels of equipment required for safe operation of the facility." As such, the Category A value for cell electrolyte level does not reflect the 10 CFR 50.36 criteria for LCOs. ITS 5.5.14, Battery Monitoring and Maintenance Program," requires a program providing controls for battery restoration and maintenance that shall be in accordance with IEEE 450 as endorsed by Regulatory Guide 1.129, with exceptions as applicable. IEEE 450 contains, in part, guidance on monitoring electrolyte level with the intention of providing recommended maintenance, test schedules, and testing procedures that can be used to optimize the life and performance of permanently installed, vented lead-acid storage batteries used for standby power applications. These values and actions associated with restoration are being replaced by a licensee-controlled program, required and described in TS Section 5.5, "Programs and Manuals," and titled the "Battery Monitoring and Maintenance Program." This provides adequate assurance that necessary battery parameter values will continue to be controlled and actions will be implemented if the battery parameter values are not met. Furthermore, the battery and its preventive maintenance and monitoring program are under the regulatory requirements of 10 CFR 50.65, "Requirements for monitoring the effectiveness of maintenance at nuclear power plants." This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

L08 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.8.2.3.2.a.1 and Unit 2 CTS 4.8.2.1.a.1 require verification that the pilot cell voltage is ≥ 2.13 V. ITS SR 3.8.6.2 requires the verification that each pilot cell voltage is ≥ 2.07 V. ITS 3.8.6 ACTION A addresses the condition in which one or more batteries with one or more battery cells float voltage less than 2.07 V. Once ACTION A has been entered, the battery cell is considered degraded and the Required Actions are to perform SR 3.8.4.1 and SR 3.8.6.1 within 2 hours. This changes the CTS by reducing the acceptance criterion for the pilot cell voltage limit from ≥ 2.13 V to ≥ 2.07 V.

The purpose of the proposed Surveillance limit in ITS SR 3.8.6.2 is to ensure the cell voltages are greater than or equal to the short-term absolute minimum voltage. Optimal long-term battery performance is obtained by maintaining a float voltage greater than or equal to the minimum established design limits provided by the battery manufacturer. This provides adequate over-potential,

which limits the formation of lead sulfate and self discharge which could eventually render the battery inoperable. Float voltages in this range or less, but greater than 2.07 V per cell, are addressed in the Battery Monitoring and Maintenance Program. Furthermore, the Battery Monitoring and Maintenance Program includes actions to restore battery cells with float voltage less than 2.13 V and actions to verify that the remaining cells are greater than or equal to 2.07 V when a cell or cells have been found to be less than 2.13 V. A cell voltage of 2.07 V or below under float conditions may indicate internal cell problems while prolonged operation of cells below 2.13 V has the potential to reduce the life expectancy of cells. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. At the lower proposed voltage, the cell can still perform its function. The battery is considered OPERABLE when the battery voltage on float is greater than or equal to the minimum establish voltage of ITS SR 3.8.4.1. This change is acceptable since ITS 5.5.14, "Battery Monitoring and Maintenance Program," requires actions to be taken to restore battery cells with float voltage < 2.13 V. This program helps ensure the cell voltage will not approach the limit of 2.07 V and that the minimum established voltage of ITS SR 3.8.4.1 is maintained. This change is designated as less restrictive because a less stringent Surveillance Requirement acceptance criterion is being applied in the ITS than applied in the CTS.

L09 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.8.2.3.2.b.1 and Unit 2 CTS 4.8.2.1.b.1 require verification that each connected cell voltage is > 2.07 V in accordance with the Surveillance Frequency Control Program. ITS SR 3.8.6.5 requires the verification that each connected cell voltage is ≥ 2.07 V. This changes the CTS by reducing the acceptance criteria for each connected cell voltage limit from > 2.07 V to ≥ 2.07 V.

The purpose of Unit 1 CTS 4.8.2.3.2.b.1 and Unit 2 CTS 4.8.2.1.b.1 is to verify each connected cell voltage > 2.07 V, thereby establishing a minimum value for battery OPERABILITY. The purpose of the ITS 3.8.6.5 requirement to verify each connected cell voltage is ≥ 2.07 V is also to establish a minimum value for battery OPERABILITY. Optimal long-term battery performance is obtained by maintaining a float voltage greater than or equal to the minimum established design limits provided by the battery manufacturer, which corresponds to 2.06 V per cell. This provides adequate over-potential, which limits the formation of lead sulfate and self discharge, which could eventually render the battery inoperable. Float voltages in this range or less, but greater than 2.07 V per cell, are addressed in the Battery Monitoring and Maintenance Program. Furthermore, the Battery Monitoring and Maintenance Program includes actions to restore battery cells with float voltage less than 2.13 V and actions to verify that the remaining cells are greater than or equal to 2.07 V when a cell or cells have been found to be less than 2.13 V. The 2.07 V per individual cell limit reflects the OPERABILITY limit for the batteries. With all battery cells at or above 2.07 V, there is adequate assurance that that the terminal voltage is at an acceptable threshold for establishing battery OPERABILITY. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L10 *(Category 5 – Deletion of Surveillance Requirement)* Unit 1 CTS 4.8.2.3.2.a.1 and Unit 2 CTS 4.8.2.1.a.1 require verification the pilot cell specific gravity is within the Category A limits of Table 4.8-2, as modified by footnote (a)). Unit 1 CTS 4.8.2.3.2.b.1 and Unit 2 CTS 4.8.2.1.b.1 require verification that each connected cell specific gravity is within the Category B limits of Table 4.8-2. As indicated in CTS Table 4.8-2 (footnote (a)), the specific gravity limit must be corrected for electrolyte temperature and level. ITS 3.8.6 does not include these Surveillances. This changes the CTS by deleting the Surveillances to verify battery cell specific gravity.

The purpose of Unit 1 CTS 4.8.2.3.2.a.1 and CTS 4.8.2.3.2.b.1 and Unit 2 CTS 4.8.2.1.a.1 and CTS 4.8.2.1.b.1 is to ensure the state of charge of each battery cell. This change is acceptable because the deleted Surveillance Requirements are not necessary to verify that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to give confidence that the equipment can perform its assumed safety function. While the specified Surveillances have been deleted, the alternative Surveillance of CTS Table 4.8-2 footnote (b), to verify battery charging current < 2 amps is retained in ITS as SR 3.8.6.1, with modifications to the acceptance criteria to reflect the information provided by the battery manufacturer. IEEE 450 states that the most accurate indicator of return to full charge is a stabilized charging or float current. Specific gravity readings may not be accurate when the battery is on charge following a discharge. Therefore, ITS SR 3.8.6.1 gives a better indication of the overall battery condition. This change is designated as less restrictive because Surveillances which are required in CTS will not be required in ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.6, BATTERY PARAMETERS

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. ISTS SR 3.8.6.6 requires a battery performance discharge or modified performance discharge test to be performed and provides acceptance criteria. However, no ACTION is provided in the ISTS 3.8.6 ACTIONS for when this SR is not met. Thus in the ISTS, LCO 3.0.3 would have to be entered. To preclude an LCO 3.0.3 entry, ISTS 3.8.6 Condition F has been modified to cover the case when SR 3.8.6.6 is not met. ACTION F will require the associated battery to be declared inoperable. This is also consistent with the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.6 Battery Parameters

BASES

BACKGROUND

This LCO delineates the limits on battery float current as well as electrolyte temperature, level, and float voltage for the DC power subsystem batteries. A discussion of these batteries and their OPERABILITY requirements is provided in the Bases for LCO 3. 8.4, "DC Sources - Operating," and LCO 3.8.5, "DC Sources - Shutdown." In addition to the limitations of this Specification, the ~~[licensee controlled program]~~ also implements a program specified in Specification 5.5.1~~6~~ for monitoring various battery parameters.

Battery Monitoring and Maintenance Program

The battery cells are of flooded lead acid construction with a nominal specific gravity of ~~[~~1.215~~]~~. This specific gravity corresponds to an open circuit battery voltage of approximately ~~120~~ V for ~~[58]~~ cell battery (i.e., cell voltage of ~~[2.065]~~ volts per cell (Vpc)). The open circuit voltage is the voltage maintained when there is no charging or discharging. ~~Once fully charged with its open circuit voltage ≥ [2.065] Vpc, the battery cell will maintain its capacity for [30] days without further charging per manufacturer's instructions.~~ Optimal long term performance however, is obtained by maintaining a float voltage ~~[~~2.20 to 2.25~~]~~ Vpc. This provides adequate over-potential which limits the formation of lead sulfate and self discharge. The nominal float voltage of ~~[2.22]~~ Vpc corresponds to a total float voltage output of ~~[128.8]~~ V for a ~~[58]~~ cell battery ~~as discussed in the FSAR, Chapter [8] (Ref. 2)~~.

APPLICABLE SAFETY ANALYSES

U

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 3) and Chapter ~~[~~15~~]~~ (Ref. 4), assume Engineered Safety Feature systems are OPERABLE. The DC electrical power system provides normal and emergency DC electrical power for the DGs, emergency auxiliaries, and control and switching during all MODES of operation.

The OPERABILITY of the DC subsystems is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This includes maintaining at least one subsystem of DC sources OPERABLE during accident conditions, in the event of:

a. An assumed loss of all offsite AC power or all onsite AC power and

b. A worst-case single failure.

Battery parameters satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

Battery parameters must remain within acceptable limits to ensure availability of the required DC power to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence or a postulated DBA. Battery parameter limits are conservatively established, allowing continued DC electrical system function even with limits not met. Additional preventative maintenance, testing, and monitoring performed in accordance with the ~~[licensee controlled program]~~ is conducted as specified in Specification 5.5.1~~6~~.

Battery Monitoring and Maintenance Program

4

2

3

APPLICABILITY

The battery parameters are required solely for the support of the associated DC electrical power subsystems. Therefore, battery parameter limits are only required when the DC power source is required to be OPERABLE. Refer to the Applicability discussion in Bases for LCO 3.8.4 and LCO 3.8.5.

ACTIONS

Insert 1

1

A.1, A.2, and A.3

battery

With one or more cells in one ~~or more batteries in one subsystem~~ < ~~[~~2.07~~]~~ V, the battery cell is degraded. Within 2 hours verification of the required battery charger OPERABILITY is made by monitoring the battery terminal voltage (SR 3.8.4.1) and of the overall battery state of charge by monitoring the battery float charge current (SR 3.8.6.1). This assures that there is still sufficient battery capacity to perform the intended function. Therefore, the affected battery is not required to be considered inoperable solely as a result of one or more cells in one or more batteries < ~~[~~2.07~~]~~ V, and continued operation is permitted for a limited period up to 24 hours.

6

2

2

Since the Required Actions only specify "perform," a failure of SR 3.8.4.1 or SR 3.8.6.1 acceptance criteria does not result in this Required Action not met. However, if one of the SRs is failed the appropriate Condition(s), depending on the cause of the failures, is entered. If SR 3.8.6.1 is failed then there is no assurance that there is still sufficient battery capacity to perform the intended function and the battery must be declared inoperable immediately.

B.1 and B.2

battery

One ~~or more batteries in one subsystem~~ with float current > ~~[~~2~~]~~ amps indicates that a partial discharge of the battery capacity has occurred. This may be due to a temporary loss of a battery charger or possibly due to one or more battery cells in a low voltage condition reflecting some loss of capacity. Within 2 hours verification of the required battery charger OPERABILITY is made by monitoring the battery terminal voltage. If the terminal voltage is found to be less than the minimum established float voltage there are two possibilities, the battery charger is inoperable or is

6

2

1

Insert 1

The Note to the ACTIONS clarifies that separate Condition entry is allowed for each battery. This is acceptable since the Required Actions for each Condition provide appropriate compensatory actions for each battery parameter not within limits. Complying with the Required Actions for one inoperable battery may allow for continued operation, and a subsequent inoperable battery is governed by separate Condition entry and application of associated Required Actions.

BASES

ACTIONS (continued)

operating in the current limit mode. Condition A addresses charger inoperability. If the charger is operating in the current limit mode after 2 hours that is an indication that the battery has been substantially discharged and likely cannot perform its required design functions. The time to return the battery to its fully charged condition in this case is a function of the battery charger capacity, the amount of loads on the associated DC system, the amount of the previous discharge, and the recharge characteristic of the battery. The charge time can be extensive, and there is not adequate assurance that it can be recharged within ~~[~~12~~]~~ hours (Required Action B.2). The battery must therefore be declared inoperable. 2

If the float voltage is found to be satisfactory but there are one or more battery cells with float voltage less than ~~[~~2.07~~]~~ V, the associated "OR" statement in Condition F is applicable and the battery must be declared inoperable immediately. If float voltage is satisfactory and there are no cells less than ~~[~~2.07~~]~~ V there is good assurance that, within ~~[~~12~~]~~ hours, the battery will be restored to its fully charged condition (Required Action B.2) from any discharge that might have occurred due to a temporary loss of the battery charger. 2 2

~~REVIEWER'S NOTE~~

~~A plant that cannot meet the 12 hour Completion Time due to an inherent battery charging characteristic can propose an alternate time equal to 2 hours plus the time experienced to accomplish the exponential charging current portion of the battery charge profile following the service test (SR 3.8.4.3).~~ 5

A discharged battery with float voltage (the charger setpoint) across its terminals indicates that the battery is on the exponential charging current portion (the second part) of its recharge cycle. The time to return a battery to its fully charged state under this condition is simply a function of the amount of the previous discharge and the recharge characteristic of the battery. Thus there is good assurance of fully recharging the battery within ~~[~~12~~]~~ hours, avoiding a premature shutdown with its own attendant risk. 2

If the condition is due to one or more cells in a low voltage condition but still greater than ~~[~~2.07~~]~~ V and float voltage is found to be satisfactory, this is not indication of a substantially discharged battery and ~~[~~12~~]~~ hours is a reasonable time prior to declaring the battery inoperable. 2

BASES

ACTIONS (continued)

Since Required Action B.1 only specifies "perform," a failure of SR 3.8.4.1 acceptance criteria does not result in the Required Action not met. However, if SR 3.8.4.1 is failed, the appropriate Condition(s), depending on the cause of the failure, is entered.

C.1, C.2, and C.3

battery

With one ~~or more batteries in one subsystem~~ with one or more cells electrolyte level above the top of the plates, but below the minimum established design limits, the battery still retains sufficient capacity to perform the intended function. Therefore, the affected battery is not required to be considered inoperable solely as a result of electrolyte level not met. Within 31 days the minimum established design limits for electrolyte level must be re-established. 6

With electrolyte level below the top of the plates there is a potential for dryout and plate degradation. Required Actions C.1 and C.2 address this potential (as well as provisions in Specification 5.5.1~~6~~, Battery Monitoring and Maintenance Program). They are modified by a Note that indicates they are only applicable if electrolyte level is below the top of the plates. Within 8 hours level is required to be restored to above the top of the plates. The Required Action C.2 requirement to verify that there is no leakage by visual inspection and the Specification 5.5.1~~6~~.b item to initiate action to equalize and test in accordance with manufacturer's recommendation are taken from IEEE Standard 450. They are performed following the restoration of the electrolyte level to above the top of the plates. Based on the results of the manufacturer's recommended testing, the batter[y][~~ies~~] may have to be declared inoperable and the affected cell[~~s~~] replaced. 4 4 3 , 1 2

D.1

battery

With one ~~or more batteries in one subsystem~~ with pilot cell temperature less than the minimum established design limits, 12 hours is allowed to restore the temperature to within limits. A low electrolyte temperature limits the current and power available. Since the battery is sized with margin, while battery capacity is degraded, sufficient capacity exists to perform the intended function and the affected battery is not required to be considered inoperable solely as a result of the pilot cell temperature not met. 6

BASES

ACTIONS (continued)

E.1

two

With ~~one or more~~ batteries ~~in redundant subsystems~~ with battery parameters not within limits there is not sufficient assurance that battery capacity has not been affected to the degree that the batteries can still perform their required function, given that redundant batteries are involved. With redundant batteries involved this potential could result in a total loss of function on multiple systems that rely upon the batteries. The longer Completion Times specified for battery parameters on ~~non-redundant batteries~~ not within limits are therefore not appropriate, and the parameters must be restored to within limits on at least one ~~subsystem~~ within 2 hours.

6

one battery

1

battery

F.1

With one or more batteries with any battery parameter outside the allowances of the Required Actions for Condition A, B, C, D, or E, sufficient capacity to supply the maximum expected load requirement is not assured and the corresponding battery must be declared inoperable. Additionally, discovering one or ~~more~~ batteries ~~in one subsystem~~ with one or more battery cells float voltage less than ~~[~~2.07~~]~~ V and float current greater than ~~[~~2~~]~~ amps indicates that the battery capacity may not be sufficient to perform the intended functions. The battery must therefore be declared inoperable immediately.

or failure of the battery performance discharge test (SR 3.8.6.6),

1

both

2

SURVEILLANCE REQUIREMENTS

SR 3.8.6.1

Verifying battery float current while on float charge is used to determine the state of charge of the battery. Float charge is the condition in which the charger is supplying the continuous charge required to overcome the internal losses of a battery and maintain the battery in a charged state. The float current requirements are based on the float current indicative of a charged battery. Use of float current to determine the state of charge of the battery is consistent with IEEE-450 (Ref. 1). ~~[The 7-day Frequency is consistent with IEEE-450 (Ref. 1).~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~ 5 2

This SR is modified by a Note that states the float current requirement is not required to be met when battery terminal voltage is less than the minimum established float voltage of SR 3.8.4.1. When this float voltage is not maintained the Required Actions of LCO 3.8.4 ACTION A are being taken, which provide the necessary and appropriate verifications of the battery condition. Furthermore, the float current limit of ~~[~~2~~]~~ amps is established based on the nominal float voltage value and is not directly applicable when this voltage is not maintained. 2

SR 3.8.6.2 and SR 3.8.6.5

allowable

Optimal long term battery performance is obtained by maintaining a float voltage greater than or equal to the minimum ~~established design~~ limit~~s~~ provided by the battery manufacturer, which corresponds to ~~[130.5] V at the battery terminals~~, or ~~[2.25]~~ Vpc. This provides adequate over-potential, which limits the formation of lead sulfate and self discharge, which could eventually render the battery inoperable. Float voltages in this range or less, but greater than ~~[~~2.07~~]~~ Vpc, are addressed in Specification 5.5.1~~6~~. SRs 3.8.6.2 and 3.8.6.5 require verification that the cell float voltages are equal to or greater than the short term absolute minimum voltage of ~~[~~2.07~~]~~ V. ~~[The Frequency for cell voltage verification every 31 days for pilot cell and 92 days for each connected cell is consistent with IEEE-450 (Ref. 1).~~

127.2 V for a 60 cell battery

SR 3.8.6.4

This Surveillance verifies that the pilot cell temperature is greater than or equal to the minimum established design limit (i.e., ~~[40]~~ 50°F). 2 Pilot cell electrolyte temperature is maintained above this temperature to assure the battery can provide the required current and voltage to meet the design requirements. Temperatures lower than assumed in battery sizing calculations act to inhibit or reduce battery capacity. ~~[The Frequency of 31 days is consistent with IEEE-450 (Ref. 1).~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

5

~~]~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.8.6.6

A battery performance discharge test is a test of constant current capacity of a battery, normally done in the as-found condition, after having been in service, to detect any change in the capacity determined by the acceptance test. The test is intended to determine overall battery degradation due to age and usage.

Either the battery performance discharge test or the modified performance discharge test is acceptable for satisfying SR 3.8.6.6; however, only the modified performance discharge test may be used to satisfy the battery service test requirements of SR 3.8.4.3.

A modified discharge test is a test of the battery capacity and its ability to provide a high rate, short duration load (usually the highest rate of the duty cycle). This will often confirm the battery's ability to meet the critical period of the load duty cycle, in addition to determining its percentage of rated capacity. Initial conditions for the modified performance discharge test should be identical to those specified for a service test.

It may consist of just two rates; for instance the one minute rate for the battery or the largest current load of the duty cycle, followed by the test rate employed for the performance test, both of which envelope the duty cycle of the service test. Since the ampere-hours removed by a one minute discharge represents a very small portion of the battery capacity, the test rate can be changed to that for the performance test without compromising the results of the performance discharge test. The battery terminal voltage for the modified performance discharge test must remain above the minimum battery terminal voltage specified in the battery service test for the duration of time equal to that of the service test.

The acceptance criteria for this Surveillance are consistent with IEEE-450 (Ref. 1) and IEEE-485 (Ref. 5). These references recommend that the battery be replaced if its capacity is below 80% of the manufacturer's rating. A capacity of 80% shows that the battery rate of deterioration is increasing, even if there is ample capacity to meet the load requirements. Furthermore, the battery is sized to meet the assumed duty cycle loads when the battery design capacity reaches this ~~[~~80~~]~~% limit. 2

~~[The Surveillance Frequency for this test is normally 60 months.~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

If the battery shows degradation, or if the battery has reached 85% of its expected life and capacity is < 100% of the manufacturer's rating, the Surveillance Frequency is reduced to 12 months. However, if the battery shows no degradation but has reached 85% of its expected life, the Surveillance Frequency is only reduced to 24 months for batteries that retain capacity ≥ 100% of the manufacturer's ratings. Degradation is indicated, according to IEEE-450 (Ref. 1), when the battery capacity drops by more than 10% relative to its capacity on the previous performance test or when it is ≥ ~~[~~10%~~]~~ below the manufacturer's rating. These Frequencies are consistent with the recommendations in IEEE-450 (Ref. 1).

This SR is modified by a Note. The reason for the Note is that performing the Surveillance would perturb the electrical distribution system and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1~~ or 2~~ is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed partial Surveillance, a successful partial Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the partial Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when portions of the Surveillance are performed in MODE 1~~ or 2~~. Risk insights or deterministic methods may be used for the assessment. Credit may be taken for unplanned events that satisfy this SR.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.6 Battery Parameters

BASES

BACKGROUND

This LCO delineates the limits on battery float current as well as electrolyte temperature, level, and float voltage for the DC power subsystem batteries. A discussion of these batteries and their OPERABILITY requirements is provided in the Bases for LCO 3. 8.4, "DC Sources - Operating," and LCO 3.8.5, "DC Sources - Shutdown." In addition to the limitations of this Specification, the ~~[licensee controlled program]~~ also implements a program specified in Specification 5.5.1~~6~~ for monitoring various battery parameters.

Battery Monitoring and Maintenance Program

The battery cells are of flooded lead acid construction with a nominal specific gravity of ~~[~~1.215~~]~~. This specific gravity corresponds to an open circuit battery voltage of approximately ~~120~~ V for ~~[58]~~ cell battery (i.e., cell voltage of ~~[2.065]~~ volts per cell (Vpc)). The open circuit voltage is the voltage maintained when there is no charging or discharging. ~~Once fully charged with its open circuit voltage ≥ [2.065] Vpc, the battery cell will maintain its capacity for [30] days without further charging per manufacturer's instructions.~~ Optimal long term performance however, is obtained by maintaining a float voltage ~~[~~2.20 to 2.25~~]~~ Vpc. This provides adequate over-potential which limits the formation of lead sulfate and self discharge. The nominal float voltage of ~~[2.22]~~ Vpc corresponds to a total float voltage output of ~~[128.8]~~ V for a ~~[58]~~ cell battery ~~as discussed in the FSAR, Chapter [8] (Ref. 2)~~.

APPLICABLE SAFETY ANALYSES

U

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[6]~~ (Ref. 3) and Chapter ~~[15]~~ (Ref. 4), assume Engineered Safety Feature systems are OPERABLE. The DC electrical power system provides normal and emergency DC electrical power for the DGs, emergency auxiliaries, and control and switching during all MODES of operation.

The OPERABILITY of the DC subsystems is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This includes maintaining at least one subsystem of DC sources OPERABLE during accident conditions, in the event of:

a. An assumed loss of all offsite AC power or all onsite AC power and

b. A worst-case single failure.

Battery parameters satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

Battery parameters must remain within acceptable limits to ensure availability of the required DC power to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence or a postulated DBA. Battery parameter limits are conservatively established, allowing continued DC electrical system function even with limits not met. Additional preventative maintenance, testing, and monitoring performed in accordance with the ~~[licensee controlled program]~~ is conducted as specified in Specification 5.5.1~~6~~.

Battery Monitoring and Maintenance Program

4

2

3

APPLICABILITY

The battery parameters are required solely for the support of the associated DC electrical power subsystems. Therefore, battery parameter limits are only required when the DC power source is required to be OPERABLE. Refer to the Applicability discussion in Bases for LCO 3.8.4 and LCO 3.8.5.

ACTIONS

Insert 1

1

A.1, A.2, and A.3

battery

With one or more cells in one ~~or more batteries in one subsystem~~ < ~~[~~2.07~~]~~ V, the battery cell is degraded. Within 2 hours verification of the required battery charger OPERABILITY is made by monitoring the battery terminal voltage (SR 3.8.4.1) and of the overall battery state of charge by monitoring the battery float charge current (SR 3.8.6.1). This assures that there is still sufficient battery capacity to perform the intended function. Therefore, the affected battery is not required to be considered inoperable solely as a result of one or more cells in one or more batteries < ~~[~~2.07~~]~~ V, and continued operation is permitted for a limited period up to 24 hours.

6

2

2

Since the Required Actions only specify "perform," a failure of SR 3.8.4.1 or SR 3.8.6.1 acceptance criteria does not result in this Required Action not met. However, if one of the SRs is failed the appropriate Condition(s), depending on the cause of the failures, is entered. If SR 3.8.6.1 is failed then there is no assurance that there is still sufficient battery capacity to perform the intended function and the battery must be declared inoperable immediately.

B.1 and B.2

battery

One ~~or more batteries in one subsystem~~ with float current > ~~[~~2~~]~~ amps indicates that a partial discharge of the battery capacity has occurred. This may be due to a temporary loss of a battery charger or possibly due to one or more battery cells in a low voltage condition reflecting some loss of capacity. Within 2 hours verification of the required battery charger OPERABILITY is made by monitoring the battery terminal voltage. If the terminal voltage is found to be less than the minimum established float voltage there are two possibilities, the battery charger is inoperable or is

6

2

1

Insert 1

The Note to the ACTIONS clarifies that separate Condition entry is allowed for each battery. This is acceptable since the Required Actions for each Condition provide appropriate compensatory actions for each battery parameter not within limits. Complying with the Required Actions for one inoperable battery may allow for continued operation, and a subsequent inoperable battery is governed by separate Condition entry and application of associated Required Actions.

BASES

ACTIONS (continued)

operating in the current limit mode. Condition A addresses charger inoperability. If the charger is operating in the current limit mode after 2 hours that is an indication that the battery has been substantially discharged and likely cannot perform its required design functions. The time to return the battery to its fully charged condition in this case is a function of the battery charger capacity, the amount of loads on the associated DC system, the amount of the previous discharge, and the recharge characteristic of the battery. The charge time can be extensive, and there is not adequate assurance that it can be recharged within ~~[~~12~~]~~ hours (Required Action B.2). The battery must therefore be declared inoperable. 2

If the float voltage is found to be satisfactory but there are one or more battery cells with float voltage less than ~~[~~2.07~~]~~ V, the associated "OR" statement in Condition F is applicable and the battery must be declared inoperable immediately. If float voltage is satisfactory and there are no cells less than ~~[~~2.07~~]~~ V there is good assurance that, within ~~[~~12~~]~~ hours, the battery will be restored to its fully charged condition (Required Action B.2) from any discharge that might have occurred due to a temporary loss of the battery charger. 2 2

~~REVIEWER'S NOTE~~

~~A plant that cannot meet the 12 hour Completion Time due to an inherent battery charging characteristic can propose an alternate time equal to 2 hours plus the time experienced to accomplish the exponential charging current portion of the battery charge profile following the service test (SR 3.8.4.3).~~ 5

A discharged battery with float voltage (the charger setpoint) across its terminals indicates that the battery is on the exponential charging current portion (the second part) of its recharge cycle. The time to return a battery to its fully charged state under this condition is simply a function of the amount of the previous discharge and the recharge characteristic of the battery. Thus there is good assurance of fully recharging the battery within ~~[~~12~~]~~ hours, avoiding a premature shutdown with its own attendant risk. 2

If the condition is due to one or more cells in a low voltage condition but still greater than ~~[~~2.07~~]~~ V and float voltage is found to be satisfactory, this is not indication of a substantially discharged battery and ~~[~~12~~]~~ hours is a reasonable time prior to declaring the battery inoperable. 2

BASES

ACTIONS (continued)

Since Required Action B.1 only specifies "perform," a failure of SR 3.8.4.1 acceptance criteria does not result in the Required Action not met. However, if SR 3.8.4.1 is failed, the appropriate Condition(s), depending on the cause of the failure, is entered.

C.1, C.2, and C.3

battery

With one ~~or more batteries in one subsystem~~ with one or more cells electrolyte level above the top of the plates, but below the minimum established design limits, the battery still retains sufficient capacity to perform the intended function. Therefore, the affected battery is not required to be considered inoperable solely as a result of electrolyte level not met. Within 31 days the minimum established design limits for electrolyte level must be re-established. 6

With electrolyte level below the top of the plates there is a potential for dryout and plate degradation. Required Actions C.1 and C.2 address this potential (as well as provisions in Specification 5.5.1~~6~~, Battery Monitoring and Maintenance Program). They are modified by a Note that indicates they are only applicable if electrolyte level is below the top of the plates. Within 8 hours level is required to be restored to above the top of the plates. The Required Action C.2 requirement to verify that there is no leakage by visual inspection and the Specification 5.5.1~~6~~.b item to initiate action to equalize and test in accordance with manufacturer's recommendation are taken from IEEE Standard 450. They are performed following the restoration of the electrolyte level to above the top of the plates. Based on the results of the manufacturer's recommended testing, the batter[y]~~[ies]~~ may have to be declared inoperable and the affected cell~~[s]~~ replaced. 4 4 3 , 1 2

D.1

battery

With one ~~or more batteries in one subsystem~~ with pilot cell temperature less than the minimum established design limits, 12 hours is allowed to restore the temperature to within limits. A low electrolyte temperature limits the current and power available. Since the battery is sized with margin, while battery capacity is degraded, sufficient capacity exists to perform the intended function and the affected battery is not required to be considered inoperable solely as a result of the pilot cell temperature not met. 6

BASES

ACTIONS (continued)

E.1

two

With ~~one or more~~ batteries ~~in redundant subsystems~~ with battery parameters not within limits there is not sufficient assurance that battery capacity has not been affected to the degree that the batteries can still perform their required function, given that redundant batteries are involved. With redundant batteries involved this potential could result in a total loss of function on multiple systems that rely upon the batteries. The longer Completion Times specified for battery parameters on ~~non-redundant batteries~~ not within limits are therefore not appropriate, and the parameters must be restored to within limits on at least one ~~subsystem~~ within 2 hours.

6

one battery

1

battery

F.1

With one or more batteries with any battery parameter outside the allowances of the Required Actions for Condition A, B, C, D, or E, sufficient capacity to supply the maximum expected load requirement is not assured and the corresponding battery must be declared inoperable. Additionally, discovering one or ~~more~~ batteries ~~in one subsystem~~ with one or more battery cells float voltage less than ~~[~~2.07~~]~~ V and float current greater than ~~[~~2~~]~~ amps indicates that the battery capacity may not be sufficient to perform the intended functions. The battery must therefore be declared inoperable immediately.

or failure of the battery performance discharge test (SR 3.8.6.6),

1

both

2

SURVEILLANCE REQUIREMENTS

SR 3.8.6.1

Verifying battery float current while on float charge is used to determine the state of charge of the battery. Float charge is the condition in which the charger is supplying the continuous charge required to overcome the internal losses of a battery and maintain the battery in a charged state. The float current requirements are based on the float current indicative of a charged battery. Use of float current to determine the state of charge of the battery is consistent with IEEE-450 (Ref. 1). ~~[The 7-day Frequency is consistent with IEEE-450 (Ref. 1).~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

This SR is modified by a Note that states the float current requirement is not required to be met when battery terminal voltage is less than the minimum established float voltage of SR 3.8.4.1. When this float voltage is not maintained the Required Actions of LCO 3.8.4 ACTION A are being taken, which provide the necessary and appropriate verifications of the battery condition. Furthermore, the float current limit of ~~[~~2~~]~~ amps is established based on the nominal float voltage value and is not directly applicable when this voltage is not maintained.

SR 3.8.6.2 and SR 3.8.6.5

allowable

Optimal long term battery performance is obtained by maintaining a float voltage greater than or equal to the minimum ~~established design~~ limit~~s~~ provided by the battery manufacturer, which corresponds to ~~[130.5] V at the battery terminals~~, or ~~[2.25]~~ Vpc. This provides adequate over-potential, which limits the formation of lead sulfate and self discharge, which could eventually render the battery inoperable. Float voltages in this range or less, but greater than ~~[~~2.07~~]~~ Vpc, are addressed in Specification 5.5.1~~6~~. SRs 3.8.6.2 and 3.8.6.5 require verification that the cell float voltages are equal to or greater than the short term absolute minimum voltage of ~~[~~2.07~~]~~ V. ~~[The Frequency for cell voltage verification every 31 days for pilot cell and 92 days for each connected cell is consistent with IEEE-450 (Ref. 1).~~

4

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

Electrolyte level is monitored as part of the "Battery Monitoring and Maintenance Program" (ITS 5.5.14). Level is maintained above the top of the plates with Action taken when level is ≤ ¼" above the maximum level indication mark.

SR 3.8.6.3

The limit specified for electrolyte level ensures that the plates suffer no physical damage and maintains adequate electron transfer capability. ~~[The Frequency of 31days is consistent with IEEE-450 (Ref. 1).~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

5

~~]~~ 2

SR 3.8.6.4

This Surveillance verifies that the pilot cell temperature is greater than or equal to the minimum established design limit (i.e., ~~[40]~~ 50°F). 2 Pilot cell electrolyte temperature is maintained above this temperature to assure the battery can provide the required current and voltage to meet the design requirements. Temperatures lower than assumed in battery sizing calculations act to inhibit or reduce battery capacity. ~~[The Frequency of 31 days is consistent with IEEE-450 (Ref. 1).~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

5

~~]~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.8.6.6

A battery performance discharge test is a test of constant current capacity of a battery, normally done in the as-found condition, after having been in service, to detect any change in the capacity determined by the acceptance test. The test is intended to determine overall battery degradation due to age and usage.

Either the battery performance discharge test or the modified performance discharge test is acceptable for satisfying SR 3.8.6.6; however, only the modified performance discharge test may be used to satisfy the battery service test requirements of SR 3.8.4.3.

A modified discharge test is a test of the battery capacity and its ability to provide a high rate, short duration load (usually the highest rate of the duty cycle). This will often confirm the battery's ability to meet the critical period of the load duty cycle, in addition to determining its percentage of rated capacity. Initial conditions for the modified performance discharge test should be identical to those specified for a service test.

It may consist of just two rates; for instance the one minute rate for the battery or the largest current load of the duty cycle, followed by the test rate employed for the performance test, both of which envelope the duty cycle of the service test. Since the ampere-hours removed by a one minute discharge represents a very small portion of the battery capacity, the test rate can be changed to that for the performance test without compromising the results of the performance discharge test. The battery terminal voltage for the modified performance discharge test must remain above the minimum battery terminal voltage specified in the battery service test for the duration of time equal to that of the service test.

The acceptance criteria for this Surveillance are consistent with IEEE-450 (Ref. 1) and IEEE-485 (Ref. 5). These references recommend that the battery be replaced if its capacity is below 80% of the manufacturer's rating. A capacity of 80% shows that the battery rate of deterioration is increasing, even if there is ample capacity to meet the load requirements. Furthermore, the battery is sized to meet the assumed duty cycle loads when the battery design capacity reaches this ~~[~~80~~]~~% limit. (2)

~~[The Surveillance Frequency for this test is normally 60 months.~~ (2)

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~[REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

If the battery shows degradation, or if the battery has reached 85% of its expected life and capacity is < 100% of the manufacturer's rating, the Surveillance Frequency is reduced to 12 months. However, if the battery shows no degradation but has reached 85% of its expected life, the Surveillance Frequency is only reduced to 24 months for batteries that retain capacity ≥ 100% of the manufacturer's ratings. Degradation is indicated, according to IEEE-450 (Ref. 1), when the battery capacity drops by more than 10% relative to its capacity on the previous performance test or when it is ≥ ~~[~~10%~~]~~ below the manufacturer's rating. These Frequencies are consistent with the recommendations in IEEE-450 (Ref. 1).

This SR is modified by a Note. The reason for the Note is that performing the Surveillance would perturb the electrical distribution system and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 ~~or 2~~ is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed partial Surveillance, a successful partial Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the partial Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when portions of the Surveillance are performed in MODE 1 ~~or 2~~. Risk insights or deterministic methods may be used for the assessment. Credit may be taken for unplanned events that satisfy this SR.

DISCUSSION OF CHANGES
ITS 3.8.7, INVERTERS - OPERATING

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS does not explicitly have a specific requirement for Train A and Train B inverters to be OPERABLE or Required Actions for inoperable inverters. ITS LCO 3.8.7 requires Train A and Train B inverters to be OPERABLE. Functionality of inverters is currently necessary to meet Unit 1 CTS 3.8.2.1 Action b and Unit 2 CTS 3.8.3.1 Action b. ITS 3.8.7 ACTION A covers the condition of one inoperable Train A or Train B inverter. ITS 3.8.7 ACTION A requires the restoration of the inoperable inverter to OPERABLE status within 24 hours or in accordance with the Risk Informed Completion Time Program and provides a Note to direct entry into ITS 3.8.9, “Distributions Systems – Operating,” ACTIONS with any 120V AC instrument bus deenergized. ITS 3.8.7 ACTION B covers the inability of Condition A to be met and requires the plant be in MODE 3 within 6 hours and MODE 4 within 12 hours with a Note stating that LCO 3.0.4.a is not applicable when entering MODE 4. These actions are equivalent to the actions specified in Unit 1 CTS 3.8.2.1 Action b and Unit 2 CTS 3.8.3.1 Action b. R1 R1 R1

These changes are designated as administrative changes and are acceptable because they provide clarity regarding the current requirements associated with the inverters and do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Not used. R1

M02 **Unit 2 only:** Unit 2 CTS 3.8.3.1 Note * provides an allowance for two inverters to be disconnected from their DC source for up to 24 hours for performing an equalizing charge on their associated battery bank if certain provisions are maintained. The provisions require that the vital busses are energized and vital busses associated with the other battery bank are energized from their associated OPERABLE inverters. ITS 3.8.7 Note provides a similar allowance and specifies that the affected 120V instrument busses are energized from their Class 1E constant voltage source transformer. This changes the CTS by specifying that the inverters that are disconnected from their DC source for the performance of an equalizing charge on the associated battery bank shall be energized from their respective Class 1E constant voltage source transformer.

The purpose of Unit 2 CTS 3.8.3.1 is to ensure stable and reliable AC electrical power for the system instrumentation required for a safe reactor shut down. CTS 3.8.3.1 Note * provides an allowance to disconnect the inverters from their DC source to preclude damage to the inverters when the associated battery bank is

undergoing an equalizing charge. Requiring the AC instrument bus to be energized from its respective inverter powered from the Class 1E constant voltage source transformer ensures the AC instrument bus continues to be powered from a stable power source to minimize perturbations on the AC instrumentation bus. This change is designated as more restrictive because ITS requires the instrumentation busses associated with inverters disconnected from their DC source during an equalizing charge on the associated battery bank to be energized from a specific source of power.

M03 Unit 1 CTS 4.8.2.1 and Unit 2 CTS 4.8.3.1 do not specifically apply to inverter operability but requires, in part, that specified buses be determined OPERABLE by verifying indicated power availability for Unit 1 and correct breaker alignment and indicated voltage on the buses for Unit 2. ITS SR 3.8.7.1 requires the verification of correct inverter voltage, frequency, and alignment to required AC vital buses. This changes the CTS by requiring the specific verification of inverter voltage and frequency. R1 R1

The purpose of this change is to ensure the instrumentation channels are provided with the proper voltage and frequency from the AC instrument bus when powered by the associated inverter. This change is acceptable because the Surveillance will verify OPERABILITY of the inverters. Proper voltage and frequency are supplied to the instrumentation channels that provide inputs to the vital instrument systems (e.g., Reactor Protective System and Engineered Safety Features Actuation System). This change is designated as more restrictive because the ITS requires verification of the correct voltage and frequency, where the CTS does not provide explicit requirements for the inverter. R1

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 **Unit 1 only:** (*Category 1 – Relaxation of LCO Requirements*) CTS 3.8.2.1 for the Onsite Power Distribution Systems lists A.C. Distribution – Operating requirements. CTS LCO 3.8.2.1 states, “The following A.C. electrical busses shall be OPERABLE and energized from sources of power other than the diesel generator sets.” The requirement specifies four 120-volt A.C. instrument buses. CTS 3.8.2.1 Action b provides actions when the A.C. instrument bus is not energized from its associated inverter or when the inverter is not connected to its associated D.C. bus. ITS LCO 3.8.7, “Inverters – Operating” requires the A and B Train inverters to be OPERABLE. A Note is added to the LCO requirements. The Note states “Two inverters may be disconnected from their associated DC bus for ≤ 24 hours to perform an equalizing charge on their associated common R1

R1

battery, provided: The associated 120V AC instrument bus(es) are energized from their Class 1E constant voltage source transformer and all other 120V AC instrument buses are energized from their associated OPERABLE inverters." This changes the CTS by allowing two inverters to be disconnected from their DC bus for up to 24 hours during a battery equalize charge without requiring entry into LCO 3.0.3.

The purpose of ITS 3.8.7 LCO Note is to allow required maintenance on a battery without entry into LCO 3.0.3, which would require a plant shutdown transient. This change is acceptable because the LCO requirements continue to ensure that the associated 120V AC instrument buses are energized and avoid a condition that would require an unnecessary plant transient. The allowance provides 24 hours to perform an equalize change on an associated battery without requiring entry into a condition for two inoperable inverters (i.e., LCO 3.0.3). In this situation, the Note provides an exception to ITS LCO 3.8.7, which requires Train A and B inverters to be OPERABLE from their associated common DC battery. A battery may periodically require an equalize charge to ensure its continued OPERABILITY. The proposed allowance provides a limited time for the required maintenance on the battery and precludes possible damage to the associated inverters. The ITS requirement is consistent with the allowance specified in the Unit 2 CTS and is consistent with the ISTS wording for this requirement. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.7, INVERTERS - OPERATING

1. The word “required” has been deleted from the LCO and SR 3.8.7.1 since all Train A and Train B inverters are required.

2. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.7 Inverters - Operating

BASES

BACKGROUND

The inverters are the preferred source of power for the AC ~~vital~~ buses because of the stability and reliability they achieve. The function of ~~the~~ inverter is to provide AC electrical power to the ~~vital~~ bus~~es~~. The inverters ~~can be~~ powered from ~~an internal AC source/rectifier or from~~ the station batter~~y~~. The ~~station battery~~ provide~~s~~ an uninterruptible power source for the instrumentation and controls for the Reactor Protective System (RPS) and the Engineered Safety Feature Actuation System (ESFAS). Specific details on inverters and their operating characteristics are found in the FSAR, Chapter ~~[~~8~~]~~ (Ref. 1).

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 2) and Chapter ~~[~~15~~]~~ (Ref. 3), assume Engineered Safety Feature systems are OPERABLE. The inverters are designed to provide the required capacity, capability, redundancy, and reliability to ensure the availability of necessary power to the RPS and ESFAS instrumentation and controls so that the fuel, Reactor Coolant System, and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, Power Distribution Limits; Section 3.4, Reactor Coolant System (RCS); and Section 3.6, Containment Systems.

The OPERABILITY of the inverters is consistent with the initial assumptions of the accident analyses and is based on meeting the design basis of the unit. This includes maintaining required AC ~~vital~~ buses OPERABLE during accident conditions in the event of:

a. An assumed loss of all offsite AC electrical power or all onsite AC electrical power and

b. A worst case single failure.

Inverters are a part of the distribution system and, as such, satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The inverters ensure the availability of AC electrical power for the systems instrumentation required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA.

BASES

LCO (continued)

Maintaining the required inverters OPERABLE ensures that the redundancy incorporated into the design of the RPS and ESFAS instrumentation and controls is maintained. The four inverters ~~[~~(two per train)~~]~~ ensure an uninterruptible supply of 120 V AC electrical power to the AC instrument ~~vital~~ buses even if the 4.16 kV safety buses are de-energized.

OPERABLE inverters require the associated instrument ~~vital~~ bus to be powered by the inverter with output voltage and frequency within tolerances, and power input to the inverter from a ~~[~~125 VDC~~]~~ station battery. ~~Alternatively, power supply may be from an internal AC source via rectifier as long as the station battery is available as the uninterruptible power supply~~.

This LCO is modified by a Note that allows ~~[one/~~two~~]~~ inverters to be disconnected from a ~~[~~common~~]~~ battery for ≤ 24 hours, if the instrument ~~vital~~ bus(es) are ~~is~~ powered from a ~~[~~Class 1E constant voltage transformer ~~or inverter using internal AC source]~~ during the period and all other inverters are OPERABLE ~~operable~~. This allows an equalizing charge to be placed on one battery. If the inverter(s) were not disconnected, the resulting voltage condition might damage the inverter(s). These provisions minimize the loss of equipment that would occur in the event of a loss of offsite power. The 24 hour time period for the allowance minimizes the time during which a loss of offsite power could result in the loss of equipment energized from the affected AC instrument ~~vital~~ bus while taking into consideration the time required to perform an equalizing charge on the battery bank.

The intent of this Note is to limit the number of inverters that may be disconnected. Only those inverters associated with the single battery undergoing an equalizing charge may be disconnected. All other inverters must be aligned to their associated batteries, regardless of the number of inverters or unit design.

APPLICABILITY

The inverters are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure that:

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients and

b. Adequate core cooling is provided, and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

Inverter requirements for MODES 5 and 6 are covered in the Bases for LCO 3.8.8, "Inverters - Shutdown."

BASES

ACTIONS

A.1

Train A or Train B | 120 V | instrument

With a ~~required~~ inverter inoperable, its associated AC ~~vital~~ bus becomes inoperable ~~until~~ it is [manually] re-energized from its [Class 1E constant voltage source transformer ~~or inverter using internal AC source~~].

unless

LCO 3.8.9, "Distribution Systems – Operating," addresses this action however, pursuant to LCO 3.0.6, this action would not have to be entered even if the 120 VAC instrument bus were de-energized.

Required Action A.1 is modified by a Note, which states to enter the applicable conditions and Required Actions of LCO 3.8.9, "Distribution Systems - Operating," when Condition A is entered with ~~one AC vital~~ bus de-energized. This ensures the ~~vital~~ bus is re-energized within 2 hours.

120 VAC instrument | any 120 VAC instrument

Required Action A.1 allows 24 hours to fix the inoperable inverter and return it to service. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.] The 24 hour limit is based upon engineering judgment, taking into consideration the time required to repair an inverter and the additional risk to which the unit is exposed because of the inverter inoperability. This has to be balanced against the risk of an immediate shutdown, along with the potential challenges to safety systems such a shutdown might entail. When the ~~AC vital~~ bus is powered from its constant voltage ~~source~~, it is relying upon interruptible AC electrical power sources (offsite and onsite). The uninterruptible inverter source to the ~~AC vital~~ buses is the preferred source for powering instrumentation trip setpoint devices.

120 VAC instrument | Class 1E | 120 VAC instrument | transformer

R1

B.1 and B.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

1. ~~[LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

2. ~~[LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

Train A or Train B inverter

If the inoperable ~~devices or components~~ cannot be restored to OPERABLE status within the required Completion Time, the unit must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

BASES

ACTIONS (continued)

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 4). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.7 Inverters - Operating

BASES

BACKGROUND

The inverters are the preferred source of power for the AC ~~vital~~ buses because of the stability and reliability they achieve. The function of ~~the~~ inverter is to provide AC electrical power to the ~~vital~~ bus~~es~~. The inverters ~~can be~~ powered from ~~an internal AC source/rectifier or from~~ the station batter~~y~~. The ~~station battery~~ provide~~s~~ an uninterruptible power source for the instrumentation and controls for the Reactor Protective System (RPS) and the Engineered Safety Feature Actuation System (ESFAS). Specific details on inverters and their operating characteristics are found in the FSAR, Chapter ~~[~~8~~]~~ (Ref. 1).

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 2) and Chapter ~~[~~15~~]~~ (Ref. 3), assume Engineered Safety Feature systems are OPERABLE. The inverters are designed to provide the required capacity, capability, redundancy, and reliability to ensure the availability of necessary power to the RPS and ESFAS instrumentation and controls so that the fuel, Reactor Coolant System, and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, Power Distribution Limits; Section 3.4, Reactor Coolant System (RCS); and Section 3.6, Containment Systems.

The OPERABILITY of the inverters is consistent with the initial assumptions of the accident analyses and is based on meeting the design basis of the unit. This includes maintaining required AC ~~vital~~ buses OPERABLE during accident conditions in the event of:

a. An assumed loss of all offsite AC electrical power or all onsite AC electrical power and

b. A worst case single failure.

Inverters are a part of the distribution system and, as such, satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The inverters ensure the availability of AC electrical power for the systems instrumentation required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA.

BASES

LCO (continued)

Maintaining the required inverters OPERABLE ensures that the redundancy incorporated into the design of the RPS and ESFAS instrumentation and controls is maintained. The four inverters ~~[~~(two per train)~~]~~ ensure an uninterruptible supply of 120 V AC electrical power to the AC instrument ~~vital~~ buses even if the 4.16 kV safety buses are de-energized.

OPERABLE inverters require the associated instrument ~~vital~~ bus to be powered by the inverter with output voltage and frequency within tolerances, and power input to the inverter from a ~~[~~125 VDC~~]~~ station battery. ~~Alternatively, power supply may be from an internal AC source via rectifier as long as the station battery is available as the uninterruptible power supply~~.

This LCO is modified by a Note that allows ~~[one/~~two~~]~~ inverters to be disconnected from a ~~[~~common~~]~~ battery for ≤ 24 hours, if the instrument ~~vital~~ bus(es) are ~~is~~ powered from a ~~[~~Class 1E constant voltage transformer ~~or inverter using internal AC source]~~ during the period and all other inverters are OPERABLE ~~operable~~. This allows an equalizing charge to be placed on one battery. If the inverter(s) were not disconnected, the resulting voltage condition might damage the inverter(s). These provisions minimize the loss of equipment that would occur in the event of a loss of offsite power. The 24 hour time period for the allowance minimizes the time during which a loss of offsite power could result in the loss of equipment energized from the affected AC instrument ~~vital~~ bus while taking into consideration the time required to perform an equalizing charge on the battery bank.

The intent of this Note is to limit the number of inverters that may be disconnected. Only those inverters associated with the single battery undergoing an equalizing charge may be disconnected. All other inverters must be aligned to their associated batteries, regardless of the number of inverters or unit design.

APPLICABILITY

The inverters are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure that:

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients and

b. Adequate core cooling is provided, and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

Inverter requirements for MODES 5 and 6 are covered in the Bases for LCO 3.8.8, "Inverters - Shutdown."

transformer

B.1 and B.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

3

Train A or Train B inverter

If the inoperable ~~devices or components~~ cannot be restored to OPERABLE status within the required Completion Time, the unit must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. 1

BASES

ACTIONS (continued)

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 4). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.8.7.1

120V AC instrument

associated

120 VAC instrument

This Surveillance verifies that the inverters are functioning properly with all required circuit breakers closed and ~~AC vital~~ buses energized from the inverter. The verification of proper voltage and frequency output ensures that the required power is readily available for the instrumentation of the RPS and ESFAS connected to the ~~AC vital~~ buses. ~~[The 7 day Frequency takes into account the redundant capability of the inverters and other indications available in the control room that alert the operator to inverter malfunctions.~~

1

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

DISCUSSION OF CHANGES
ITS 3.8.8, INVERTERS - SHUTDOWN

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 2 only:** CTS does not have a specific requirement for inverters to be OPERABLE or Required Actions for inoperable required inverters. However, CTS 3.8.3.2, “Onsite Power Distribution – Shutdown” requires 120V AC instrument busses to be powered from their associated inverters, requiring functionality of the inverters. A new ITS LCO 3.8.8, specifically requires “required” inverters to be OPERABLE to support the 120V AC electrical distribution subsystems required by LCO 3.8.10 when in MODE 5, MODE 6, and during movement of irradiated fuel assemblies. This changes the CTS by adding specific operability requirements for inverters associated with the 120V AC instrument busses necessary to support LCO 3.8.10 requirements.

These changes are designated as administrative changes as they are a clarification of the intent of CTS 3.8.3.2 and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS does not have a requirement for inverters to be OPERABLE, Required Actions or Surveillance Requirements. ITS LCO 3.8.8 requires inverters to be OPERABLE in MODES 5 and 6 and during movement of irradiated fuel assemblies to support the 120V AC electrical distribution subsystem required by ITS LCO 3.8.10, “Distribution Systems - Shutdown.”. In addition, ITS 3.8.8 provides the necessary Required Actions and Surveillance Requirement that support inverter OPERABILITY. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per CTS 6.8.4.o. Therefore, SR 3.8.8.1 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 7 days consistent with the ISTS. This changes the CTS by incorporating the requirements of ITS 3.8.8.

The safety related function of required inverters is to provide an uninterruptible power supply for the 120 VAC instrument buses. This change is acceptable because the safety analyses assume that the loads supported by the 120 VAC instrument buses have an uninterruptible supply of AC electrical power. This change is designated as more restrictive because it adds new requirements to the CTS.

M02 **Unit 2 only:** CTS does not have a specific requirement for inverters to be OPERABLE or Applicability requirements. See DOC A02 discussion. ITS LCO 3.8.8 is applicable in MODE 5, MODE 6, and during movement of irradiated fuel assemblies. In addition, a Note modifies the ACTIONS to state that LCO 3.0.3 is not applicable. This changes the CTS by adding an Applicability of "during movement of irradiated fuel assemblies" and adds the Note to the ACTIONS stating that LCO 3.0.3 is not applicable.

This change is acceptable because the proposed requirements are necessary to ensure the inverters are OPERABLE to support equipment required to be OPERABLE during movement of irradiated fuel assemblies. Movement of fuel normally occurs during MODES 5 and 6, however, it can also occur outside of containment in other plant MODES (MODES 1, 2, 3, and 4) or other conditions (i.e., reactor defueled). This Specification is needed to ensure the appropriate distribution system requirements are specified during fuel handling and ensure that appropriate ACTIONS are taken (i.e. stop fuel movement) when the minimum electrical supply is not available. This change adds a clarification Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODES 5 or 6, LCO 3.0.3 is not applicable and would not specify any action. If moving irradiated fuel assemblies while in MODES 1, 2, 3, or 4, the fuel movement is independent of reactor operations and the inability to suspend movement in accordance with the ITS 3.8.8 Required Actions would not be sufficient reason to require a reactor shutdown. This Note has been added for clarification and is necessary since defaulting to LCO 3.0.3 would require the reactor to be shutdown but would not require suspension of activities with a potential for releasing radioactive materials. This change is designated as more restrictive because the ITS requires the equipment to be OPERABLE during movement of irradiated fuel assemblies both inside and outside of the containment in conditions other than MODES 5 and 6.

M03 **Unit 2 only:** Unit 2 CTS 4.8.3.2 does not specifically apply to inverter operability but requires, in part, that specified 120V AC instrument buses be determined OPERABLE by verifying correct breaker alignment. ITS SR 3.8.8.1 requires the verification of correct inverter voltage, frequency, and alignment to required AC vital buses. This changes the CTS by requiring the specific verification of inverter voltage output and frequency.

The purpose of this requirement is to ensure the required instrumentation channels are provided with the proper voltage and frequency from the AC instrument bus when powered by the associated inverter. This change is acceptable because the Surveillance will verify OPERABILITY of the required inverters with the proper voltage and frequency supplied to the instrumentation channels that provide inputs to the vital instrument systems (e.g., Reactor Protective System and Engineered Safety Features Actuation System). This change is designated as more restrictive because the ITS requires verification of the correct voltage and frequency, where the CTS does not provide explicit requirements for the inverter.

DISCUSSION OF CHANGES
ITS 3.8.8, INVERTERS - SHUTDOWN

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* CTS does not have specific actions for inoperable required inverters. However, CTS 3.8.3.2, "Onsite Power Distribution – Shutdown" requires 120V ac instrument busses to be powered from the associated inverter which infers the CTS 3.8.3.2 actions also apply to the inverters. CTS 3.8.3.2 in part states "With any of the above required electrical busses not energized in the required manner, immediately suspend all operations involving CORE ALTERATIONS, operations involving positive reactivity changes that could result in loss of required SHUTDOWN MARGIN or boron concentration, or movement of irradiated fuel." For one or more required inverters inoperable, ITS 3.8.8 Action A.1 states "Declare affected required feature(s) inoperable." This must be performed immediately, or other specific Required Actions must be followed. This changes the CTS by allowing the affected required feature(s) with an inoperable inverter to be declared inoperable instead of suspending the specified activities.

The purpose of ITS Required Action A.1 is to provide an alternative to stopping movement of irradiated fuel assemblies and positive reactivity changes with required inverters inoperable. This change is acceptable because the Required Actions of the required supported features are also acceptable remedial actions in response to degraded conditions. These actions also minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a design basis accident occurring during the repair period. The addition of the allowance provides for declaring affected features with electrical power inverters inoperable instead of immediately suspending movement of irradiated fuel assemblies and stopping positive reactivity changes. The ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* CTS does not have specific actions for inoperable required inverters. However, CTS 3.8.3.2, "Onsite Power Distribution – Shutdown" requires 120V ac instrument busses to be powered from the associated inverter which infers the CTS 3.8.3.2 actions also apply to the inverters. CTS 3.8.3.2 ACTION states, in part, "With any of the above required electrical busses not energized in the required manner, immediately suspend all operations involving CORE ALTERATIONS. ITS 3.8.8

ACTIONS do not include the requirement to suspend CORE ALTERATIONS. This changes the CTS by removing the Required Action to suspend all operations involving CORE ALTERATIONS.

The purpose of the CTS 3.8.3.2 ACTION is to minimize the possibility of an event that may require the electrical power source to mitigate the consequences of a design basis event. CORE ALTERATIONS is defined in CTS 1.9, in part, as "the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity, within the reactor vessel with the head removed and fuel in the vessel." CORE ALTERATIONS only occur when the reactor vessel head is removed - it only applies in MODE 6. There is only one accident considered during MODE 6 that involves a Core Alteration - a fuel handling accident. According to UFSAR Section 15.7.4.1.2, a fuel handling accident is initiated by the dropping of an irradiated fuel assembly either in the containment or in the fuel handling building. Suspension of CORE ALTERATIONS, except for suspension of movement of irradiated fuel, will not prevent or impair the mitigation of a fuel handling accident. ITS 3.8.8 retains the requirement to suspend movement of irradiated fuel assemblies as Required Action A.2.1 (for one or more inoperable inverters). R1

Deleting the reference to “CORE ALTERATIONS” is acceptable because the only CORE ALTERATION analyzed in the safety analysis that is potentially affected by an inoperable inverter is covered by the ITS Required Actions. Additionally, CORE ALTERATIONS that may be capable of damaging a fuel assembly prior to the 72 hour decay period is improbable because of the physical time required to perform plant shutdown, cooldown, depressurize the Reactor Coolant System (RCS), and the additional operations required to expose irradiated fuel in the reactor vessel (e.g., containment entry, removal of vessel head, removal of vessel internals, etc.) is greater than 72 hours. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.8 Inverters - Shutdown

BASES

BACKGROUND

A description of the inverters is provided in the Bases for LCO 3.8.7, "Inverters - Operating."

APPLICABLE SAFETY ANALYSES

U

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 1) and Chapter ~~[~~15~~]~~ (Ref. 2), assume Engineered Safety Feature systems are OPERABLE. The DC to AC inverters are designed to provide the required capacity, capability, redundancy, and reliability to ensure the availability of necessary power to the Reactor Protective System and Engineered Safety Features Actuation System instrumentation and controls so that the fuel, Reactor Coolant System, and containment design limits are not exceeded. 1 2

The OPERABILITY of the inverters is consistent with the initial assumptions of the accident analyses and the requirements for the supported systems' OPERABILITY.

The OPERABILITY of the ~~minimum~~ inverter required to each ~~AC vital~~ 120 VAC instrument bus during MODES 5 and 6 and during movement of irradiated fuel assemblies ensures that: 1 5

a. The unit can be maintained in the shutdown or refueling condition for extended periods,

b. Sufficient instrumentation and control capability is available for monitoring and maintaining the unit status, and

c. Adequate power is available to mitigate events postulated during shutdown, such as a fuel handling accident ~~[involving handling recently irradiated fuel. Due to radioactive decay, the inverters are only required to mitigate fuel handling accidents involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~. 2

In general, when the unit is shut down, the Technical Specification requirements ensure that the unit has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. The rationale for this is based on the fact that many DBAs that are analyzed in MODES ~~[~~1, 2, 3, and 4~~]~~ have no specific analyses in MODES ~~[~~5 and 6~~]~~ because the energy contained within the reactor pressure boundary, reactor coolant temperature and pressure, and the corresponding stresses result in the probabilities of occurrence being 2

BASES

APPLICABLE SAFETY ANALYSES (continued)

significantly reduced or eliminated, and in minimal consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCO for required systems.

The shutdown Technical Specification requirements are designed to ensure that the unit has the capability to mitigate the consequences of certain postulated accidents. Worst case DBAs which are analyzed for operating MODES are generally viewed not to be a significant concern during shutdown MODES due to the lower energies involved. The Technical Specifications therefore require a lesser complement of electrical equipment to be available during shutdown than is required during operating MODES. More recent work completed on the potential risks associated with shutdown, however, have found significant risk associated with certain shutdown evolutions. As a result, in addition to the requirements established in the Technical Specifications, the industry has adopted NUMARC 91-06, "Guidelines for Industry Actions to Assess Shutdown Management," as an Industry initiative to manage shutdown tasks and associated electrical support to maintain risk at an acceptable low level. This may require the availability of additional equipment beyond that required by the shutdown Technical Specifications.

The inverters were previously identified as part of the distribution system and, as such, satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

electrical power

1

LCO

The inverter~~[s]~~ ensure the availability of electrical power for the instrumentation for systems required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence or a postulated DBA. The ~~battery powered~~ inverter~~[s]~~ provide~~[s]~~ uninterruptible supply of AC electrical power to the ~~AC vital~~ bus~~[es] even if the 4.16 kV safety buses are de-energized~~. OPERABILITY of the inverter~~[s]~~ requires ~~that the vital bus be powered by the inverter~~. This ensures the availability of sufficient inverter power sources to operate the unit in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents ~~[involving handling recently irradiated fuel]~~).

2

120 VAC instrument

the associated 120 VAC instrument bus to be powered by the inverter with the output voltage and frequency within tolerances, and power input from a 125 VDC station battery.

2 1

2

APPLICABILITY

The inverter~~[s]~~ required to be OPERABLE in MODES 5 and 6 during movement of ~~[recently]~~ irradiated fuel assemblies provide assurance that:

, and

5

2

a. Systems to provide adequate coolant inventory makeup are available for the irradiated fuel in the core,

b. Systems needed to mitigate a fuel handling accident ~~[involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~ are available,

2

BASES

APPLICABILITY (continued)

c. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available, and

d. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition or refueling condition.

Inverter requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.7.

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

3

4

A.1, A.2.1, A.2.2, and A.2.3

one or more inverters

~~[~~If ~~two trains~~ are required by LCO 3.8.10, "Distribution Systems - Shutdown," the remaining OPERABLE inverters may be capable of supporting sufficient required features to allow continuation of ~~[recently]~~ irradiated fuel movement, operations with a potential for draining the reactor vessel, and operations with a potential for positive reactivity additions that could result in loss of required SDM (MODE 5) or boron concentration (MODE 6).~~]~~ Suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum SDM or refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation. Introduction of temperature changes including temperature increases when operating with a positive ~~MTC~~ must also be evaluated to ensure they do not result in a loss of required SDM. By the allowance of the option to declare required features inoperable with the associated inverter(s) inoperable, appropriate restrictions will be implemented in accordance with the affected required features LCOs' Required Actions. In many instances, this option may involve undesired administrative efforts. Therefore, the allowance for sufficiently conservative actions is made (i.e., to suspend movement of ~~[recently]~~ irradiated fuel assemblies, and operations involving positive reactivity additions).

2

moderator temperature coefficient

4

2

BASES

ACTIONS (continued)

Suspension of these activities shall not preclude completion of actions to establish a safe conservative condition. These actions minimize the probability of the occurrence of postulated events. It is further required to immediately initiate action to restore the required inverter[s] and to continue this action until restoration is accomplished in order to provide the necessary inverter power to the unit safety systems. 2

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required inverters should be completed as quickly as possible in order to minimize the time the unit safety systems may be without power or powered from a constant voltage source transformer. 1

the associated

SURVEILLANCE REQUIREMENTS

SR 3.8.8.1

This Surveillance verifies that the inverters are functioning properly with all required circuit breakers closed and AC vital buses energized from the inverter. The verification of proper voltage and frequency output ensures that the required power is readily available for the instrumentation connected to the AC vital buses. [The 7-day Frequency takes into account the redundant capability of the inverters and other indications available in the control room that alert the operator to inverter malfunctions. 1 2

120 VAC instrument

This may require the availability of additional equipment beyond that required by the shutdown Technical Specifications.

The inverters were previously identified as part of the electrical power distribution system and, as such, satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii). (1)

LCO

The inverter~~[s]~~ ensure the availability of electrical power for the instrumentation for systems required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence or a postulated DBA. The ~~battery powered~~ inverter~~[s]~~ provide~~[s]~~ uninterruptible supply of AC electrical power to the ~~AC vital~~ bus~~[es] even if the 4.16 kV safety buses are de-energized~~. OPERABILITY of the inverter~~[s]~~ requires ~~that the vital bus be powered by the inverter~~. This ensures the availability of sufficient inverter power sources to operate the unit in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents ~~[involving handling recently irradiated fuel]~~). (2) (2) (1) (2)

120 VAC instrument

the associated 120 VAC instrument bus to be powered by the inverter with the output voltage and frequency within tolerances, and power input from a 125 VDC station battery.

APPLICABILITY

The inverter~~[s]~~ required to be OPERABLE in MODES 5 and 6 during movement of ~~[recently]~~ irradiated fuel assemblies provide assurance that: (, and) (5) (2)

a. Systems to provide adequate coolant inventory makeup are available for the irradiated fuel in the core,

b. Systems needed to mitigate a fuel handling accident ~~[involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~ are available, (2)

BASES

APPLICABILITY (continued)

c. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available, and

d. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition or refueling condition.

Inverter requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.7.

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

3

4

A.1, A.2.1, A.2.2, and A.2.3

one or more inverters

~~[~~If ~~two trains~~ are required by LCO 3.8.10, "Distribution Systems - Shutdown," the remaining OPERABLE inverters may be capable of supporting sufficient required features to allow continuation of ~~[recently]~~ irradiated fuel movement, operations with a potential for draining the reactor vessel, and operations with a potential for positive reactivity additions that could result in loss of required SDM (MODE 5) or boron concentration (MODE 6).~~]~~ Suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum SDM or refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation. Introduction of temperature changes including temperature increases when operating with a positive ~~MTC~~ must also be evaluated to ensure they do not result in a loss of required SDM. By the allowance of the option to declare required features inoperable with the associated inverter(s) inoperable, appropriate restrictions will be implemented in accordance with the affected required features LCOs' Required Actions. In many instances, this option may involve undesired administrative efforts. Therefore, the allowance for sufficiently conservative actions is made (i.e., to suspend movement of ~~[recently]~~ irradiated fuel assemblies, and operations involving positive reactivity additions).

2

moderator temperature coefficient

4

2

1

BASES

ACTIONS (continued)

Suspension of these activities shall not preclude completion of actions to establish a safe conservative condition. These actions minimize the probability of the occurrence of postulated events. It is further required to immediately initiate action to restore the required inverter[s] and to continue this action until restoration is accomplished in order to provide the necessary inverter power to the unit safety systems. 2

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required inverters should be completed as quickly as possible in order to minimize the time the unit safety systems may be without power or powered from a constant voltage source transformer. 1

the associated

SURVEILLANCE REQUIREMENTS

SR 3.8.8.1

This Surveillance verifies that the inverters are functioning properly with all required circuit breakers closed and AC vital buses energized from the inverter. The verification of proper voltage and frequency output ensures that the required power is readily available for the instrumentation connected to the AC vital buses. [The 7-day Frequency takes into account the redundant capability of the inverters and other indications available in the control room that alert the operator to inverter malfunctions. 1 2

120 VAC instrument

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

REVIEWER'S NOTE
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.] 3 2

DISCUSSION OF CHANGES
ITS 3.8.9, DISTRIBUTION SYSTEMS - OPERATING

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.8.2.1 Action a states that with less than the above complement of AC buses OPERABLE, to restore the inoperable bus to OPERABLE status within 8 hours. Unit 1 CTS 3.8.2.3 Action a states that with one required 125 VDC bus inoperable, to restore the inoperable bus to OPERABLE status within 2 hours. Unit 2 CTS 3.8.3.1 Action a states with one required train of A.C. Emergency busses not fully energized, re-energize the train within 8 hours, Action b states that with one A.C. Instrument Bus either not energized from its associated inverter, or with the inverter not connected to its associated D.C. Bus reenergize the instrument bus within 2 hours, and Action c states that with one D.C. bus not energized from its associated Battery Bank to re-energize the D.C. Bus from its associated Battery Bank with 2 hours. However, there are no limitations to preclude a loss of function due to numerous concurrently inoperable AC and DC buses. ITS 3.8.9 ACTION E has been added, requiring entry into ITS LCO 3.0.3 if two or more inoperable electrical power distribution subsystems result in a loss of safety function. | R1 | R1

The purpose of the CTS Actions is to limit the time the unit can operate under these conditions. Unit 1 CTS 3.8.2.3 Action a specifies the compensatory actions for one inoperable DC bus. With two inoperable DC buses, Unit 1 CTS 3.8.2.3 does not provide any actions and entry into LCO 3.0.3 would be required. Unit 1 CTS 3.8.2.1 Action a is applicable to all inoperable AC buses even if there is a loss of safety function. Certain combinations of inoperable AC and DC electrical power distribution subsystems may result in a loss of safety function (e.g., an inoperable Train A AC electrical power distribution subsystem in combination with an inoperable Train B DC electrical power distribution subsystem). Unit 2 CTS 3.8.3.1 specifies the compensatory actions for one inoperable A.C. Emergency bus train inoperable, one A.C. Instrument Bus inoperable, or one D.C. bus inoperable but does not provide specific actions for conditions that result in a loss of safety function. ITS 3.8.9 includes ACTION E, which requires immediate entry into LCO 3.0.3 if two or more inoperable electrical power distribution subsystems result in a loss of safety function. ITS 3.8.9 Required Action E.1 preserves the intent of ITS LCO 3.0.3 and reflects an additional restriction on plant operation. This change is designated as more restrictive because an explicit action has been added which requires entry into LCO 3.0.3 with any combination of AC and/or DC buses inoperable that result in a loss of safety function. | R1 | R1

M02 **Unit 1 only:** CTS 4.8.2.1 requires, in part, the specified A.C. busses shall be determined OPERABLE by verifying "indicated power availability" and CTS 4.8.2.3.1 states each D.C. bus train shall be determined OPERABLE by verifying "indicated power availability." ITS SR 3.8.9.1 requires the verification of correct breaker alignments and "voltage" to required AC, DC, and 120 VAC instrument bus electrical power distribution subsystems. This changes the CTS by requiring the verification of the correct voltages and breaker alignments to the required AC, DC, and 120 VAC instrument bus electrical power distribution subsystems, whereas the CTS only requires verification of indicated power availability.

The purpose of this Surveillance is to ensure required electrical buses are properly energized to support their required function. This is more appropriately accomplished by verifying the correct breaker alignment and proper voltage is supplied to the required AC, DC, and 120 VAC instrument bus electrical power distribution subsystems. This change is acceptable because the Surveillance will continue to verify OPERABILITY of the required AC, DC and instrument bus electrical power distribution subsystems. Proper voltage from the required subsystems ensures proper voltage is supplied to the required safety features. This change is designated as more restrictive because the ITS requires verification of the correct breaker alignments and voltage, whereas the CTS only requires a verification of indicated power availability.

M03 **Unit 1 only:** CTS 3.8.2.3 Action a requires the unit to be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours when one of the required battery banks or buses is inoperable and cannot be restored to OPERABLE status within 2 hours. There is also an additional statement that LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN. ITS 3.8.9 ACTION D requires the unit to be in MODE 3 within 6 hours and MODE 5 within 36 hours. This changes the CTS by requiring the unit to be placed in COLD SHUTDOWN within the following 30 hours instead of HOT SHUTDOWN within the following 6 hours and eliminates the note associated with LCO 3.0.4.a.

The purpose of the CTS Actions is to ensure when an inoperable battery bank or bus cannot be restored to OPERABLE status, that the unit is placed in a MODE in which overall plant risk is minimized. PSL adopted TSTF-422, "Change in Technical Specifications End States (CE NPSD-1186)," Revision 2, with application of site-specific variations and deviations from TSTF-422, on August 30, 2016, in License Amendment 234 (NRC ADAMS Accession No. ML16210A374). The CTS Action was revised in Amendment 234 applying the end state action to one required battery bank or DC bus. However, TSTF-422 and the associated Combustion Engineering Topical Report CE NPSD-1186-A, “Technical Justification for the Risk-Informed Modification to Selected Required Action End States for CEOG Member PWRs,” Revision 00 (NRC ADAMS Accession No. ML110410539), did not include an evaluation of applying the end state to an inoperable DC bus. Therefore, when one DC electrical power distribution subsystem (i.e., required DC bus) is inoperable and cannot be restored within 2 hours, ITS 3.8.9 ACTION D requires the unit to be in MODE 3 (Hot Standby) within 6 hours and MODE 5 (Cold Shutdown) within 36 hours. As a result of the end state change, the Note associated with LCO 3.0.4.a is also unnecessary and deleted. This change is consistent with the ISTS and

TSTF-422. This change does not impact the allowance for an inoperable battery bank (Refer to ITS 3.8.4 for DC sources). The Completion Times to be in MODES 3 and 5 are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. This change is designated as more restrictive because the plant must be brought to a lower MODE than required by CTS when an inoperable DC electrical power distribution subsystem cannot be restored within the required Completion Time.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.8.2.1 and 3.8.2.3 require AC, AC instrument, and DC electrical buses to be OPERABLE and lists the specific busses, including applicable nominal AC bus voltages. Unit 2 CTS 3.8.3.1 requires specified electrical busses to be “energized in the specified manner” and lists the specified AC, DC, and 120 V instrument busses, including applicable nominal bus voltage.

ITS LCO 3.8.9 requires the applicable electrical power distribution subsystems; Train A and Train B AC, DC, and AC instrument buses to be OPERABLE. This changes the CTS by moving the specific names of the buses and the associated nominal bus voltages (i.e., 4160 V, 480 V, 120 V and 125 VDC) from the CTS to the ITS Bases.

The removal of these details related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 3.8.9 retains the requirement for the required electrical buses to be OPERABLE. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 1 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS 3.8.2.1 requires the AC electrical busses to be OPERABLE "and energized from sources of power other than the diesel generator sets.” Unit 1 CTS 4.8.2.1 also requires the AC buses to be determined OPERABLE "and energized from AC sources of power other than the diesel generator sets” by verifying indicated power availability. Unit 1 CTS 4.8.2.3.1 requires DC bus trains to be determined OPERABLE "and energized" by verifying indicated power availability. See DOC L01 for discussion of changes related to indicated power availability.

Unit 2 CTS LCO 3.8.3.1 requires the AC and DC electrical busses to "to be energized in the specified manner with both tie breakers open between redundant busses and between St. Lucie Unit 1 and Unit 2." Unit 2 CTS 4.8.3.1 also requires the specified buses to be determined "energized in the required manner" by verifying correct breaker alignment and indicated voltage.

ITS LCO 3.8.9 requires the applicable electrical power distribution subsystems to be OPERABLE and ITS SR 3.8.9.1 requires the verification of correct breaker alignment and voltage to required AC, DC, and AC instrument bus electrical power distribution subsystems. This changes the Unit 1 CTS by moving the procedural detail that the AC buses must be "energized from AC sources of power other than the diesel generator sets" and that the DC busses must be "energized" from the CTS to the ITS Bases. This changes the Unit 2 CTS by moving the procedural detail that the specified busses must be "energized in the specified manner with both tie breakers open between redundant busses and between St. Lucie Unit 1 and Unit 2."

The removal of these details for meeting Technical Specification requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the electrical power distribution subsystems to be OPERABLE and requires the verification of correct breaker alignment and voltage to required AC, DC, and AC instrument bus electrical power distribution subsystems. Also, this change is acceptable because these type of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 1 – Relaxation of LCO Requirements)* Unit 1 CTS 3.8.2.1 specifies that the AC electrical busses shall be OPERABLE "and energized from sources of power other than the diesel generator sets." Unit 2 CTS 3.8.3.1 requires electrical buses to be energized in a specified manner as listed in CTS 3.8.3.1.a through CTS 3.8.3.1.h. ITS LCO 3.8.9 does not include the requirement that an electrical bus be energized from a specific source of power. With regard to power sources, the ITS definition of OPERABLE includes the clarification that "normal or emergency electrical power sources" are acceptable. The CTS definition for OPERABLE simply states "electrical power" as a necessary component for OPERABILITY. This changes the CTS by removing the requirement that electrical busses be energized from specific sources of power.

The purpose of ITS 3.8.9 is to ensure required AC, DC, and AC instrument bus electrical power distribution subsystems are available to support the OPERABILITY of required systems, equipment and components and ensure the availability of sufficient power to operate the unit in a safe manner to mitigate the

consequences of postulated events. ITS 3.8.9 retains the requirement for the required electrical buses to be OPERABLE. The change is acceptable since it is consistent with the definition of OPERABILITY and the ability of the subsystem to support the dependent components and systems is not dependent of the specific source of the power provided the power source is a qualified electrical power source. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than applied in the CTS.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.9 Distribution Systems - Operating

BASES

BACKGROUND

The onsite Class 1E AC, DC, and AC ~~vital~~ bus electrical power distribution systems are divided by train into ~~[~~two~~]~~ redundant and independent AC, DC, and AC ~~vital~~ bus electrical power distribution subsystems.

The AC electrical power subsystem for each train consists of a 4.16 kV ~~Engineered Safety Feature (ESF)~~ bus, having at least ~~[~~one separate and independent offsite source of power~~]~~ as well as a dedicated onsite diesel generator (DG) source. Each ~~[~~4.16 kV ~~ESF~~ bus~~]~~ is normally connected to ~~a preferred offsite source~~. After a loss of the ~~preferred offsite~~ power source to a 4.16 kV ~~ESF~~ bus, a transfer to the ~~alternate~~ offsite source is accomplished by utilizing ~~a time delayed bus undervoltage relay~~. If ~~all~~ offsite sources are unavailable, the onsite emergency DG supplies power to the 4.16 kV ~~ESF~~ bus. Control power for the 4.16 kV breakers is supplied from the Class 1E batteries. Additional description of this system may be found in the Bases for LCO 3.8.1, "AC Sources - Operating," and the Bases for LCO 3.8.4, "DC Sources - Operating."

The ~~secondary~~ AC electrical power distribution subsystem for each train includes the safety related ~~load centers, motor control centers, and distribution panels~~ shown in Table B 3.8.9-1.

The 120 VAC ~~vital~~ bus~~es~~ ~~are~~ arranged in two load groups per train and are normally powered from the inverters. The alternate power supply for the ~~vital~~ buses are Class 1E constant voltage source transformers powered from the same train as the associated inverter, and its use is governed by LCO 3.8.7, "Inverters - Operating." Each constant voltage source transformer is powered from a Class 1E AC bus.

The DC electrical power distribution subsystem consists of ~~[~~125~~]~~ V bus~~(~~es~~) and distribution panel(s)~~ (one for each train) with an interconnecting swing bus. The list of all required DC and ~~vital AC distribution~~ buses ~~[and panels]~~ is presented in Table B 3.8.9-1.

BASES

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 1) and Chapter ~~[~~15~~]~~ (Ref. 2), assume ~~ESF~~ systems are OPERABLE. The AC, DC, and AC ~~vital~~ bus electrical power distribution systems are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to ESF systems so that the fuel, Reactor Coolant System, and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, Power Distribution Limits; Section 3.4, Reactor Coolant System (RCS); and Section 3.6, Containment Systems.

The OPERABILITY of the AC, DC, and AC ~~vital~~ bus electrical power distribution systems is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This includes maintaining power distribution systems OPERABLE during accident conditions in the event of:

a. An assumed loss of all offsite power or all onsite AC electrical power and

b. A worst case single failure.

The distribution systems satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The required power distribution subsystems listed in Table B 3.8.9-1 ensure the availability of AC, DC, and AC ~~vital~~ bus electrical power for the systems required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA. The AC, DC, and AC ~~vital~~ bus electrical power distribution subsystems are required to be OPERABLE.

Maintaining the Train A and Train B AC, DC, and AC ~~vital~~ bus electrical power distribution subsystems OPERABLE ensures that the redundancy incorporated into the design of ESF is not defeated. Therefore, a single failure within any system or within the electrical power distribution subsystems will not prevent safe shutdown of the reactor.

OPERABLE AC electrical power distribution subsystems require the associated buses~~, load centers, motor control centers, and distribution panels~~ to be energized to their proper voltages. OPERABLE DC electrical power distribution subsystems require the associated buses ~~and distribution panels~~ to be energized to their proper voltage from either the associated battery or charger. OPERABLE ~~vital~~ bus electrical power distribution subsystems require the associated buses to be energized to their proper voltage from the associated ~~[~~inverter via inverted DC voltage~~,~~ ~~inverter using internal AC source,~~ or Class 1E constant voltage transformer~~]~~.

BASES

LCO (continued)

In addition, tie breakers between redundant safety related AC, DC, and AC ~~vital~~ bus power distribution subsystems~~, if they exist,~~ must be open. This prevents any electrical malfunction in any power distribution subsystem from propagating to the redundant subsystem, which could cause the failure of a redundant subsystem and a loss of essential safety function(s). If any tie breakers are closed, the affected redundant electrical power distribution subsystems are considered inoperable. This applies to the onsite, safety related redundant electrical power distribution subsystems. ~~It does not, however, preclude redundant Class 1E 4.16 kV buses from being powered from the same offsite circuit.~~

APPLICABILITY

The electrical power distribution subsystems are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure that:

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients and

b. Adequate core cooling is provided, and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

Electrical power distribution subsystem requirements for MODES 5 and 6 are covered in the Bases for LCO 3.8.10, "Distribution Systems - Shutdown."

ACTIONS

A.1

With one or more Train A and B required AC ~~buses, load centers, motor control centers, or distribution panels~~ (except AC ~~vital~~ buses), in one train inoperable and a loss of function has not occurred, the remaining AC electrical power distribution subsystems are capable of supporting the minimum safety functions necessary to shut down the reactor and maintain it in a safe shutdown condition, assuming no single failure. The overall reliability is reduced, however, because a single failure in the remaining power distribution subsystems could result in the minimum required ESF functions not being supported. Therefore, the required AC buses~~, load centers, motor control centers, and distribution panels~~ must be restored to OPERABLE status within 8 hours ~~[or in accordance with the Risk Informed Completion Time Program]~~.

1

Insert 1

Based on the number of safety significant electrical loads associated with each bus listed in Table B 3.8.9-1, if one or more of the buses becomes inoperable, entry into the appropriate ACTIONS of LCO 3.8.9 is required. Some buses, such as distribution panels and motor control centers, which help comprise the AC and DC distribution systems, are not listed in Table B 3.8.9-1. The loss of electrical loads associated with these buses may not result in a complete loss of a redundant safety function necessary to shut down the reactor and maintain it in a safe condition. Therefore, should one or more of these buses become inoperable due to a failure not affecting the OPERABILITY of a bus listed in Table B 3.8.9-1 (e.g., a breaker supplying a single distribution panel fails open), the individual loads on the bus would be declared inoperable, and the appropriate Conditions and Required Actions of the LCOs governing the individual loads would be entered. However, if one or more of these buses is inoperable due to a failure also affecting the OPERABILITY of a bus listed in Table B 3.8.9-1 (e.g., loss of 4.16 kV essential bus, which results in de-energization of all buses powered from the 4.16 kV essential bus), then the Conditions and Required Actions of LCO 3.8.9 must be entered. | R1

BASES

ACTIONS (continued)

Condition A worst scenario is one train without AC power (i.e., no offsite power to the train and the associated DG inoperable). In this condition, the unit is more vulnerable to a complete loss of AC power. It is, therefore, imperative that the unit operator's attention be focused on minimizing the potential for loss of power to the remaining train by stabilizing the unit, and on restoring power to the affected train. The 8 hour time limit before requiring a unit shutdown in this condition is acceptable because of:

a. The potential for decreased safety if the unit operator's attention is diverted from the evaluations and actions necessary to restore power to the affected train, to the actions associated with taking the unit to shutdown within this time limit and

b. The potential for an event in conjunction with a single failure of a redundant component in the train with AC power.

Required Action A.1 is modified by a Note that requires the applicable Conditions and Required Actions of LCO 3.8.4, "DC Sources - Operating," to be entered for DC trains made inoperable by inoperable power distribution subsystems. This is an exception to LCO 3.0.6 and ensures the proper actions are taken for these components. Inoperability of a distribution system can result in loss of charging power to batteries and eventual loss of DC power. This Note ensures that the appropriate attention is given to restoring charging power to batteries, if necessary, after loss of distribution systems.

B.1

instrument

instrument With one or more AC ~~vital~~ buses inoperable, and a loss of function has not yet occurred, the remaining OPERABLE AC ~~vital~~ buses are capable of supporting the minimum safety functions necessary to shut down the unit and maintain it in the safe shutdown condition. Overall reliability is reduced, however, since an additional single failure could result in the minimum required ESF functions not being supported. Therefore, the instrument ~~[~~required~~]~~ AC ~~vital~~ bus must be restored to OPERABLE status within 2 hours by powering the bus from the associated ~~[~~inverter via inverted DC~~, inverter using internal AC source,~~ or Class 1E constant voltage transformer~~]~~. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~

1

1 R1

2 R1

BASES

ACTIONS (continued)

Condition B represents one or more AC ~~vital~~ buses without power; potentially both the DC source and the associated AC source are nonfunctioning. In this situation, the unit is significantly more vulnerable to a complete loss of all noninterruptible power. It is, therefore, imperative that the operator's attention focus on stabilizing the unit, minimizing the potential for loss of power to the remaining ~~vital~~ buses, and restoring power to the affected ~~vital~~ bus.

This 2 hour limit is more conservative than Completion Times allowed for the vast majority of components that are without adequate ~~vital~~ AC power. Taking exception to LCO 3.0.2 for components without adequate ~~vital~~ AC power, which would have the Required Action Completion Times shorter than 2 hours if declared inoperable, is acceptable because of:

a. The potential for decreased safety by requiring a change in unit conditions (i.e., requiring a shutdown) and not allowing stable operations to continue,

b. The potential for decreased safety by requiring entry into numerous Applicable Conditions and Required Actions for components without adequate ~~vital~~ AC power and not providing sufficient time for the operators to perform the necessary evaluations and actions for restoring power to the affected train, and

c. The potential for an event in conjunction with a single failure of a redundant component.

The 2 hour Completion Time takes into account the importance to safety of restoring the AC ~~vital~~ bus to OPERABLE status, the redundant capability afforded by the other OPERABLE ~~vital~~ buses, and the low probability of a DBA occurring during this period.

C.1

With one ~~or more~~ DC ~~buses or distribution panels~~ inoperable, and a loss of function has not yet occurred, the remaining DC electrical power distribution subsystems are capable of supporting the minimum safety functions necessary to shut down the reactor and maintain it in a safe shutdown condition, assuming no single failure. The overall reliability is reduced, however, because a single failure in the remaining DC electrical power distribution subsystem could result in the minimum required ESF functions not being supported. Therefore, the ~~[required]~~ DC ~~buses and~~

BASES

ACTIONS (continued)

~~distribution panels~~ must be restored to OPERABLE status within 2 hours by powering the bus from the associated battery or charger. 1

~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 2

Condition C represents one ~~or more DC buses or distribution panels~~ without adequate DC power; potentially both with the battery significantly degraded and the ~~associated~~ charger nonfunctioning. In this situation, the unit is significantly more vulnerable to a complete loss of all DC power. It is, therefore, imperative that the operator's attention focus on stabilizing the unit, minimizing the potential for loss of power to the remaining trains and restoring power to the affected train. 1

electrical power distribution subsystem

s

This 2 hour limit is more conservative than Completion Times allowed for the vast majority of components which would be without power. Taking exception to LCO 3.0.2 for components without adequate DC power, which would have Required Action Completion Times shorter than 2 hours, is acceptable because of:

a. The potential for decreased safety by requiring a change in unit conditions (i.e., requiring a shutdown) while allowing stable operations to continue,

b. The potential for decreased safety by requiring entry into numerous applicable Conditions and Required Actions for components without DC power and not providing sufficient time for the operators to perform the necessary evaluations and actions for restoring power to the affected train, and

c. The potential for an event in conjunction with a single failure of a redundant component.

The 2 hour Completion Time for the electrical power distribution subsystem DC ~~buses~~ is consistent with Regulatory Guide 1.93 (Ref. 3). 1

the

electrical power distribution subsystem

D.1 and D.2

If the inoperable distribution subsystem cannot be restored to OPERABLE status within the required Completion Time, the unit must be brought to a MODE in which the LCO does not apply. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

BASES

ACTIONS (continued)

E.1

Condition E corresponds to a level of degradation in the electrical distribution system that causes a required safety function to be lost. When more than one inoperable electrical power distribution subsystem results in the loss of a required function, the plant is in a condition outside the accident analysis. Therefore, no additional time is justified for continued operation. LCO 3.0.3 must be entered immediately to commence a controlled shutdown.

SURVEILLANCE REQUIREMENTS

SR 3.8.9.1

instrument

This Surveillance verifies that the AC, DC, and AC ~~vital~~ bus electrical power distribution systems are functioning properly, with the correct circuit breaker alignment. The correct breaker alignment ensures the appropriate separation and independence of the electrical divisions is maintained, and the appropriate voltage is available to each required bus. The verification of proper voltage availability on the buses ensures that the required voltage is readily available for motive as well as control functions for critical system loads connected to these buses. ~~[The 7 day Frequency takes into account the redundant capability of the AC, DC, and AC vital bus electrical power distribution subsystems, and other indications available in the control room that alert the operator to subsystem malfunctions.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.9 Distribution Systems - Operating

BASES

BACKGROUND

The onsite Class 1E AC, DC, and AC ~~vital~~ bus electrical power distribution systems are divided by train into ~~[~~two~~]~~ redundant and independent AC, DC, and AC ~~vital~~ bus electrical power distribution subsystems.

The AC electrical power subsystem for each train consists of a 4.16 kV ~~Engineered Safety Feature (ESF)~~ bus, having at least ~~[~~one separate and independent offsite source of power~~]~~ as well as a dedicated onsite diesel generator (DG) source. Each ~~[~~4.16 kV ~~ESF~~ bus~~]~~ is normally connected to ~~a preferred offsite source~~. After a loss of the ~~preferred offsite~~ power source to a 4.16 kV ~~ESF~~ bus, a transfer to the ~~alternate~~ offsite source is accomplished by utilizing ~~a time delayed bus undervoltage relay~~. If ~~all~~ offsite sources are unavailable, the onsite emergency DG supplies power to the 4.16 kV ~~ESF~~ bus. Control power for the 4.16 kV breakers is supplied from the Class 1E batteries. Additional description of this system may be found in the Bases for LCO 3.8.1, "AC Sources - Operating," and the Bases for LCO 3.8.4, "DC Sources - Operating."

The ~~secondary~~ AC electrical power distribution subsystem for each train includes the safety related ~~load centers, motor control centers, and distribution panels~~ shown in Table B 3.8.9-1.

The 120 VAC ~~vital~~ bus~~es~~ ~~are~~ arranged in two load groups per train and are normally powered from the inverters. The alternate power supply for the ~~vital~~ buses are Class 1E constant voltage source transformers powered from the same train as the associated inverter, and its use is governed by LCO 3.8.7, "Inverters - Operating." Each constant voltage source transformer is powered from a Class 1E AC bus.

The DC electrical power distribution subsystem consists of ~~[~~125~~]~~ V bus~~(es) and distribution panel(s)~~.

The list of all required DC and ~~vital AC distribution~~ buses ~~[and panels]~~ is presented in Table B 3.8.9-1.

BASES

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 1) and Chapter ~~[~~15~~]~~ (Ref. 2), assume ~~ESF~~ systems are OPERABLE. The AC, DC, and AC ~~vital~~ bus electrical power distribution systems are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to ESF systems so that the fuel, Reactor Coolant System, and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, Power Distribution Limits; Section 3.4, Reactor Coolant System (RCS); and Section 3.6, Containment Systems.

The OPERABILITY of the AC, DC, and AC ~~vital~~ bus electrical power distribution systems is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This includes maintaining power distribution systems OPERABLE during accident conditions in the event of:

a. An assumed loss of all offsite power or all onsite AC electrical power and

b. A worst case single failure.

The distribution systems satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The required power distribution subsystems listed in Table B 3.8.9-1 ensure the availability of AC, DC, and AC ~~vital~~ bus electrical power for the systems required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA. The AC, DC, and AC ~~vital~~ bus electrical power distribution subsystems are required to be OPERABLE.

Maintaining the Train A and Train B AC, DC, and AC ~~vital~~ bus electrical power distribution subsystems OPERABLE ensures that the redundancy incorporated into the design of ESF is not defeated. Therefore, a single failure within any system or within the electrical power distribution subsystems will not prevent safe shutdown of the reactor.

OPERABLE AC electrical power distribution subsystems require the associated buses~~, load centers, motor control centers, and distribution panels~~ to be energized to their proper voltages. OPERABLE DC electrical power distribution subsystems require the associated buses ~~and distribution panels~~ to be energized to their proper voltage from either the associated battery or charger. OPERABLE ~~vital~~ bus electrical power distribution subsystems require the associated buses to be energized to their proper voltage from the associated ~~[~~inverter via inverted DC voltage~~,~~ ~~inverter using internal AC source,~~ or Class 1E constant voltage transformer~~]~~.

BASES

LCO (continued)

R1

instrument

In addition, tie breakers between redundant safety related AC, DC, and AC ~~vital~~ bus power distribution subsystems~~, if they exist,~~ must be open. This prevents any electrical malfunction in any power distribution subsystem from propagating to the redundant subsystem, which could cause the failure of a redundant subsystem and a loss of essential safety function(s). If any tie breakers are closed, the affected redundant electrical power distribution subsystems are considered inoperable. This applies to the onsite, safety related redundant electrical power distribution subsystems. ~~It does not, however, preclude redundant Class 1E 4.16 kV buses from being powered from the same offsite circuit.~~

1

1

APPLICABILITY

The electrical power distribution subsystems are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure that:

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients and

b. Adequate core cooling is provided, and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

Electrical power distribution subsystem requirements for MODES 5 and 6 are covered in the Bases for LCO 3.8.10, "Distribution Systems - Shutdown."

s

This 2 hour limit is more conservative than Completion Times allowed for the vast majority of components which would be without power. Taking exception to LCO 3.0.2 for components without adequate DC power, which would have Required Action Completion Times shorter than 2 hours, is acceptable because of:

a. The potential for decreased safety by requiring a change in unit conditions (i.e., requiring a shutdown) while allowing stable operations to continue,

b. The potential for decreased safety by requiring entry into numerous applicable Conditions and Required Actions for components without DC power and not providing sufficient time for the operators to perform the necessary evaluations and actions for restoring power to the affected train, and

c. The potential for an event in conjunction with a single failure of a redundant component.

The 2 hour Completion Time for the electrical power distribution subsystem DC ~~buses~~ is consistent with Regulatory Guide 1.93 (Ref. 3). 1

the

electrical power distribution subsystem

D.1 and D.2

If the inoperable distribution subsystem cannot be restored to OPERABLE status within the required Completion Time, the unit must be brought to a MODE in which the LCO does not apply. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

BASES

ACTIONS (continued)

E.1

Condition E corresponds to a level of degradation in the electrical distribution system that causes a required safety function to be lost. When more than one inoperable electrical power distribution subsystem results in the loss of a required function, the plant is in a condition outside the accident analysis. Therefore, no additional time is justified for continued operation. LCO 3.0.3 must be entered immediately to commence a controlled shutdown.

SURVEILLANCE REQUIREMENTS

SR 3.8.9.1

This Surveillance verifies that the AC, DC, and AC ~~vital~~ instrument bus electrical power distribution systems are functioning properly, with the correct circuit breaker alignment. The correct breaker alignment ensures the appropriate separation and independence of the electrical divisions is maintained, and the appropriate voltage is available to each required bus. The verification of proper voltage availability on the buses ensures that the required voltage is readily available for motive as well as control functions for critical system loads connected to these buses. ~~[The 7-day Frequency takes into account the redundant capability of the AC, DC, and AC vital bus electrical power distribution subsystems, and other indications available in the control room that alert the operator to subsystem malfunctions.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.9 BASES, DISTRIBUTION SYSTEMS - OPERATING

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

Specific No Significant Hazards Considerations (NSHCs)

DISCUSSION OF CHANGES
ITS 3.8.10, DISTRIBUTION SYSTEMS - SHUTDOWN

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.8.2.2 lists the minimum AC and AC instrument buses required to be OPERABLE. Unit 1 CTS 3.8.2.4 requires one 125 VDC bus to be OPERABLE. Unit 2 CTS 3.8.3.2 lists the minimum AC, DC, and AC instrument buses required to be OPERABLE and energized in the manner specified therein.

ITS LCO 3.8.10 requires the necessary portion of AC, DC, and AC instrument bus electrical power subsystems must be OPERABLE to support equipment required to be OPERABLE. In addition, an optional Required Action (ITS 3.8.10 Required Action A.1) has been added which allows the associated supported required feature(s) to be declared inoperable. This changes CTS by adding a requirement that the applicable portions of the AC, DC, and AC instrument bus electrical power distribution subsystems must be OPERABLE when required to support equipment required to be OPERABLE by the Technical Specifications. This could require more buses to be OPERABLE than is currently required based on plant conditions. In addition, an action has been added to allow an option to the existing actions to compensate for the additional required electrical buses.

The purpose of Unit 1 CTS 3.8.2.2 and 3.8.2.4 and Unit 2 CTS 3.8.3.2 is to ensure that the minimum necessary A.C. and D.C. distribution systems are OPERABLE to support shutdown and refueling for extended periods with sufficient instrumentation and controls available for monitoring and maintaining plant status. This change adds a requirement that the necessary portions of AC, DC, and AC instrument bus electrical power distribution subsystems must be OPERABLE when required to support the equipment required to be OPERABLE by the Technical Specifications. This added restriction conservatively assures the needed electrical power distribution buses are OPERABLE, even if it results in more electrical power distribution systems being required. Since the ITS 3.8.10 electrical power distribution subsystem OPERABILITY requirements require the necessary portions of the distribution subsystems to be OPERABLE to support equipment required to be OPERABLE, if a portion of the electrical power distribution subsystem cannot supply any required equipment, that electrical power distribution subsystem is inoperable. In this event it may not be necessary to suspend irradiated fuel handling and positive reactivity additions. Conservative actions can be assured if the required equipment without the necessary power is declared inoperable, and the associated ACTIONS of the individual equipment is taken (ITS 3.8.10 Required Action A.1). Therefore, along with the conservative

additional requirements placed on the electrical power distribution subsystems, Required Action A.1, requires the associated supported equipment to be declared inoperable. These changes are acceptable since the additions represent restrictions consistent with implicit assumptions for operation in shutdown conditions (required equipment receiving the necessary required power), and these restrictions are not currently imposed by the Technical Specifications. This change is designated as more restrictive because it adds a new requirement to the CTS.

M02 Unit 1 CTS 3.8.2.2 and CTS 3.8.2.4 and Unit 2 CTS 3.8.3.2 are applicable in MODES 5 and 6. ITS 3.8.10 is applicable in MODE 5 and 6 and during movement of irradiated fuel assemblies. In addition, a Note has been added to the ACTIONS which states that LCO 3.0.3 is not applicable. This changes the CTS by adding the Applicability of “during movement of irradiated fuel assemblies” and adds an ACTIONS Note stating that LCO 3.0.3 is not applicable. | R1

The purpose of CTS Applicability is to ensure that sufficient electrical power subsystems are OPERABLE to support equipment required to mitigate the consequences of an analyzed event during shutdown modes. This change is acceptable because the proposed requirements are necessary to ensure the electrical power subsystems are OPERABLE to support equipment required to OPERABLE during movement of irradiated fuel assemblies. Movement of fuel normally occurs during MODES 5 and 6, however, it can also occur outside of containment in other plant MODES (MODES 1, 2, 3, and 4) or other conditions (i.e., reactor defueled). This Specification is needed to ensure the appropriate distribution system requirements are specified during fuel handling and ensure the appropriate actions are taken (i.e., stop fuel movement) when the minimum electrical supply is not available (See Unit 1 DOC L02 and Unit 2 DOCS L03 and L04 for additional changes to the Required Actions). This change adds a clarification Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODES 5 or 6, LCO 3.0.3 is not applicable and would not specify any action. If moving irradiated fuel assemblies while in MODES 1, 2, 3, or 4, the fuel movement is independent of reactor operations and the inability to suspend movement in accordance with the ITS 3.8.10 Required Actions would not be sufficient reason to require a reactor shutdown. The Note has been added for clarification and is necessary since defaulting to LCO 3.0.3 would require the reactor to be shutdown but would not require suspension of the activities with a potential for releasing radioactive materials. This change is designated as more restrictive because the ITS requires the equipment to be OPERABLE during movement of irradiated fuel assemblies both inside and outside of the containment in conditions other than MODES 5 and 6.

M03 **Unit 1 only:** CTS 4.8.2.2 requires, in part, the specified A.C. busses shall be determined OPERABLE by verifying "indicated power availability" and CTS 4.8.2.4.1 states each D.C. bus train shall be determined OPERABLE by verifying "indicated power availability." ITS SR 3.8.10.1 requires the verification of correct breaker alignments and "voltage" to required AC, DC, and 120 VAC instrument bus electrical power distribution subsystems. This changes the CTS by requiring the verification of the correct voltages and breaker alignments to the required AC, DC, and 120 VAC instrument bus electrical power distribution subsystems, whereas the CTS only requires verification of indicated power availability.

The purpose of this Surveillance is to ensure required electrical buses are properly energized to support their required function. This is more appropriately accomplished by verifying the correct breaker alignment and proper voltage is supplied to the required AC, DC, and 120 VAC instrument bus electrical power distribution subsystems. This change is acceptable because the Surveillance will continue to verify OPERABILITY of the required AC, DC and instrument bus electrical power distribution subsystems. Proper voltage from the required subsystems ensures proper voltage is supplied to the required safety features. This change is designated as more restrictive because the ITS requires verification of the correct breaker alignments and voltage, whereas the CTS only requires a verification of indicated power availability.

M04 With less than the minimum specified AC and DC busses energized, Unit 2 CTS 3.8.3.2 action requires, in part, the immediate suspension of operations involving positive reactivity additions that could result in loss of required SDM or boron concentration or movement of irradiated fuel. Unit 1 CTS 3.8.2.2 and 3.8.2.4 require establishing CONTAINMENT INTEGRITY within 8 hours. ITS 3.8.10 includes an additional required action (Required Action A.2.4) to "declare associated required shutdown cooling subsystem(s) inoperable and not in operation." This changes the CTS by adding a requirement to declare the required shutdown cooling subsystem(s) (SDCs) inoperable and not in operation that is not currently specifically imposed by the Technical Specification.

This change is necessary because the CTS actions do not adequately address the concern relating to coolant circulation and heat removal. Pursuant to CTS 3.0.6 (ITS LCO 3.0.6), the SDC actions would not be entered unless a loss of safety function was determined to exist. Therefore, Required Action A.2.4 is added to immediately take appropriate SDC actions. This change is designated as more restrictive because it adds a new requirement to the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.8.2.2 and 3.8.2.4 require AC AC instrument, and DC electrical buses to be OPERABLE and lists the specific busses, including applicable nominal AC bus voltages. Unit 2 CTS 3.8.3.2 requires electrical busses to be "energized in the specified manner" and lists the specified AC, DC, and 120 V instrument busses, including applicable nominal bus voltage.

ITS LCO 3.8.10 requires the necessary portion of AC, DC, and AC instrument bus electrical power subsystems must be OPERABLE to support equipment required to be OPERABLE. This changes the CTS by moving the specific names of the buses and the associated nominal bus voltages (i.e., 4160 V, 480 V, 120 V and 125 VDC) from the CTS to the ITS Bases.

The removal of these details related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 3.8.10 retains the requirement for the required electrical buses to be OPERABLE. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 1 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS 3.8.2.2 requires specific AC electrical busses to be OPERABLE "and energized from sources of power other than a diesel generator set but aligned to an OPERABLE diesel generator set.” Unit 1 CTS 4.8.2.2 also requires the specified AC buses to be determined OPERABLE "and energized from AC sources of power other than the diesel generators” by verifying indicated power availability. Unit 1 CTS 3.8.2.4 requires the DC bus to be “energized” and OPERABLE. Unit 1 CTS 4.8.2.4.1 requires DC busses to be determined OPERABLE and "energized" by verifying indicated power availability.

Unit 2 CTS LCO 3.8.3.2 requires AC and DC electrical busses to "to be energized in the specified manner.” Unit 2 CTS 4.8.3.2 requires the specified buses to be determined "energized in the required manner” by verifying correct breaker alignment and indicated voltage.

ITS LCO 3.8.10 requires the necessary portions of the electrical power distribution subsystems to be OPERABLE to support equipment required to be OPERABLE and ITS SR 3.8.10.1 requires the verification of correct breaker alignments and voltage to required AC, DC, and AC instrument bus electrical power distribution subsystems.

This changes the Unit 1 and Unit 2 CTS by moving the procedural detail that the AC buses and DC busses must be “energized” from the CTS to the ITS Bases. See DOC L01 for discussion of additional changes to the respective CTS LCO and Surveillance Requirement.

The removal of these details for meeting Technical Specification requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for the electrical power distribution subsystems to be OPERABLE and requires the verification of correct breaker alignments and voltage to required AC, DC, and AC instrument bus electrical power distribution subsystems. Also, this change is acceptable because these type of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail

change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 1 – Relaxation of LCO Requirements)* Unit 1 CTS 3.8.2.2 specifies that the AC electrical busses shall be OPERABLE "and energized from sources of power other than the diesel generator sets but aligned to an OPERABLE diesel generator set." Unit 2 CTS 3.8.3.2 requires that specified electrical busses be energized "and in the specified manner," as listed in CTS 3.8.3.2.a through CTS 3.8.3.2.c. ITS LCO 3.8.10 does not include the requirement that the busses be energized by any specific method. ITS defines OPERABLE to include the clarification that "normal or emergency electrical power sources" are acceptable. The CTS definition for OPERABLE simply states "electrical power" as a necessary component for OPERABILITY. This changes the CTS by removing the requirement that electrical busses be energized in any specific manner or from a specific source of power.

The purpose of ITS 3.8.10 is to ensure the necessary AC, DC, and AC instrument bus electrical power distribution subsystems are available to support the OPERABILITY of required systems, equipment and components and ensure the availability of sufficient power to operate the unit in a safe manner to mitigate the consequences of postulated events during shutdown. ITS 3.8.10 retains the requirement for the required electrical buses to be OPERABLE. The change is acceptable since it is consistent with the definition of OPERABILITY and the ability of the subsystem to support the dependent components and systems is independent of the specific source of the power provided the power source is a qualified electrical power source. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than applied in the CTS.

L02 **Unit 1 only:** *(Category 4 – Relaxation of Required Action)* With less than the minimum complement of electrical busses OPERABLE and energized, CTS 3.8.2.2 and 3.8.2.4 require the establishment of containment integrity within 8 hours. ITS 3.8.10 ACTION A requires suspending movement of irradiated fuel assemblies, suspension of operations involving positive reactivity additions that could result in the loss of required SDM or boron concentration, the initiation of actions to restore required AC, DC, and AC instrument bus electrical power distribution subsystems to OPERABLE status, and the declaration of the associated required shutdown cooling subsystems(s) inoperable and not in operation. This changes the CTS by replacing the existing Required Action to restore containment integrity with Actions that will prevent a fuel handling accident from occurring, ensure the reactor remains subcritical, and ensure decay heat removal is reestablished.

The purpose of the CTS 3.8.2.2 and 3.8.2.4 Actions is to isolate the containment to minimize any release from the plant if an event were to occur during shutdown conditions. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe

operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the repair period. The proposed Required Actions require the suspension of movement of irradiated fuel assemblies, the suspension of operations involving positive reactivity additions that could result in the loss of required SDM or boron concentration, the initiation of actions to restore required AC, DC, and AC vital bus electrical power distribution subsystems to OPERABLE status, and the declaration of the associated required decay heat removal subsystems(s) inoperable and not in operation. Suspending the movement of irradiated fuel assemblies will prevent a fuel handling accident from occurring. Suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit is required to assure continued safe operation. The requirement to initiate action to restore required AC, DC, and AC instrument bus electrical power distribution subsystems to OPERABLE status will place the plant in compliance with the LCO in an expeditious manner. Declaration of the associated required shutdown cooling subsystem(s) inoperable and not in operation will require the plant to enter the applicable LCOs to apply additional Required Actions. The proposed actions will also minimize the potential for any accident releases outside of the containment and are considered acceptable in lieu of the current action to restore containment integrity within 8 hours. The actions may be considered somewhat more restrictive since immediate action is required, however, is classified as less restrictive since the current actions to restore containment integrity have been deleted. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* CTS 3.8.3.2 ACTION states, in part, “With any of the above required electrical busses not energized in the required manner, immediately suspend all operations involving CORE ALTERATIONS, operations involving positive reactivity changes that could result in loss of required SHUTDOWN MARGIN or boron concentration, or movement of irradiated fuel.” ITS 3.8.10 ACTIONS do not include the requirement to suspend CORE ALTERATIONS. This changes the CTS by removing the Required Action to suspend all operations involving CORE ALTERATIONS.

The purpose of the CTS 3.8.3.2 ACTION is to minimize the possibility of an event that may require the electrical power source to mitigate the consequences of a design basis event. CORE ALTERATIONS is defined in CTS 1.9, in part, as "the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity, within the reactor vessel with the head removed and fuel in the vessel." Core Alterations only occur when the reactor vessel head is removed - it only applies in MODE 6. There is only one accident considered during MODE 6 that involves a Core Alteration - a fuel handling accident. According to UFSAR Section 15.7.4.1.2, a fuel handling accident is initiated by the dropping of an irradiated fuel assembly either in the containment or in the fuel handling building. Suspension of CORE ALTERATIONS, except for suspension of movement of irradiated fuel, will not prevent or impair the mitigation of a fuel handling accident. ITS 3.8.10 retains the requirement to suspend movement of irradiated fuel assemblies as Required Action A.2.1 (for one or more electrical distribution subsystems). R1

Deleting the reference to “CORE ALTERATIONS” is acceptable because the only CORE ALTERATION analyzed in the safety analysis that is potentially affected by an inoperable electrical distribution subsystem is covered by the ITS Required Actions. Additionally, CORE ALTERATIONS that may be capable of damaging a fuel assembly prior to the 72 hour decay period is improbable because of the physical time required to perform plant shutdown, cooldown, depressurize the Reactor Coolant System (RCS), and the additional operations required to expose irradiated fuel in the reactor vessel (e.g., containment entry, removal of vessel head, removal of vessel internals, etc.) is greater than 72 hours. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS. R1

L04 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* Unit 2 CTS 3.8.3.2 ACTION requires, in part, with any of the specified electrical busses not energized in the required manner, venting of the RCS through a 3.58 square inch vent within 8 hours. ITS 3.8.10 does not include the venting requirement.

The purpose of CTS is to ensure the minimum electrical power distribution buses are OPERABLE. CTS 3.4.9.3 provides specific OPERABILITY requirements for overpressure protection systems when in MODE 5 and MODE 6 with the reactor vessel head on. The definition of OPERABLE in CTS 1.19 requires necessary electrical power to components so they can perform their required safety function. This change is acceptable because CTS 3.4.9.3 Action a.1 requires depressurization and venting of the RCS when adequate pressure relief methods are inoperable, including the loss of electrical power necessary to support the required pressure relief components. ITS 3.4.12 retains the requirement to depressurize and establish the required RCS vent size (Refer to ITS 3.4.12 for any changes to CTS 3.4.9.3 requirements). Therefore, the CTS 3.8.1.2 action to depressurize the RCS and vent through a greater than or equal to 3.58 square inch vent is unnecessary. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.10 Distribution Systems - Shutdown

BASES

BACKGROUND

A description of the AC, DC, and AC ~~vital~~ bus electrical power distribution systems is provided in the Bases for LCO 3.8.9, "Distribution Systems - Operating."

APPLICABLE SAFETY ANALYSES

The initial conditions of Design Basis Accident and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 1) and Chapter ~~[~~15~~]~~ (Ref. 2), assume Engineered Safety Feature (ESF) systems are OPERABLE. The AC, DC, and AC ~~vital~~ bus electrical power distribution systems are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to ESF systems so that the fuel, Reactor Coolant System, and containment design limits are not exceeded.

The OPERABILITY of the AC, DC, and AC ~~vital~~ bus electrical power distribution system is consistent with the initial assumptions of the accident analyses and the requirements for the supported systems' OPERABILITY.

The OPERABILITY of the minimum AC, DC, and AC ~~vital~~ bus electrical power distribution subsystems during MODES 5 and 6, and during movement of ~~[recently]~~ irradiated fuel assemblies, ensures that:

a. The unit can be maintained in the shutdown or refueling condition for extended periods,

b. Sufficient instrumentation and control capability is available for monitoring and maintaining the unit status, and

c. Adequate power is provided to mitigate events postulated during shutdown, such as a fuel handling accident ~~[involving handling recently irradiated fuel. Due to radioactive decay, AC, DC, and AC vital bus electrical power is only required to mitigate fuel handling accidents involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~.

The AC and DC electrical power distribution systems satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

Various combinations of subsystems, equipment, and components are required OPERABLE by other LCOs, depending on the specific unit condition. Implicit in those requirements is the required OPERABILITY of necessary support required features. This LCO explicitly requires energization of the portions of the electrical distribution ~~system~~ necessary to support OPERABILITY of required systems, equipment and components - all specifically addressed in each LCO and implicitly required via the definition of OPERABILITY.

power

subsystems

1

Maintaining these portions of the distribution system energized ensures the availability of sufficient power to operate the unit in a safe manner to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents ~~[involving handling recently irradiated fuel]~~).

2

APPLICABILITY

The AC and DC electrical power distribution subsystems required to be OPERABLE in MODES 5 and 6, and during movement of ~~[recently]~~ irradiated fuel assemblies, provide assurance that:

2

a. Systems to provide adequate coolant inventory makeup are available for the irradiated fuel in the core,

b. Systems needed to mitigate a fuel handling accident ~~[involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~ are available,

2

c. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available, and

d. Instrumentation and control capability is available for monitoring and maintaining the unit in a cold shutdown condition and refueling condition.

instrument

The AC, DC, and AC ~~vital~~ bus electrical power distribution subsystem requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.9.

1

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

BASES

ACTIONS (continued)

A.1, A.2.1, A.2.2, A.2.3, and A.2.4

Although redundant required features may require redundant trains of electrical power distribution subsystems to be OPERABLE, one OPERABLE distribution subsystem train may be capable of supporting sufficient required features to allow continuation of ~~[recently]~~ irradiated fuel movement. By allowing the option to declare required features associated with an inoperable distribution subsystem inoperable, appropriate restrictions are implemented in accordance with the affected distribution subsystems LCO's Required Actions. In many instances, this option may involve undesired administrative efforts. Therefore, the allowance for sufficiently conservative actions is made (i.e., to suspend movement of ~~[recently]~~ irradiated fuel assemblies, and operations involving positive reactivity additions that could result in loss of required SDM (MODE 5) or boron concentration (MODE 6). Suspending positive reactivity additions that could result in failure to meet the minimum SDM or boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum SDM or refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation. Introduction of temperature changes including temperature increases when operating with a positive MTC must also be evaluated to ensure they do not result in a loss of required SDM.

Suspension of these activities shall not preclude completion of actions to establish a safe conservative condition. These actions minimize the probability of the occurrence of postulated events. It is further required to immediately initiate action to restore the required AC and DC electrical power distribution subsystems and to continue this action until restoration is accomplished in order to provide the necessary power to the unit safety systems.

Notwithstanding performance of the above conservative Required Actions, a required shutdown cooling (SDC) subsystem may be inoperable. In this case, Required Actions A.2.1 through A.2.~~4~~ do not adequately address the concerns relating to coolant circulation and heat removal. Pursuant to LCO 3.0.6, the SDC ACTIONS would not be entered. Therefore, Required Action A.2.~~5~~ is provided to direct declaring SDC inoperable, which results in taking the appropriate SDC actions.

BASES

ACTIONS (continued)

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required distribution subsystems should be completed as quickly as possible in order to minimize the time the unit safety systems may be without power.

SURVEILLANCE REQUIREMENTS

SR 3.8.10.1

instrument

This Surveillance verifies that the AC, DC, and AC ~~vital~~ bus electrical power distribution system is functioning properly, with all the buses energized. The verification of proper voltage availability on the buses ensures that the required power is readily available for motive as well as control functions for critical system loads connected to these buses.

DISCUSSION OF CHANGES
ITS 3.9.1, BORON CONCENTRATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.9.1 Applicability is MODE 6 with the footnote (*) reactor vessel head unbolted (i.e., not fully tensioned) or with the reactor vessel head removed. CTS 3.9.1 also includes this Applicability requirement in the LCO statement. ITS 3.9.1 requires the LCO in MODE 6. This changes the CTS by deleting the Applicability footnote and the LCO Applicability requirement.

CTS Table 1.2 defines MODE 6 with fuel in the reactor vessel and with the vessel head closure bolts less than fully tensioned (i.e., unbolted) or with the reactor vessel head removed. ITS Table 1.1-1 also defines MODE 6 with one or more reactor vessel head closure bolts less than fully tensioned, which encompasses vessel head removed. Additionally, the ITS definition of a MODE specifically defines a MODE, "…with fuel in the reactor vessel." Therefore, the CTS Applicability footnote and repeating the Applicability requirement in the LCO statement are not necessary because they duplicate requirements found in the definition.

This change is designated as an administrative change and is acceptable because it does not result in technical changes to the CTS.

A03 CTS 3.9.1 provides requirements on the boron concentration of all filled portions of the Reactor Coolant System (RCS) and the refueling cavity. ITS 3.9.1 provides requirements on the boron concentration of the RCS, the refueling canal, and the refueling cavity. This changes the CTS by explicitly including the refueling canal in the volumes required to have boron concentration maintained and removing the clarification related to all filled portions of the RCS. This change is acceptable because the technical requirements have not changed. It is inherently understood that the boron concentration requirement is related to the reactor coolant volume, and therefore, it is unnecessary to clarify "all filled portions." The refueling canal is considered an extension of the refueling cavity and contains the same water when connected to the RCS. Therefore, the refueling canal is governed by the CTS requirements because the refueling canal is connected to the refueling cavity during refueling operations, and therefore, connected to the RCS.

This change is designated as administrative because the technical requirements of the specifications have not changed.

DISCUSSION OF CHANGES
ITS 3.9.1, BORON CONCENTRATION

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS 4.9.1.2 requires a determination of boron concentration of the refueling cavity "by chemical analysis" in accordance with the Surveillance Frequency Control Program. Unit 2 CTS 4.9.1.2 requires a determination of boron concentration of the reactor coolant system and the refueling canal "by chemical analysis" in accordance with the Surveillance Frequency Control Program. CTS 4.9.1.2 requires that the boron concentration of the Reactor Coolant System and the refueling canal be determined "by chemical analysis" in accordance with the Surveillance Frequency Control Program. ITS SR 3.9.1.1 requires verification that boron concentration is within the limit specified in the COLR. ITS SR 3.9.1.1 does not specify where boron concentration is to be determined and that the boron concentration be determined by chemical analysis. This changes the CTS by moving details of where and how the boron concentration is determined from the CTS to the Bases.

The removal of these procedural details for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement that the boron concentration be verified within its limit. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Section 5.5. This program provides for the evaluation of changes to ensure the Bases are properly controlled.

This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* CTS 3.9.1 provides limits on the boron concentration of all filled portions of the Reactor Coolant System and the refueling cavity when in MODE 6. ITS 3.9.1 modifies this requirement with a Note which states "Only applicable to the refueling canal and refueling cavity when connected to the RCS." This changes the CTS by eliminating the

applicability of the boron concentration limits on the refueling canal and refueling cavity when those volumes are not connected to the RCS. In addition, ITS SR 3.9.1.1 requires a verification that the boron is within the limit specified in the COLR in accordance with the Surveillance Frequency Control Program.

The purpose of CTS 3.9.1 is to ensure the boron concentration of the water surrounding the reactor fuel is sufficient to maintain the required SHUTDOWN MARGIN. This change is acceptable because the requirements continue to ensure that process variables are maintained in the MODES and other specified conditions assumed in the safety analyses and licensing basis. If the refueling canal and refueling cavity are not connected to the RCS (such as when the reactor vessel head is on the reactor vessel while de-tensioned), the boron concentration of those volumes cannot affect the reactor core SHUTDOWN MARGIN. In addition, the general requirements of ITS SR 3.0.1 (CTS 4.0.1) and SR 3.0.4 (CTS 4.0.4) ensure a boron concentration verification is performed prior to connecting the refueling canal and refueling cavity to the RCS, to ensure the newly connected portions cannot decrease the boron concentration below the limit.

This change is designated as less restrictive because the LCO requirements are applicable in fewer operating conditions than in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* The CTS 3.9.1 Action specifies the compensatory action for when the boron concentration requirement is not met. One of the compensatory actions is to suspend CORE ALTERATIONS. Under similar conditions, ITS 3.9.1 does not require suspension of CORE ALTERATIONS. This changes the CTS by deleting the requirement to suspend CORE ALTERATIONS when the boron concentration requirement is not met.

The purpose of CTS 3.9.1 is to ensure the boron concentration of the water surrounding the reactor fuel is sufficient to maintain the required SHUTDOWN MARGIN. Thus, when the limit is not met, the CTS 3.9.1 Action suspends CORE ALTERATIONS to preclude an event that could result in not meeting the SHUTDOWN MARGIN limit. CORE ALTERATION is defined in CTS 1.9, in part, as "the movement of any fuel, sources, or reactivity control components, within the reactor vessel with the vessel head removed and fuel in the vessel." There are two evolutions encompassed under the term CORE ALTERATION that could affect the SHUTDOWN MARGIN: addition of fuel to the reactor vessel and withdrawal of control rods. However, ITS 3.9.1 Required Action A.1 requires immediate suspension of positive reactivity additions. This would include both the addition of fuel to the reactor vessel and the withdrawal of control rods. Furthermore, another accident considered in MODE 6 that could affect SHUTDOWN MARGIN is a boron dilution event. A boron dilution accident is initiated by a dilution source which results in the boron concentration dropping below that required to maintain the SHUTDOWN MARGIN. A boron dilution accident is mitigated by stopping the dilution. Suspension of CORE ALTERATIONS has no effect on the mitigation of a boron dilution accident.

Therefore, since the only CORE ALTERATIONS that could affect the SHUTDOWN MARGIN are suspended by ITS 3.9.1 Required Action A.1, deletion of the requirement to suspend CORE ALTERATIONS is acceptable.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 *(Category 4 – Relaxation of Required Action)* CTS 3.9.1 Action states that when the boron concentration requirement is not met, initiate, and continue boration at ≥ 40 gpm of a solution containing 1900 pm boron or greater to restore boron concentration to within limits. ITS 3.9.1 Required Action A.2 requires initiation of action to restore boron concentration to within limit. This changes the CTS by eliminating the specific requirements for the boric acid solution to be used to restore compliance with the LCO.

The purpose of CTS 3.9.1 Action is to restore the required SHUTDOWN MARGIN in a timely manner. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. Removing the specific values of flow rate and boron concentration from the CTS ACTION provides flexibility in the restoration of the SHUTDOWN MARGIN and eliminates conflicts between the SDM value specified in the COLR and the specific boration values in the CTS ACTION. As stated, in the ITS Bases for ACTION A:

> "In determining the required combination of boration flow rate and concentration, there is no unique design basis event that must be satisfied. The only requirement is to restore the boron concentration to its required value as soon as possible. In order to raise the boron concentration as soon as possible, the operator should begin boration with the best source available for unit conditions. Once boration is initiated, it must be continued until the boron concentration is restored."

Specifying a minimum flow rate and concentration in the ACTION may not accomplish the objective of raising the RCS boron concentration as soon as possible. Specifying the boric acid solution requirements in the Action is not necessary, since the ITS requires that action to restore the boron concentration to within limit be initiated immediately. This prompt action will result in the boron concentration being restored in a timely manner, consistent with the CTS requirement.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L04 *(Category 5 – Deletion of Surveillance Requirement*) CTS 4.9.1.1 requires the boron concentration to be determined prior to removing or unbolting the reactor vessel head, and prior to withdrawal of any control element assembly (CEA) in excess of 3 feet from its fully inserted position. ITS 3.9.1 does not contain this Surveillance Requirement.

The purpose of CTS 4.9.1.1 is to ensure that the LCO requirements are met prior to entering MODE 6 and that the reactor has sufficient SHUTDOWN MARGIN prior to withdrawing any CEAs. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify that the values used to meet the LCO are consistent with the safety analyses. Thus, appropriate values

continue to be tested in a manner and at a frequency necessary to give confidence that the assumptions in the safety analyses are protected. ITS 3.9.1 requires that the boron concentration be met in MODE 6 or that action be immediately initiated to restore the boron concentration and that all positive reactivity additions be suspended. CTS 4.0.4 (ITS SR 3.0.4) requires the SR to be met within its Frequency requirements prior to entering the MODE or other specified conditions in the Applicability except as provided by CTS 4.0.3 (ITS SR 3.0.3 – missed SR). Therefore, verification that the boron concentration is within the required limit must be performed prior to entering MODE 6 in order to avoid immediately entering into an Action that prohibits withdrawal of CEAs when the boron concentration requirement is not met. While the CTS Surveillance is not required, the level of protection provided is appropriate.

This change is designated as less restrictive because Surveillances required in the CTS will not be required in the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.9.1, BORON CONCENTRATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.9 REFUELING OPERATIONS

B 3.9.1 Boron Concentration

BASES

BACKGROUND

The limit on the boron concentrations of the Reactor Coolant System (RCS), the refueling canal, and refueling cavity during refueling ensures that the reactor remains subcritical during MODE 6. Refueling boron concentration is the soluble boron concentration in the coolant in each of these volumes having direct access to the reactor core during refueling.

The soluble boron concentration offsets the core reactivity and is measured by chemical analysis of a representative sample of the coolant in each of the volumes. The refueling boron concentration limit is specified in the COLR. Unit procedures ensure the specified boron concentration in order to maintain an overall core reactivity of $k_{eff} \leq 0.95$ during fuel handling, with control element assemblies (CEAs) and fuel assemblies assumed to be in the most adverse configuration (least negative reactivity) allowed by unit procedures.

GDC 26 of 10 CFR 50, Appendix A, requires that two independent reactivity control systems of different design principles be provided (Ref. 1). One of these systems must be capable of holding the reactor core subcritical under cold conditions. The Chemical and Volume Control System (CVCS) is the system capable of maintaining the reactor subcritical in cold conditions by maintaining the boron concentration.

The reactor is brought to shutdown conditions before beginning operations to open the reactor vessel for refueling. After the RCS is cooled and depressurized and the vessel head is unbolted, the head is slowly removed to form the refueling cavity. The refueling canal and the refueling cavity are then flooded with borated water from the refueling water tank into the open reactor vessel by gravity feeding or by the use of the Shutdown Cooling (SDC) System pumps.

or other borated water source

1

The pumping action of the SDC System in the RCS and the natural circulation due to thermal driving heads in the reactor vessel and the refueling cavity mix the added concentrated boric acid with the water in the refueling canal. The SDC System is in operation during refueling (see LCO 3.9.4, "Shutdown Cooling and Coolant Circulation - High Water Level," and LCO 3.9.5, "Shutdown Cooling and Coolant Circulation - Low Water Level") to provide forced circulation in the RCS and assist in maintaining the boron concentrations in the RCS, the refueling canal, and the refueling cavity above the COLR limit.

BASES

APPLICABLE SAFETY ANALYSES

During refueling operations, the reactivity condition of the core is consistent with the initial conditions assumed for the boron dilution accident in the accident analysis and is conservative for MODE 6. The boron concentration limit specified in the COLR is based on the core reactivity at the beginning of each fuel cycle (the end of refueling) and includes an uncertainty allowance.

The required boron concentration and the unit refueling procedures that demonstrate the correct fuel loading plan (including full core mapping) ensure the k_{eff} of the core will remain ≤ 0.95 during the refueling operation. Hence, at least a 5% $\Delta k/k$ margin of safety is established during refueling.

During refueling, the water volume in the spent fuel pool, the transfer canal, the refueling canal, the refueling cavity, and the reactor vessel form a single mass. As a result, the soluble boron concentration is relatively the same in each of these volumes.

The limiting boron dilution accident analyzed occurs in MODE 5 (Ref. 2). A detailed discussion of this event is provided in B 3.1.1, “SHUTDOWN MARGIN (SDM).”

The RCS boron concentration satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires that a minimum boron concentration be maintained in the RCS, the refueling canal, and refueling cavity while in MODE 6. The boron concentration limit specified in the COLR ensures a core k_{eff} of ≤ 0.95 is maintained during fuel handling operations. Violation of the LCO could lead to an inadvertent criticality during MODE 6.

APPLICABILITY

This LCO is applicable in MODE 6 to ensure that the fuel in the reactor vessel will remain subcritical. The required boron concentration ensures a k_{eff} ≤ 0.95. Above MODE 6, LCO 3.1.1, "SHUTDOWN MARGIN (SDM)," ensures that an adequate amount of negative reactivity is available to shut down the reactor and to maintain it subcritical.

The Applicability is modified by a Note. The Note states that the limits on boron concentration are only applicable to the refueling canal and the refueling cavity when those volumes are connected to the RCS. When the refueling canal and the refueling cavity are isolated from the RCS, no potential path for boron dilution exists.

BASES

ACTIONS

A.1

Continuation of positive reactivity additions (including actions to reduce boron concentration) is contingent upon maintaining the unit in compliance with the LCO. If the boron concentration of any coolant volume in the RCS, the refueling canal, or the refueling cavity is less than its limit, all operations involving positive reactivity additions must be suspended immediately. Operations that individually add limited positive reactivity (e.g., temperature fluctuations from inventory addition or temperature control fluctuations), but when combined with all other operations affecting core reactivity (e.g., intentional boration) result in overall net negative reactivity addition, are not precluded by this action.

Suspension of positive reactivity additions shall not preclude moving a component to a safe position.

A.2

In addition to immediately suspending positive reactivity additions, boration to restore the concentration must be initiated immediately.

In determining the required combination of boration flow rate and concentration, there is no unique design basis event that must be satisfied. The only requirement is to restore the boron concentration to its required value as soon as possible. In order to raise the boron concentration as soon as possible, the operator should begin boration with the best source available for unit conditions.

Once boration is initiated, it must be continued until the boron concentration is restored. The restoration time depends on the amount of boron that must be injected to reach the required concentration.

SURVEILLANCE REQUIREMENTS

SR 3.9.1.1

This SR ensures the coolant boron concentration in the RCS, and connected portions of the refueling canal and the refueling cavity, is within the COLR limits. The boron concentration of the coolant in each required volume is determined periodically by chemical analysis. Prior to re-connecting portions of the refueling canal or the refueling cavity to the RCS, this SR must be met per SR 3.0.4. If any dilution activity has occurred while the cavity or canal were disconnected from the RCS, this SR ensures the correct boron concentration prior to communication with the RCS.

BASES

SURVEILLANCE REQUIREMENTS (continued)

B 3.9 REFUELING OPERATIONS

B 3.9.1 Boron Concentration

BASES

BACKGROUND

The limit on the boron concentrations of the Reactor Coolant System (RCS), the refueling canal, and refueling cavity during refueling ensures that the reactor remains subcritical during MODE 6. Refueling boron concentration is the soluble boron concentration in the coolant in each of these volumes having direct access to the reactor core during refueling.

The soluble boron concentration offsets the core reactivity and is measured by chemical analysis of a representative sample of the coolant in each of the volumes. The refueling boron concentration limit is specified in the COLR. Unit procedures ensure the specified boron concentration in order to maintain an overall core reactivity of $k_{eff} \leq 0.95$ during fuel handling, with control element assemblies (CEAs) and fuel assemblies assumed to be in the most adverse configuration (least negative reactivity) allowed by unit procedures.

GDC 26 of 10 CFR 50, Appendix A, requires that two independent reactivity control systems of different design principles be provided (Ref. 1). One of these systems must be capable of holding the reactor core subcritical under cold conditions. The Chemical and Volume Control System (CVCS) is the system capable of maintaining the reactor subcritical in cold conditions by maintaining the boron concentration.

The reactor is brought to shutdown conditions before beginning operations to open the reactor vessel for refueling. After the RCS is cooled and depressurized and the vessel head is unbolted, the head is slowly removed to form the refueling cavity. The refueling canal and the refueling cavity are then flooded with borated water from the refueling water tank into the open reactor vessel by gravity feeding or by the use of the Shutdown Cooling (SDC) System pumps.

or other borated water source

1

The pumping action of the SDC System in the RCS and the natural circulation due to thermal driving heads in the reactor vessel and the refueling cavity mix the added concentrated boric acid with the water in the refueling canal. The SDC System is in operation during refueling (see LCO 3.9.4, "Shutdown Cooling and Coolant Circulation - High Water Level," and LCO 3.9.5, "Shutdown Cooling and Coolant Circulation - Low Water Level") to provide forced circulation in the RCS and assist in maintaining the boron concentrations in the RCS, the refueling canal, and the refueling cavity above the COLR limit.

BASES

APPLICABLE SAFETY ANALYSES

During refueling operations, the reactivity condition of the core is consistent with the initial conditions assumed for the boron dilution accident in the accident analysis and is conservative for MODE 6. The boron concentration limit specified in the COLR is based on the core reactivity at the beginning of each fuel cycle (the end of refueling) and includes an uncertainty allowance.

The required boron concentration and the unit refueling procedures that demonstrate the correct fuel loading plan (including full core mapping) ensure the k_{eff} of the core will remain ≤ 0.95 during the refueling operation. Hence, at least a 5% $\Delta k/k$ margin of safety is established during refueling.

During refueling, the water volume in the spent fuel pool, the transfer canal, the refueling canal, the refueling cavity, and the reactor vessel form a single mass. As a result, the soluble boron concentration is relatively the same in each of these volumes.

The limiting boron dilution accident analyzed occurs in MODE 5 (Ref. 2). A detailed discussion of this event is provided in B 3.1.1, “SHUTDOWN MARGIN (SDM).”

The RCS boron concentration satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires that a minimum boron concentration be maintained in the RCS, the refueling canal, and refueling cavity while in MODE 6. The boron concentration limit specified in the COLR ensures a core k_{eff} of ≤ 0.95 is maintained during fuel handling operations. Violation of the LCO could lead to an inadvertent criticality during MODE 6.

APPLICABILITY

This LCO is applicable in MODE 6 to ensure that the fuel in the reactor vessel will remain subcritical. The required boron concentration ensures a k_{eff} ≤ 0.95. Above MODE 6, LCO 3.1.1, "SHUTDOWN MARGIN (SDM)," ensures that an adequate amount of negative reactivity is available to shut down the reactor and to maintain it subcritical.

The Applicability is modified by a Note. The Note states that the limits on boron concentration are only applicable to the refueling canal and the refueling cavity when those volumes are connected to the RCS. When the refueling canal and the refueling cavity are isolated from the RCS, no potential path for boron dilution exists.

BASES

ACTIONS

A.1

Continuation of positive reactivity additions (including actions to reduce boron concentration) is contingent upon maintaining the unit in compliance with the LCO. If the boron concentration of any coolant volume in the RCS, the refueling canal, or the refueling cavity is less than its limit, all operations involving positive reactivity additions must be suspended immediately. Operations that individually add limited positive reactivity (e.g., temperature fluctuations from inventory addition or temperature control fluctuations), but when combined with all other operations affecting core reactivity (e.g., intentional boration) result in overall net negative reactivity addition, are not precluded by this action.

Suspension of positive reactivity additions shall not preclude moving a component to a safe position.

A.2

In addition to immediately suspending positive reactivity additions, boration to restore the concentration must be initiated immediately.

In determining the required combination of boration flow rate and concentration, there is no unique design basis event that must be satisfied. The only requirement is to restore the boron concentration to its required value as soon as possible. In order to raise the boron concentration as soon as possible, the operator should begin boration with the best source available for unit conditions.

Once boration is initiated, it must be continued until the boron concentration is restored. The restoration time depends on the amount of boron that must be injected to reach the required concentration.

SURVEILLANCE REQUIREMENTS

SR 3.9.1.1

This SR ensures the coolant boron concentration in the RCS, and connected portions of the refueling canal and the refueling cavity, is within the COLR limits. The boron concentration of the coolant in each required volume is determined periodically by chemical analysis. Prior to re-connecting portions of the refueling canal or the refueling cavity to the RCS, this SR must be met per SR 3.0.4. If any dilution activity has occurred while the cavity or canal were disconnected from the RCS, this SR ensures the correct boron concentration prior to communication with the RCS.

DISCUSSION OF CHANGES
ITS 3.9.2, NUCLEAR INSTRUMENTATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.9.2 requires, in part, that two neutron flux monitors are to be operating; wide range logarithmic (Unit 1) and startup range (Unit 2). Additionally, CTS 3.9.2 Actions contain compensatory actions to take when one or more neutron flux monitors are not operating. ITS LCO 3.9.2 requires, in part, two source range monitors (SRMs) to be OPERABLE but does not require the SRMs to be operating. Furthermore, ITS 3.9.2 ACTIONS A and B do not contain compensatory actions to take when one or more of the SRMs are not operating. This changes the CTS by removing the statement that the neutron flux monitors are required to be operating.

ITS refers to the neutron flux monitors as SRMs consistent with the ISTS because, for the purpose of CTS 3.9.2, both types of monitors (wide range logarithmic (Unit 1) and startup range (Unit 2)) provide neutron flux indication in the source range. The purpose of the SRMs is to monitor core reactivity during refueling operations and provide a signal to the operators if an unexpected reactivity change occurs. This change is acceptable because the requirements have not changed. In accordance with the ITS definition of OPERABLE, a device must be capable of performing its specified safety function. For the SRMs, this requires them to be operating in order to perform their safety function (i.e., monitor neutron flux in the source range). This change is considered administrative and acceptable because it does not result in a technical change to the CTS.

A03 Unit 1 CTS 3.9.2 Action and Unit 2 CTS Action a require, in part, with one neutron flux monitor inoperable to immediately suspend all operations involving CORE ALTERATIONS or immediately suspend operations that would cause introduction into the RCS, coolant with boron concentration less than required to meet the boron concentration of Technical Specification 3.9.1, “Boron Concentration.” Under similar conditions, ITS 3.9.2 Required Action A.1 requires immediate suspension of positive reactivity additions. Additionally, ITS 3.9.2 Required Action A.2 requires immediate suspension of movement of fuel, sources, and reactivity control components within the reactor vessel. This changes the CTS by immediately suspending positive reactivity additions and movement of fuel, sources, and reactivity control components within the reactor vessel, instead of suspending CORE ALTERATIONS.

The purpose of the SRMs is to monitor core reactivity during refueling operations and provide a signal to the operators if an unexpected reactivity change occurs. Thus, when an SRM is inoperable, CORE ALTERATIONS are suspended to

preclude an unmonitored reactivity change. CORE ALTERATIONS is defined in CTS 1.9, in part, as "the movement of any fuel, sources, reactivity control components or other components affecting reactivity within the reactor vessel with the head removed and fuel in the vessel." CORE ALTERATIONS only occur when the reactor vessel head is removed; therefore, it only applies to MODE 6. There are two evolutions encompassed under the term CORE ALTERATION that could affect the reactivity of the core; the addition of fuel to the reactor vessel and the withdrawal of control rods. ITS 3.9.2 Required Action A.1 requires immediate suspension of these two positive reactivity changes and prohibits diluting the boron concentration of the coolant in the RCS. Therefore, since the CORE ALTERATIONS of concern are only those that could affect positive reactivity in the core and these are suspended by ITS 3.9.2 Required Action A.1, changing the requirement from suspending "CORE ALTERATIONS" to suspending "positive reactivity additions" is acceptable.

ITS 3.9.2 Required Action A.2 prohibits the movement of fuel assemblies, sources, and reactivity control components when an SRM is inoperable. The proposed changes ensure that no actions are taken that could alter the core reactivity when an SRM is inoperable. With one SRM inoperable, the operator may not be able to monitor the core reactivity condition in part of the reactor. Therefore, the conservative action is to suspend movement of any core components that may affect reactivity until the SRM is restored. While unlikely, movement of fuel assemblies from one core location to another, the movement of sources, or the removal of reactivity control components, could result in an undetected change in core reactivity. These changes are considered administrative and acceptable because they do not result in a technical change to the CTS.

A04 Unit 1 CTS 3.9.2 Action and Unit 2 CTS 3.9.2 Action c. contain the statement, "The provisions of Specification 3.0.3 are not applicable." ITS 3.9.2 does not contain an equivalent statement. This changes the CTS by deleting the Specification 3.0.3 exception. This change is acceptable because the technical requirements have not changed. As explicitly stated in CTS 3.0.3 (ITS LCO 3.0.3), LCO 3.0.3 is not applicable in MODE 6. Therefore, the CTS LCO 3.0.3 exception statement is not needed. This change is designated as administrative because it does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS 3.9.2 states that two wide range logarithmic neutron flux monitors shall be operating, each with continuous visual indication in the control room and one with audible indication "in the containment." ITS 3.9.2 states that two source range monitors (SRMs) shall be OPERABLE. Details of what constitutes an OPERABLE SRM channel are provided in the ITS Bases (Refer to Discussion of Change (DOC) LA01). The ITS Bases explicitly states: To alert the operator of a boron dilution accident, at least one SRM must include audible indication in the control room to be considered OPERABLE. This changes the CTS by changing the location requirement for the audible indication from “the containment” to the “control room.”

This change is necessary to ensure that the SRM channels are maintained consistent with the safety analyses and licensing basis in MODE 6. The boron dilution analysis assumes that the operator has prompt and definite indication from an audible indication. The analysis does not explicitly specify how many audible channels are required or the location of the audible indication. However, action to terminate a boron dilution event is either initiated from an operator in the control room or directed by an operator in the control room. Therefore, it is more appropriate to specify that an audible indication be available in the control room instead of in the containment. This change is designated as more restrictive because a specific location of the audible alarm indication not previously required in the CTS is being applied in the ITS.

M02 Unit 1 CTS 3.9.1 Action and Unit 2 CTS 3.9.2 Action a require, in part, with one neutron flux monitor inoperable to, optionally, suspend operations that would cause introduction into the RCS, coolant with boron concentration less than required to meet the boron concentration of Technical Specification 3.9.1, "Boron Concentration." Under similar conditions, ITS 3.9.2 Required Action A.1 requires immediate suspension of positive reactivity additions. This changes the CTS requiring suspension of positive reactivity additions, which is not optional and includes RCS dilution activities even if the introduced coolant has a boron concentration greater than the limit in LCO 3.9.1.

The purpose of the source range flux monitoring requirements while in MODE 6 is to provide a signal to alert the operator to unexpected changes in core reactivity such as by a boron dilution accident or an improperly loaded fuel assembly. Pursuant to the requirements of 10 CFR 50.36(c)(2), the required action provides appropriate remedial actions when the required source range monitoring capability is degraded to ensure continued safe operation without adequate monitoring capability until the degraded condition can be corrected. The CTS Action that prohibits introducing coolant into the RCS unless that coolant has a boron concentration greater than or equal to the boron concentration limit in LCO 3.9.1 is deleted. This current action would allow dilution of the boron concentration in the RCS with one SRM inoperable provided the boron concentration is not reduced to less than the limit in LCO 3.9.1. This change is necessary to minimize the possibility of a boron dilution event when monitoring capability is unavailable or degraded by suspending any positive reactivity additions, including any RCS dilution activity suspended. This change is more restrictive because it requires an action that was optional in CTS and expands the action to include suspension of any boron dilution activity regardless of existing RCS boron concentration.

M03 Unit 1 CTS provides no action when two required wide range logarithmic neutron flux monitors are inoperable. Unit 2 CTS 3.9.2 Action b provides action for two inoperable required startup range neutron flux monitors, requiring determination of the Reactor Coolant System boron concentration at least once per 12 hours. ITS 3.9.2 ACTION B requires actions when two SRMs are inoperable. The ITS requires immediate initiation of action to restore one SRM to OPERABLE status and to perform a verification of boron concentration (per ITS SR 3.9.1.1) once per 12 hours. This changes the Unit 1 CTS requirements by requiring an additional verification of boron concentration every 12 hours when both SRMs

are inoperable, and changes Unit 1 and Unit 2 CTS by requiring an additional action to initiate immediate action to restore one SRM to OPERABLE status.

The purpose of this change is to provide necessary Required Actions that are appropriate for a possible condition that could be encountered. This change is acceptable because the proposed Required Actions are reasonable and necessary to ensure the reactor is maintained in a safe condition. This change is more restrictive because it provides for additional actions that the CTS does not require.

M04 CTS 4.9.2 requires the performance of a CHANNEL CHECK of the SRMs but does not require the performance of a CHANNEL CALIBRATION. ITS SR 3.9.2.2 requires performance of CHANNEL CALIBRATION of the SRMs at a periodic Frequency in accordance with the Surveillance Frequency Control Program (SFCP). This Surveillance is modified by a Note which states that the Neutron detectors are excluded from the CHANNEL CALIBRATION. This changes the CTS by adding a new Surveillance Requirement to periodically verify the calibration of the SRMs.

The purpose of ITS SR 3.9.2.2 is to provide additional assurance that the SRMs are capable of providing a reliable and accurate indication of core subcritical neutron flux. This change is acceptable because a CHANNEL CALIBRATION will continue to ensure OPERABILITY and proper operation of the SRMs in MODE 6. This Surveillance is modified by a Note which states that the Neutron detectors are excluded from the CHANNEL CALIBRATION.

PSL controls periodic Frequencies for Surveillances in accordance with the SFCP per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, SR 3.9.2.2 will be performed at a Frequency in accordance with the SFCP with an initial Frequency of 18 months consistent with the ISTS SR 3.9.2.2 and considers operating experience that these components usually pass the Surveillance when performed on an 18 month Frequency.

The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) “Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program” (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066).This change is more restrictive because it provides an additional Surveillance Requirement that was not required in the CTS.

M05 **Unit 1 only**: CTS 4.9.2.c requires a CHANNEL CHECK to be performed in accordance the Surveillance Frequency Control Program during CORE ALTERATIONS. ITS SR 3.9.2.1 requires a CHANNEL CHECK to be performed in accordance with the Surveillance Frequency Control Program. This changes the CTS by requiring the CHANNEL CHECK to be performed in accordance with the Surveillance Frequency Control Program even if CORE ALTERATIONS are not in progress.

The purpose of this change is to routinely verify the OPERABILITY of the neutron flux monitors in all conditions in which the LCO applies, not just during CORE ALTERATIONS. This change is acceptable because the Surveillance verifies OPERABILITY of both monitors to ensure the reactor is maintained in a safe condition. This change is more restrictive because it provides for additional testing that the CTS does not require.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.9.2 states, in part, that two source range neutron flux monitors shall be operating, "each with continuous visual indication in the control room." CTS also requires one neutron flux monitor to have audible indication; in the containment for Unit 1 and in the control room and containment for Unit 2. ITS 3.9.2 LCO states that two source range monitors (SRMs) shall be OPERABLE. This changes the CTS by moving the requirement that each channel has a continuous visual indication in the control room and one with audible indication from the CTS to the Bases.

The removal of this detail, which is related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement that two channels be OPERABLE and continues to require the associated Surveillance to verify OPERABILITY. The ITS Bases provides the description of the SRM detectors providing continuous visual indication and an audible alarm in the control room. The ITS Bases also includes a statement to ensure at least one SRM includes audible indication in the control room to be considered OPERABLE. Refer to other DOCs for CTS requirement specifying the location of the audible alarm indication. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 (*Category 4 – Relaxation of Required Action*) CTS 3.9.2 ACTION a requires, in part, with one neutron flux monitor inoperable to immediately suspend all operations involving CORE ALTERATIONS. Under similar conditions, ITS 3.9.2 Required Action A.2 requires immediate suspension of movement of fuel,

sources, and reactivity control components within the reactor vessel, which is equivalent to suspending CORE ALTERATIONS. Additionally, ITS 3.9.2 Required Action A.2 is modified by a Note that permits fuel assemblies, sources, and reactivity control components to be moved, if necessary, to restore an inoperable source range monitor or to complete movement of a component to a safe condition. This changes the CTS by allowing certain CORE ALTERATIONS to be continued in order to restore the SRM to OPERABLE status or complete movement of a component to a safe condition.

Pursuant to the requirements of 10 CFR 50.36(c)(2), the required action provides appropriate remedial actions when the required source range monitoring capability is degraded to ensure continued safe operation without adequate monitoring capability until the degraded condition can be corrected. The SRMs are located outside the reactor core. Troubleshooting, repair, or replacement of the inoperable source range neutron flux monitors may require moving fuel, sources, or reactivity control components away from the SRM location to minimize the radiation dose to the workers. As a result, suspension of activities specified in ITS 3.9.2, Required Action A.2 (i.e., CORE ALTERATIONS) with no exceptions has the adverse impact of precluding restoring the SRMs to OPERABLE status. This change is acceptable because the required actions continue to minimize actions that could result in reactivity changes within the core, while providing the ability to safely restore source range neutron monitoring capability. This change is consistent with the Note specified in ISTS Traveler TSTF-571-T, "Revise Actions for Inoperable Source Range Neutron Flux Monitor," Revision 2, dated April 13, 2000. ISTS Traveler TSTF-571-T addressed, in part, NRC concerns with the adoption of ISTS Traveler TSTF-286 as documented in a letter to the TSTF dated October 4, 2018 (NRC ADAMS Accession No. ML17346A587). ISTS Traveler TSTF-571-T was incorporated into Revision 5 of the ISTS as recommended by the NRC staff. The October 4, 2018, letter states, in part, that "If a licensee includes the changes of traveler TSTF-571-T when adopting TSTF-286, the NRC staff's technical concerns should be adequately addressed with regard to TSTF-286. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than applied in the CTS.

L02 *(Category 5 – Deletion of Surveillance Requirement)* Unit 1 CTS 4.9.2.a and b, and Unit 2 CTS 4.9.2.b and c, state that a CHANNEL FUNCTIONAL TEST is required for the neutron flux monitors in accordance with the Surveillance Frequency Control Program and within 8 hours prior to the initial start of CORE ALTERATIONS, respectively. ITS 3.9.2 does not require the performance of similar tests for the required neutron flux monitors. This changes the CTS by deleting the CHANNEL FUNCTIONAL TEST Frequency of within 8 hours of CORE ALTERATIONS.

This change is acceptable because the deleted Surveillance Requirement Frequency is not necessary to verify that the equipment used to meet the LCO is consistent with the safety analysis. The SRMs continue to be tested in a manner and at a frequency necessary to give confidence that the assumptions in the safety analyses are protected. This change is designated as less restrictive because a Surveillance required in the CTS will not be required in the ITS.

L03 **Unit 2 only:** (*Category 1 – Relaxation of LCO Requirements*) CTS 3.9.2 requires two startup range neutron flux monitors to be operating, each with continuous visual indication in the control room and one with audible indication "in the containment and the control room." ITS 3.9.2 states that two source range monitors (SRMs) shall be OPERABLE. Details of what is constitutes an OPERABLE SRM channel are provided in the ITS Bases (Refer to DOC LA01). The ITS Bases explicitly states: To alert the operator of a boron dilution accident, at least one SRM must include audible indication in the control room to be considered OPERABLE. This changes the CTS by deleting the requirement for an audible indication to be "in the containment."

This change is acceptable because the LCO requirements continue to ensure that the SRM channels are maintained consistent with the safety analyses and licensing basis in MODE 6. The boron dilution analysis assumes that the operator has prompt and definite indication from an audible indication. The analysis does not explicitly specify how many audible channels are required or the location of the audible indication. However, action to terminate a boron dilution event is either initiated from an operator in the control room or directed by an operator in the control room. Therefore, it is unnecessary to specify that an audible indication be available in the containment. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.9.2, NUCLEAR INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.9 REFUELING OPERATIONS

B 3.9.2 Nuclear Instrumentation

BASES

BACKGROUND

The source range monitors (SRMs) are used during refueling operations to monitor the core reactivity condition. The installed SRMs are part of the Nuclear Instrumentation System (NIS). These detectors are located external to the reactor vessel and detect neutrons leaking from the core. The use of portable detectors is permitted, provided the LCO requirements are met.

include wide range logarithmic gamma-metric

The installed SRMs ~~are BF3~~ detectors ~~operating in the proportional region of the gas filled detector characteristic curve~~. ~~The~~ detectors monitor the neutron flux in counts per second. ~~The instrument range covers five decades of neutron flux (1E+5 cps) with a [5%] instrument accuracy~~. The detectors ~~also~~ provide continuous visual indication ~~in the control room~~ and an audible alarm to alert operators to a possible dilution accident. The NIS is designed in accordance with the criteria presented in Reference 1.

In the source range, the

(cps). The instrument range of the wide range logarithmic detectors is 1 to 10^5 cps, each

in the control room

or other neutron flux detectors

If used, portable detectors should be functionally equivalent to the ~~NIS~~ SRMs.

described herein

1

APPLICABLE SAFETY ANALYSES

Two OPERABLE SRMs are required to provide a signal to alert the operator to unexpected changes in core reactivity such as by a boron dilution accident or an improperly loaded fuel assembly. The safety analysis of the uncontrolled boron dilution accident is described in Reference 2. The analysis of the uncontrolled boron dilution accident shows that normally available SHUTDOWN MARGIN would be reduced, but there is sufficient time for the operator to take corrective actions.

The SRMs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires two SRMs OPERABLE to ensure that redundant monitoring capability is available to detect changes in core reactivity.

1

APPLICABILITY

In MODE 6, the SRMs must be OPERABLE to determine changes in core reactivity. There is no other direct means available to check core reactivity levels.

logarithmic fission

In MODES ~~2,~~ 3, 4, and 5, the installed ~~source range~~ detectors and circuitry are required to be OPERABLE by ~~LCO 3.3.2, "RPS Instrumentation Shutdown."~~

LCO 3.3.11, "Logarithmic Neutron Flux Monitor."

1

To alert the operator of a boron dilution accident, at least one SRM must include audible indication in the control room to be considered OPERABLE.

BASES

ACTIONS

A.1 and A.2

of visual indication

With only one SRM OPERABLE, redundancy has been lost. Since these instruments are the only direct means of monitoring core reactivity conditions, positive reactivity additions and movement of fuel, sources, and reactivity control components within the reactor vessel must be suspended immediately. Performance of Required Action A.1 shall not preclude completion of movement of a component to a safe position. Suspending the movement of fuel, sources, and reactivity control components ensures that positive reactivity is not inadvertently added to the reactor core while the SRM is inoperable. Required Action A.2 is modified by a Note that states that fuel assemblies, sources, and reactivity control components may be moved if necessary to facilitate repair or replacement of the inoperable SRM. It may be necessary to move these items away from the locations in the core close to the SRM to minimize personnel radiation dose during troubleshooting or repair. The Note also permits completion of movement of a component to a safe position, should the SRM be discovered inoperable during component movement.

B.1

With no SRM OPERABLE, action to restore a monitor to OPERABLE status shall be initiated immediately. Once initiated, action shall be continued until an SRM is restored to OPERABLE status.

B.2

and no audible indication in the control room to detect a boron dilution event

With no SRM OPERABLE, there is no direct means of detecting changes in core reactivity. However, since positive reactivity additions are not to be made, the core reactivity condition is stabilized until the SRMs are OPERABLE. This stabilized condition is determined by performing SR 3.9.1.1 to verify that the required boron concentration exists.

, including boron dilution activities

The Completion Time of once per 12 hours is sufficient to obtain and analyze a reactor coolant sample for boron concentration and ensures that unplanned changes in boron concentration would be identified. The 12 hour Frequency is reasonable, considering the low probability of a change in core reactivity during this period.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.9.2.1

SR 3.9.2.1 is the performance of a CHANNEL CHECK, which is a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that the two indication channels should be consistent with core conditions. Changes in fuel loading and core geometry can result in significant differences between source range channels, but each channel should be consistent with its local conditions.

~~[The Frequency of 12 hours is consistent with the CHANNEL CHECK Frequency specified similarly for the same instruments in LCO 3.3.1, "Reactor Protection System."~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

SR 3.9.2.2

SR 3.9.2.2 is the performance of a CHANNEL CALIBRATION. This SR is modified by a Note stating that neutron detectors are excluded from the CHANNEL CALIBRATION. The CHANNEL CALIBRATION for the source range neutron flux monitors consists of obtaining the detector plateau or preamp discriminator curves, evaluating those curves, and comparing the curves to the manufacturer's data. ~~[The 18 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage. Operating experience has shown these components usually pass the Surveillance when performed on the 18 month Frequency.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

LA01

DISCUSSION OF CHANGES
ITS 3.9.3, CONTAINMENT PENETRATIONS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 4.9.4 requires that each required containment penetration is in its required position in accordance with the Surveillance Frequency Control Program during movement of recently irradiated fuel assemblies within containment. CTS 4.9.9 requires that the containment isolation system be demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program during movement of recently irradiated fuel assemblies within containment. ITS SR 3.9.3.1 also requires verification that that each required containment penetration is in its required position in accordance with the Surveillance Frequency Control Program. The CTS and ITS applicability is also during movement of recently irradiated fuel assemblies within containment. This changes the CTS by deleting the Applicability requirement from the Surveillance. ITS LCO 3.0.1 establishes the Applicability statement within each individual Specification as the requirement for when the LCO is required to be met (i.e., when the unit is in the MODES or other specified conditions of the Applicability statement of each Specification). Additionally, SR 3.0.1 establishes the requirement that Surveillance Requirements must be met during the MODES or other specified conditions in the Applicability for which the requirements of the LCO apply, unless otherwise specified in the individual SRs. Therefore, maintaining the Applicability requirement in the Surveillance is not necessary.

This change is designated as an administrative change and is acceptable because it does not result in technical changes to the CTS.

A03 **Unit 1 only:** CTS 3.9.4.c.1 states, in part, “except for valves that are open on an intermittent basis under administrative control.” CTS 3.9.4 Note provides this exception. ITS 3.9.3 Note provides this exception. This changes the CTS by deleting the CTS 3.9.4.c.1 statement “except for valves that are open on an intermittent basis under administrative control.”

This change is designated as administrative because it does not result in a technical change to the CTS.

A04 **Unit 1 only:** CTS 3.9.4.c.1 and c.3 state that each penetration providing direct access from the containment atmosphere to the outside atmosphere shall be closed by isolation valve, blind flange, or manual valve (c.1), or be capable of being closed by an OPERABLE containment vacuum relief valve (c.3). Similarly, ITS 3.9.3 c.1 requires each penetration providing direct access from the containment atmosphere to the outside atmosphere shall be closed by a manual or automatic isolation valve, blind flange, or equivalent, however; ITS does not

contain a specific requirement for the containment vacuum relief valve. This changes the CTS by deleting the explicit requirement for the containment vacuum relief valve. This change is acceptable because a containment vacuum relief valve is normally closed and automatically opens using a pneumatic operator under certain conditions. The valves automatically open and allow free air flow across the containment vessel boundary whenever a vacuum condition inside containment threatens vessel integrity. Since the vacuum relief valves also perform a containment isolation function in the event of a LOCA, the valves fail closed on loss of air. CTS and ITS both allow containment penetrations to be closed by a manual or automatic isolation valve. Therefore, it is not necessary to retain the explicit requirement for the containment vacuum relief valves because for the purpose of containment penetration Specifications, these valves are considered containment isolation valves.

This change is designated as administrative because it does not result in a technical change to the CTS.

A05 **Unit 1 only:** CTS 3.9.4 states "The provisions of Specification 3.0.3 are not applicable." ITS 3.9.3 does not include this statement. This changes the CTS by deleting the Specification 3.0.3 exception. This change is acceptable because LCO 3.0.3 is not applicable in MODE 6. Therefore, the CTS 3.0.3 exception is not necessary.

This change is designated as administrative because it does not result in a technical change to the CTS.

A06 CTS 3.9.9 requires the containment isolation system to be OPERABLE during movement of recently irradiated fuel assemblies within containment. CTS 3.9.9 Action requires either suspending movement of recently irradiated fuel assemblies within containment or close each of the penetrations providing direct access from the containment atmosphere to the outside atmosphere. ITS 3.9.3 ACTIONS do not include the action to close each of the penetrations providing direct access from the containment atmosphere to the outside atmosphere. This changes the CTS by removing an unnecessary action. The purpose of the CTS 3.9.9 actions is to provide appropriate remedial actions when an LCO is not met consistent with the requirements of 10 CFR 50.36(c)(2)(i). The action to suspend movement of recently irradiated fuel assemblies within containment results in the LCO no longer being required. CTS 3.0.2 (ITS LCO 3.0.2) states, in part, that when an LCO is met or is no longer applicable prior to expiration of the specified time interval(s), completion of the ACTIONS is not required, unless otherwise stated. As indicated in the ISTS Bases of ITS LCO 3.0.2, “Whether stated as a Required Action or not, correction of the entered Condition is an action that may always be considered upon entering ACTIONS.” Therefore, it is unnecessary to provide an action to specifically require the LCO to be met, as this is inherent in LCO 3.0.1 and LCO 3.0.2.

This change is designated as an administrative change and is acceptable because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 4.9.9 requires a verification that containment isolation occurs on manual initiation and on a high radiation signal from two of the containment radiation monitoring instrumentation channels. ITS SR 3.9.3.2 requires verifying each required containment isolation valve actuates to the isolation position on an actual or simulated actuation signal. This changes the CTS by moving the details of the actuation signal that isolates the required containment isolation valves to the ITS Bases.

The removal of these details, which are related to system actuation design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The Technical Specifications still retain the surveillance requirement to verify the required containment isolation valves close from the applicable actuation instrumentation. This change is acceptable because the removed information will be adequately controlled in the Technical Specification Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Section 5.5 of the Technical Specifications. This program provides for the evaluation of Bases changes in accordance with 10 CFR 50.59 to ensure the Bases are properly controlled. The ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 7 – Relaxation Of Surveillance Frequency)* CTS 4.9.4 requires a determination that each containment penetration is either in its closed/isolated condition or capable of being closed by an OPERABLE automatic containment isolation valve within 72 hours prior to the start of movement of recently irradiated fuel assemblies in containment and in accordance with the Surveillance Frequency Control Program (i.e., 7 days). CTS 4.9.9 requires that the containment isolation system shall be demonstrated OPERABLE within 72 hours prior to the start of and in accordance with the Surveillance Frequency Control Program (i.e., 7 days). ITS SR 3.9.3.1 requires verification that each required containment penetration is in the required status in accordance with the Surveillance Frequency Control Program (i.e., 7 days). This changes the CTS by reducing the Frequency for verifying the status of the containment penetrations

and the containment isolation system from 72 hours before entering the Applicability of the LCO to 7 days before entering the Applicability of the LCO.

The purpose of CTS 4.9.4 and 4.9.9 is to verify that the valves associated with containment penetrations providing direct access to the outside atmosphere are in the correct position or the containment isolation valves are capable of being closed by an actuation signal to support handling or recently irradiated fuel assemblies. This change is acceptable because the Surveillance Frequency has been evaluated to ensure that the containment penetrations are verified on a periodicity commensurate with the normal duration of time to complete fuel handling operations such that the verification will occur two or three times during the applicable period of the Specification, including once prior to movement of recently irradiated fuel. The Frequency of 7 days is sufficient during the movement of recently irradiated fuel assemblies; and therefore, it is sufficient before recently irradiated fuel assemblies are moved. CTS 4.0.4 (ITS SR 3.0.4) requires the SR to be met within its Frequency requirements prior to entering the MODE or other specified conditions in the Applicability except as provided by CTS 4.0.3 (ITS SR 3.0.3 – missed SR). The containment penetrations must be in the required state prior to commencing movement of recently irradiated fuel assemblies or fuel assembly movement must be suspended immediately (thereby exiting the Applicability of the Specification). Additionally, it is improbable to move irradiated fuel within 72 hours from entering MODE 3 (i.e., keff < 0.99) because of the physical time required to perform plant shutdown, cooldown, depressurize the Reactor Coolant System, and the additional operations required prior to moving recently irradiated fuel in the reactor vessel (e.g., containment entry, removal of vessel head, removal of vessel internals, etc.). Therefore, changing the Frequency from 72 hours before moving recently irradiated fuel assemblies to within 7 days before moving recently irradiated fuel assemblies has no effect on plant safety. This change is designated as less restrictive because Surveillances will be performed less frequently under the ITS than under the CTS.

L02 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.9.4.b does not provide an exception to performance of the Surveillance for containment isolation valve(s) in penetrations closed to comply with the LCO 3.9.4.c.1. ITS SR 3.9.3.2 is modified by a Note that states that SR 3.9.3.2 is not required to be met for containment isolation valve(s) in penetrations closed to comply with ITS LCO 3.9.3.c.1. This changes the CTS by adding a Note that the SR is not required to be met for containment ventilation isolation valve(s) in penetrations closed to comply with LCO 3.9.4.c.1.

The purpose of CTS 4.9.4.b is to verify the equipment required to meet the LCO is OPERABLE. This change is acceptable because when containment ventilation isolation valves are closed to comply with ITS LCO 3.9.3.c.1, the penetrations are in the expected condition (isolated) to mitigate the effects of a fuel handling accident inside containment. Therefore, it is not necessary for the actuation signal to reposition valves to the closed position. This change is designated as less restrictive because Surveillances will be performed less frequently under the ITS than under the CTS.

L03 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)*
Unit 1 CTS 4.9.4 requires testing containment isolation valves per the applicable portions of 4.6.3.1.1 and 4.6.3.1.2. Unit 2 CTS 4.9.4 requires testing containment isolation valves per the applicable portions of 4.6.3.2. Unit 1 CTS 4.6.3.1.1 and Unit 2 CTS 4.9.4 require isolation valves shall be demonstrated OPERABLE prior to returning the valve to service after maintenance, repair or replacement work is performed on the valve or its associated actuator, control or power circuit by performance of the cycling test, and verification of isolation time. CTS 4.6.3.1.2 (Unit 1) and 4.6.3.2 (Unit 2) require, in part, verification that on a Containment Isolation (and Containment High Radiation – Unit 2) test signal, the isolation valve actuates to its isolation position. ITS SR 3.9.3.2 specifies that the signal may be from either an "actual" or simulated (i.e., test) signal. Also, Unit 1 ITS SR 3.9.3.2 does not include the CTS 4.6.3.1.1 Frequency. This changes the Unit 1 and Unit 2 CTS by explicitly allowing the use of either an actual or simulated signal for the test and also changes Unit 1 CTS by deleting the requirement to perform the Surveillance prior to return the valve to service following certain activities per CTS 4.6.3.1.1.

The purpose of CTS 4.9.4 is to ensure that the required containment isolation valves operate correctly upon receipt of an actuation signal. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual," "simulated," or "test" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. Additionally, Unit 1 CTS 4.6.3.1.1 and Unit 2 CTS 4.9.4 are proposed to be deleted in ITS 3.6.3 and thus, is not addressed here (Refer to Discussion of Change L03 associated with ITS 3.6.3, Containment Isolation Valves). This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.9.3, CONTAINMENT PENETRATIONS

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.9 REFUELING OPERATIONS

B 3.9.3 Containment Penetrations

BASES

BACKGROUND

During movement of ~~[~~recently~~]~~ irradiated fuel assemblies within containment, a release of fission product radioactivity within the containment will be restricted from escaping to the environment when the LCO requirements are met. In MODES 1, 2, 3, and 4, this is accomplished by maintaining containment OPERABLE as described in LCO 3.6.1, "Containment." In MODE 6, the potential for containment pressurization as a result of an accident is not likely; therefore, requirements to isolate the containment from the outside atmosphere can be less stringent. The LCO requirements are referred to as "containment closure" rather than "containment OPERABILITY." Containment closure means that all potential escape paths are closed or capable of being closed. Since there is no potential for containment pressurization, the Appendix J leakage criteria and tests are not required.

The containment serves to contain fission product radioactivity that may be released from the reactor core following an accident, such that offsite radiation exposures are maintained well within the requirements of 10 CFR ~~100~~ 50.67. Additionally, the containment structure provides radiation shielding from the fission products that may be present in the containment atmosphere following accident conditions.

The containment equipment hatch, which is part of the containment pressure boundary, provides a means for moving large equipment and components into and out of containment. During movement of ~~[~~recently~~]~~ irradiated fuel assemblies within containment, the equipment hatch must be held in place by at least four bolts. Good engineering practice dictates that the bolts required by this LCO be approximately equally spaced.

The containment air locks, which are also part of the containment pressure boundary, provide a means for personnel access during MODES 1, 2, 3, and 4 operation in accordance with LCO 3.6.2, "Containment Air Locks." Each air lock has a door at both ends. The doors are normally interlocked to prevent simultaneous opening when containment OPERABILITY is required. During periods of shutdown when containment closure is not required, the door interlock mechanism may be disabled, allowing both doors of an air lock to remain open for extended periods when frequent containment entry is necessary. During movement of ~~[~~recently~~]~~ irradiated fuel assemblies within containment, containment closure is required; therefore, the door interlock mechanism may remain disabled, but one air lock door must ~~always~~ remain ~~[capable of being]~~ closed.

BASES

BACKGROUND (continued)

The requirements on containment penetration closure ensure that a release of fission product radioactivity within containment will be restricted to within regulatory limits.

INSERT 1

~~The Containment Purge and Exhaust System includes two subsystems. The normal subsystem includes a 42 inch purge penetration and a 42 inch exhaust penetration. The second subsystem, a minipurge system, includes an 8 inch purge penetration and an 8 inch exhaust penetration. During MODES 1, 2, 3, and 4, the two valves in each of the normal purge and exhaust penetrations are secured in the closed position. The two valves in each of the two minipurge penetrations can be opened intermittently, but are closed automatically by the Engineered Safety Features Actuation System (ESFAS). Neither of the subsystems is subject to a Specification in MODE 5.~~

1

~~In MODE 6, large air exchanges are necessary to conduct refueling operations. The normal 42 inch purge system is used for this purpose and all valves are closed by the ESFAS in accordance with LCO 3.3.2, "Reactor Protective System (RPS) - Shutdown."~~

~~[The minipurge system remains operational in MODE 6 and all four valves are also closed by the ESFAS.~~

~~[or]~~

~~The minipurge system is not used in MODE 6. All four [8] inch valves are secured in the closed position.]~~

The ~~other~~ containment penetrations that provide direct access from containment atmosphere to outside atmosphere must be isolated ~~on at least one side~~. Isolation may be achieved by an OPERABLE automatic isolation valve, or by a manual isolation valve, blind flange, or equivalent. Equivalent isolation methods must be approved and may include use of a material that can provide a temporary, atmospheric pressure ventilation barrier for the other containment penetrations during ~~[~~recently~~]~~ irradiated fuel movements ~~(Ref. 1)~~.

1

2

1

APPLICABLE SAFETY ANALYSES

During movement of irradiated fuel assemblies within containment, the most severe radiological consequences result from a fuel handling accident ~~[involving handling recently irradiated fuel]~~. The fuel handling accident is a postulated event that involves damage to irradiated fuel (Ref. ~~2~~). Fuel handling accidents, ~~analyzed in Ref. 3, include~~ dropping a

2

1

1

involve

1

1

INSERT 1

The Containment Purge and Exhaust System includes 48 inch purge supply and exhaust penetrations, and a second subsystem, the Hydrogen Purge System, includes a 2 inch makeup penetration (containing two manual isolation valves) and a 2 inch exhaust penetration (containing two 3 inch air operated isolation valves). During MODES 1, 2, 3, and 4, the two 48 inch valves in the purge supply and exhaust penetrations are secured in the closed position. The 2 inch and 3 inch valves can be opened intermittently. The purge supply and exhaust valves (48 inch and 3 inch) are closed automatically by the containment isolation signal (CIS).

BASES

APPLICABLE SAFETY ANALYSES (continued)

INSERT 2

single irradiated fuel assembly ~~and handling tool or a heavy object onto other irradiated fuel assemblies.~~ ~~The requirements of LCO 3.9.6, "Refueling Water Level," in conjunction with minimum decay time of [72] hours prior to [irradiated fuel movement with containment closure capability or a minimum decay time of [x] days without containment closure capability], ensure that the release of fission product radioactivity, subsequent to a fuel handling accident, results in doses that are well within the guideline values specified in 10 CFR 100. The acceptance limits for offsite radiation exposure are contained in Standard Review Plan Section 15.7.4, Rev. 1 (Ref. 3), which defines "well within" 10 CFR 100 to be 25% or less of the 10 CFR 100 values.~~ 1

Containment penetrations satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

~~----------REVIEWER'S NOTE----------~~
~~The allowance to have containment personnel air lock doors open and penetration flow paths with direct access from the containment atmosphere to the outside atmosphere to be unisolated during fuel movement is based on (1) confirmatory dose calculations of a fuel handling accident as approved by the NRC staff which indicate acceptable radiological consequences and (2) commitments from the licensee to implement acceptable administrative procedures that ensure in the event of a refueling accident (even though the containment fission product control function is not required to meet acceptable dose consequences) that the open air lock can and will be promptly closed following containment evacuation and that the open penetration(s) can and will be promptly closed. The time to close penetrations or combination of penetrations shall be included in the confirmatory dose calculations.~~
~~---------- 3~~

This LCO limits the consequences of a fuel handling accident ~~[~~involving handling recently irradiated fuel~~]~~ in containment by limiting the potential escape paths for fission product radioactivity released within containment. The LCO requires any penetration providing direct access from the containment atmosphere to the outside atmosphere to be closed except for the OPERABLE containment purge ~~and exhaust penetrations [and the containment personnel air locks]. For the OPERABLE containment purge and exhaust penetrations, this LCO ensures that these penetrations are isolable by the Containment Purge and Exhaust Isolation System.~~ The 2

supply and exhaust isolation valves capable of being closed by an OPERABLE CIS. 2 1

1

1

INSERT 2

The fuel handling accident analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. Additionally, containment closure is not assumed for a fuel handling accident inside containment. The Technical Requirements Manual includes a decay time requirement that no fuel movement will commence until 72 hours after shutdown. This ensures that the fuel handling accident analysis assumptions, including an open containment, are preserved.

The requirements of LCO 3.9.6, "Refueling Water Level," in conjunction with the minimum decay time prior to irradiated fuel movement, ensure that the release of fission product radioactivity, subsequent to a fuel handling accident, results in doses that are a small fraction of the guideline values specified in 10 CFR 50.67. The acceptance limits for offsite radiation exposure are contained in Table 1 of Standard Review Plan Section 15.0.1, Rev. 0 (Ref. 2), which are a small fraction of the 10 CFR 50.67 values.

BASES

LCO (continued)

OPERABILITY requirements for this LCO ensure that the automatic ~~purge and exhaust~~ valve closure times specified in the FSAR can be achieved ~~and therefore meet the assumptions used in the safety analysis to ensure releases through the valves are terminated, such that the radiological doses are within the acceptance limit.~~ The LCO is modified by a Note allowing penetration flow paths with direct access from the containment atmosphere to the outside atmosphere to be unisolated under administrative controls. Administrative controls ensure that 1) appropriate personnel are aware of the open status of the penetration flow path during movement of irradiated fuel assemblies within containment, and 2) specified individuals are designated and readily available to isolate the flow path in the event of a fuel handling accident.

~~The containment personnel air lock doors may be open during movement of [recently] irradiated fuel in the containment provided that one door is capable of being closed in the event of a fuel handling accident. Should a fuel handling accident occur inside containment, one personnel airlock door will be closed following an evacuations of containment.~~

APPLICABILITY

The containment penetration requirements are applicable during movement of ~~[~~recently~~]~~ irradiated fuel assemblies within containment ~~because this is when there is a potential for the limiting~~ fuel handling accident. In MODES 1, 2, 3, and 4, containment penetration requirements are addressed by LCO 3.6.1~~, "Containment."~~ In MODES 5 and 6, when movement of irradiated fuel assemblies within containment is not being conducted, the potential for a fuel handling accident does not exist. ~~[~~Additionally, due to radioactive decay, ~~a fuel handling~~ accident ~~involving~~ handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous ~~[X] days~~) will result in doses that are well within the guideline values specified in 10 CFR ~~100~~ even without containment closure capability.~~]~~ Therefore, under these conditions no requirements are placed on containment penetration status.

~~REVIEWER'S NOTE~~

~~The addition of the term "recently" associated with handling irradiated fuel in all of the containment function Technical Specification requirements is only applicable to those licensees who have demonstrated by analysis that after sufficient radioactive decay has occurred, off-site doses resulting from a fuel handling accident remain below the Standard Review Plan limits (well within 10 CFR 100).~~

BASES

APPLICABILITY (continued)

~~Additionally, licensees adding the term "recently" must make the following commitment which is consistent with NUMARC 93-01, Revision [4F], Section 11.3.6.5 "Safety Assessment for Removal of Equipment from Service During Shutdown Conditions," subheading "Containment - Primary (PWR)/Secondary (BWR)."~~

~~"The following guidelines are included in the assessment of systems removed from service during movement of irradiated fuel:~~

~~- During fuel handling/core alterations, ventilation system and radiation monitor availability (as defined in NUMARC 91-06) should be assessed, with respect to filtration and monitoring of releases from the fuel. Following shutdown, radioactivity in the fuel decays away fairly rapidly. The basis of the Technical Specification operability amendment is the reduction in doses due to such decay. The goal of maintaining ventilation system and radiation monitor availability is to reduce doses even further below that provided by the natural decay.~~

~~- A single normal or contingency method to promptly close primary or secondary containment penetrations should be developed. Such prompt methods need not completely block the penetration or be capable of resisting pressure.~~

~~The purpose of the "prompt methods" mentioned above are to enable ventilation systems to draw the release from a postulated fuel handling accident in the proper direction such that it can be treated and monitored."~~

3

ACTIONS

A.1~~ and A.2~~

1

With the containment equipment hatch, air locks, or any containment penetration that provides direct access from the containment atmosphere to the outside atmosphere not in the required status, including the ~~Containment Purge and Exhaust Isolation System~~ not capable of automatic actuation when ~~the purge and exhaust valves are open~~, the unit must be placed in a condition in which the isolation function is not needed. This is accomplished by immediately suspending movement of ~~[~~recently~]~~ irradiated fuel assemblies within containment. Performance of these actions shall not preclude completion of movement of a component to a safe position.

CIS

a required containment isolation valve in one or more penetrations with direct access from the containment atmosphere to the outside atmosphere is open

1

2

1

BASES

SURVEILLANCE REQUIREMENTS

SR 3.9.3.1

This Surveillance demonstrates that each of the containment penetrations required to be in its closed position is in that position. The Surveillance on the open ~~purge and exhaust~~ valves will demonstrate that the valves are not blocked from closing. Also, the Surveillance will demonstrate that each valve operator has motive power, which will ensure each valve is capable of being closed by an OPERABLE automatic ~~containment purge and exhaust isolation signa~~l.

containment isolation

in penetrations with direct access from the containment atmosphere to the outside atmosphere

CIS

1

1

~~[The Surveillance is performed every 7 days during movement of [recently] irradiated fuel assemblies within the containment. The Surveillance interval is selected to be commensurate with the normal duration of time to complete fuel handling operations. A surveillance before the start of refueling operations will provide two or three surveillance verifications during the applicable period for this LCO. As such, this Surveillance ensures that a postulated fuel handling accident [involving handling recently irradiated fuel] that releases fission product radioactivity within the containment will not result in a release of significant fission product radioactivity to the environment in excess of those recommended by Standard Review Plan Section 15.7.4 (Ref. 3).~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

3

SR 3.9.3.2

This Surveillance demonstrates that each containment ~~purge and exhaust~~ valve actuates to its isolation position on manual initiation or on an actual or simulated high radiation signal. ~~[The 18 month Frequency maintains consistency with other similar ESFAS instrumentation and valve testing requirements. In LCO 3.3.4 [(Digital) or 3.3.3 (Analog)], "Miscellaneous Actuations," the Containment Purge Isolation Signal System requires a CHANNEL CHECK every 7 days and a CHANNEL FUNCTIONAL TEST every 31 days to ensure the channel OPERABILITY during refueling~~

B 3.9 REFUELING OPERATIONS

B 3.9.3 Containment Penetrations

BASES

BACKGROUND

During movement of ~~[~~recently~~]~~ irradiated fuel assemblies within containment, a release of fission product radioactivity within the containment will be restricted from escaping to the environment when the LCO requirements are met. In MODES 1, 2, 3, and 4, this is accomplished by maintaining containment OPERABLE as described in LCO 3.6.1, "Containment." In MODE 6, the potential for containment pressurization as a result of an accident is not likely; therefore, requirements to isolate the containment from the outside atmosphere can be less stringent. The LCO requirements are referred to as "containment closure" rather than "containment OPERABILITY." Containment closure means that all potential escape paths are closed or capable of being closed. Since there is no potential for containment pressurization, the Appendix J leakage criteria and tests are not required. 2

The containment serves to contain fission product radioactivity that may be released from the reactor core following an accident, such that offsite radiation exposures are maintained well within the requirements of 10 CFR ~~100~~ 50.67. Additionally, the containment structure provides radiation shielding from the fission products that may be present in the containment atmosphere following accident conditions. 1

The containment equipment hatch, which is part of the containment pressure boundary, provides a means for moving large equipment and components into and out of containment. During movement of ~~[~~recently~~]~~ irradiated fuel assemblies within containment, the equipment hatch must be held in place by at least four bolts. Good engineering practice dictates that the bolts required by this LCO be approximately equally spaced. 2

The containment air locks, which are also part of the containment pressure boundary, provide a means for personnel access during MODES 1, 2, 3, and 4 operation in accordance with LCO 3.6.2, "Containment Air Locks." Each air lock has a door at both ends. The doors are normally interlocked to prevent simultaneous opening when containment OPERABILITY is required. During periods of shutdown when containment closure is not required, the door interlock mechanism may be disabled, allowing both doors of an air lock to remain open for extended periods when frequent containment entry is necessary. During movement of ~~[~~recently~~]~~ irradiated fuel assemblies within containment, containment closure is required; therefore, the door interlock mechanism may remain disabled, but one air lock door must ~~always~~ remain ~~[capable of being]~~ closed. 2 2

BASES

BACKGROUND (continued)

The requirements on containment penetration closure ensure that a release of fission product radioactivity within containment will be restricted to within regulatory limits.

INSERT 1

~~The Containment Purge and Exhaust System includes two subsystems. The normal subsystem includes a 42 inch purge penetration and a 42 inch exhaust penetration. The second subsystem, a minipurge system, includes an 8 inch purge penetration and an 8 inch exhaust penetration. During MODES 1, 2, 3, and 4, the two valves in each of the normal purge and exhaust penetrations are secured in the closed position. The two valves in each of the two minipurge penetrations can be opened intermittently, but are closed automatically by the Engineered Safety Features Actuation System (ESFAS). Neither of the subsystems is subject to a Specification in MODE 5.~~

1

~~In MODE 6, large air exchanges are necessary to conduct refueling operations. The normal 42 inch purge system is used for this purpose and all valves are closed by the ESFAS in accordance with LCO 3.3.2, "Reactor Protective System (RPS) - Shutdown."~~

~~[The minipurge system remains operational in MODE 6 and all four valves are also closed by the ESFAS.~~

~~[or]~~

~~The minipurge system is not used in MODE 6. All four [8] inch valves are secured in the closed position.]~~

The ~~other~~ containment penetrations that provide direct access from containment atmosphere to outside atmosphere must be isolated ~~on at least one side~~. Isolation may be achieved by an OPERABLE automatic isolation valve, or by a manual isolation valve, blind flange, or equivalent. Equivalent isolation methods must be approved and may include use of a material that can provide a temporary, atmospheric pressure ventilation barrier for the other containment penetrations during ~~[~~recently~~]~~ irradiated fuel movements ~~(Ref. 1)~~.

1

2

1

APPLICABLE SAFETY ANALYSES

During movement of irradiated fuel assemblies within containment, the most severe radiological consequences result from a fuel handling accident ~~[involving handling recently irradiated fuel]~~. The fuel handling accident is a postulated event that involves damage to irradiated fuel (Ref. ~~2~~). Fuel handling accidents, ~~analyzed in Ref. 3, include~~ dropping a

2

1

1

involve

1

1

INSERT 1

The Containment Purge and Exhaust System includes 48 inch purge supply and exhaust penetrations and 8 inch purge supply and exhaust penetrations. The second subsystem, a mini purge system, includes an 8 inch purge supply penetration and an 8 inch exhaust penetration. During MODES 1, 2, 3, and 4, the two 48 inch valves in the purge supply and exhaust penetrations are secured in the closed position. The two 8 inch valves can be opened intermittently. The purge supply and exhaust valves (48 inch and 8 inch) are closed automatically by the containment isolation actuation signal (CIAS).

BASES

APPLICABLE SAFETY ANALYSES (continued)

INSERT 2

single irradiated fuel assembly ~~and handling tool or a heavy object onto other irradiated fuel assemblies.~~ ~~The requirements of LCO 3.9.6, "Refueling Water Level," in conjunction with minimum decay time of [72] hours prior to [irradiated fuel movement with containment closure capability or a minimum decay time of [x] days without containment closure capability], ensure that the release of fission product radioactivity, subsequent to a fuel handling accident, results in doses that are well within the guideline values specified in 10 CFR 100. The acceptance limits for offsite radiation exposure are contained in Standard Review Plan Section 15.7.4, Rev. 1 (Ref. 3), which defines "well within" 10 CFR 100 to be 25% or less of the 10 CFR 100 values.~~

Containment penetrations satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

~~----------REVIEWER'S NOTE----------~~
~~The allowance to have containment personnel air lock doors open and penetration flow paths with direct access from the containment atmosphere to the outside atmosphere to be unisolated during fuel movement is based on (1) confirmatory dose calculations of a fuel handling accident as approved by the NRC staff which indicate acceptable radiological consequences and (2) commitments from the licensee to implement acceptable administrative procedures that ensure in the event of a refueling accident (even though the containment fission product control function is not required to meet acceptable dose consequences) that the open air lock can and will be promptly closed following containment evacuation and that the open penetration(s) can and will be promptly closed. The time to close penetrations or combination of penetrations shall be included in the confirmatory dose calculations.~~
~~----------~~

This LCO limits the consequences of a fuel handling accident ~~[~~involving handling recently irradiated fuel~~]~~ in containment by limiting the potential escape paths for fission product radioactivity released within containment. The LCO requires any penetration providing direct access from the containment atmosphere to the outside atmosphere to be closed except for the OPERABLE containment purge ~~and exhaust penetrations [and the containment personnel air locks]. For the OPERABLE containment purge and exhaust penetrations, this LCO ensures that these penetrations are isolable by the Containment Purge and Exhaust Isolation System.~~ The

supply and exhaust isolation valves capable of being closed by an OPERABLE CIS.

1

INSERT 2

The fuel handling accident analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. Additionally, containment closure is not assumed for a fuel handling accident inside containment. The Technical Requirements Manual includes a decay time requirement that no fuel movement will commence until 72 hours after shutdown. This ensures that the fuel handling accident analysis assumptions, including an open containment, are preserved.

The requirements of LCO 3.9.6, "Refueling Water Level," in conjunction with the minimum decay time prior to irradiated fuel movement, ensure that the release of fission product radioactivity, subsequent to a fuel handling accident, results in doses that are a small fraction of the guideline values specified in 10 CFR 50.67. The acceptance limits for offsite radiation exposure are contained in Table 1 of Standard Review Plan Section 15.0.1, Rev. 0 (Ref. 2), which are a small fraction of the 10 CFR 50.67 values.

BASES

LCO (continued)

OPERABILITY requirements for this LCO ensure that the automatic ~~purge and exhaust~~ valve closure times specified in the FSAR can be achieved ~~and therefore meet the assumptions used in the safety analysis to ensure releases through the valves are terminated, such that the radiological doses are within the acceptance limit.~~ The LCO is modified by a Note allowing penetration flow paths with direct access from the containment atmosphere to the outside atmosphere to be unisolated under administrative controls. Administrative controls ensure that 1) appropriate personnel are aware of the open status of the penetration flow path during movement of irradiated fuel assemblies within containment, and 2) specified individuals are designated and readily available to isolate the flow path in the event of a fuel handling accident.

~~The containment personnel air lock doors may be open during movement of [recently] irradiated fuel in the containment provided that one door is capable of being closed in the event of a fuel handling accident. Should a fuel handling accident occur inside containment, one personnel airlock door will be closed following an evacuations of containment.~~

APPLICABILITY

The containment penetration requirements are applicable during movement of ~~[~~recently~]~~ irradiated fuel assemblies within containment ~~because this is when there is a potential for the limiting~~ fuel handling accident. In MODES 1, 2, 3, and 4, containment penetration requirements are addressed by LCO 3.6.1~~, "Containment."~~ In MODES 5 and 6, when movement of irradiated fuel assemblies within containment is not being conducted, the potential for a fuel handling accident does not exist. ~~[~~Additionally, due to radioactive decay, ~~a fuel handling~~ accident ~~involving~~ handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous ~~[X] days~~) will result in doses that are well within the guideline values specified in 10 CFR ~~100~~ even without containment closure capability.~~]~~ Therefore, under these conditions no requirements are placed on containment penetration status.

~~REVIEWER'S NOTE~~

~~The addition of the term "recently" associated with handling irradiated fuel in all of the containment function Technical Specification requirements is only applicable to those licensees who have demonstrated by analysis that after sufficient radioactive decay has occurred, off-site doses resulting from a fuel handling accident remain below the Standard Review Plan limits (well within 10 CFR 100).~~

BASES

APPLICABILITY (continued)

~~Additionally, licensees adding the term "recently" must make the following commitment which is consistent with NUMARC 93-01, Revision [4F], Section 11.3.6.5 "Safety Assessment for Removal of Equipment from Service During Shutdown Conditions," subheading "Containment - Primary (PWR)/Secondary (BWR)."~~

~~"The following guidelines are included in the assessment of systems removed from service during movement of irradiated fuel:~~

~~- During fuel handling/core alterations, ventilation system and radiation monitor availability (as defined in NUMARC 91-06) should be assessed, with respect to filtration and monitoring of releases from the fuel. Following shutdown, radioactivity in the fuel decays away fairly rapidly. The basis of the Technical Specification operability amendment is the reduction in doses due to such decay. The goal of maintaining ventilation system and radiation monitor availability is to reduce doses even further below that provided by the natural decay.~~

~~- A single normal or contingency method to promptly close primary or secondary containment penetrations should be developed. Such prompt methods need not completely block the penetration or be capable of resisting pressure.~~

~~The purpose of the "prompt methods" mentioned above are to enable ventilation systems to draw the release from a postulated fuel handling accident in the proper direction such that it can be treated and monitored."~~

3

ACTIONS

A.1~~ and A.2~~

1

With the containment equipment hatch, air locks, or any containment penetration that provides direct access from the containment atmosphere to the outside atmosphere not in the required status, including the ~~Containment Purge and Exhaust Isolation System~~ not capable of automatic actuation when ~~the purge and exhaust valves are open~~, the unit must be placed in a condition in which the isolation function is not needed. This is accomplished by immediately suspending movement of ~~[~~recently~]~~ irradiated fuel assemblies within containment. Performance of these actions shall not preclude completion of movement of a component to a safe position.

CIS

a required containment isolation valve in one or more penetrations with direct access from the containment atmosphere to the outside atmosphere is open

DISCUSSION OF CHANGES
ITS 3.9.4, SHUTDOWN COOLING (SDC) AND COOLANT CIRCULATION – HIGH WATER LEVEL

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.9.8.1 Action a. states, in part, that with less than one shutdown cooling (SDC) loop in operation, suspend all operations involving an increase in the reactor decay heat load of the RCS. Similarly, Unit 2 CTS 3.9.8.1 Action states, in part, that with no SDC loop in operation, suspend all operations involving an increase in the reactor decay heat load of the RCS. ITS 3.9.4 Required Action A.3 states, in part, that with one required SDC loop inoperable or not in operation, suspend loading irradiated fuel assemblies in the core. This changes the CTS by requiring that the loading of irradiated fuel assemblies be suspended instead of requiring that all operations involving an increase in the reactor decay heat load be suspended.

This change is acceptable because the requirements have not changed. The reactor decay heat load is generated only by irradiated fuel. The only method of increasing the decay heat load of a reactor in MODE 6 is to load additional irradiated fuel assemblies into the core. Therefore, the CTS and ITS requirements are equivalent. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 **Unit 1 only:** CTS 3.9.8.1 Action b. states "The provisions of Specification 3.0.3 are not applicable." ITS 3.9.4 does not include this statement. This changes CTS by deleting the Specification 3.0.3 exception. This change is acceptable because the technical requirements have not changed. ITS LCO 3.0.3 is not applicable in MODE 6. Therefore, the CTS LCO 3.0.3 exception is not needed. This change is designated as administrative because it does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS 3.9.8.1 requires at least one SDC loop to be OPERABLE and in operation in MODE 6 when the water level above the top of the irradiated fuel assemblies seated within the reactor pressure vessel is ≥ 23 feet. ITS 3.9.4 requires one SDC loop to be OPERABLE and in operation when water level is ≥ 23 feet above the top of the reactor vessel flange. This changes the CTS by changing the point at which one SDC loop is required to be OPERABLE and in operation.

The purpose of CTS 3.9.8.1 is to ensure adequate SDC is available and in operation for heat removal and coolant circulation. CTS 3.9.8.1 and CTS 3.9.8.2

provide the requirements when water level is ≥ 23 feet and < 23 feet above the top of the irradiated fuel assemblies seated within the reactor pressure vessel, respectively. When water level is ≥ 23 feet above the top of the irradiated fuel assemblies seated within the reactor pressure vessel, only one SDC loop is required to be OPERABLE and in operation. When water level is < 23 feet above the top of the irradiated fuel assemblies seated within the reactor pressure vessel, two SDC loops are required to be OPERABLE, and one must be in operation. In ITS 3.9.4 and ITS 3.9.5, the equivalent ITS requirements, the water level reference point is the top of the reactor vessel flange, not the top of the irradiated fuel assemblies seated within the reactor pressure vessel. Changing this reference point effectively requires a larger complement of SDC loops to be OPERABLE between 23 feet above the top of the irradiated fuel assemblies seated within the reactor pressure vessel and 23 feet above the top of the reactor vessel flange. Therefore, this change is acceptable because more loops will be required to be OPERABLE under certain water level conditions to ensure the decay heat can be removed and the coolant circulated. This change is designated more restrictive because more SDC loops are required OPERABLE in the ITS under certain water level conditions than were required in the CTS.

M02 **Unit 1 only:** CTS 3.9.8.1 Actions do not include an action to immediately initiate action to satisfy the SDC loop requirements in the event the SDC loop requirements are not met. ITS 3.9.4 Required Action A.1 requires that action be immediately initiated to satisfy the SDC loop requirements. This changes the CTS by requiring action be taken immediately to satisfy the SDC loop requirements.

The purpose of CTS 3.9.8.1 is to ensure that adequate decay heat removal and coolant circulation are available in MODE 6. Although decay heat is removed from the Reactor Coolant System via natural circulation to the bulk of water contained in the refueling cavity, this method of heat transfer can continue for only a discrete amount of time before boiling would occur. In addition, with no forced circulation, RCS flow may not be adequate to support coolant mixing to maintain uniform boron concentrations. This change is acceptable because it requires that action be initiated to restore the SDC loop requirements in order to restore forced coolant flow and heat removal. This change is designated as more restrictive because additional actions will be required in the ITS than are required in the CTS.

M03 **Unit 2 only**: CTS 3.9.8.1 Action states, in part, within one (1) hour initiate corrective action to return the required shutdown cooling loop to operation. ITS 3.9.4 Required Action A.1 states immediately initiate action to restore one SDC loop to OPERABLE status and operation. This changes the CTS by revising the Actions to “immediately” require actions to be taken when a required SDC loop is not in operation. | R1 | R1

This change is acceptable because it provides appropriate immediate actions for a required SDC loop not in operation. This action is required to assure continued safe operation. Action to restore one SDC loop to OPERABLE status and operation is necessary to be able to remove the decay heat generated by the reactor. The immediate Completion Time reflects the importance of maintaining operation for decay heat removal. This change is designated as more restrictive

because the time to complete the actions is added in the ITS that is not required in the CTS.

M04 CTS 3.9.8.1 Actions do not include a Completion Time to immediately initiate action to suspend operations that would cause the introduction into the RCS, coolant with boron concentration less than required to meet the boron concentration of Technical Specification 3.9.1. ITS 3.9.4 Required Action A.2 requires that action be immediately initiated to suspend operations that would cause introduction of coolant into the RCS that does not meet the minimum boron concentration requirement. This changes the CTS by requiring that action be taken immediately to perform a Required Action.

The purpose of CTS 3.9.8.1 is to ensure that adequate decay heat removal and coolant circulation are available in MODE 6. If SDC loop requirements are not met, there will be no forced circulation to provide mixing to establish uniform boron concentrations. Immediately suspending operations that could result in failure to meet the minimum boron concentration limit is required to assure continued safe operation. This change is designated as more restrictive because a Completion Time in ITS is being added to the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.9.8.1 Action a. states, in part, that with less than one SDC loop in operation, close all containment penetrations providing direct access from the containment atmosphere to the outside atmosphere within 4 hours. Similarly, Unit 2 CTS 3.9.8.1 Action states, in part, that with no SDC loop in operation, close all containment penetrations providing direct access from the containment atmosphere to the outside atmosphere within 4 hours. ITS 3.9.4 Required Actions A.4, A.5, and A.6 state that with the SDC loop requirements not met, within 4 hours close and secure the equipment hatch with at least four bolts, close one door in each air lock, and verify each penetration providing direct access from the containment atmosphere to the outside atmosphere is either closed with a manual or automatic isolation valve, blind flange, or equivalent, or is capable of being closed by an OPERABLE Containment Isolation System. This changes the CTS Actions by specifying the applicable containment penetration requirements to satisfy “each penetration” and by separating the CTS action into allowing penetrations capable of being closed by an OPERABLE Containment Isolation System to remain open when the SDC requirements are not met.

The purpose of the CTS 3.9.8.1 Action is to ensure that radioactive material does not escape the containment should the SDC requirements continue to not be met and boiling occurs in the core. Therefore, containment penetrations are closed to seal the containment. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of an accident occurring during the repair period. The Required Actions are consistent with the actions taken for containment closure in CTS 3.9.4 (ITS 3.9.3). Penetrations which can be closed by an OPERABLE Containment Isolation System do not need to be closed if SDC is inoperable, since the presence of radioactivity in the containment will cause the valves to close automatically, thus performing the isolation function. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 3 – Relaxation of Completion Time)* CTS 3.9.8.1 Footnote * states, in part, that the SDC loop may be removed from operation for up to 1 hour per 8 hour period during the performance of CORE ALTERATIONS in the vicinity of the reactor pressure vessel hot legs, provided no operations are permitted that would cause introduction into the RCS, coolant with boron concentration less than required to meet the SHUTDOWN MARGIN of Technical Specification 3.9.1. ITS LCO 3.9.4 Note states that the required SDC loop may be removed from operation for ≤ 1 hour per 8 hour period, provided no operations are permitted that would cause introduction of coolant into the Reactor Coolant System with boron concentration less than that required to meet the minimum required boron concentration of LCO 3.9.1, "Boron Concentration." The allowance to remove SDC from operation is no longer restricted to CORE ALTERATIONS in the vicinity of the reactor pressure vessel hot legs. This changes the CTS by allowing the SDC loop to be removed from operation during conditions other than CORE ALTERATIONS in the vicinity of the reactor pressure vessel hot legs. | R1

The purpose of the allowance to remove the SDC loop from operation for up to 1 hour per 8 hour period is to perform certain activities that cannot be performed with a SDC loop in service; for example, core mapping or alterations in the vicinity of the reactor vessel hot leg nozzles, and RCS to SDC isolation valve testing. This change is acceptable because, during the 1 hour period, decay heat is removed by natural convection due to the large mass of water in the refueling cavity and appropriate controls are continue to be provided in the Technical Specifications during periods when SDC is not in operation prohibiting activities that would cause introduction of coolant into the RCS with boron concentration less than the minimum required boron concentration to preserve SHUTDOWN MARGIN and avoid unexpected reactivity changes. This change is designated as less restrictive because the scope of the current allowance is expanded to be less stringent in the ITS than applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.9.4, SHUTDOWN COOLING (SDC) AND COOLANT CIRCULATION – HIGH WATER LEVEL

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Change made to be consistent with the ISTS format as specified in the Writer's Guide for the Improved Standard Technical Specifications, TSTF GG 05 01 and other Specifications; for example, LCO 3.8.2.a reference to LCO 3.8.10, “Distribution Systems – Shutdown.”

4. ISTS 3.9.4 Required Actions A.6.1 and A.6.2 are connected by an "OR" logical connector, such that either one can be performed to meet the requirements of the ACTION. However, the two Required Actions as presented in the ISTS are applicable to all the applicable containment penetrations; either Required Action A.6.1 or Required Action A.6.2 must be performed. Thus, the ISTS presentation will not allow one penetration to be isolated by use of a manual valve and another penetration to be capable of being closed by an OPERABLE Containment Isolation System. This is not the intent of the requirement. The requirement is based on ISTS LCO 3.9.3, which requires each penetration to be either: a) closed by a manual or automatic isolation valve, blind flange, or equivalent; or b) capable of being closed by an OPERABLE Containment Isolation System. For consistency with the actual LCO requirement, ISTS 3.9.4 Required Actions A.6.1 and A.6.2 have been combined into a single Required Action in ITS 3.9.4 Required Action A.6. This will allow each of the applicable containment penetrations to be either isolated or capable of being isolated, as required, to ensure containment closure can be achieved.

5. **Unit 2 only:** A Note is added to ITS SR 3.9.4.1 that allows a reduction of reactor coolant flow rate when specific conditions are met consistent with the St. Lucie Plant Unit 2 current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.9 REFUELING OPERATIONS

B 3.9.4 Shutdown Cooling (SDC) and Coolant Circulation - High Water Level

BASES

BACKGROUND

The purposes of the SDC System in MODE 6 are to remove decay heat and sensible heat from the Reactor Coolant System (RCS) ~~, as required by GDC 34,~~ to provide mixing of borated coolant, to provide sufficient coolant circulation to minimize the effects of a boron dilution accident, and to prevent boron stratification (Ref. 1). Heat is removed from the RCS by circulating reactor coolant through the SDC heat exchanger(s), where the heat is transferred to the Component Cooling Water (CCW) System via the SDC heat exchanger(s). The coolant is then returned to the RCS via the RCS cold leg(s). Operation of the SDC System for normal cooldown or decay heat removal is manually accomplished from the control room. The heat removal rate is adjusted by controlling the flow of reactor coolant through the SDC heat exchanger(s) and bypassing the heat exchanger(s). Mixing of the reactor coolant is maintained by this continuous circulation of reactor coolant through the SDC System, as well as adjustments in CCW temperature and flow.

APPLICABLE SAFETY ANALYSES

If the reactor coolant temperature is not maintained below 200°F, boiling of the reactor coolant could result. This could lead to inadequate cooling of the reactor fuel due to a resulting loss of coolant in the reactor vessel. Additionally, boiling of the reactor coolant could lead to a reduction in boron concentration in the coolant due to the boron plating out on components near the areas of the boiling activity, and because of the possible addition of water to the reactor vessel with a lower boron concentration than is required to keep the reactor subcritical. The loss of reactor coolant and the reduction of boron concentration in the reactor coolant would eventually challenge the integrity of the fuel cladding, which is a fission product barrier. One ~~train~~ loop of the SDC System is required to be operational in MODE 6, with the water level ≥ 23 ft above the top of the reactor vessel flange, to prevent this challenge. The LCO does permit the SDC pump to be removed from operation for short durations under the condition that the boron concentration is not diluted. This conditional stopping of the SDC pump does not result in a challenge to the fission product barrier.

SDC and Coolant Circulation - High Water Level satisfies Criterion ~~2~~ 4 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

Only one SDC loop is required for decay heat removal in MODE 6, with water level ≥ 23 ft above the top of the reactor vessel flange. Only one SDC loop is required because the volume of water above the reactor vessel flange provides backup decay heat removal capability. At least one SDC loop must be OPERABLE and in operation to provide:

a. Removal of decay heat, and

b. Mixing of borated coolant to minimize the possibility of a criticality~~, and~~

~~c. Indication of reactor coolant temperature~~.

An OPERABLE SDC loop includes an SDC pump, a heat exchanger, valves, piping, instruments, and controls to ensure an OPERABLE flow path ~~and to determine the low end temperature~~. The flow path starts in one of the RCS hot legs and is returned to the RCS cold legs. Management of gas voids is important to SDC System OPER~~E~~ABILITY.

Additionally, since the SDC System is a manually operated system (i.e., it is not automatically actuated), each SDC loop is OPERABLE if it can be manually aligned (remote or local) to the SDC mode.

Both SDC pumps may be aligned to the Refueling Water Storage Tank to support filing or draining the refueling cavity or for performance of required testing.

The LCO is modified by a Note that allows the required operating SDC loop to be removed from operation for up to 1 hour in each 8 hour period, provided no operations are permitted that would dilute the RCS boron concentration by introduction of coolant into the RCS with boron concentration less than required to meet the minimum boron concentration of LCO 3.9.1~~.~~ Boron concentration reduction with coolant at boron concentrations less than required to assure the RCS boron concentration is maintained is prohibited because uniform concentration distribution cannot be ensured without forced circulation. This permits operations such as core mapping or alterations in the vicinity of the reactor vessel hot leg nozzles, and RCS to SDC isolation valve testing. During this 1 hour period, decay heat is removed by natural convection to the large mass of water in the refueling cavity.

APPLICABILITY

One SDC loop must be in operation in MODE 6, with the water level ≥ 23 ft above the top of the reactor vessel flange, to provide decay heat removal. The 23 ft level was selected because it corresponds to the 23 ft requirement established for fuel movement in LCO 3.9.6, "Refueling Water Level." Requirements for the SDC System in other MODES are covered by LCOs in Section 3.4, Reactor Coolant System (RCS)~~, and Section 3.5, Emergency Core Cooling Systems (ECCS)~~. SDC loop requirements in MODE 6, with the water level < 23 ft above the top of the reactor vessel flange, are located in LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level."

BASES

ACTIONS

SDC loop requirements are met by having one SDC loop OPERABLE and in operation, except as permitted in the Note to the LCO.

A.1

If one required SDC loop is inoperable or not in operation, action shall be immediately initiated and continued until the SDC loop is restored to OPERABLE status and to operation. An immediate Completion Time is necessary for an operator to initiate corrective actions.

A.2

If SDC loop requirements are not met, there will be no forced circulation to provide mixing to establish uniform boron concentrations. Suspending positive reactivity additions that could result in failure to meet the minimum boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation.

A.3

If SDC loop requirements are not met, actions shall be taken immediately to suspend loading irradiated fuel assemblies in the core. With no forced circulation cooling, decay heat removal from the core occurs by natural convection to the heat sink provided by the water above the core. A minimum refueling water level of 23 ft above the reactor vessel flange provides an adequate available heat sink. Suspending any operation that would increase the decay heat load, such as loading a fuel assembly, is a prudent action under this condition.

A.4, A.5~~, A.6.1,~~ and A.6~~.2~~ 6

If no SDC loop is in operation, the following actions must be taken:

a. The equipment hatch must be closed and secured with ~~[~~four~~]~~ bolts, 2

b. One door in each air lock must be closed, and

BASES

ACTIONS (continued)

c. Each penetration providing direct access from the containment atmosphere to the outside atmosphere must be either closed by a manual or automatic isolation valve, blind flange, or equivalent, or verified to be capable of being closed by an OPERABLE Containment ~~Purge and Exhaust~~ Isolation System. 1

With SDC loop requirements not met, the potential exists for the coolant to boil and release radioactive gas to the containment atmosphere. Performing the actions described above ensures that all containment penetrations are either closed or can be closed so that the dose limits are not exceeded.

The Completion Time of 4 hours allows fixing of most SDC problems and is reasonable, based on the low probability of the coolant boiling in that time.

SURVEILLANCE REQUIREMENTS

SR 3.9.4.1

This Surveillance demonstrates that the SDC loop is in operation and circulating reactor coolant. The flow rate is determined by the flow rate necessary to provide sufficient decay heat removal capability and to prevent thermal and boron stratification in the core. ~~[The Frequency of 12 hours is sufficient, considering the flow, temperature, pump control, and alarm indications available to the operator in the control room for monitoring the SDC System.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~----------]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.9.4.2

SDC System piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the required SDC loop(s) and may also prevent water hammer, pump cavitation, and pumping of noncondensible gas into the reactor vessel.

Selection of SDC System locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

The SDC System is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. If accumulated gas is discovered that exceeds the acceptance criteria for the susceptible location (or the volume of accumulated gas at one or more susceptible locations exceeds an acceptance criteria for gas volume at the suction or discharge of a pump), the Surveillance is not met. If the accumulated gas is eliminated or brought within the acceptance criteria limits during performance of the Surveillance, the Surveillance is met and past system OPERABILITY is evaluated under the Corrective Action Program. If it is determined by subsequent evaluation that the SDC System is not rendered inoperable by the accumulated gas (i.e., the system is sufficiently filled with water), the Surveillance may be declared met. Accumulated gas should be eliminated or brought within the acceptance criteria limits.

SDC System locations susceptible to gas accumulation are monitored and, if gas is found, the gas volume is compared to the acceptance criteria for the location. Susceptible locations in the same system flow path which are subject to the same gas intrusion mechanisms may be verified by monitoring a representative sub-set of susceptible locations. Monitoring may not be practical for locations that are inaccessible due to radiological or environmental conditions, the plant configuration, or personnel safety. For these locations alternative methods (e.g., operating parameters, remote monitoring) may be used to monitor the susceptible

BASES

SURVEILLANCE REQUIREMENTS (continued)

location. Monitoring is not required for susceptible locations where the maximum potential accumulated gas void volume has been evaluated and determined to not challenge system OPERABILITY. The accuracy of the method used for monitoring the susceptible locations and trending of the results should be sufficient to assure system OPERABILITY during the Surveillance interval.

~~[The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the SDC System piping and the procedural controls governing system operation.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. The Surveillance Frequency may vary by location susceptible to gas accumulation.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

, Boron Concentration."

APPLICABILITY

One SDC loop must be in operation in MODE 6, with the water level ≥ 23 ft above the top of the reactor vessel flange, to provide decay heat removal. The 23 ft level was selected because it corresponds to the 23 ft requirement established for fuel movement in LCO 3.9.6, "Refueling Water Level." Requirements for the SDC System in other MODES are covered by LCOs in Section 3.4, Reactor Coolant System (RCS)~~, and Section 3.5, Emergency Core Cooling Systems (ECCS)~~. SDC loop requirements in MODE 6, with the water level < 23 ft above the top of the reactor vessel flange, are located in LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level."

BASES

ACTIONS

SDC loop requirements are met by having one SDC loop OPERABLE and in operation, except as permitted in the Note to the LCO.

A.1

If one required SDC loop is inoperable or not in operation, action shall be immediately initiated and continued until the SDC loop is restored to OPERABLE status and to operation. An immediate Completion Time is necessary for an operator to initiate corrective actions.

A.2

If SDC loop requirements are not met, there will be no forced circulation to provide mixing to establish uniform boron concentrations. Suspending positive reactivity additions that could result in failure to meet the minimum boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation.

A.3

If SDC loop requirements are not met, actions shall be taken immediately to suspend loading irradiated fuel assemblies in the core. With no forced circulation cooling, decay heat removal from the core occurs by natural convection to the heat sink provided by the water above the core. A minimum refueling water level of 23 ft above the reactor vessel flange provides an adequate available heat sink. Suspending any operation that would increase the decay heat load, such as loading a fuel assembly, is a prudent action under this condition.

A.4, A.5~~, A.6.1,~~ and A.6~~.2~~ 6

If no SDC loop is in operation, the following actions must be taken:

a. The equipment hatch must be closed and secured with ~~[~~four~~]~~ bolts, 2

b. One door in each air lock must be closed, and

BASES

ACTIONS (continued)

c. Each penetration providing direct access from the containment atmosphere to the outside atmosphere must be either closed by a manual or automatic isolation valve, blind flange, or equivalent, or verified to be capable of being closed by an OPERABLE Containment ~~Purge and Exhaust~~ Isolation System. 1

With SDC loop requirements not met, the potential exists for the coolant to boil and release radioactive gas to the containment atmosphere. Performing the actions described above ensures that all containment penetrations are either closed or can be closed so that the dose limits are not exceeded.

The Completion Time of 4 hours allows fixing of most SDC problems and is reasonable, based on the low probability of the coolant boiling in that time.

SURVEILLANCE REQUIREMENTS

SR 3.9.4.1

This Surveillance demonstrates that the SDC loop is in operation and circulating reactor coolant. The flow rate is determined by the flow rate necessary to provide sufficient decay heat removal capability and to prevent thermal and boron stratification in the core. ~~[The Frequency of 12 hours is sufficient, considering the flow, temperature, pump control, and alarm indications available to the operator in the control room for monitoring the SDC System.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

The SR is modified by a Note that provides an allowance to reduce the required RCS flow rate when specific conditions are met. The time after reactor shutdown, RCS temperature, and CCW temperature to the shutdown cooling heat exchanger are initial conditions to ensure a reduced SDC flow rate will not result in a temperature transient exceeding the established refueling operational temperature limit. 1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.9.4.2

SDC System piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the required SDC loop(s) and may also prevent water hammer, pump cavitation, and pumping of noncondensible gas into the reactor vessel.

Selection of SDC System locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

The SDC System is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. ITS 3.9.4, BASES, SHUTDOWN COOLING (SDC) AND COOLANT CIRCULATION – HIGH WATER LEVEL

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The SDC and Coolant Circulation Technical Specification requirements in MODE 6 do not represent a process variable, design feature, or operating restriction that is an initial condition of a design basis accident or transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier. Therefore, these requirements do not meet Criterion 2 of 10 CFR 50.35(c)(2)(ii) at St. Lucie Plant Unit 1 and Unit 2. The SDC and Coolant Circulation Technical Specification requirements in MODE 6 do meet Criterion 4 of 10 CFR 50.35(c)(2)(ii) because this system is an important contributor to risk reduction in the plant specific probabilistic risk assessment. Therefore, the ISTS reference to the 10 CFR 50.36(c)(2)(ii) criterion is changed from 2 to 4 in the ITS.

4. Typographical/grammatical error corrected.

5. Change made to be consistent with the ISTS format as specified in the Writer's Guide for the Improved Standard Technical Specifications, TSTF GG 05 01 and other ISTS Bases (e.g., ISTS Bases 3.9.1 refers to LCO 3.9.4, "Shutdown Cooling and Coolant Circulation - High Water Level").

6. Changes are made to reflect changes made to the Specification.

DISCUSSION OF CHANGES
ITS 3.9.5, SHUTDOWN COOLING (SDC) AND COOLANT CIRCULATION – LOW WATER LEVEL

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 1 only:** CTS 3.9.8.2 Action c. states "The provisions of Specification 3.0.3 are not applicable." ITS 3.9.5 does not include this statement. This changes CTS by deleting the Specification 3.0.3 exception. This change is acceptable because the technical requirements have not changed. ITS LCO 3.0.3 is not applicable in MODE 6. Therefore, the CTS LCO 3.0.3 exception is not needed. This change is designated as administrative because it does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS 3.9.8.2 requires two shutdown cooling (SDC) loops to be OPERABLE and one SDC loop in operation in MODE 6 when the water level above the top of the irradiated fuel assemblies seated within the reactor pressure vessel is < 23 feet. ITS 3.9.5 requires two SDC loops to be OPERABLE and one SDC loop in operation when water level is < 23 feet above the top of the reactor vessel flange. This changes the CTS by changing the point at which two SDC loops are required to be OPERABLE and one in operation.

The purpose of CTS 3.9.8.2 is to ensure adequate SDC is available and in operation for heat removal and coolant circulation. CTS 3.9.8.1 and CTS 3.9.8.2 provide the requirements when water level is ≥ 23 feet and < 23 feet above the top of the irradiated fuel assemblies seated within the reactor pressure vessel, respectively. When water level is ≥ 23 feet above the top of the irradiated fuel assemblies seated within the reactor pressure vessel, only one SDC loop is required to be OPERABLE and in operation. When water level is < 23 feet above the top of the irradiated fuel assemblies seated within the reactor pressure vessel, two SDC loops are required to be OPERABLE, and one must be in operation. In ITS 3.9.4 and ITS 3.9.5, the equivalent ITS requirements, the water level reference point is the top of the reactor vessel flange, not the top of the irradiated fuel assemblies seated within the reactor pressure vessel. Changing this reference point effectively requires a larger complement of SDC loops to be OPERABLE between 23 feet above the top of the irradiated fuel assemblies seated within the reactor pressure vessel and 23 feet above the top of the reactor vessel flange. Therefore, this change is acceptable because more loops will be required to be OPERABLE under certain water level conditions to ensure the decay heat can be removed and the coolant circulated. This change is designated more restrictive because more SDC loops are required OPERABLE in the ITS under certain water level conditions than were required in the CTS.

M02 CTS 3.9.8.2 Action a. states, in part, that with one SDC loop inoperable, within one (1) hour initiate corrective action to return the required loop to OPERABLE status or to restore reactor cavity water level to greater than or equal to the limit. CTS 3.9.8.2 Action b. states that with no SDC loop OPERABLE or in operation, within one (1) hour initiate corrective action to return the required shutdown cooling loop to operation. ITS 3.9.5 ACTIONS A and B require similar actions but require the initiation of the Required Actions immediately.

CTS 3.9.8.2 Action b does not include a Completion Time to initiate action to suspend operations that would cause the introduction into the RCS, coolant with boron concentration less than required to meet the boron concentration of Technical Specification 3.9.1. ITS 3.9.5 Required Action B.1 requires that action be immediately initiated to suspend operations that would cause introduction of coolant into the RCS that does not meet the minimum boron concentration requirement. This changes the CTS by requiring that actions be taken immediately to satisfy the SDC loop requirements.

The purpose of CTS 3.9.8.2 is to ensure that adequate decay heat removal and coolant circulation are available in MODE 6. If the SDC loop requirements are not met, there will be no forced circulation to provide decay heat removal or coolant circulation to maintain uniform boron concentrations. Immediately initiating action to restore SDC loops to OPERABLE status with one in operation and immediately suspending operations that could result in failure to meet the minimum boron concentration limit are required to assure continued safe operation. The immediate Completion Time reflects the importance of restoring operation for decay heat removal and suspending the specified operations. This change is designated as more restrictive because the immediate Completion Time in ITS is more restrictive than the CTS Completion Time of 1 hour.

M03 The CTS 3.9.8.2 requires two independent SDC loops to be OPERABLE. ITS SR 3.9.5.2 requires periodic verification of correct breaker alignment and that indicated power is available to the required SDC pump not in operation in accordance with the Surveillance Frequency Control Program. This changes the CTS by adding a Surveillance Requirement.

The purpose of ITS 3.9.5 is to require one SDC loop to be in operation and one SDC loop to be held in readiness should it be needed. This change is necessary to ensure that the SDC loop that is in standby will be ready should it be needed to provide decay heat removal and coolant circulation.

PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, SR 3.9.5.2 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 7 days consistent with the ISTS SR 3.9.5.2 Frequency. The initial Frequency is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.

This change is designated as more restrictive because it adds a new Surveillance Requirement to the CTS.

DISCUSSION OF CHANGES
ITS 3.9.5, SHUTDOWN COOLING (SDC) AND COOLANT CIRCULATION – LOW WATER LEVEL

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 1 – Relaxation of LCO Requirements)* ITS 3.9.5 is modified by a Note (Note 1) that allows all SDC pumps to be removed from operation for ≤ 15 minutes when switching from one loop to another, provided several conditions are met. CTS 3.9.8.2 does not contain this allowance. This changes the CTS by allowing the LCO to not be met under certain situations.

The purpose of CTS 3.9.8.2 is to ensure sufficient decay heat removal is available in the specified MODE and condition. The ITS Note allows an operational evolution for switching from one loop to another while in the Applicability of the Specification. This evolution is necessary to demonstrate SDC OPERABILITY. This change is acceptable because the time period is short and specific controls are required to preclude reaching saturation conditions and to preclude reducing the required RCS boron concentration. The circumstances for stopping both SDC pumps are to be limited to 15 minutes when switching SDC loops and requires the core outlet temperature to be maintained > 10°F below saturation temperature. The Note also prohibits boron dilution by introduction of coolant into the RCS with boron concentration less than that required to meet the minimum boron concentration of LCO 3.9.1, Boron Concentration, and draining operations that could further reduce RCS water volume. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than were applied in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.9.8.2 Action b. states, in part, that with no SDC loop in operation, close all containment penetrations providing direct access from the containment atmosphere to the outside atmosphere within 4 hours. ITS 3.9.5 Required Actions B.3, B.4, and B.5 state that with the SDC loop requirements not met, within 4 hours close and secure the equipment hatch with at least four bolts, close one door in each air lock, and verify each penetration providing direct access from the containment atmosphere to the outside atmosphere is either closed with a manual or automatic isolation valve, blind flange, or equivalent, or is capable of being closed by an OPERABLE Containment Isolation System. This changes the CTS Actions by specifying the applicable containment penetration requirements to satisfy “each containment penetration” and by separating the CTS action into allowing penetrations capable of being closed by an OPERABLE Containment Isolation System to remain open when the SDC requirements are not met.

The purpose of the CTS 3.9.8.2 Action is to ensure that radioactive material does not escape the containment should the SDC requirements continue to not be met

and boiling occurs in the core. Therefore, containment penetrations are closed to seal the containment. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering a reasonable time for repairs or replacement of required features, and the low probability of an accident occurring during the repair period. The Required Actions are consistent with the actions taken for containment closure in CTS 3.9.4 (i.e., ITS 3.9.3). Penetrations which can be closed by an OPERABLE Containment Isolation System do not need to be closed if SDC is inoperable, since the presence of radioactivity in the containment will cause the valves to close automatically, thus performing the isolation function. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.9.5, SHUTDOWN COOLING (SDC) AND COOLANT CIRCULATION – LOW WATER LEVEL

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. Change made to be consistent with the ISTS format as specified in the Writer's Guide for the Improved Standard Technical Specifications, TSTF-GG-05-01 and other Specifications; for example, LCO 3.8.2.a reference to LCO 3.8.10, “Distribution Systems – Shutdown.”

3. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

4. ISTS 3.9.5 Required Actions B.5.1 and B.5.2 are connected by an "OR" logical connector, such that either one can be performed to meet the requirements of the ACTION. However, the two Required Actions as presented in the ISTS are applicable to all the containment penetrations; either Required Action B.5.1 or Required Action B.5.2 must be performed. Thus, the ISTS presentation will not allow one penetration to be isolated by use of a manual valve and another penetration to be capable of being closed by an OPERABLE Containment Isolation System. This is not the intent of the requirement. The requirement is based on ISTS LCO 3.9.3, which requires each penetration to be either: a) closed by a manual or automatic isolation valve, blind flange, or equivalent; or b) capable of being closed by an OPERABLE Containment Isolation System. For consistency with the actual LCO requirement, ISTS 3.9.5 Required Actions B.5.1 and B.5.2 have been combined into a single Required Action in ITS 3.9.5 Required Action B.5. This will allow each of the applicable containment penetrations to be either isolated or capable of being isolated, as required, to ensure containment closure can be achieved.

5. **Unit 2 only**: A Note is added to ITS SR 3.9.5.1 that allows a reduction of reactor coolant flow rate when specific conditions are met consistent with the St. Lucie Plant Unit 2 current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.9 REFUELING OPERATIONS

B 3.9.5 Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level

BASES

BACKGROUND

The purposes of the SDC System in MODE 6 are to remove decay heat and sensible heat from the Reactor Coolant System (RCS)~~, as required by GDC 34,~~ to provide mixing of borated coolant, to provide sufficient coolant circulation to minimize the effects of a boron dilution accident, and to prevent boron stratification (Ref. 1). Heat is removed from the RCS by circulating reactor coolant through the SDC heat exchanger(s), where the heat is transferred to the Component Cooling Water (CCW) System via the SDC heat exchanger(s). The coolant is then returned to the RCS via the RCS cold leg(s). Operation of the SDC System for normal cooldown or decay heat removal is manually accomplished from the control room. The heat removal rate is adjusted by controlling the flow of reactor coolant through the SDC heat exchanger(s) and bypassing the heat exchanger(s). Mixing of the reactor coolant is maintained by this continuous circulation of reactor coolant through the SDC System, as well as adjustments in CCW temperature and flow.

APPLICABLE SAFETY ANALYSES

If the reactor coolant temperature is not maintained below 200°F, boiling of the reactor coolant could result. This could lead to inadequate cooling of the reactor fuel due to the resulting loss of coolant in the reactor vessel. Additionally, boiling of the reactor coolant could lead to a reduction in boron concentration in the coolant due to the boron plating out on components near the areas of the boiling activity, and because of the possible addition of water to the reactor vessel with a lower boron concentration than is required to keep the reactor subcritical. The loss of reactor coolant and the reduction of boron concentration in the reactor coolant would eventually challenge the integrity of the fuel cladding, which is a fission product barrier. Two ~~trains~~ loops of the SDC System are required to be OPERABLE, and one train is required to be in operation in MODE 6, with the water level < 23 ft above the top of the reactor vessel flange, to prevent this challenge.

SDC and Coolant Circulation - Low Water Level satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

In MODE 6, with the water level < 23 ft above the top of the reactor vessel flange, both SDC loops must be OPERABLE. Additionally, one loop of the SDC System must be in operation in order to provide: at least

a. Removal of decay heat, and

b. Mixing of borated coolant to minimize the possibility of a criticality~~, and~~

BASES

LCO (continued)

~~c. Indication of reactor coolant temperature~~.

This LCO is modified by two Notes. Note 1 permits the SDC pumps to be removed from operation for ≤ 15 minutes when switching from one train to another. The circumstances for stopping both SDC pumps are to be limited to situations when the outage time is short ~~[~~and the core outlet temperature is maintained > 10 degrees F below saturation temperature~~]~~. The Note prohibits boron dilution by introduction of coolant into the RCS with boron concentration less than that required to meet the minimum boron concentration of LCO 3.9.1, or draining operations when SDC forced flow is stopped.

, "Boron Concentration."

Note 2 allows one SDC loop to be inoperable for a period of 2 hours provided the other loop is OPERABLE and in operation. Prior to declaring the loop inoperable, consideration should be given to the existing plant configuration. This consideration should include that the core time to boil is short, there is no draining operation to further reduce RCS water level and that the capability exists to inject borated water into the reactor vessel. This permits surveillance tests to be performed on the inoperable loop during a time when these tests are safe and possible.

An OPERABLE SDC loop consists of an SDC pump, a heat exchanger, valves, piping, instruments, and controls to ensure an OPERABLE flow path ~~and to determine the low end temperature~~. The flow path starts in one of the RCS hot legs and is returned to the RCS cold legs.

at least one of

Management of gas voids is important to SDC System OPERABILITY.

Additionally, since the SDC System is a manually operated system (i.e., it is not automatically actuated), each SDC loop is OPERABLE if it can be manually aligned (remote or local) to the SDC mode.

Both SDC pumps may be aligned to the Refueling Water Storage Tank to support filling or draining the refueling cavity or for performance of required testing.

APPLICABILITY

Two SDC loops are required to be OPERABLE, and one SDC loop must be in operation in MODE 6, with the water level < 23 ft above the top of the reactor vessel flange, to provide decay heat removal. Requirements for the SDC System in other MODES are covered by LCOs in Section 3.4, Reactor Coolant System. MODE 6 requirements, with a water level ≥ 23 ft above the reactor vessel flange, are covered in LCO 3.9.4, "Shutdown Cooling and Coolant Circulation - High Water Level."

ACTIONS

A.1 and A.2

If one SDC loop is inoperable, action shall be immediately initiated and continued until the SDC loop is restored to OPERABLE status and to operation, or until ≥ 23 ft of water level is established above the reactor vessel flange. When the water level is established at ≥ 23 ft above the

BASES

ACTIONS (continued)

reactor vessel flange, the Applicability will change to that of LCO 3.9.4, "Shutdown Cooling and Coolant Circulation - High Water Level," and only one SDC loop is required to be OPERABLE and in operation. An immediate Completion Time is necessary for an operator to initiate corrective actions.

B.1

If no SDC loop is in operation or no SDC loops are OPERABLE, there will be no forced circulation to provide mixing to establish uniform boron concentrations. Suspending positive reactivity additions that could result in failure to meet the minimum boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation.

B.2

If no SDC loop is in operation or no SDC loops are OPERABLE, action shall be initiated immediately and continued without interruption to restore one SDC loop to OPERABLE status and operation. Since the unit is in Conditions A and B concurrently, the restoration of two OPERABLE SDC loops and one operating SDC loop should be accomplished expeditiously.

B.3, B.4~~, B.5.1,~~ and B.5~~.2~~ 4

If no SDC loop is in operation, the following actions must be taken:

a. The equipment hatch must be closed and secured with ~~[~~four~~]~~ bolts, 2

b. One door in each air lock must be closed, and

c. Each penetration providing direct access from the containment atmosphere to the outside atmosphere must be either closed by a manual or automatic isolation valve, blind flange, or equivalent, or verified to be capable of being closed by an OPERABLE Containment ~~Purge and Exhaust~~ Isolation System. 1

BASES

ACTIONS (continued)

With SDC loop requirements not met, the potential exists for the coolant to boil and release radioactive gas to the containment atmosphere. Performing the actions stated above ensures that all containment penetrations are either closed or can be closed so that the dose limits are not exceeded.

The Completion Time of 4 hours allows fixing of most SDC problems and is reasonable, based on the low probability of the coolant boiling in that time.

SURVEILLANCE REQUIREMENTS

SR 3.9.5.1

This Surveillance demonstrates that one SDC loop is operating and circulating reactor coolant. The flow rate is determined by the flow rate necessary to provide sufficient decay heat removal capability and to prevent thermal and boron stratification in the core. In addition, this Surveillance demonstrates that the other SDC loop is OPERABLE.

In addition, during operation of the SDC loop with the water level in the vicinity of the reactor vessel nozzles, the SDC loop flow rate determination must also consider the SDC pump suction requirements.

~~[The Frequency of 12 hours is sufficient, considering the flow, temperature, pump control, and alarm indications available to the operator to monitor the SDC System in the control room.~~ 2

~~Verification that the required loops are OPERABLE and in operation ensures that loops can be placed in operation as needed, to maintain decay heat and retain forced circulation. The Frequency of 12 hours is considered reasonable, since other administrative controls are available and have proven to be acceptable by operating experience.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~----------]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.9.5.2

Verification that the required pump is OPERABLE ensures that an additional SDC pump can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power available to the required pump. ~~[The Frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~]~~

SR 3.9.5.3

SDC System piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the SDC loops and may also prevent water hammer, pump cavitation, and pumping of noncondensible gas into the reactor vessel.

Selection of SDC System locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The SDC System is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. If accumulated gas is discovered that exceeds the acceptance criteria for the susceptible location (or the volume of accumulated gas at one or more susceptible locations exceeds an acceptance criteria for gas volume at the suction or discharge of a pump), the Surveillance is not met. If the accumulated gas is eliminated or brought within the acceptance criteria limits during performance of the Surveillance, the Surveillance is met and past system OPERABILITY is evaluated under the Corrective Action Program. If it is determined by subsequent evaluation that the SDC System is not rendered inoperable by the accumulated gas (i.e., the system is sufficiently filled with water), the Surveillance may be declared met. Accumulated gas should be eliminated or brought within the acceptance criteria limits.

SDC System locations susceptible to gas accumulation are monitored and, if gas is found, the gas volume is compared to the acceptance criteria for the location. Susceptible locations in the same system flow path which are subject to the same gas intrusion mechanisms may be verified by monitoring a representative sub-set of susceptible locations. Monitoring may not be practical for locations that are inaccessible due to radiological or environmental conditions, the plant configuration, or personnel safety. For these locations alternative methods (e.g., operating parameters, remote monitoring) may be used to monitor the susceptible location. Monitoring is not required for susceptible locations where the maximum potential accumulated gas void volume has been evaluated and determined to not challenge system OPERABILITY. The accuracy of the method used for monitoring the susceptible locations and trending of the results should be sufficient to assure system OPERABILITY during the Surveillance interval.

~~[The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the SDC System piping and the procedural controls governing system operation.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. The Surveillance Frequency may vary by location susceptible to gas accumulation.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

B 3.9 REFUELING OPERATIONS

B 3.9.5 Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level

BASES

BACKGROUND

The purposes of the SDC System in MODE 6 are to remove decay heat and sensible heat from the Reactor Coolant System (RCS)~~, as required by GDC 34,~~ to provide mixing of borated coolant, to provide sufficient coolant circulation to minimize the effects of a boron dilution accident, and to prevent boron stratification (Ref. 1). Heat is removed from the RCS by circulating reactor coolant through the SDC heat exchanger(s), where the heat is transferred to the Component Cooling Water (CCW) System via the SDC heat exchanger(s). The coolant is then returned to the RCS via the RCS cold leg(s). Operation of the SDC System for normal cooldown or decay heat removal is manually accomplished from the control room. The heat removal rate is adjusted by controlling the flow of reactor coolant through the SDC heat exchanger(s) and bypassing the heat exchanger(s). Mixing of the reactor coolant is maintained by this continuous circulation of reactor coolant through the SDC System, as well as adjustments in CCW temperature and flow.

APPLICABLE SAFETY ANALYSES

If the reactor coolant temperature is not maintained below 200°F, boiling of the reactor coolant could result. This could lead to inadequate cooling of the reactor fuel due to the resulting loss of coolant in the reactor vessel. Additionally, boiling of the reactor coolant could lead to a reduction in boron concentration in the coolant due to the boron plating out on components near the areas of the boiling activity, and because of the possible addition of water to the reactor vessel with a lower boron concentration than is required to keep the reactor subcritical. The loss of reactor coolant and the reduction of boron concentration in the reactor coolant would eventually challenge the integrity of the fuel cladding, which is a fission product barrier. Two ~~trains~~ loops of the SDC System are required to be OPERABLE, and one train is required to be in operation in MODE 6, with the water level < 23 ft above the top of the reactor vessel flange, to prevent this challenge.

SDC and Coolant Circulation - Low Water Level satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

In MODE 6, with the water level < 23 ft above the top of the reactor vessel flange, both SDC loops must be OPERABLE. Additionally, at least one loop of the SDC System must be in operation in order to provide:

a. Removal of decay heat, and

b. Mixing of borated coolant to minimize the possibility of a criticality~~, and~~

BASES

LCO (continued)

~~c. Indication of reactor coolant temperature~~.

This LCO is modified by two Notes. Note 1 permits the SDC pumps to be removed from operation for ≤ 15 minutes when switching from one train to another. The circumstances for stopping both SDC pumps are to be limited to situations when the outage time is short ~~[~~and the core outlet temperature is maintained > 10 degrees F below saturation temperature~~]~~. The Note prohibits boron dilution by introduction of coolant into the RCS with boron concentration less than that required to meet the minimum boron concentration of LCO 3.9.1, "Boron Concentration," or draining operations when SDC forced flow is stopped.

Note 2 allows one SDC loop to be inoperable for a period of 2 hours provided the other loop is OPERABLE and in operation. Prior to declaring the loop inoperable, consideration should be given to the existing plant configuration. This consideration should include that the core time to boil is short, there is no draining operation to further reduce RCS water level and that the capability exists to inject borated water into the reactor vessel. This permits surveillance tests to be performed on the inoperable loop during a time when these tests are safe and possible.

An OPERABLE SDC loop consists of an SDC pump, a heat exchanger, valves, piping, instruments, and controls to ensure an OPERABLE flow path ~~and to determine the low end temperature~~. The flow path starts in one of the RCS hot legs and is returned to at least one of the RCS cold legs. Management of gas voids is important to SDC System OPERABILITY.

Additionally, since the SDC System is a manually operated system (i.e., it is not automatically actuated), each SDC loop is OPERABLE if it can be manually aligned (remote or local) to the SDC mode.

Both SDC pumps may be aligned to the Refueling Water Storage Tank to support filling or draining the refueling cavity or for performance of required testing.

APPLICABILITY

Two SDC loops are required to be OPERABLE, and one SDC loop must be in operation in MODE 6, with the water level < 23 ft above the top of the reactor vessel flange, to provide decay heat removal. Requirements for the SDC System in other MODES are covered by LCOs in Section 3.4, Reactor Coolant System. MODE 6 requirements, with a water level ≥ 23 ft above the reactor vessel flange, are covered in LCO 3.9.4, "Shutdown Cooling and Coolant Circulation - High Water Level."

ACTIONS

A.1 and A.2

If one SDC loop is inoperable, action shall be immediately initiated and continued until the SDC loop is restored to OPERABLE status and to operation, or until ≥ 23 ft of water level is established above the reactor vessel flange. When the water level is established at ≥ 23 ft above the

BASES

ACTIONS (continued)

reactor vessel flange, the Applicability will change to that of LCO 3.9.4, "Shutdown Cooling and Coolant Circulation - High Water Level," and only one SDC loop is required to be OPERABLE and in operation. An immediate Completion Time is necessary for an operator to initiate corrective actions.

B.1

If no SDC loop is in operation or no SDC loops are OPERABLE, there will be no forced circulation to provide mixing to establish uniform boron concentrations. Suspending positive reactivity additions that could result in failure to meet the minimum boron concentration limit is required to assure continued safe operation. Introduction of coolant inventory must be from sources that have a boron concentration greater than that what would be required in the RCS for minimum refueling boron concentration. This may result in an overall reduction in RCS boron concentration, but provides acceptable margin to maintaining subcritical operation.

B.2

If no SDC loop is in operation or no SDC loops are OPERABLE, action shall be initiated immediately and continued without interruption to restore one SDC loop to OPERABLE status and operation. Since the unit is in Conditions A and B concurrently, the restoration of two OPERABLE SDC loops and one operating SDC loop should be accomplished expeditiously.

B.3, B.4~~, B.5.1,~~ and B.5~~.2~~ 4

If no SDC loop is in operation, the following actions must be taken:

a. The equipment hatch must be closed and secured with ~~[~~four~~]~~ bolts, 2

b. One door in each air lock must be closed, and

c. Each penetration providing direct access from the containment atmosphere to the outside atmosphere must be either closed by a manual or automatic isolation valve, blind flange, or equivalent, or verified to be capable of being closed by an OPERABLE Containment ~~Purge and Exhaust~~ Isolation System. 1

BASES

ACTIONS (continued)

With SDC loop requirements not met, the potential exists for the coolant to boil and release radioactive gas to the containment atmosphere. Performing the actions stated above ensures that all containment penetrations are either closed or can be closed so that the dose limits are not exceeded.

The Completion Time of 4 hours allows fixing of most SDC problems and is reasonable, based on the low probability of the coolant boiling in that time.

SURVEILLANCE REQUIREMENTS

SR 3.9.5.1

This Surveillance demonstrates that one SDC loop is operating and circulating reactor coolant. The flow rate is determined by the flow rate necessary to provide sufficient decay heat removal capability and to prevent thermal and boron stratification in the core. In addition, this Surveillance demonstrates that the other SDC loop is OPERABLE.

In addition, during operation of the SDC loop with the water level in the vicinity of the reactor vessel nozzles, the SDC loop flow rate determination must also consider the SDC pump suction requirements.

~~[The Frequency of 12 hours is sufficient, considering the flow, temperature, pump control, and alarm indications available to the operator to monitor the SDC System in the control room.~~ 2

~~Verification that the required loops are OPERABLE and in operation ensures that loops can be placed in operation as needed, to maintain decay heat and retain forced circulation. The Frequency of 12 hours is considered reasonable, since other administrative controls are available and have proven to be acceptable by operating experience.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 2

The SR is modified by a Note that provides an allowance to reduce the required RCS flow rate when specific conditions are met. The time after reactor shutdown, RCS temperature, and CCW temperature to the shutdown cooling heat exchanger are initial conditions to ensure a reduced SDC flow rate will not result in a temperature transient exceeding the established refueling operational temperature limit. 1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.9.5.2

Verification that the required pump is OPERABLE ensures that an additional SDC pump can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power available to the required pump. ~~[The Frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.~~ 2

~~OR~~ 2

DISCUSSION OF CHANGES
ITS 3.9.6, REFUELING WATER LEVEL

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.9.10 requires the refueling cavity water level to be within the specified limit. CTS 3.9.10 Action requires immediate action to suspend CORE ALTERATIONS and movement of irradiated fuel assemblies in containment; and immediately initiate action to restore the refueling cavity water level to within the limit. ITS 3.9.6 ACTIONS do not include the action to initiate action to restore refueling cavity water level to within the limit. This changes the CTS by removing an unnecessary action. The purpose of the CTS 3.9.10 actions is to provide appropriate remedial actions when an LCO is not met consistent with the requirements of 10 CFR 50.36(c)(2)(i). The action to suspend CORE ALTERATIONS and movement of irradiated fuel assemblies within containment results in the LCO no longer being required (Refer to Discussion of Change L01 for removal of CORE ALTERATION Applicability and Action). CTS 3.0.2 (ITS LCO 3.0.2) state, in part, that when an LCO is met or is no longer applicable prior to expiration of the specified time interval(s), completion of the ACTIONS is not required, unless otherwise stated. As indicated in the ISTS Bases of ITS LCO 3.0.2, “Whether stated as a Required Action or not, correction of the entered Condition is an action that may always be considered upon entering ACTIONS.” Therefore, it is unnecessary to provide an action to specifically require the LCO to be met, as this is inherent in LCO 3.0.1 and LCO 3.0.2.

This change is designated as an administrative change and is acceptable because it does not result in technical changes to the CTS.

A03 CTS 4.9.10 requires the refueling cavity water level to be determined to be within limit in accordance with the Surveillance Frequency Control Program during movement of irradiated fuel assemblies within containment. ITS SR 3.9.6.1 requires verification that the refueling water level is within limit in accordance with the Surveillance Frequency Control Program. The CTS and ITS applicability are also during movement of irradiated fuel assemblies within containment. This changes the CTS by deleting the Applicability requirement from the Surveillance. ITS LCO 3.0.1 establishes the Applicability statement within each individual Specification as the requirement for when the LCO is required to be met (i.e., when the unit is in the MODES or other specified conditions of the Applicability statement of each Specification). Additionally, SR 3.0.1 establishes the requirement that Surveillance Requirements must be met during the MODES or other specified conditions in the Applicability for which the requirements of the LCO apply, unless otherwise specified in the individual SRs. Therefore, maintaining the Applicability requirement in the Surveillance is not necessary.

This change is designated as an administrative change and is acceptable because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only**: CTS 3.9.10 requires a minimum of 23 feet of water be maintained over the top of irradiated fuel assemblies seated within the reactor pressure vessel. ITS 3.9.6 requires 23 feet of water be maintained above the top of the reactor vessel flange. This changes the CTS by increasing the amount of water that must be in the refueling cavity during irradiated fuel movement.

Refueling water level is required to ensure the consequences of a design basis refuel accident remain within the bounds of the radiological dose calculations. Since the fuel handling accident could occur anywhere in the refueling cavity, the water level in the reactor vessel and refueling cavity must be at least 23 feet above the top of the reactor vessel flange. Therefore, the increased water level requirement is acceptable. This change is made consistent with the requirements of PSL Unit 2 CTS and the ISTS. This change is designated as more restrictive because it adds new requirements to the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* CTS 3.9.10 is applicable during CORE ALTERATIONS and movement of irradiated fuel assemblies within the containment. ITS 3.9.3 is applicable during movement of irradiated fuel assemblies within containment. References to CORE ALTERATIONS in CTS 3.9.4 are eliminated in the Applicability, Action, and Surveillances. This changes the CTS by eliminating requirements for maintaining refueling water level during CORE ALTERATIONS. | R1

The purpose of CTS 3.9.4 is to ensure the refueling water level satisfies the condition assumed in the Fuel Handling Accident (FHA) inside containment analysis. This change is acceptable because the requirements continue to ensure that the structures, systems, and components are maintained in the MODES and other specified conditions assumed in the safety analyses and licensing basis. CORE ALTERATIONS is defined in CTS 1.9, in part, as "the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity, within the reactor vessel with the head removed and fuel in the vessel." There is only one accident considered that

involves a CORE ALTERATION: An FHA. According to the Unit 1 UFSAR Section 15.4.3 and Unit 2 UFSAR Section 15.7.4.1.2, an FHA is initiated by the dropping of an irradiated fuel assembly either in the containment or in the fuel building. Suspension of CORE ALTERATIONS, except for suspension of movement of irradiated fuel, will not prevent or impair the mitigation of an FHA.

This change is acceptable because the likelihood of dropping a reactivity component other than an irradiated fuel assembly is minimized by following the regulatory guidelines of NUREG-0612, “Control of Heavy Loads at Nuclear Power Plants,” which includes establishing safe load paths, establishing and maintaining procedures for load-handling operations; training of crane operators; design, testing, inspection, and maintenance of cranes and lifting devices. The PSL crane design precludes the handling of heavy objects, such as shipping casks, over the reactor vessel. Administrative controls that control of movement of light loads or prevent movement of light loads over irradiated fuel assemblies are similar to those used for control of heavy loads, to the extent practicable, as advised in NUREG-0612. Consequently, the possibility of dropping a reactivity component other than an irradiated fuel assembly and damaging of fuel assemblies in the reactor vessel is remote. Therefore, imposing requirements during CORE ALTERATIONS in addition to during movement of irradiated fuel is unnecessary. This change is consistent with the ISTS and designated as less restrictive because the ITS LCO requirements are applicable in fewer operating conditions than in the CTS.

L02 *(Category 7 – Relaxation Of Surveillance Frequency)* CTS 4.9.10 requires the refueling cavity water level to be determined to be within limit "within 2 hours prior to the start of" and in accordance with the Surveillance Frequency Control Program (i.e., at least once per 24 hours). ITS SR 3.9.6.1 requires verification that the refueling water level is ≥ 23 feet above the top of the reactor vessel flange in accordance with the Surveillance Frequency Control Program (i.e., at least once per 24 hours). This changes the CTS by reducing the Frequency for verifying refueling water level from 2 hours before entering the Applicability of the LCO to 24 hours before entering the Applicability of the LCO.

The purpose of CTS 4.9.10 is to ensure that the refueling water level is greater than or equal to that assumed in the fuel handling accident analysis. This change is acceptable because the Surveillance Frequency has been evaluated to ensure that the refueling water level is verified on a periodicity considering the large volume of water and the normal procedural controls of valve positions, which make significant unplanned level changes unlikely. The Frequency of 24 hours is sufficient during the movement of fuel assemblies; therefore, it is sufficient before fuel assemblies are moved. CTS 4.0.4 (ITS SR 3.0.4) requires the SR to be met within its Frequency requirements prior to entering the MODE or other specified conditions in the Applicability except as provided by CTS 4.0.3 (ITS SR 3.0.3 – missed SR). The reactor cavity minimum water level must be met prior to commencing movement of irradiated fuel assemblies or fuel assembly movement must be suspended immediately (thereby exiting the Applicability of the Specification). Therefore, changing the Frequency from 2 hours before moving irradiated fuel assemblies to within 24 hours before moving irradiated fuel assemblies has no effect on plant safety. This change is

designated as less restrictive because Surveillances will be performed less frequently under the ITS than under the CTS.

BASES

BACKGROUND

The movement of irradiated fuel assemblies within containment requires a minimum water level of 23 ft above the top of the reactor vessel flange. During refueling this maintains sufficient water level in the containment, ~~the refueling canal,~~ the fuel transfer canal, the refueling cavity, and the spent fuel pool. Sufficient water is necessary to retain iodine fission product activity in the water in the event of a fuel handling accident (FHA) (Refs. 1 and 2). Sufficient iodine activity would be retained to limit offsite doses from the accident to ~~< 25% of 10 CFR 100 limits, as provided by the guidance of Reference 3.~~ within the radiation dose criteria set forth in 10 CFR 50.67, as provided by the guidance of Reference 1

1 R1 1

APPLICABLE SAFETY ANALYSES

~~During movement of irradiated fuel assemblies, the water level in the refueling canal and refueling cavity is an initial condition design parameter in the analysis of the fuel handling accident in containment postulated by Regulatory Guide 1.25 (Ref. 1). A minimum water level of 23 ft (Regulatory Position C.1.c of Ref. 1) allows a decontamination factor of 100 (Regulatory Position C.1.g of Ref. 1) to be used in the accident analysis for iodine. This relates to the assumption that 99% of the total iodine released from the pellet to cladding gap of all the dropped fuel assembly rods is retained by the refueling cavity water. The fuel pellet to cladding gap is assumed to contain 10% of the total fuel rod iodine inventory (Ref. 1).~~

INSERT 1

1

~~The fuel handling accident analysis inside containment is described in Reference 2. With a minimum water level of 23 ft and a minimum decay time of [X] hours prior to fuel handling, the analysis and test programs demonstrate that the iodine release due to a postulated fuel handling accident is adequately captured by the water and offsite doses are maintained within allowable limits (Ref. 4).~~

1

Refueling water level satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

A minimum refueling water level of 23 ft above the reactor vessel flange is required to ensure that the radiological consequences of a postulated ~~fuel handling accident~~ FHA inside containment are within acceptable limits as provided by the guidance of Reference 3.

1

APPLICABILITY

LCO 3.9.6 is applicable when moving fuel assemblies in the presence of irradiated fuel assemblies. The LCO minimizes the possibility of ~~a fuel handling accident~~ an FHA in containment that is beyond the assumptions of the safety analysis. If irradiated fuel is not present in containment, there can be no significant radioactivity release as a result of a postulated ~~fuel handling accident~~ FHA. Requirements for ~~fuel handling accidents~~ FHAs in the spent fuel pool are covered by LCO 3.7.~~10~~ 13, "Fuel Storage Pool Water Level." Spent

1 1 3

1

1

INSERT 1

The FHA analysis is described in Reference 2. During movement of irradiated fuel assemblies, the water level in the reactor cavity is an initial condition design parameter in the analysis of the FHA in containment postulated in Appendix B or Regulatory Guide 1.183 (Ref. 1). A minimum water level of 23 feet is maintained above the damaged fuel assembly for both the containment and fuel handling building (FHB) release locations. Fuel handling accidents consist of dropping a single irradiated fuel assembly either in the FHB or inside the containment and assumes all the fuel rods in the assembly are damaged. The offsite dose analysis does not credit filtration during an FHA inside containment with the maintenance hatch open or in the spent fuel storage pool. The control room dose analysis credits control room emergency ventilation filtration during an FHA inside or outside the containment. R1

In the event of an FHA, a minimum water level of 23 feet and a minimum decay time of 72 hours prior to fuel handling ensures an effective iodine decontamination factor of 200 per the guidance provided in NRC Regulatory Issue Summary 2006-04 (Ref. 3). The FHA assumes 100% of the noble gas is released from the damaged fuel assembly and escapes from the reactor cavity. All of the non-iodine particulates released from the damaged fuel assembly are assumed to be retained by the water. Iodine released from the damaged fuel assembly is assumed to be composed of 99.85% elemental and 0.15% organic. Activity released from the FHA is assumed to leak to the environment over a two-hour period and no credit is taken for dilution in the containment.

BASES

ACTIONS

A.1

With a water level of < 23 ft above the top of the reactor vessel flange, all operations involving movement of irradiated fuel assemblies shall be suspended immediately to ensure that a fuel handling accident cannot occur.

The suspension of fuel movement shall not preclude completion of movement of a component to a safe position.

SURVEILLANCE REQUIREMENTS

SR 3.9.6.1

Verification of a minimum water level of 23 ft above the top of the reactor vessel flange ensures that the design basis for the postulated ~~fuel~~ FHA ~~handling accident~~ analysis during refueling operations is met. Water at the required level above the top of the reactor vessel flange limits the consequences of damaged fuel rods that are postulated to result from ~~a~~ an FHA ~~fuel handling accident~~ inside containment (Ref. 2). 1

~~[The Frequency of 24 hours is based on engineering judgment and is considered adequate in view of the large volume of water and the normal procedural controls of valve positions, which make significant unplanned level changes unlikely.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

B 3.9 REFUELING OPERATIONS

B 3.9.6 Refueling Water Level

BASES

BACKGROUND

The movement of irradiated fuel assemblies within containment requires a minimum water level of 23 ft above the top of the reactor vessel flange. During refueling this maintains sufficient water level in the containment, ~~the refueling canal,~~ the fuel transfer canal, the refueling cavity, and the spent fuel pool. Sufficient water is necessary to retain iodine fission product activity in the water in the event of a fuel handling accident (FHA) (Refs. 1 and 2). Sufficient iodine activity would be retained to limit offsite doses from the accident to ~~< 25% of 10 CFR 100 limits, as provided by the guidance of Reference 3.~~ within the radiation dose criteria set forth in 10 CFR 50.67, as provided by the guidance of Reference 1

R1

1

1

APPLICABLE SAFETY ANALYSES

~~During movement of irradiated fuel assemblies, the water level in the refueling canal and refueling cavity is an initial condition design parameter in the analysis of the fuel handling accident in containment postulated by Regulatory Guide 1.25 (Ref. 1). A minimum water level of 23 ft (Regulatory Position C.1.c of Ref. 1) allows a decontamination factor of 100 (Regulatory Position C.1.g of Ref. 1) to be used in the accident analysis for iodine. This relates to the assumption that 99% of the total iodine released from the pellet to cladding gap of all the dropped fuel assembly rods is retained by the refueling cavity water. The fuel pellet to cladding gap is assumed to contain 10% of the total fuel rod iodine inventory (Ref. 1).~~

INSERT 1

1

~~The fuel handling accident analysis inside containment is described in Reference 2. With a minimum water level of 23 ft and a minimum decay time of [X] hours prior to fuel handling, the analysis and test programs demonstrate that the iodine release due to a postulated fuel handling accident is adequately captured by the water and offsite doses are maintained within allowable limits (Ref. 4).~~

1

Refueling water level satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

A minimum refueling water level of 23 ft above the reactor vessel flange is required to ensure that the radiological consequences of a postulated ~~fuel handling accident~~ FHA inside containment are within acceptable limits as provided by the guidance of Reference 3.

APPLICABILITY

LCO 3.9.6 is applicable when moving fuel assemblies in the presence of irradiated fuel assemblies. The LCO minimizes the possibility of ~~a fuel handling accident~~ an FHA in containment that is beyond the assumptions of the safety analysis. If irradiated fuel is not present in containment, there can be no significant radioactivity release as a result of a postulated ~~fuel handling accident~~ FHA. Requirements for ~~fuel handling accidents~~ FHAs in the spent fuel pool are covered by LCO 3.7.~~10~~13, "Fuel Storage Pool Spent Water Level."

1

1

3

1

1

INSERT 1

The FHA analysis is described in Reference 2. During movement of irradiated fuel assemblies, the water level in the reactor cavity is an initial condition design parameter in the analysis of the FHA in containment postulated in Appendix B or Regulatory Guide 1.183 (Ref. 1). A minimum water level of 23 feet is maintained above the damaged fuel assembly for both the containment and fuel handling building (FHB) release locations. Fuel handling accidents consist of dropping a single irradiated fuel assembly either in the FHB or inside the containment and assumes all the fuel rods in the assembly are damaged. The offsite dose analysis does not credit filtration during an FHA inside containment with the maintenance hatch open or in the spent fuel storage pool. The control room dose analysis credits control room emergency ventilation filtration during an FHA inside or outside the containment. R1

In the event of an FHA, a minimum water level of 23 feet and a minimum decay time of 72 hours prior to fuel handling ensures an effective iodine decontamination factor of 200 per the guidance provided in NRC Regulatory Issue Summary 2006-04 (Ref. 3). The FHA assumes 100% of the noble gas is released from the damaged fuel assembly and escapes from the reactor cavity. All of the non-iodine particulates released from the damaged fuel assembly are assumed to be retained by the water. Iodine released from the damaged fuel assembly is assumed to be composed of 99.85% elemental and 0.15% organic. Activity released from the FHA is assumed to leak to the environment over a two-hour period and no credit is taken for dilution in the containment.

BASES

ACTIONS

A.1

With a water level of < 23 ft above the top of the reactor vessel flange, all operations involving movement of irradiated fuel assemblies shall be suspended immediately to ensure that a fuel handling accident cannot occur.

The suspension of fuel movement shall not preclude completion of movement of a component to a safe position.

SURVEILLANCE REQUIREMENTS

SR 3.9.6.1

Verification of a minimum water level of 23 ft above the top of the reactor vessel flange ensures that the design basis for the postulated ~~fuel~~ FHA ~~handling accident~~ analysis during refueling operations is met. Water at the required level above the top of the reactor vessel flange limits the consequences of damaged fuel rods that are postulated to result from a an FHA ~~fuel handling accident~~ inside containment (Ref. 2). 1

~~[The Frequency of 24 hours is based on engineering judgment and is considered adequate in view of the large volume of water and the normal procedural controls of valve positions, which make significant unplanned level changes unlikely.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

JUSTIFICATION FOR DEVIATIONS
ITS 3.9.6, BASES, REFUELING WATER LEVEL

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes have been made to be consistent with title and number changes made to other Specifications.

REMOVED DETAIL CHANGES

LA01 (Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program) CTS 3/4.9.3 provides requirements associated with Decay Time. Specifically, CTS 4.9.3 requires a determination of verifying that the reactor has been subcritical for at least 72 hours by a verification of the date and time of subcriticality prior to movement of irradiated fuel in the reactor pressure vessel. With the reactor subcritical for less than 72 hours, the CTS 3.9.3 Action requires suspension of all operations involving movement of irradiated fuel in the reactor pressure vessel (RPV). ITS does not include a requirement for decay time. This changes the CTS by moving the explicit decay time requirements from the Technical Specifications to the Technical Requirements Manual (TRM).

The purpose of CTS 3/4.9.3 is to ensure that sufficient time has elapsed to allow radioactive decay of the short-lived fission products in the irradiated fuel consistent with the assumptions used in the fuel handling accident analysis. The removal of this administrative control detail from the Technical Specifications is acceptable because this type of information is not necessary to provide adequate protection of public health and safety. It is improbable to move irradiated fuel within 72 hours from entering MODE 3 (i.e., keff < 0.99) because of the physical time required to perform plant shutdown, cooldown, depressurize the Reactor Coolant System (RCS), and the additional operations required prior to moving recently irradiated fuel in the reactor vessel (e.g., containment entry, removal of vessel head, removal of vessel internals, etc.). Therefore, movement of irradiated fuel prior to the 72 hour decay is precluded. Thus, it is unnecessary to retain the decay time requirement in Technical Specifications. ITS retains Specifications to mitigate a fuel handling accident associated with the movement of recently irradiated fuel, which encompasses the unlikely movement of fuel prior to a decay period of 72 hours. Specifically, Specifications associated with the following systems will ensure these systems are OPERABLE during movement of recently irradiated fuel:

- engineered safety feature ventilation systems, the Unit 1 fuel building ventilation system, and associated instrumentation actuation functions;

R1

- control room emergency ventilation system and associated instrumentation actuation functions;
- reactor vessel and spent fuel pool minimum water level;
- containment penetration requirements and associated containment isolation instrumentation; and
- electrical systems needed to support systems listed herein.

The administrative requirement to determine that the reactor has been subcritical for at least 72 hours by verification of the date and time of subcriticality prior to movement of irradiated fuel in the RPV will be relocated to the TRM, along with the action requirement to immediately suspend irradiated fuel movement in the unlikely event that irradiated fuel movement did occur < 72 hours from subcriticality. Any change to the decay time input assumption in the fuel handling accident analysis will be evaluated pursuant to the criteria of 10 CFR 50.59 c(2). This change is acceptable because the removed information will be adequately controlled in the TRM. Changes to the TRM are controlled by the provisions of 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because a requirement is being removed from the Technical Specifications.

4.3.1.1.b

1. A k_{eff} equivalent to less than 1.0 when flooded with unborated water, including a conservative allowance for biases and uncertainties as described in Section 9.1 of the Updated Final Safety Analysis Report.

4.3.1.1.c Insert 2

2. A k_{eff} equivalent to less than or equal to 0.95 when flooded with water containing 500 ppm boron, including a conservative allowance for biases and uncertainties as described in Section 9.1 of the Updated Final Safety Analysis Report.

4.3.1.1.d 4.3.1.1.e 4.3.1.1.f

3. A nominal 8.965 inch center-to-center distance between fuel assemblies placed in the spent fuel pool storage racks and a nominal 8.80 inch center-to-center distance between fuel assemblies placed in the cask pit storage rack.

Region 1 and 2

Region 2

~~4. For storage of enriched fuel assemblies, requirements of Specification 5.6.1.a.1 and 5.6.1.a.2 shall be met by positioning fuel in the spent fuel pool storage racks consistent with the requirements of Specification 5.6.1.c.~~

~~5. Fissile material, not contained in a fuel assembly lattice, shall be stored in accordance with the requirements of Specifications 5.6.1.a.1 and 5.6.1.a.2.~~

A03

~~6. The Metamic neutron absorber inserts shall have a ^{10}B areal density greater than or equal to 0.015 grams $^{10}B/cm^2$.~~

LA03

~~b. The cask pit storage rack shall contain neutron absorbing material (Boral) between stored fuel assemblies when installed in the spent fuel pool.~~

c. Loading of spent fuel pool storage racks shall be controlled as described below.

See ITS 3.7.15

1. The maximum initial planar average U-235 enrichment of any fuel assembly inserted in a spent fuel pool storage rack shall be less than or equal to 4.6 weight percent.

2. Fuel placed in Region 1 of the spent fuel pool storage racks shall comply with the storage pattern definitions of Figure 5.6-1 and the minimum burnup requirements as defined in Table 5.6-1. (See Specification 5.6.1.c.7 for exceptions)

3. Fuel placed in Region 2 of the spent fuel pool storage racks shall comply with the storage pattern definitions or allowed special arrangement definitions of Figure 5.6-2 and the minimum burnup requirements as defined in Table 5.6-1. (See Specification 5.6.1.c.7 for exceptions)

DESIGN FEATURES (continued)

CRITICALITY (continued)

See ITS 3.7.15

5.6.1 c. (continued)

4. The 2x2 array of fuel assemblies that span the interface between Region 1 and Region 2 of the spent fuel pool storage racks shall comply with the storage pattern definitions of Figure 5.6-3 and the minimum burnup requirements as defined in Table 5.6-1. The allowed special arrangements in Region 2 as shown in Figure 5.6-2 shall not be placed adjacent to Region 1. (See Specification 5.6.1.c.7 for exceptions)

5. Fuel placed in the cask pit storage rack shall comply with the storage pattern definitions of Figure 5.6-4 and the minimum burnup requirements as defined in Table 5.6-1. (See Specification 5.6.1.c.7 for exceptions)

6. The same directional orientation for Metamic inserts is required for contiguous groups of 2x2 arrays where Metamic inserts are required.

7. Fresh or spent fuel in any allowed configuration may be replaced with non-fuel hardware, and fresh fuel in any allowed configuration may be replaced with a fuel rod storage basket containing fuel rod(s). Also, storage of Metamic inserts or control rods, without any fissile material, is acceptable in locations designated as completely water-filled cells.

4.3.1.2.a
4.3.1.2.b
4.3.1.2.c

d. The new fuel storage racks ~~are designed for dry storage of unirradiated fuel assemblies~~ having a maximum planar average U-235 enrichment less than or equal to 4.6 weight percent, while maintaining a k_{eff} of less than or equal to 0.98 ~~under the most reactive condition~~.

LA02

if fully flooded with unborated water or if moderated by aqueous foam including allowances for uncertainties as described in UFSAR Section 9.1.

DRAINAGE

4.3.2 5.6.2 The spent fuel storage pool is designed and shall be maintained to prevent inadvertent draining of the pool below elevation 56 feet.

Add ITS 4.3.1.2.d

M02

CAPACITY

4.3.3 5.6.3 The spent fuel pool storage racks are designed and shall be maintained with a storage capacity limited to no more than 1491 fuel assemblies, and the cask pit storage rack is designed and shall be maintained with a storage capacity limited to no more than 225 fuel assemblies. The total Unit 2 spent fuel pool and cask pit storage capacity is limited to no more than 1716 fuel assemblies.

DISCUSSION OF CHANGES
ITS 4.0, DESIGN FEATURES

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 5.3.2 includes the descriptor “full length” and “no part length” in reference to control element assemblies (CEAs).

The purpose of the CTS requirement is to describe the number of CEAs and the control material used in the CEA design. Unit 1 and Unit 2 no longer use partial length CEA(s). Since partial length CEA(s) are no longer a design feature for Unit 1 and Unit 2, it is unnecessary to describe CEA types that PSL does not have. Therefore, the “full length” and “no partial length” descriptors used for CEA(s) are deleted. This change is designated as administrative and is acceptable because it does not result in a technical change to the CTS.

A03 Unit 1 CTS 5.6.1.a.6 requires compliance with CTS 5.6.1.a.1 and a.3. Unit 2 CTS 5.6.1.a.4 requires compliance with CTS 5.6.1.a.1 and a.2 when positioning fuel in the spent fuel pool storage racks consistent with the requirements of CTS 5.6.1.c. Unit 2 CTS 5.6.1.a.5 requires compliance with CTS 5.6.1.a.1 and a.2. This changes the CTS by not including a specific requirement to comply with another CTS requirement.

The purpose of CTS 5.6.1 requirements is to ensure the spent fuel storage racks are designed and maintained to comply with 10 CFR 50.68, “Criticality accident requirements.” Since the spent fuel storage racks are designed, as stated in CTS 5.6.1.a.1, a.2, and a.3 and Section 9.1 of the Updated Safety Analysis Report (UFSAR), to comply with the requirements of 10 CFR 50.68, it is unnecessary to restate that other CTS 5.6.1 Specifications shall be met when positioning fuel assemblies in the spent fuel storage racks and when storing fissile material not contained in a fuel assembly lattice. It is not an ITS convention to include this type of references to comply with other Technical Specification requirements. ITS 4.3.1.1 continues to require spent fuel storage racks be designed to comply with 10 CFR 50.68 regardless of whether fissile material is contained in a fuel assembly lattice or not and the requirements provided in CTS 5.6.1.c (ITS 3.7.15) continue to assure control of fuel storage in the spent fuel storage pool. This change is designated as administrative because unnecessarily duplicative requirements to comply with other Technical Specification requirements are eliminated with no technical change to the CTS.

A04 **Unit 1 only**: CTS 5.6.1.a.4 states that the spent fuel storage rack criteria of CTS 5.6.1.a.1 and 5.6.1.a.3 shall be met for storage of enriched fuel assemblies by positioning fuel in the spent fuel storage racks consistent with the requirements of Specification 5.6.1.c. ITS 4.3.1.1 does not include this statement of fact. The

purpose of CTS 5.6.1.a.4 is to ensure enriched fuel assemblies are stored consistent with the pattern and location requirements specified in CTS 5.6.1.c to ensure the criticality requirements of CTS 5.6.1.a.1 and 5.6.1.a.3 are met. Compliance with the requirements of CTS 5.6.1.c are required for irradiated fuel assemblies, including enriched fuel assemblies. The location and pattern requirements of CTS 5.6.1.c ensure the requirements of CTS 5.6.1.a.1 and 5.6.1.a.3 are met. Therefore, it is unnecessary to include an explicit requirement for enriched fuel assemblies to be stored in a specific manner to ensure criticality limits are met. This change is designated as administrative because an unnecessarily duplicative requirement to comply with other Specification requirements is eliminated with no technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 ITS 4.2.2 requires the control material of the CEAs to consist of silver indium cadmium or boron carbide as approved by the NRC. The CTS does not include explicit detail on the type of CEA control material that must be used. This changes the CTS by adding specific CEA control material requirements.

The purpose of the CEA design feature requirement is to provide information considered as a design feature description as described in 10 CFR 50.36(c)(4). The specific CEA control material is considered a CEA material of construction, which, if altered or modified, would have a significant effect on safety. This change is designated more restrictive because design feature information is added to the CTS consistent with the ISTS.

M02 CTS 5.6.1.a requires the spent fuel storage racks to be maintained within specific criticality requirements; however, CTS does not specify U-235 enrichment for irradiated fuel assemblies. ITS 4.3.1.1.a requires fuel assemblies in the spent fuel storage racks (i.e., spent fuel pool and cask pit storage racks) to be limited to a maximum U-235 enrichment of 4.6 weight percent. This changes the CTS by adding a specific fuel assembly U-235 enrichment limit.

CTS 5.6.1.d requires new fuel storage racks, in part, to maintain a k_{eff} less than or equal to 0.98 under the most reactive conditions. ITS 4.3.1.2.b and c require new fuel storage racks to be designed and maintained with a $k_{eff} \leq 0.98$ if fully flooded with unborated water and if moderated by aqueous foam, respectively, including allowance for uncertainties described in Section 9.1 of the UFSAR. ITS 4.3.1.2.d also requires that new fuel storage racks are designed and maintained to have a nominal 21 inch, for Unit 1, and 23 inch, for Unit 2, center to center distance between fuel assemblies in order to prevent criticality of the fuel assemblies. This changes the CTS by adding specific reactivity conditions and fuel assembly spacing requirements for the design and maintenance of the new fuel storage racks.

The purpose of ITS 4.3.1.1 is to prevent criticality in the spent fuel storage pool and cask pit. U-235 enrichment is an important input in spent fuel pool and cask pit criticality analyses.

The purpose of ITS 4.3.1.2 is to prevent criticality in the new fuel storage vault. Unit 1 UFSAR Section 9.1.1.1 states that the new fuel storage racks are designed, in part, to provide sufficient spacing between the fuel assemblies to maintain a subcritical array during flooding with nonborated water. Unit 2 UFSAR Section 9.1.1.1 states that the new fuel storage racks are designed, in part, to provide sufficient spacing between the fuel assemblies to maintain a subcritical (Keff ≤ 0.98) array assuming the most reactive condition. The establishment of minimum spacing design requirements for the new fuel storage racks assists in meeting this design basis and provides assurance that no incident could occur that would result in a hazard to public health and safety. The specific new fuel keff criteria is added consistent with 10 CFR 50.68(b)(2) and (b)(3).

This change is acceptable because it provides appropriate limits for the new and spent fuel storage racks and is designated more restrictive because general design requirements in CTS have been replaced with specific requirements in ITS consistent with the ISTS and 10 CFR 50.68.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 and Unit 2 CTS 5.2 and 5.4 provide description details of the containment systems and the reactor coolant system (RCS), respectively. Unit 1 CTS 5.5 and 5.7 provides description details of the emergency core cooling systems (ECCS) and seismic classifications, respectively. This changes the CTS by moving the description details of these systems to the UFSAR.

The removal of these details, which are related to system description, from the Technical Specifications, is acceptable because this type of information is not considered a design feature requirement as described in 10 CFR 50.36(c)(4); and therefore, is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains requirements on containment systems OPERABILITY in ITS Section 3.6, “Containment Systems,” RCS OPERABILITY in ITS Section 3.4, “Reactor Coolant Systems (RCS),” and ECCS OPERABILITY in ITS Section 3.5, “Emergency Core Cooling Systems (ECCS).” Seismic classification requirements continue to be required as promulgated by regulation; specifically, Appendix B, Section III, Design Control, and Appendix S, Section IV, Application To Engineering Design, of 10 CFR 50. Also, this change is acceptable because the information will be adequately controlled in the UFSAR. Any changes to the UFSAR are made per the provisions of 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS and Unit 2 CTS 5.3.1 state that each fuel assembly, in part, consists of "and/or poison rods." In addition, Unit 1 CTS 5.3.1.1 states that, except for special test as authorized by the NRC, fuel assemblies under CEAs must be sleeved with an NRC approved sleeve design. Unit 1 CTS 5.3.2 contains reference to the original CEA design provisions in the FSAR and allows for normal degradation allowance pursuant to applicable Surveillance Requirements. Unit 1 and Unit 2 CTS 5.6.1.d explicitly state that the new fuel storage racks are designed for dry storage of unirradiated fuel. ITS 4.2.1, 4.2.2, and 4.3.1.2 do not include this level of detail and is revised consistent with the ISTS. This changes the CTS by moving this level of detail to the UFSAR.

The removal of these details, which are related to system design, from the CTS is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retain fuel assembly and CEA material description (refer to DOC M01), which, if altered or modified, would have a significant effect on safety. Additionally, ITS retains requirements on CEA OPERABILITY in Section 3.1. ITS also retains sufficient criticality information associated with the new fuel storage racks, which, if altered or modified, would have a significant effect on safety. These requirements provide adequate assurance the fuel assemblies, CEAs, and new fuel storage racks are capable of performing their safety function. Additionally, the removed information is more appropriately contained in the UFSAR. The inclusion of the details of component design and material in the UFSAR is consistent with the content and purpose of the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures that changes to the material contained in the UFSAR are properly evaluated. Therefore, the removal of this information from the CTS and placement in the UFSAR is acceptable. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the CTS.

LA03 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 5.6.1.a.5 allows Vessel Flux Reduction Assemblies (VFRAs), as defined in Section 9.1 of the Updated Final Safety Analysis Report, to be placed in any allowable fuel storage location. Unit 1 CTS 5.6.1.a.7 and Unit 2 CTS 5.6.1.a.6 require the Metamic neutron absorber inserts to have a ^{10}B areal density greater than or equal to 0.015 grams $^{10}B/cm^2$ and Unit 1 and Unit 2 CTS 5.6.1.b requires the cask pit storage rack to contain neutron absorbing material (Boral) between stored fuel assemblies when installed in the spent fuel pool. ITS 4.3.1.1 does not include this level of detail and is revised consistent with the ISTS. This changes the CTS by moving this level of detail to the UFSAR.

The removal of these details, which are related to specific rack design, from the CTS is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains sufficient criticality information associated with the spent fuel and cask pit storage racks, which, if altered or modified, would have a significant effect on safety. The removed information is more appropriately contained in the UFSAR. The inclusion of the details of component design and material in the UFSAR is consistent with the content and purpose of

the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures that changes to the material contained in the UFSAR are properly evaluated. Therefore, the removal of this information from the CTS and placement in the UFSAR is acceptable. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 4.0, DESIGN FEATURES

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. The St. Lucie Plant (PSL) spent fuel storage criticality analyses for Units 1 and 2 indicate that to maintain keff ≤ 0.95 under normal conditions, boron concentration must be at least 500 ppm, including an allowance for biases and uncertainties as described in Section 9.1 of the Updated Final Safety Analysis Report (UFSAR). Additionally, if fully flooded with unborated water, spent fuel storage criticality analyses indicate keff will remain below 1.0, which includes an allowance for biases and uncertainties as described in UFSAR, Section 9.1. Therefore, these changes are made to reflect the PSL fuel storage criticality safety analyses.

4. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The bracketed information is not included in the PSL Unit 1 and Unit 2 ITS. The bracketed information is not related to the spent fuel storage rack design, but rather is related to storage allowances of specific fuel assemblies. PSL is adopting ISTS 3.7.18, “Spent Fuel Storage” (ITS 3.7.15), which defines the plant specific requirements for location of fuel assemblies in the spent fuel storage pool. In addition, specific requirements associated with fuel assembly storage are provided in UFSAR Section 9.1.

the unit is

6.2 ORGANIZATION

See ITS 5.2

ONSITE AND OFFSITE ORGANIZATION

6.2.1 An onsite and an offsite organization shall be established for unit operation and corporate management. This onsite and offsite organizations shall include the positions for activities affecting the safety of the nuclear power plant.

a. Lines of authority, responsibility and communication shall be established and defined from the highest management levels through intermediate levels to and including all operating organization positions. Those relationships shall be documented and updated, as appropriate, in the form of organizational charts. These organizational charts will be documented in the Quality Assurance Topical Report and updated in accordance with 10 CFR 50.54(a)(3).
The plant-specific titles of those personnel fulfilling the responsibilities of the positions delineated in these Technical Specifications shall be documented in the UFSAR or the Quality Assurance Topical Report.

b. A specified corporate officer shall be responsible for overall plant nuclear safety. This individual shall take any measures needed to ensure acceptable performance of the staff in operating, maintaining, and providing technical support in the plant so that continued nuclear safety is assured.

c. The plant manager shall be responsible for overall safe operation and shall have control over those onsite resources necessary for safe operation and maintenance of the plant.

d. Although the individuals who train the operating staff and those who carry out the quality assurance functions may report to the appropriate manager onsite, they shall have sufficient organizational freedom to be independent from operating pressures.

e. Although health physics individuals may report to any appropriate manager onsite, for matters relating to radiological health and safety of employees and the public, the radiation protection manager shall have direct access to that onsite individual having responsibility for overall unit management. Health physics personnel shall have the authority to cease any work activity when worker safety is jeopardized or in the event of unnecessary personnel radiation exposures.

ITS

e. Although health physics individuals may report to any appropriate manager onsite, for matters relating to radiological health and safety of employees and the public, the radiation protection manager shall have direct access to that onsite individual having responsibility for overall unit management. Health physics personnel shall have the authority to cease any work activity when worker safety is jeopardized or in the event of unnecessary personnel radiation exposures.

DISCUSSION OF CHANGES
ITS 5.1, RESPONSIBILITY

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 6.1.1 provides requirements related to responsibility of the plant manager but does not contain any information concerning the plant manager's (or designee's) role in plant activities that affect nuclear safety. ITS 5.1.1 requires the plant manager or his designee to approve, prior to implementation, each proposed test, experiment, or modification to systems or equipment that affect nuclear safety. This changes the CTS by requiring the plant manager or his designee to approve certain activities to systems and equipment, prior to implementation, that affect nuclear safety.

The purpose of CTS 6.1.1 is to provide specific responsibilities for the plant manager. The proposed change adds a requirement for the plant manager (or his designee) to approve, prior to implementation, proposed tests, experiments, and modifications to systems or equipment that affect nuclear safety. The addition of this responsibility will not alter any of the existing responsibilities. The requirement is being added to ensure the plant manager is cognizant of those activities to plant systems or equipment that can potentially affect nuclear safety. This change is designated as more restrictive because it adds an additional responsibility for the plant manager in the administrative controls chapter of the ITS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 1 – Relaxation of LCO Requirements)* CTS 6.1.2 requires an individual with an active Senior Reactor Operator (SRO) license to provide control room command function during any absence of the Shift Supervisor from

the control room while either unit is in MODE 1, 2, 3, or 4. An individual with an active Reactor Operator (RO) license may also assume the control room command function during any absence of the Shift Supervisor from the control room while both units are in MODE 5 or 6. ITS 5.1.2 provides similar requirements except an individual with an active RO license may assume the control room command function during the absence of the Shift Supervisor while the unit associated with the control room is in MODE 5 or 6 irrespective of the operational status of the other unit. This changes the CTS by relaxing the control room command function requirement from requiring an SRO to assume these responsibilities while either unit is in MODE 1, 2, 3, or 4 to requiring the SRO to assume the control room command function only when the associated unit is in MODE 1, 2, 3, or 4 and allowing the RO to assume these responsibilities when the unit associated with the control room is in MODE 5 or 6.

The purpose of CTS 6.1.2 is to ensure compliance with the 10 CFR 50.54(m)(iii) requirement that, when a unit is in an operational mode other than cold shutdown or refueling, a person holding a senior operator license for the unit is present at the controls at all times and that when the unit is fueled, including cold shutdown and refueling operational modes, either a senior licensed operator or a licensed operator is present at the controls at all times. Each PSL unit is controlled from a separate control room. The CTS requirement is written for a two unit site with a common control room to ensure an SRO maintains the control room command function when either unit is in MODES 1, 2, 3, and 4. However, with separate and independent control rooms, the assignment of the control room command function is based on the operational status of the associated unit and is irrespective of the operational status of other unit.

This change is acceptable because the ITS continues to assure that a senior licensed operator (i.e., Shift Supervisor or SRO) maintains control room command function in the control room when the associated unit is in MODE 1, 2, 3, or 4 and either a senior licensed operator or a licensed operator (i.e., RO) maintains control room command function in the control room when the associated unit is shutdown and still fueled (i.e., in MODES 5 and 6). Therefore, ITS 5.1.2 will continue to satisfy the requirements of 10 CFR 50.54(m)(iii). Additionally, this change does not alter the minimum emergency response organizational requirements of the PSL emergency plan and therefore, does not impact PSL compliance with 10 CFR 50.45, Emergency plan, or 10 CFR 50, Appendix E, Emergency Planning and Preparedness for Production and Utilization Facilities. This change is designated as less restrictive because less stringent requirements are being applied in the ITS than were applied in the CTS.

Improved Standard Technical Specifications (ISTS) Markup and Justification for Deviations (JFDs)

JUSTIFICATION FOR DEVIATIONS
ITS 5.1, RESPONSIBILITY

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal. Titles used in ITS Section 5.1 align with the titles used in ANSI Standard ANSI/ANS 3.1-1978, “Standard for Selection and Training of Personnel for Nuclear Power Plants,” and alternate titles are not used. ANSI/ANS 3.1-1978 is the same ANS Standard referenced in ITS Section 5.3 (CTS 6.3).

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

DISCUSSION OF CHANGES
ITS 5.2, ORGANIZATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 6.2.1 requires, in part, to update the organizational charts documented in the Quality Assurance Topical Report (QATR) in accordance with 10 CFR 50.54(a)(3). CTS 6.2.2 requires, in part, for the unit staff organization to meet the requirements of 10 CFR 50.54(m). The ITS does not include these statements. This changes the CTS by removing the duplicate requirement to comply with the requirements of 10 CFR 50.54. Each PSL facility operating license requires the licensee to be subject to the conditions specified in 10 CFR Section 50.54. Therefore, it is unnecessary to state organizational charts in the QATR be updated in accordance with 10 CFR 50.54(a)(3) and the unit staff meet the requirements of 10 CFR 50.54(m) because it is duplicative. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 CTS 6.2.2.c requires, in part, that a health physics technician be on site when fuel is in the reactor. ITS 5.2.2.c requires a radiation protection technician to be on site when fuel is in the reactor. This changes the CTS by modifying the generic title of health physics technician with the more appropriate generic title of radiation protection technician. The purpose of CTS 6.2.2.c is to ensure there is an individual responsible for radiation protection on site when fuel is in the reactor. This change is consistent with the generic position in the ISTS and the current plant-specific title for these technicians. The generic title also aligns with the position title provided in ANSI/ANS 3.1-1978, “American National Standard for Selection and Training of Nuclear Power Plant Personnel.” This change is designated as administrative because it does not result in technical changes to the CTS.

A04 CTS 6.2.2.e requires an individual (Shift Technical Advisor (STA)) to provide advisory technical support to the unit operations shift crew, specifically be manned in MODES 1, 2, 3, or 4, and if the STA position is filled by an STA qualified Shift Supervisor or dedicated STA, then the individual may fill the same position on both units. ITS 5.2.2.e requires an individual to provide advisory technical support to the unit operations shift crew but is revised to eliminate reference to the STA position, when the position must be manned, and the details of who may fill STA role for both units. This changes the CTS by eliminating the inference that the STA role is a separate shift crew position instead of a function.

The purpose of the CTS requirement is to ensure engineering expertise is available on shift to provide advisory technical support. NRC Generic Letter

86-04 “Policy Statement on Engineering Expertise on Shift,” promulgated the policy statement regarding engineering expertise on shift and established the requirements for eliminating the separate STA position. The NRC policy statement offers the licensees two options for meeting the NUREG-0737, “Clarification of TMI Action Plan Requirements,” Enclosure 3, Item I.A.1.1 requirement regarding engineering expertise on shift and meeting licensed operator staffing requirements pursuant to 10 CFR 50.54(m)(2). Option 1 provides for elimination of the separate STA position by allowing licensees to combine one of the required SRO positions with the STA position into a dual-role (SRO/STA) function. Option 2 allows a licensee to continue use of an NRC-approved STA program while meeting licensed operator staffing requirements. Per the policy statement, the Commission encourages licensees to move toward the dual-role (SRO/STA) function, with the eventual goal of the shift supervisor serving in the dual role. Additionally, Item I.A.1.1 of NUREG-0737, Enclosure 3, allows the individual providing advisory technical support function to serve more than one unit at a multiunit site if qualified to perform the advisor function for the various units.

ITS 5.2.2.e eliminates the title of "Shift Technical Advisor (STA)," because the on shift advisory technical support function may be fulfilled by one or more of the other on-shift individuals. This change is necessary so that it does not imply that the STA and the shift supervisor must be different individuals. As a result of eliminating the STA “position,” it is unnecessary to state when the STA “position” must be manned. In addition, Item I.A.1.1 of NUREG-0737, Enclosure 3, allows the individual providing advisory technical support to serve more than one unit at a multiunit site if qualified to perform the advisor function for the various units and there is no regulatory requirement that conflicts with this statement. Therefore, it is unnecessary to restate this as an allowance in the Technical Specifications and does not prevent PSL from utilizing this allowance. This change is designated as administrative because an individual with engineering expertise (i.e., dedicated individual or dual role individual) will continue to be required on shift and this same individual may provide support to both units as allowed by NUREG-0737. Therefore, the change does not result in technical changes to the CTS.

A05 CTS 6.2.2.e, in part, includes a description of who specifically may provide advisory technical support to the unit operations shift crew: either a dedicated STA, a Shift Supervisor who meets the qualifications for the STA as required by Technical Specification 6.3.1, or an individual assigned to the unit with a Senior Reactor Operator's license who meets the qualifications for the STA as required by Technical Specification 6.3.1. ITS 5.2.2.e requires an individual to provide advisory technical support to the unit operations shift crew but is revised to eliminate the details of who is qualified to assume the duties. This changes the CTS by eliminating details regarding the individual assigned to provide technical advisory support to the unit operations shift crew.

The purpose of the CTS requirement is to ensure engineering expertise is available on shift to provide advisory technical support. NRC Generic Letter 86-04, promulgated the policy statement regarding engineering expertise on shift and established the requirements for eliminating the separate STA position. The NRC policy statement allowed for the elimination of the separate STA position by

allowing licensees to combine one of the required SRO positions with the STA position into a dual-role (SRO/STA) function. The policy statement indicates that either a dedicated STA, a Shift Supervisor who meets the qualifications or an individual assigned to the unit with a Senior Reactor Operator's license who meets the qualifications may serve the dual-role function.

It is an ITS convention to not include cross-references to comply with other Specification requirements. Compliance with other Specifications is understood. Compliance with CTS 6.3.1 (ITS 5.3.1) is required and referencing this Specification is unnecessary. Refer to ITS 5.3, “Unit Staff Qualifications,” for changes to CTS 6.3.1 requirements. This change is designated as administrative because an individual with engineering expertise and appropriate qualifications will continue to be required on shift. Therefore, the change does not result in technical changes to the CTS.

A06 CTS 6.2.1.a, regarding documentation and updating of the relationships between operating organization positions, requires that the lines of authority, responsibility and communication be established and defined from the highest management levels through intermediate levels to, and including, all operating organization positions. Those relationships shall be documented and updated, as appropriate, in the form of organizational charts. These organizational charts will be documented in the Quality Assurance Topical Report and updated in accordance with 10 CFR 50.54(a)(3). ITS 5.2.1.a states "Lines of authority, responsibility, and communication shall be defined and established throughout highest management levels, intermediate levels, and all operating organization positions. These relationships shall be documented and updated, as appropriate, in organization charts, functional descriptions of departmental responsibilities and relationships, and job descriptions for key personnel positions, or in equivalent forms of documentation." This changes the CTS by further clarifying the methods of documenting the organizational relationships in the QA Topical Report. R1

The purpose of the CTS requirement is to ensure the organizational relationships are described and maintained in the QA Topical Report. This change clarifies methods of documenting the organizational relationships in the QA Topical Report and is acceptable because the ITS continues to require the organizational relationships documented and updated in the QA Topical Report. This change is designated as administrative because it includes clarification as to methods of documenting organizational relationships in the QA Topical Report.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 (*Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program, or Surveillance Frequency Control Program)* CTS 6.2.1.a requires, in part, to document the organizational charts in the QATR. ITS 5.2.1.a does not include this requirement. The requirement that organizational charts be documented in the QATR is moved to the Updated Final Safety Analysis Report (UFSAR). This changes the CTS by moving a requirement to the UFSAR. The removal of this requirement from the Technical Specifications is acceptable because this type of information is administrative and not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement to document and update, in organizational charts, the relationship of the management levels through intermediate levels to and including operating organization positions, as appropriate. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because requirements for meeting Technical Specifications are being relocated from the Technical Specifications to the UFSAR.

LA02 (*Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements*) CTS 6.2.1.e states that, although health physics individuals may report to any appropriate manager onsite, for matters relating to radiological health and safety of employees and the public, the radiation protection manager shall have direct access to that onsite individual having responsibility for overall unit management. Health physics personnel shall have the authority to cease any work activity when worker safety is jeopardized or in the event of unnecessary personnel radiation exposures. ITS 5.2.1.d provides a similar requirement but does not provide procedural detail related to organizational freedom for health physics individuals (e.g., radiation manager shall have direct access to the individual having responsibility for overall unit management and health physics individuals' authority to cease any work activity when worker safety is jeopardized). ITS 5.2.1.d states, in part, "The individuals who… carry out health physics… functions… shall have sufficient organizational freedom to ensure their independence from operating pressures." The procedural detail of what activities constitute operational independence for health physics individuals, including the radiation protection manager's direct access to overall unit management individual, is moved to the UFSAR. This changes the CTS by moving procedural detail related to health physics individuals' responsibilities to the UFSAR and replacing the information with a general statement. The removal of these details from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for health physics individuals to have sufficient freedom to ensure their operational independence. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

None

Improved Standard Technical Specifications (ISTS) Markup and Justification for Deviations (JFDs)

5.0 ADMINISTRATIVE CONTROLS

6.2 5.2 Organization

6.2.1 5.2.1 Onsite and Offsite Organizations

Onsite and offsite organizations shall be established for unit operation and corporate management, respectively. The onsite and offsite organizations shall include the positions for activities affecting safety of the nuclear power plant.

6.2.1.a a. Lines of authority, responsibility, and communication shall be defined and established throughout highest management levels, intermediate levels, and all operating organization positions. These relationships shall be documented and updated, as appropriate, in organization charts, functional descriptions of departmental responsibilities and relationships, and job descriptions for key personnel positions, or in equivalent forms of documentation. These requirements including the plant-specific titles of those personnel fulfilling the responsibilities of the positions delineated in these Technical Specifications shall be documented in the ~~[FSAR/QA Plan]~~, (2)

Updated Final Safety Analysis Report or the Quality Assurance Topical Report

6.2.1.c b. The plant manager shall be responsible for overall safe operation of the plant and shall have control over those onsite activities necessary for safe operation and maintenance of the plant,

6.2.1.b c. A specified corporate officer shall have corporate responsibility for overall plant nuclear safety and shall take any measures needed to ensure acceptable performance of the staff in operating, maintaining, and providing technical support to the plant to ensure nuclear safety, and (4)

functions

6.2.1.d
6.2.1.e d. The individuals who train the operating staff, carry out health physics, or perform quality assurance functions may report to the appropriate onsite manager; however, these individuals shall have sufficient organizational freedom to ensure their independence from operating pressures.

6.2.2 5.2.2 Unit Staff

The unit staff organization shall include the following:

6.2.2.a a. A non-licensed operator shall be assigned to each reactor containing fuel and an additional non-licensed operator shall be assigned for each control room from which a reactor is operating in MODES 1, 2, 3, or 4.

~~REVIEWER'S NOTE~~

~~Two unit sites with both units shutdown or defueled require a total of three non-licensed operators for the two units.~~ (3)

A total of three non-licensed operators are required for both units when both units are in MODE 5 or 6.

5.2 Organization

6.2.2 5.2.2 Unit Staff (continued)

6.2.2.b b. Shift crew composition may be less than the minimum requirement of 10 CFR 50.54(m)(2)(i) and 5.2.2.a and 5.2.2.e for a period of time not to exceed 2 hours in order to accommodate unexpected absence of on-duty shift crew members provided immediate action is taken to restore the shift crew composition to within the minimum requirements.

6.2.2.c c. A radiation protection technician shall be on site when fuel is in the reactor. The position may be vacant for not more than 2 hours, in order to provide for unexpected absence, provided immediate action is taken to fill the required position.

6.2.2.d d. The operations manager or assistant operations manager shall hold an SRO license.

6.2.2.e e. An individual shall provide advisory technical support to the unit operations shift crew in the areas of thermal hydraulics, reactor engineering, and plant analysis with regard to the safe operation of the unit. This individual shall meet the qualifications specified by the Commission Policy Statement on Engineering Expertise on Shift.

5.0 ADMINISTRATIVE CONTROLS

6.2 5.2 Organization

6.2.1 5.2.1 Onsite and Offsite Organizations

Onsite and offsite organizations shall be established for unit operation and corporate management, respectively. The onsite and offsite organizations shall include the positions for activities affecting safety of the nuclear power plant.

6.2.1.a

a. Lines of authority, responsibility, and communication shall be defined and established throughout highest management levels, intermediate levels, and all operating organization positions. These relationships shall be documented and updated, as appropriate, in organization charts, functional descriptions of departmental responsibilities and relationships, and job descriptions for key personnel positions, or in equivalent forms of documentation. These requirements including the plant-specific titles of those personnel fulfilling the responsibilities of the positions delineated in these Technical Specifications shall be documented in the ~~[FSAR/QA Plan]~~, (2)

Updated Final Safety Analysis Report or the Quality Assurance Topical Report

6.2.1.c

b. The plant manager shall be responsible for overall safe operation of the plant and shall have control over those onsite activities necessary for safe operation and maintenance of the plant,

6.2.1.b

c. A specified corporate officer shall have corporate responsibility for overall plant nuclear safety and shall take any measures needed to ensure acceptable performance of the staff in operating, maintaining, and providing technical support to the plant to ensure nuclear safety, and (4)

functions

6.2.1.d
6.2.1.e

d. The individuals who train the operating staff, carry out health physics, or perform quality assurance functions may report to the appropriate onsite manager; however, these individuals shall have sufficient organizational freedom to ensure their independence from operating pressures.

6.2.2 5.2.2 Unit Staff

The unit staff organization shall include the following:

6.2.2.a

a. A non-licensed operator shall be assigned to each reactor containing fuel and an additional non-licensed operator shall be assigned for each control room from which a reactor is operating in MODES 1, 2, 3, or 4.

~~REVIEWER'S NOTE~~

~~Two unit sites with both units shutdown or defueled require a total of three non-licensed operators for the two units.~~ (3)

A total of three non-licensed operators are required for both units when both units are in MODE 5 or 6.

5.2 Organization

6.2.2 5.2.2 Unit Staff (continued)

6.2.2.b b. Shift crew composition may be less than the minimum requirement of 10 CFR 50.54(m)(2)(i) and 5.2.2.a and 5.2.2.e for a period of time not to exceed 2 hours in order to accommodate unexpected absence of on-duty shift crew members provided immediate action is taken to restore the shift crew composition to within the minimum requirements.

6.2.2.c c. A radiation protection technician shall be on site when fuel is in the reactor. The position may be vacant for not more than 2 hours, in order to provide for unexpected absence, provided immediate action is taken to fill the required position.

6.2.2.d d. The operations manager or assistant operations manager shall hold an SRO license.

6.2.2.e e. An individual shall provide advisory technical support to the unit operations shift crew in the areas of thermal hydraulics, reactor engineering, and plant analysis with regard to the safe operation of the unit. This individual shall meet the qualifications specified by the Commission Policy Statement on Engineering Expertise on Shift.

JUSTIFICATION FOR DEVIATIONS
ITS 5.2, ORGANIZATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal. Since the PSL is a two unit site, ISTS 5.2.2.a includes an additional statement requiring a total of three non-licensed operators for both units when both units are in MODE 5 or 6 (i.e., shutdown) consistent with the CTS requirement. This requirement does not extend to when both units are defueled because the ISTS nor 10 CFR 50.54(m) require licensed operators assigned to the reactor or control room when the reactor is defueled. Therefore, it unnecessary to require non-licensed operators when both units are defueled.

4. Grammatical correction made to the ITS to clarify ISTS 5.5.2.d includes individuals required to carry out health physics “functions.”

DISCUSSION OF CHANGES
ITS 5.3, UNIT STAFF QUALIFICATIONS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 (*Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program, or Surveillance Frequency Control Program)* CTS 6.3.1(3) provides minimum education, experience, and training requirements for multi-discipline supervisors. ITS 5.3.1 does not include these requirements. The minimum education, experience, and training requirements for multi-discipline supervisors are moved to the Updated Final Safety Analysis Report (UFSAR). This changes the CTS by moving an administrative requirement to the UFSAR. The removal of this requirement from the Technical Specifications is acceptable because this type of information is administrative and not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains minimum qualification requirements for members of the facility staff for comparable positions as defined in ANSI/ANS-3.1-1978 or Regulatory Guide 1.8, as appropriate. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because administrative requirements in Technical Specifications are being relocated from the Technical Specifications to the UFSAR.

LESS RESTRICTIVE CHANGES

L01 (*Category 1 – Relaxation of LCO Requirements*) CTS 6.3.1(2) provides specific training requirements and minimum educational requirements for the Shift Technical Advisor. ITS 5.3.1 does not include these requirements. This changes

the CTS by deleting explicit administrative training and qualification requirements for the shift technical advisor function.

The purpose of CTS 6.3.1(2) is to ensure the individual that provides advisory technical support to the unit operations shift crew (i.e., shift technical advisor) meets minimum qualifications and training pursuant to NUREG-0737, "Clarification of TMI Action Plan Requirements," Enclosure 3, Item I.A.1.1 This change is acceptable because the Florida Power & Light Company Quality Assurance Topical Report requires training for positions identified in 10CFR50.120, which includes the shift technical advisor position, be accomplished according to programs accredited by the National Nuclear Accrediting Board of the National Academy for Nuclear Training that implements a systematic approach to training. The systematic approach to training process develops and maintains training programs to ensure individuals are trained and meet minimum educational requirements necessary to perform their required tasks. Therefore, an individual who provides the shift technical advisor function will continue to be adequately trained and qualified to provide engineering expertise on shift. This change is designated as less restrictive because less stringent administrative LCO requirements are being applied in the ITS than were applied in the CTS.

Improved Standard Technical Specifications (ISTS) Markup and Justification for Deviations (JFDs)

DISCUSSION OF CHANGES
ITS 5.4, PROCEDURES

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 6.8.1.a requires written procedures to be established, implemented, and maintained, in part, for those required for implementing the requirements of NUREG-0737. ITS 5.4.1.b provides a similar requirement specifically stating, "The emergency operating procedures required to implement the requirements of NUREG-0737 and NUREG-0737, Supplement 1, as stated in Generic Letter 82-33." Supplement 1 to NUREG-0737 enclosed with Generic Letter 82-33 is part of the implementation of the Three Mile Island (TMI) action items of NUREG-0737. The purpose of the generic letter was to provide additional clarification regarding, in part, upgrade of emergency operating procedures associated with TMI Action Item I.C.1. As a result, the change clarifies the existing requirement to comply with NUREG-0737 and NUREG-0737, Supplement 1, as stated in Generic Letter 82-33, for emergency operating procedures. This change is designated as an administrative change and is acceptable because it does not result in a technical change to the CTS.

A03 CTS 6.8.1.b and c require written procedures be established, implemented, and maintained covering refueling operations and surveillance and test activities of safety-related equipment, respectively. ITS 5.4.1 does not explicitly require these activities but rather requires written procedures shall be established, implemented, and maintained to the applicable procedures recommended in Regulatory Guide 1.33, Revision 2, Appendix A, February 1978 consistent with CTS 6.8.1.a. This changes the CTS by removing the specific wording of CTS 6.8.1.b and CTS 6.8.1.c. This change is considered administrative because the recommendations of Regulatory Guide 1.33, Revision 2, Appendix A, February 1978 require procedures for refueling operations and surveillance tests for safety related activities. Therefore, specifically citing these requirements individually is unnecessary. This change is designated as administrative because it does not result in a technical change to the CTS.

A04 CTS 6.8.1.h requires written procedures be established, implemented, and maintained for OFFSITE DOSE CALCULATION MANUAL (ODCM) implementation. ITS 5.4.1 requires procedures for various activities but does not specifically list the ODCM. This changes the CTS by removing the specific requirement for written procedures to implement the ODCM. This change is acceptable because implementing procedures for the ODCM are required by ITS 5.4.1.d. ITS 5.4.1.d (as described in DOC M01) requires that written procedures be established, implemented, and maintained for programs and manuals listed in ITS Section 5.5. ITS Section 5.5 includes the ODCM. Therefore, it is not necessary to specifically identify the ODCM in ITS 5.4.1. This

change is designated as administrative because it does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 ITS 5.4.1.d requires written procedures be established, implemented, and maintained for programs specified in Specification 5.5. The CTS does not include this requirement for any program except the OFFSITE DOSE CALCULATION MANUAL. This changes the CTS by adopting a new requirement for procedures to address programs described in ITS Section 5.5. The purpose of ITS 5.4.1.d is to ensure that written procedures are established, implemented, and maintained covering programs specified in ITS Section 5.5. This change is acceptable because it requires written procedures, including proper procedure control, to address programs required by ITS Section 5.5. This change is designated as more restrictive because it imposes new administrative requirements for procedures within the Technical Specifications.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 (*Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, or ISI Program*) CTS 6.8.1.g requires that written procedures for the PROCESS CONTROL PROGRAM (PCP) be established, implemented, and maintained. The ITS does not include these requirements. This changes the CTS by moving the requirements to the Updated Safety Analysis Report (UFSAR). The removal of these details, which are related to meeting Specification requirements, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety.

The PCP implements the requirements of 10 CFR 20, 10 CFR 61, and 10 CFR 71 and written procedures are necessary to ensure compliance with regulations. Regulations provide an adequate level of control for the affected requirements, and thus, inclusion of this requirement in the Technical Specifications is not necessary. Also, this change is acceptable because these details will be adequately controlled in the UFSAR. Any changes to the UFSAR are made under 10 CFR 50.59 or 10 CFR 50.71(e), which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because details for meeting Technical Specification and regulatory requirements are being removed from the Technical Specifications.

LA02 (*Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, or ISI Program*) CTS 6.8.1.i and j require written procedures be established, implemented, and maintained

covering the Quality Control Program for effluent and environmental monitoring, respectively, "using the guidance in Regulatory Guide 1.21, Revision 1, 1974, and Regulatory Guide 4.1, Revision 1, April 1975." ITS 5.4.1.c does not include the Regulatory Guide references. This changes the CTS by moving the references to the regulatory guides to the UFSAR. The removal of these details, which are related to meeting Technical Specification requirements, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for written procedures covering quality assurance for effluent and environmental monitoring. Also, this change is acceptable because these details will be adequately controlled in the UFSAR. Any changes to the UFSAR are made under 10 CFR 50.59 or 10 CFR 50.71(e), which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because references for meeting Technical Specification requirements are being removed from the Technical Specifications.

~~Modifications to the CPC software (including changes of algorithms and fuel cycle specific data) shall be performed in accordance with the most recent version of "CPC Protection Algorithm Software Change Procedure," CEN-39(A)-P, which has been determined to be applicable to the facility. Additions or deletions to CPC addressable constants or changes to addressable constant software limit values shall not be implemented without prior NRC approval.]~~

JUSTIFICATION FOR DEVIATIONS
ITS 5.4, PROCEDURES

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. Grammatical error corrected.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. ISTS 5.4.1.d is deleted consistent with St. Lucie (PSL) Unit 1 and Unit 2 current licensing basis. PSL Units 1 and 2 transitioned to a risk-informed, performance-based fire protection program in accordance with National Fire Protection Association Standard NFPA 805 pursuant to 10 CFR 50.48(c). This transition was approved March 31, 2016 as issued in License Amendments 231 and 181, for Unit 1 and Unit 2 respectively (ADAMS Accession No. ML15344A346). As stated in the NRC Safety Evaluation supporting the license amendments, the administrative requirement that procedures be established, implemented, and maintained for Fire Protection Program implementation is contained in regulations 10 CFR 50.48(a) and 10 CFR 50.48(c); and in NFPA 805 Chapter 3. The NRC staff concluded that maintaining a procedure requirement for Fire Protection Program (FPP) implementation in Technical Specifications is redundant to the NFPA 805 requirement to establish FPP procedures, and as such, is unnecessary. Therefore, ISTS 5.4.1.d is not included in the ITS. The list in ITS 5.4.1 has been relabeled, as applicable.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 5.4, PROCEDURES

6.0 ADMINISTRATIVE CONTROLS

~~6.8.3 DELETED~~

5.5 ~~6.8.4~~ The following programs shall be established, implemented, and maintained.

5.5.2 a. Primary Coolant Sources Outside Containment

A program to reduce leakage from those portions of systems outside containment that could contain highly radioactive fluids during a serious transient or accident to as low as practical levels. The systems include ~~the Shutdown Cooling System~~, High Pressure Safety Injection ~~System~~, Containment Spray ~~System~~, and RCS Sampling. The program shall include the following:

A02

Low Pressure Safety Injection

5.5.2.a (i) Preventive maintenance and periodic visual inspection requirements, and

5.5.2.b (ii) Integrated leak test requirements for each system ~~at least once per 18 months~~.

LA01

in accordance with the Surveillance Frequency Control Program

SR 3.0.2

The provisions of ~~Specification 4.0.2~~ are applicable.

~~b. In-Plant Radioiodine Monitoring~~

~~A program which will ensure the capability to accurately determine the airborne iodine concentration in vital areas under accident conditions. This program shall include the following:~~

LA02

~~(i) Training of personnel,~~

~~(ii) Procedures for monitoring, and~~

~~(iii) Provisions for maintenance of sampling and analysis equipment.~~

5.5.7 c. Secondary Water Chemistry

A program for monitoring of secondary water chemistry to inhibit steam generator tube degradation. This program shall include:

5.5.7.a (i) Identification of a sampling schedule for the critical variables and control points of these variables,

5.5.7.b (ii) Identification of the procedures used to measure the values of the critical variables,

5.5.7.c (iii) Identification of process sampling points, which shall include monitoring the discharge of the condensate pumps for evidence of condenser in-leakage,

5.5.7.d (iv) Procedures for the recording and management of data,

5.5.7.e (v) Procedures defining corrective actions for all off-control point chemistry conditions, and

5.5.7.f (vi) A procedure identifying ~~(a)~~ the authority responsible for the interpretation of the data, and ~~(b)~~ the sequence and timing of administrative events required to initiate corrective action.

~~d. Backup Method for Determining Subcooling Margin~~

~~A program which will ensure the capability to accurately monitor the Reactor Coolant System subcooling margin. This program shall include the following:~~

~~(i) Training of personnel, and~~

~~(ii) Procedures for monitoring.~~

LA03

~~e. DELETED~~

5.5.3 f. Radioactive Effluent Controls Program

A program shall be provided conforming with 10 CFR 50.36a for the control of radioactive effluents and for maintaining the doses to MEMBERS OF THE PUBLIC from radioactive effluents as low as reasonably achievable. The program ~~(1)~~ shall be contained in the ODCM, ~~(2)~~ shall be implemented by ~~operating~~ procedures, and ~~(3)~~ shall include remedial actions to be taken whenever the program limits are exceeded. The program shall include the following elements:

functional capability

5.5.3.a 1) Limitations on the ~~operability~~ of radioactive liquid and gaseous monitoring instrumentation including surveillance tests and setpoint determination in accordance with the methodology in the ODCM,

5.5.3.b 2) Limitations on the concentrations of radioactive material released in liquid effluents to UNRESTRICTED AREAS conforming to ten times the concentration values in 10 CFR 20.1001 - 20.240~~1~~2, Appendix B, Table 2, Column 2.

A03

5.5.3.c 3) Monitoring, sampling, and analysis of radioactive liquid and gaseous effluents in accordance with 10 CFR 20.1302 and with the methodology and parameters in the ODCM,

5.5.3.d 4) Limitations on the annual and quarterly doses or dose commitment on a MEMBER OF THE PUBLIC from radioactive materials in liquid effluents released from each unit to UNRESTRICTED AREAS conforming to Appendix I to 10 CFR Part 50,

5.5.3.e 5) Determination of cumulative dose contributions from radioactive effluents for the current calendar quarter and current calendar year in accordance with the methodology and parameters in the ODCM at least every 31 days. Determination of projected dose contributions from radioactive effluents in accordance with the methodology in the ODCM at least every 31 days.

5.5.3.f 6) Limitations on the ~~operability~~ functional capability and use of the liquid and gaseous effluent treatment systems to ensure that the appropriate portions of these systems are used to reduce releases of radioactivity when the projected doses in a 31-day period would exceed 2 percent of the guidelines for the annual dose or dose commitment conforming to Appendix I to 10 CFR Part 50,

5.5.3.g 7) Limitations on the dose rate resulting from radioactive material released in gaseous effluents to areas at or beyond the SITE BOUNDARY shall be limited to the following:

a) For noble gases: Less than or equal to 500 mrem/yr to the total body and less than or equal to 3000 mrem/yr to the skin, and

b) For Iodine-131, for Iodine-133, for tritium, and for all radionuclides in particulate form with half-lives greater than 8 days: Less than or equal to 1500 mrem/yr to any organ;

5.5.3.h 8) Limitations on the annual and quarterly air doses resulting from noble gases released in gaseous effluents from each unit to areas beyond the SITE BOUNDARY conforming to Appendix I to 10 CFR Part 50,

5.5.3.i 9) Limitations on the annual and quarterly doses to a MEMBER OF THE PUBLIC from Iodine-131, Iodine-133, tritium, and all radionuclides in particulate form with half-lives greater than 8 days in gaseous effluents released from each unit to areas beyond the SITE BOUNDARY conforming to Appendix I to 10 CFR Part 50,

5.5.3.j 10) Limitations on the annual dose or dose commitment to any MEMBER OF THE PUBLIC, beyond the site boundary, due to releases of radioactivity and to radiation from uranium fuel cycle sources conforming to 40 CFR Part 190.

The provisions of ~~Specifications 4.0.2~~ SR 3.0.2 and ~~4.0.3~~ SR 3.0.3 are applicable to the Radioactive Effluent Controls Program surveillance frequency.

~~g. Radiological Environmental Monitoring Program~~

~~A program shall be provided to monitor the radiation and radio-nuclides in the environs of the plant. The program shall provide (1) representative measurements of radioactivity in the highest potential exposure pathways, and (2) verification of the accuracy of the effluent monitoring program and modeling of the environmental exposure pathways. The program shall (1) be contained in the ODCM;~~

LA04

~~(2) conform to the guidance of Appendix I to 10 CFR Part 50, and~~
~~(3) include the following:~~

~~1) Monitoring, sampling, analysis, and reporting of radiation and radionuclides in the environment in accordance with the methodology and parameters in the ODCM.~~

~~2) A Land Use Census to ensure that changes in the use of areas at and beyond the SITE BOUNDARY are identified and that modifications to the monitoring program are made if required by the results of this census, and~~

~~3) Participation in a Interlaboratory Comparison Program to ensure that independent checks on the precision and accuracy of the measurements of radioactive materials in environmental sample matrices are performed as part of the quality assurance program for environmental monitoring.~~

LA04

5.5.13 h. Containment Leakage Rate Testing Program

5.5.13.a A program to implement the leakage rate testing of the containment as required by 10 CFR 50.54(o) and 10 CFR 50 Appendix J, Option B, as modified by approved exemptions. This program is in accordance with the guidelines contained in NEI 94-01, Revision 2-A, "Industry Guideline for Implementing Performance-Based Option of 10 CFR Part 50, Appendix J~~,~~." ~~except that the next Type A test performed after the December 8, 2005 Type A test shall be performed no later than December 8, 2020~~.

A04

5.5.13.b The peak calculated containment internal pressure for the design basis loss of coolant accident P_a, is 42.~~8~~ psig. The containment design pressure is 44 psig.

77

M04 | R1

5.5.13.c The maximum allowed containment leakage rate, L_a, at P_a, shall be 0.50% of containment air weight per day.

5.5.13.d Leakage rate acceptance criteria are:

5.5.13.d.1 a. Containment leakage rate acceptance criterion is $\leq$ 1.0 L_a. During the first unit startup following testing in accordance with this program, the leakage rate acceptance criteria are < 0.60 L_a for the Type B and C tests, $\leq$ 0.75 L_a for Type A tests, and $\leq$ 0.096 L_a for secondary containment bypass leakage paths.

5.5.13.d.2 b. Air lock testing acceptance criteria are:

See ITS 3.6.3

5.5.13.d.2.a) 1) Overall air lock leakage rate is $\leq$ 0.05 L_a when tested at $\geq$ P_a.

5.5.13.d.2.b) 2) For ~~the~~ personnel air lock door ~~seal~~, leakage rate is < 0.01 L_a when pressurized to $\geq$ 1.0 P_a.

each

5.5.13.d.2.c) 3) For ~~the~~ emergency air lock door ~~seal~~, leakage rate is < 0.01 L_a when pressurized to $\geq$ 10 psig.

5.5.11 j. Technical Specifications (TS) Bases Control Program

This program provides a means for processing changes to the Bases of these Technical Specifications.

5.5.11.a 1. Changes to the Bases of the TS shall be made under appropriate administrative controls and reviews.

5.5.11.b 2. Licensees may make changes to Bases without prior NRC approval provided the changes do not require either of the following:

5.5.11.b.1 a. a change in the TS incorporated in the license; or

5.5.11.b.2 b. a change to the ~~updated~~ UFSAR or Bases that requires NRC approval pursuant to 10 CFR 50.59.

5.5.11.c 3. The Bases Control Program shall contain provisions to ensure that the Bases are maintained consistent with the UFSAR.

5.5.11.b

5.5.11.d 4. Proposed changes that meet the criteria of ~~Specification 6.8.4.j.2.a or 6.8.4.j.2.b~~, above, shall be reviewed and approved by the NRC prior to implementation. Changes to the Bases implemented without prior NRC approval shall be provided to the NRC on a frequency consistent with 10 CFR 50.71(e).

ADMINISTRATIVE CONTROLS (continued)

5.5.8 k. Ventilation Filter Testing Program (VFTP)

A program shall be established to implement the following required testing of Engineered Safety Feature (ESF) filter ventilation systems ~~at the frequencies specified in Regulatory Guide 1.52, Revision 3.~~ Insert 1 A06

5.5.8.a 1. Demonstrate for each of the ESF systems that an inplace test of the high efficiency particulate air (HEPA) filters shows a penetration and system bypass ~~less than the value specified below~~ ≤ 0.05% when tested in accordance with ASME N510-1989 at the system flowrate specified below. ± 10%

ESF Ventilation System	Penetration	Flowrate
Control Room Emergency Ventilation System (CREVS)	~~≤ 0.05%~~	2000 ~~± 200 cfm~~
Shield Building Ventilation System SBVS	~~≤ 0.05%~~	6000 ~~± 600 cfm~~
Emergency Core Cooling System (ECCS) Area Ventilation System	~~≤ 0.05%~~	30,000 ~~± 3000 cfm~~

5.5.8.b 2. Demonstrate for each of the ESF systems that an inplace test of the charcoal adsorber shows a penetration and system bypass ~~less than the value specified below~~ when tested in accordance with ASME N510-1989 at the system flowrate specified below. ± 10%

ESF Ventilation System	Penetration	Flowrate
CREVS ~~Control Room Emergency Ventilation~~	≤ 0.05%	2000 ~~± 200 cfm~~
SBVS ~~Shield Building Ventilation System~~	~~≤ 0.05%~~	6000 ~~± 600 cfm~~
ECCS Area Ventilation System	~~≤ 0.05%~~	30,000 ~~± 3000 cfm~~

5.5.8.c 3. Demonstrate for each of the ESF systems that a laboratory test of a sample of the charcoal adsorber, when obtained as described in Regulatory Guide 1.52, Revision 3, shows the methyl iodide penetration ~~less than the value specified below~~ when tested in accordance with ASTM D3803-1989 at a temperature of 30°C (86°F) and ~~the~~ a relative humidity ~~specified below~~ ≤ 70%.

ESF Ventilation System	Penetration	RH
CREVS ~~Control Room Emergency Ventilation~~	≤ 2.5%	~~70%~~
SBVS ~~Shield Building Ventilation System~~	~~≤ 2.5%~~	~~70%~~
ECCS Area Ventilation System	~~≤ 2.5%~~	~~70%~~

5.5.8.d 4. Demonstrate for each of the ESF systems that the pressure drop across the combined HEPA filters and charcoal adsorbers is less than the value specified below when tested at the system flowrate specified below. ± 10%

ESF Ventilation System	Delta P	Flowrate
CREVS ~~Control Room Emergency Ventilation~~	< 4.15" W.G.	2000 ~~± 200 cfm~~
SBVS ~~Shield Building Ventilation System~~	≤ 6.15" W.G.	6000 ~~± 600 cfm~~
ECCS Area Ventilation System	< 4.15" W.G.	30,000 ~~± 3000 cfm~~

At a frequency in accordance with the Surveillance Frequency Control Program

5.5.8.f 5. ~~At least once per 18 months~~, demonstrate that the heaters for each of the ESF systems dissipate the value specified below when tested in accordance with ASME N510-1989. LA01

ESF Ventilation System	Wattage
SBVS ~~Shield Building Ventilation System~~	
Main Heaters	30 ± 3 kW
Auxiliary Heaters	1.5 ± 0.25 kW

ITS

Insert 1

5.5.8 and the Fuel Pool Area Ventilation System in accordance with Regulatory Guide 1.52, Revision 3, ASME N510-1989, ASTM D3803-1989 and, ANSI N510-1975, as described herein.

ADMINISTRATIVE CONTROLS (continued)

M01

The provisions of SR ~~4.0.2~~ and SR ~~4.0.3~~ are applicable to the VFTP test frequencies.

3.0.2 3.0.3

5.5.6 l. Steam Generator (SG) Program

Insert proposed 5.5.5, "RCP Flywheel Inspection Program"

A Steam Generator Program shall be established and implemented to ensure that SG tube integrity is maintained. In addition, the Steam Generator Program shall include the following provisions:

5.5.6.a a. Provisions for condition monitoring assessments. Condition monitoring assessment means an evaluation of the "as found" condition of the tubing with respect to the performance criteria for structural integrity and accident induced leakage. The "as found" condition refers to the condition of the tubing during an SG inspection outage, as determined from the inservice inspection results or by other means, prior to the plugging of tubes. Condition monitoring assessments shall be conducted during each outage during which the SG tubes are inspected or plugged to confirm that the performance criteria are being met.

5.5.6.b b. Performance criteria for SG tube integrity. SG tube integrity shall be maintained by meeting the performance criteria for tube structural integrity, accident induced leakage, and operational leakage.

1. Structural integrity performance criterion: All in-service SG tubes shall retain structural integrity over the full range of normal operating conditions (including startup, operation in the power range, hot standby, and cooldown and all anticipated transients included in the design specification) and design basis accidents. This includes retaining a safety factor of 3.0 against burst under normal steady state full power operation primary-to-secondary pressure differential and a safety factor of 1.4 against burst applied to the design basis accident primary-to-secondary pressure differentials. Apart from the above requirements, additional loading conditions associated with the design basis accidents, or combination of accidents in accordance with the design and licensing basis, shall also be evaluated to determine if the associated loads contribute significantly to burst or collapse. In the assessment of tube integrity, those loads that do significantly affect burst or collapse shall be determined and assessed in combination with the loads due to pressure with a safety factor of 1.2 on the combined primary loads and 1.0 on axial secondary loads.

2. Accident induced leakage performance criterion: The primary-to-secondary accident induced leakage rate for any design basis accident, other than SG tube rupture, shall not exceed the leakage rate assumed in the accident analysis in terms of total leakage rate for all SGs and leakage rate for an individual SG. Leakage is not to exceed 0.5 gpm total through all SGs and 0.25 gpm through any one SG.

3. The operational leakage performance criterion is specified in LCO ~~3.4.6.2.c~~, "Reactor Coolant System Operational Leakage."

3.4.13

plugging

5.5.6.c c. Provisions for SG tube ~~repair~~ criteria. Tubes found by inservice inspection to contain flaws with a depth equal to or exceeding 40% of the nominal tube wall thickness shall be plugged.

A07

ADMINISTRATIVE CONTROLS (continued)

5.5.6 l. Steam Generator (SG) Program (continued)

5.5.6.d d. Provisions for SG tube inspections. Periodic SG tube inspections shall be performed. The number and portions of the tubes inspected and methods of inspection shall be performed with the objective of detecting flaws of any type (e.g., volumetric flaws, axial and circumferential cracks) that may be present along the length of the tube, from the tube-to-tubesheet weld at the tube inlet to the tube-to-tubesheet weld at the tube outlet, and that may satisfy the applicable tube ~~repair~~ criteria. The tube-to-tubesheet weld is not part of the tube. In addition to meeting the requirements of d.1, d.2, and d.3 below, the inspection scope, inspection methods, and inspection intervals shall be such as to ensure that SG tube integrity is maintained until the next SG inspection. An assessment of degradation shall be performed to determine the type and location of flaws to which the tube may be susceptible and, based on this assessment, to determine which inspection methods need to be employed and at what locations.

plugging

A07

5.5.6.d.1 1. Inspect 100% of the tubes in each SG during the first refueling outage following SG replacement.

5.5.6.d.2 2. Inspect 100% of the tubes at ~~sequential periods of 144, 108, 72, and, thereafter, 60~~ 96 effective full power months. The first sequential period shall be considered to begin after the first inservice inspection of the SGs. ~~In addition, inspect 50% of the tubes by the refueling outage nearest the midpoint of the period and the remaining 50% by the refueling outages nearest the end of the period. No SG shall operate for more than 72 effective full power months or three refueling outages (whichever is less) without being inspected.~~

L01

affected and potentially affected

5.5.6.d.3 3. If crack indications are found in any SG tube, then the next inspection for each SG for the degradation mechanism that caused the crack indication shall ~~not exceed 24 effective full power months or one~~ be at the next refueling outage ~~(whichever is less)~~. If definitive information, such as from examination of a pulled tube, diagnostic non-destructive testing, or engineering evaluation indicates that a crack-like indication is not associated with a crack(s), then the indication need not be treated as a crack.

5.5.6.e e. Provisions for monitoring operational primary-to-secondary leakage.

M02

Insert proposed 5.5.14, "Battery Monitoring and Maintenance Program"

5.5.15 m. Control Room Envelope Habitability Program

A Control Room Envelope (CRE) Habitability Program shall be established and implemented to ensure that CRE habitability is maintained such that, with an OPERABLE Control Room Emergency Ventilation System (CREVS), CRE occupants can control the reactor safely under normal conditions and maintain it in a safe condition following a radiological event, hazardous chemical release, or a smoke challenge. The program shall ensure that adequate radiation protection is provided to permit access and occupancy of the CRE under design basis accident (DBA) conditions without personnel receiving radiation exposures in excess of 5 rem total effective dose equivalent (TEDE) for the duration of the accident.

The program shall include the following elements:

a. The definition of the CRE and the CRE boundary.

b. Requirements for maintaining the CRE boundary in its design condition including configuration control and preventive maintenance.

ADMINISTRATIVE CONTROLS (continued)

5.5.15 m. Control Room Envelope Habitability Program (continued)

c. Requirements for (i) determining the unfiltered air inleakage past the CRE boundary into the CRE in accordance with the testing methods and at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, "Demonstrating Control Room Envelope Integrity at Nuclear Power Reactors," Revision 0, May 2003, and (ii) assessing CRE habitability at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, Revision 0.

d. Measurement, at designated locations, of the CRE pressure relative to all external areas adjacent to the CRE boundary during the pressurization mode of operation by one train of the CREVS, operating at the flow rate required by the VFTP, at a Frequency ~~of 36 months on a STAGGERED TEST BASIS~~. The results shall be trended and used as part of the 36 month assessment of the CRE boundary.

in accordance with the Surveillance Frequency Control Program

LA01

e. The quantitative limits on unfiltered air inleakage into the CRE. These limits shall be stated in a manner to allow direct comparison to the unfiltered air inleakage measured by the testing described in paragraph c. The unfiltered air inleakage limit for radiological challenges is the inleakage flow rate assumed in the licensing basis analyses of DBA consequences. Unfiltered air inleakage limits for hazardous chemicals must ensure that exposure of CRE occupants to these hazards will be within the assumptions in the licensing basis.

3.0.2

f. The provisions of SR ~~4.0.2~~ are applicable to the Frequencies for assessing CRE habitability, determining CRE unfiltered inleakage, and measuring CRE pressure and assessing the CRE boundary as required by paragraphs c and d, respectively.

n. Diesel Fuel Oil Testing Program

5.5.10

A diesel fuel oil testing program to implement required testing of both new fuel oil and stored fuel oil shall be established. The program shall include sampling and testing requirements, and acceptance criteria, all in accordance with applicable ASTM Standards. The purpose of the program is to establish the following:

5.5.10.a (i) Acceptability of new fuel oil for use prior to addition to storage tanks by determining that the fuel oil has:

1. An API gravity or an absolute specific gravity within limits,
2. A flash point and kinematic viscosity within limits for ASTM 2D fuel oil, and
3. A clear and bright appearance with proper color or a water and sediment content within limits;

5.5.10.b (ii) Other properties for ASTM 2D fuel oil are within limits within 31 days following ~~sampling and~~ addition to storage tanks; and

5.5.10.c (iii) Total particulate concentration of the fuel oil is ≤ 10 mg/l when tested ~~every 31 days~~.

LA01

in accordance with the Surveillance Frequency Control Program

The provisions of SR ~~4.0.2~~ and SR ~~4.0.3~~ are applicable to the Diesel Fuel Oil Testing Program test frequencies.

3.0.2

3.0.3

5.5.16 o. Surveillance Frequency Control Program

This program provides controls for Surveillance Frequencies. The program shall ensure that Surveillance Requirements specified in the Technical Specifications are performed at intervals sufficient to assure the associated Limiting Conditions for Operation are met.

a. The Surveillance Frequency Control Program shall contain a list of frequencies of those Surveillance Requirements for which the frequency is controlled by the program.

b. Changes to the frequencies listed in the Surveillance Frequency Control Program shall be made in accordance with NEI 04-10, "Risk-Informed Method for Control of Surveillance Frequencies," Revision 1.

SR 3.0.2 SR 3.0.3

c. The provisions of ~~Surveillance Requirements~~ 4.0.2 and ~~4.0.3~~ are applicable to the frequencies established in the Surveillance Frequency Control Program.

~~p. Snubber Testing Program~~ R1

~~This program conforms to the examination, testing and service life monitoring for dynamic restraints (snubbers) in accordance with 10 CFR 50.55a inservice inspection (ISI) requirements for supports. The program shall be in accordance with the following:~~

~~1. This program shall meet 10 CFR 50.55a(g) ISI requirements for supports.~~

~~2. The program shall meet the requirements for ISI of supports set forth in subsequent editions of the Code of Record and addenda of the American Society of Mechanical Engineers (ASME) Boiler and Pressure (BPV) Code and the ASME Code for Operation and Maintenance of Nuclear Power Plants (OM Code) that are incorporated by reference in 10 CFR 50.55a(b) subject to the conditions listed in 10 CFR 50.55a(b) and subject to Commission approval.~~ LA08

~~3. The program shall, as required by 10 CFR 50.55a(b)(3)(v), meet Subsection ISTA, "General Requirements" and Subsection ISTD, "Preservice and Inservice Examination and Testing of Dynamic Restraints (Snubbers) in Light-Water Reactor Nuclear Power Plants".~~

~~4. The 120-month program updates shall be made in accordance with 10 CFR 50.55a(g)(4), 10 CFR 50.55a(g)(3)(v) and 10 CFR 50.55a(b) (including 10 CFR 50.55a(b)(3)(v)) subject to the conditions listed therein.~~

5.5.4 q. Component Cyclic or Transient Limit Program U

The program provides controls to track the FSAR, Section 5.2, cyclic and transient occurrences to ensure that components are maintained within the design limits.

5.5.17 r. Risk Informed Completion Time Program

This program provides controls to calculate a Risk Informed Completion Time (RICT) and must be implemented in accordance with NEI 06-09-A, ~~"Risk-Informed Technical Specifications Initiative 4b:~~ Risk-Managed Technical Specifications (RMTS) Guidelines~~,~~." Revision 0 ~~-A, November 2006.~~ The program shall include the following:

a. The RICT may not exceed 30 days;

b. A RICT may only be utilized in MODES 1 and 2;

5.5.17

c. When a RICT is being used, any plant configuration change within the scope of the Configuration Risk Management Program must be considered for the effect on the RICT.

1. For planned changes, the revised RICT must be determined prior to implementation of the change in configuration.

2. For emergent conditions, the revised RICT must be determined within the time limits of the Required Action Completion Time (i.e., not the RICT) or 12 hours after the plant configuration change, whichever is less.

3. Revising the RICT is not required If the plant configuration change would lower plant risk and would result in a longer RICT.

d. Use of a RICT is not permitted for entry into a configuration which represents a loss of a specified safety function or inoperability of all required trains of a system required to be OPERABLE.

e. If the extent of condition evaluation for inoperable structures, systems, or components (SSCs) is not complete prior to exceeding the Completion Time, the RICT shall account for the increased possibility of common cause failure (CCF) by either:

1. Numerically accounting for the increased possibility of CCF in the RICT calculation, or

2. Risk Management Actions (RMAs) not already credited in the RICT calculation shall be implemented that support redundant or diverse SSCs that perform the function(s) of the inoperable SSCs, and, if practicable, reduce the frequency of initiating events that challenge the function(s) performed by the inoperable SSCs.

s. Safety Function Determination Program (SFDP)

5.5.12

limitations and remedial or compensatory

A08

This program ensures loss of safety function is detected and appropriate actions taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other appropriate actions may be taken as a result of the support system inoperability and corresponding exception to entering supported system ~~ACTIONS~~. This program implements the requirements of LCO 3.0.6. The SFDP shall contain the following:

Conditions and Required Actions

A09

a. Provisions for cross train checks to ensure a loss of the capability to perform the safety function assumed in the accident analysis does not go undetected,

b Provisions for ensuring the plant is maintained in a safe condition if a loss of function condition exists,

Completion Time

A09

c. Provisions to ensure that an inoperable supported system's ~~allowed outage time~~ is not inappropriately extended as a result of multiple support system inoperabilites, and

d. Other appropriate limitations and remedial or compensatory actions.

5.5.12 A loss of safety function exists when, assuming no concurrent single failure, no concurrent loss of offsite power, or no concurrent loss of onsite diesel generator(s), a safety function assumed in the accident analysis cannot be performed. For the purpose of this program, a loss of safety function may exist when a support system is inoperable, and:

a. A required system redundant to the system(s) supported by the inoperable support system is also inoperable, or

b. A required system redundant to the system(s) in turn supported by the inoperable supported system is also inoperable, or

c. A required system redundant to the support system(s) for the supported systems (a) and (b) above is also inoperable.

Conditions and Required Actions

A09

The SFDP identifies where a loss of safety function exists. If a loss of safety function is determined to exist by this program, the appropriate ~~ACTIONS~~ of the LCO in which the loss of safety function exists are required to be entered. When a loss of safety function is caused by the inoperability of a single Technical Specification support system, the appropriate ~~ACTIONS~~ to enter are those of the support system.

Conditions and Required Actions

A09

6.9 REPORTING REQUIREMENTS

See ITS 5.6

ROUTINE REPORTS

6.9.1 In addition to the applicable reporting requirements of Title 10, Code of Federal Regulations, the following reports shall be submitted to the NRC.

STARTUP REPORT

6.9.1.1 A summary report of plant startup and power escalation testing shall be submitted following:

(1) receipt of an operating license,

(2) amendment of the license involving a planned increase in power level,

(3) installation of fuel that has a different design or has been manufactured by a different fuel supplier, and

(4) modifications that may have significantly altered the nuclear, thermal or hydraulic performance of the plant.

6.13 PROCESS CONTROL PROGRAM (PCP)

Changes to the PCP:

1. Shall be documented and this documentation shall contain:

   a) Sufficient information to support the change together with the appropriate analyses or evaluations justifying the change(s) and

   b. A determination that the change will maintain the overall conformance of the solidified waste product to existing requirements of Federal, State, or other applicable regulations.

2. Shall become effective after the approval of the plant manager.

See CTS 6.0

5.5.1 ## 6.14 OFFSITE DOSE CALCULATION MANUAL (ODCM)

Changes to the ODCM:

and records of reviews performed shall be retained.

M03

5.5.1.a 1. Shall be documented ~~and~~ this documentation shall contain:

5.5.1.a.1 a) Sufficient information to support the change together with the appropriate analyses or evaluations justifying the change(s) and

5.5.1.a.2 b. A determination that the change ~~will~~ maintain the level of radioactive effluent control required by 10 CFR 20.1302, 40 CFR Part 190, 10 CFR 50.36a, and Appendix I to 10 CFR Part 50 and not adversely impact the accuracy or reliability of effluent, dose, or setpoint calculations.

5.5.1.b 2. Shall become effective after the approval of the plant manager.

5.5.1.c 3. Shall be submitted to the Commission in the form of a complete, legible copy of the entire ODCM as part of or concurrent with the ~~Annual~~ Radioactive Effluent Release Report for the period of the report in which any change to the ODCM was made. Each change shall be identified by markings in the margin of the affected pages, clearly indicating the area of the page that was changed, and shall indicate the date (e.g., month/year) the change was implemented.

DEFINITIONS

IDENTIFED LEAKAGE

1.15 IDENTIFIED LEAKAGE shall be:

a. Leakage (except CONTROLLED LEAKAGE) into closed systems, such as pump seal or valve packing leaks that are captured, and conducted to a sump or collecting tank, or

b. Leakage into the containment atmosphere from sources that are both specifically located and known either not to interfere with the operation of leakage detection systems or not to be PRESSURE BOUNDARY LEAKAGE, or

c. Reactor Coolant System leakage through a steam generator to the secondary system (Primary-to-secondary leakage).

INSERVICE TESTING PROGRAM

1.16 The INSERVICE TESTING PROGRAM is the licensee program that fulfills the requirements of 10 CFR 50.55a(f).

MEMBER(S) OF THE PUBLIC

1.17 MEMBER OF THE PUBLIC means an individual in a controlled or unrestricted area. However, an individual is not a member of the public during any period in which the individual receives an occupational dose.

OFFSITE DOSE CALCULATION MANUAL (ODCM)

5.5.1.a
5.5.1.b

~~1.18~~ THE OFFSITE DOSE CALCULATION MANUAL (ODCM) shall contain the methodology and parameters used in the calculation of offsite doses resulting from radioactive gaseous and liquid effluents, in the calculation of gaseous and liquid effluent monitoring Alarm/Trip Setpoints, and in the conduct of the Environmental Radiological Monitoring Program. The ODCM shall also contain ~~(1)~~ the Radioactive Effluent Controls and Radiological Environmental Monitoring ~~Programs required by Section 6.8.4~~ and ~~(2)~~ descriptions of the information that should be included in the Annual Radiological Environmental Operating and ~~Annual~~ Radioactive Effluent Release Reports required by Specifications ~~6.9.1.7~~ and ~~6.9.1.8~~.

activities

5.6.1

5.6.2

CONTAINMENT SYSTEMS

3/4.6.6 SECONDARY CONTAINMENT

SHIELD BUILDING VENTILATION SYSTEM

See ITS 3.6.9

LIMITING CONDITION FOR OPERATION

3.6.6.1 Two independent shield building ventilation systems shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

a. With one shield building ventilation system inoperable, restore the inoperable system to OPERABLE status within 7 days or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

NOTE

Action not applicable when second shield building ventilation system intentionally made inoperable.

b. With two shield building ventilation systems inoperable, within 1 hour verify at least one train of containment spray is OPERABLE, and restore at least one shield building ventilation system to OPERABLE status within 24 hours; otherwise, be in at least HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.6.6.1 Each shield building ventilation system shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by initiating, from the control room, flow through the HEPA filter and charcoal adsorber train and verifying that the train operates for at least 15 continuous minutes with the heaters on.

b. By performing required shield building ventilation system filter testing in accordance with the Ventilation Filter Testing Program.

5.5.8

c. In accordance with the Surveillance Frequency Control Program by:

5.5.8.e

1. Verifying that the air flow distribution is uniform within 20% across HEPA filters and charcoal adsorbers when tested in accordance with ASME N510-1989.

2. Verifying that the filtration system starts automatically on a Containment Isolation Signal (CIS).

See ITS 3.6.9

3. Verifying that the filter cooling makeup air and cross connection valves can be manually opened.

See ITS 3.6.7

4. Verifying that each system produces a negative pressure of $\geq$ 2.0 inches W.G. in the annulus within 2 minutes after a Containment Isolation Signal (CIS).

PLANT SYSTEMS

See ITS 3.7.12

3/4.7.8 ECCS AREA VENTILATION SYSTEM

LIMITING CONDITION FOR OPERATION

3.7.8.1 Two independent ECCS area exhaust air filter trains shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

With one ECCS area exhaust air filter train inoperable, restore the inoperable train to OPERABLE status within 7 days or be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

SURVEILLANCE REQUIREMENTS

4.7.8.1 Each ECCS area exhaust air filter train shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by initiating, from the control room, flow through the HEPA filter and charcoal adsorber train and verifying that the train operates for at least 15 minutes.

b. By performing required ECCS area ventilation system filter testing in accordance with the Ventilation Filter Testing Program.

5.5.8

c. In accordance with the Surveillance Frequency Control Program:

5.5.8.e

1. Verifying that the air flow distribution is uniform within 20% across HEPA filters and charcoal adsorbers when tested in accordance with ASME N510-1989.

See ITS 3.7.12

2. Verifying that the filter train starts on a Safety Injection Actuation Signal.

ITS

TABLE 4.8-2

BATTERY SURVEILLANCE REQUIREMENT

	CATEGORY A(1)	CATEGORY B(2)	
Parameter	Limits for each designated pilot cell	Limits for each connected cell	Allowable(3) value for each connected cell
Electrolyte Level	> Minimum level indication mark, and ≤ 1/4" above maximum level indication mark	> Minimum level indication mark, and ≤ 1/4" above maximum level indication mark	Above top of plates and not overflowing
Float Voltage	≥ 2.13 volts	≥ 2.13 volts	> 2.07 volts
Specific Gravity(a)	≥ 1.195(b)	≥ 1.190 Average of all connected cells > 1.200	Not more than .020 below the average of all connected cells Average of all connected cells ≥ 1.190(b)

5.5.14. b.1 and b.2

(a) Corrected for electrolyte temperature and level.

(b) Or battery charging current is less than 2 amps when on charge.

5.5.14

~~(c) Corrected for average electrolyte temperature.~~

LA05

(1) For any Category A parameter(s) outside the limit(s) shown, the battery may be considered OPERABLE provided that within 24 hours all the Category B measurements are taken and found to be within their allowable values, and provided all Category A and B parameter(s) are restored to within limits within the next 6 days.

(2) For any Category B parameter(s) outside the limit(s) shown, the battery may be considered OPERABLE provided that the Category B parameters are within their allowable values and provided the Category B parameter(s) are restored to within the limits within 7 days.

(3) With any Category B parameter not within its allowable value, declare the battery inoperable.

See ITS 3.8.6

REFUELING OPERATIONS

FUEL POOL VENTILATION SYSTEM – FUEL STORAGE

See ITS 3.7.17

LIMITING CONDITION FOR OPERATION

3.9.12 At least one fuel pool ventilation system shall be OPERABLE.

APPLICABILITY: Whenever recently irradiated fuel is in the spent fuel pool.

ACTION:

a. With no fuel pool ventilation system OPERABLE, suspend all operations involving movement of recently irradiated fuel within the spent fuel pool or crane operation with loads over the recently irradiated spent fuel until at least one fuel pool ventilation system is restored to OPERABLE status.

b. The provisions of Specification 3.0.3 are not applicable.

SURVEILLANCE REQUIREMENTS

4.9.12 The above required fuel pool ventilation system shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by initiating flow through the HEPA filter and charcoal adsorber train and verifying that the train operates for at least 15 minutes.

5.5.8 Insert 2

b. In accordance with the Surveillance Frequency Control Program or (1) after any structural maintenance on the HEPA filter or charcoal adsorber housings, or (2) following painting, fire or chemical release in any ventilation zone communicating with the system by:

REFUELING OPERATIONS

SURVEILLANCE REQUIREMENTS (Continued)

5.5.8.h

1. Verifying that the charcoal adsorbers remove ≥ 99% of a halogenated hydrocarbon refrigerant test gas when they are tested in-place in accordance with ANSI N510-1975 while operating the ventilation system at a flow rate of 10,350 cfm ± 10%.

5.5.8.g

2. Verifying that the HEPA filter banks remove ≥ 99% of the ~~DOP~~ dioctyl phthalate when they are tested in-place in accordance with ANSI N510-1975 while operating the ventilation system at a flow rate of 10,350 cfm ± 10%.

5.5.8.i

3. Verifying that a laboratory analysis of a carbon sample from either at least one test canister or at least two carbon samples removed from one of the charcoal adsorbers demonstrates a removal efficiency of ≥ 85% for radioactive methyl iodide when the sample is tested in accordance with ASTM D3803-1989 (30°C, 95% RH). The carbon samples not obtained from test canisters shall be prepared by either:

5.5.8.i.1

a) Emptying one entire bed from a removed adsorber tray, mixing the adsorbent thoroughly, and obtaining samples at least two inches in diameter and with a length equal to the thickness of the bed, or

5.5.8.i.2

b) Emptying a longitudinal sample from an adsorber tray, mixing the adsorbent thoroughly, and obtaining samples at least two inches in diameter and with a length equal to the thickness of the bed.

~~4. Verifying a system flow rate of 10,350 cfm ± 10% during system operation when tested in accordance with ANSI N510-1975.~~

A10

REFUELING OPERATIONS

SURVEILLANCE REQUIREMENTS (Continued)

5.5.8

c. In accordance with the Surveillance Frequency Control Program by:

5.5.8.j

1. Verifying that the pressure drop across the combined HEPA filters and charcoal adsorber banks is < 4.15 inches Water Gauge while operating the ventilation system at a flow rate of 10,350 cfm ± 10%.

5.5.8.k

2. Verifying that the air flow distribution is uniform within 20% across HEPA filters and charcoal adsorbers when tested in accordance with ANSI N510-1975.

3. Verifying that the ventilation system maintains the spent fuel storage pool area at a negative pressure of ≥ 1/8 inches Water Gauge relative to the outside atmosphere during system operation.

See ITS 3.7.17

5.5.8

d. After each complete or partial replacement of a HEPA filter bank by verifying that the HEPA filter banks remove ≥ 99% of the ~~DOP~~ dioctyl phthalate when they are tested in-place in accordance with ANSI N510-1975 while operating the ventilation system at a flow rate of 10,350 cfm ± 10%.

5.5.8.g

5.5.8

e. After each complete or partial replacement of a charcoal adsorber bank by verifying that the charcoal adsorbers remove ≥ 99% of a halogenated hydrocarbon refrigerant test gas when they are tested in-place in accordance with ANSI N510-1975 while operating the ventilation system at a flow rate of 10,350 cfm ± 10%.

5.5.8.h

~~RADIOACTIVE EFFLUENTS~~

~~GAS STORAGE TANKS~~

Explosive Gas and Storage Tank Radioactivity Monitoring Program

Add proposed ITS 5.5.9 generic program statement

A11

~~LIMITING CONDITION FOR OPERATION~~

5.5.9.a

3.11.2.6 The quantity of radioactivity contained in each gas storage tank ~~shall be limited to less than or equal to 165,000 curies noble gases (considered as Xe-133).~~

LA06

~~**APPLICABILITY:** At all times.~~

~~**ACTION:**~~

~~a. With the quantity of radioactive material in any gas storage tank exceeding the above limit, immediately suspend all additions of radioactive material to the tank.~~

~~b. The provisions of Specification 3.0.3 are not applicable.~~

SURVEILLANCE REQUIREMENTS

5.5.9 a and b

4.11.2.6 The quantity of radioactive material contained in each gas storage tank shall be determined to be within the above limit ~~in accordance with the Surveillance Frequency Control Program when radioactive materials are being added to the tank when reactor coolant system activity exceeds 518.9 µCi/gram DOSE EQUIVALENT XE-133.~~

LA06

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Explosive Gas and Storage Tank Radioactivity Monitoring Program surveillance frequencies.

A11

6.0 ADMINISTRATIVE CONTROLS

PROCEDURES AND PROGRAMS (Continued)

5.5 **~~6.8.4~~** The following programs shall be established, implemented, and maintained.

5.5.2 a. Primary Coolant Sources Outside Containment

A program to reduce leakage from those portions of systems outside containment that could contain highly radioactive fluids during a serious transient or accident to as low as practical levels. The systems include ~~the Shutdown Cooling System~~, High Pressure Safety Injection ~~System~~, Containment Spray System, and RCS Sampling. The program shall include the following:

A02

Low Pressure Safety Injection

5.5.2.a (i) Preventive maintenance and periodic visual inspection requirements, and

5.5.2.b (ii) Integrated leak test requirements for each system ~~at least once per 18 months~~.

LA01

in accordance with the Surveillance Frequency Control Program

SR 3.0.2

The provisions of ~~Specification 4.0.2~~ are applicable.

~~b. In-Plant Radioiodine Monitoring~~

~~A program which will ensure the capability to accurately determine the airborne iodine concentration in vital areas under accident conditions. This program shall include the following:~~

LA02

~~(i) Training of personnel,~~

~~(ii) Procedures for monitoring, and~~

~~(iii) Provisions for maintenance of sampling and analysis equipment.~~

PROCEDURES AND PROGRAMS (continued)

5.5.7

c. Secondary Water Chemistry

A program for monitoring of secondary water chemistry to inhibit steam generator tube degradation. This program shall include:

5.5.7.a

(i) Identification of a sampling schedule for the critical variables and control points of these variables,

5.5.7.b

(ii) Identification of the procedures used to measure the values of the critical variables,

5.5.7.c

(iii) Identification of process sampling points, which shall include monitoring the discharge of the condensate pumps for evidence of condenser in-leakage,

5.5.7.d

(iv) Procedures for the recording and management of data,

5.5.7.e

(v) Procedures defining corrective actions for all off-control point chemistry conditions, and

5.5.7.f

(vi) A procedure identifying ~~(a)~~ the authority responsible for the interpretation of the data, and ~~(b)~~ the sequence and timing of administrative events required to initiate corrective action.

~~d. Backup Method for Determining Subcooling Margin~~

~~A program which will ensure the capability to accurately monitor the Reactor Coolant System subcooling margin. This program shall include the following:~~

~~(i) Training of personnel, and~~

~~(ii) Procedures for monitoring.~~

LA03

~~e. DELETED~~

5.5.3 f. Radioactive Effluent Controls Program

A program shall be provided conforming with 10 CFR 50.36a for the control of radioactive effluents and for maintaining the doses to MEMBERS OF THE PUBLIC from radioactive effluents as low as reasonably achievable. The program ~~(1)~~ shall be contained in the ODCM, ~~(2)~~ shall be implemented by operating procedures, and ~~(3)~~ shall include remedial actions to be taken whenever the program limits are exceeded. The program shall include the following elements:

functional capability

5.5.3.a 1) Limitations on the ~~operability~~ of radioactive liquid and gaseous monitoring instrumentation including surveillance tests and setpoint determination in accordance with the methodology in the ODCM,

5.5.3.b 2) Limitations on the concentration of radioactive material released in liquid effluents to UNRESTRICTED AREAS conforming to ten times the concentration values in 10 CFR 20.1001 – 20.2401, Appendix B, Table 2, Column 2.

2

A03

5.5.3.c 3) Monitoring, sampling, and analysis of radioactive liquid and gaseous effluents in accordance with 10 CFR 20.1302 and with the methodology and parameters in the ODCM,

5.5.3.d 4) Limitations on the annual and quarterly doses or dose commitment on a MEMBER OF THE PUBLIC from radioactive materials in liquid effluents released from each unit to UNRESTRICTED AREAS conforming to Appendix I to 10 CFR Part 50,

5.5.3.e 5) Determination of cumulative dose contributions from radioactive effluents for the current calendar quarter and current calendar year in accordance with the methodology and parameters in the ODCM at least every 31 days. Determination of projected dose contributions from radioactive effluents in accordance with the methodology in the ODCM at least every 31 days.

functional capability

5.5.3.f 6) Limitations on the ~~operability~~ and use of the liquid and gaseous effluent treatment systems to ensure that the appropriate portions of these systems are used to reduce releases of radioactivity when the projected doses in a 31-day period would exceed 2 percent of the guidelines for the annual dose or dose commitment conforming to Appendix I to 10 CFR Part 50,

5.5.3.g 7) Limitations on the dose rate resulting from radioactive material released in gaseous effluents to areas at or beyond the SITE BOUNDARY shall be limited to the following:

a) For noble gases: Less than or equal to 500 mrem/yr to the total body and less than or equal to 3000 mrem/yr to the skin, and

b) For Iodine-131, for Iodine-133, for tritium, and for all radionuclides in particulate form with half-lives greater than 8 days: Less than or equal to 1500 mrem/yr to any organ;

5.5.3.h 8) Limitations on the annual and quarterly air doses resulting from noble gases released in gaseous effluents from each unit to areas beyond the SITE BOUNDARY conforming to Appendix I to 10 CFR Part 50,

5.5.3.i 9) Limitations on the annual and quarterly doses to a MEMBER OF THE PUBLIC from Iodine-131, Iodine-133, tritium, and all radionuclides in particulate form with half-lives greater

than 8 days in gaseous effluents released from each unit to areas beyond the SITE BOUNDARY conforming to Appendix I to 10 CFR Part 50,

5.5.3.j

10) Limitations on the annual dose or dose commitment to any MEMBER OF THE PUBLIC, beyond the site boundary, due to releases of radioactivity and to radiation from uranium fuel cycle sources conforming to 40 CFR Part 190.

SR 3.0.2 SR 3.0.3

The provisions of ~~Specifications 4.0.2~~ and ~~4.0.3~~ are applicable to the Radioactive Effluent Controls Program surveillance frequency.

~~g. Radiological Environmental Monitoring Program~~

LA04

~~A program shall be provided to monitor the radiation and radionuclides in the environs of the plant. The program shall provide (1) representative measurements of radioactivity in the highest potential exposure pathways, and (2) verification of the accuracy of the effluent monitoring program and modeling of the environmental exposure pathways. The program shall (1) be contained in the ODCM, (2) conform to the guidance of Appendix I to 10 CFR Part 50, and (3) include the following:~~

~~1) Monitoring, sampling, analysis, and reporting of radiation and radionuclides in the environment in accordance with the methodology and parameters in the ODCM.~~

~~2) A Land Use Census to ensure that changes in the use of areas at and beyond the SITE BOUNDARY are identified and that modifications to the monitoring program are made if required by the results of this census, and~~

~~3) Participation in a Interlaboratory Comparison Program to ensure that independent checks on the precision and accuracy of the measurements of radioactive materials in environmental sample matrices are performed as part of the quality assurance program for environmental monitoring.~~

5.5.13

h. Containment Leakage Rate Testing Program

5.5.13.a

A program to implement the leakage rate testing of the containment as required by 10 CFR 50.54(o) and 10 CFR 50 Appendix J, Option B, as modified by approved exemptions. This program is in accordance with the guidelines contained in NEI 94-01, Revision 2-A, "Industry Guideline for Implementing Performance-Based Option of 10 CFR Part 50, Appendix J," except that the next Type A test performed after the December 18, 2007 Type A test shall be performed no later than December 18, 2022.

5.5.13.b

The peak calculated containment internal pressure for the design basis loss of coolant accident P_a, is 43.4~~8~~ 3 psig. The containment design pressure is 44 psig.

M04 | R1

5.5.13.c

The maximum allowed containment leakage rate, L_a, at P_a, shall be 0.50% of containment air weight per day.

ADMINISTRATIVE CONTROLS (Continued)

5.5.13.d Leakage rate acceptance criteria are:

5.5.13.d.1 a. Containment leakage rate acceptance criterion is $\leq$ 1.0 L_a. During the first unit startup following testing in accordance with this program, the leakage rate acceptance criteria are < 0.60 L_a for the Type B and C tests, $\leq$ 0.75 L_a for Type A tests, and $\leq$ 0.096 L_a for secondary containment bypass leakage paths.

See ITS 3.6.3

5.5.13.d.2 b. Air lock testing acceptance criteria are:

5.5.13.d.2.a) 1) Overall air lock leakage is $\leq$ 0.05 L_a when tested at $\geq$ P_a.

air lock

5.5.13.d.2.b) 2) For each door ~~seal~~, leakage rate is < 0.01 L_a when pressurized to $\geq$ P_a.

ADMINISTRATIVE CONTROLS (continued)

5.5.11 j. Technical Specifications (TS) Bases Control Program

This program provides a means for processing changes to the Bases of these Technical Specifications.

5.5.11.a 1. Changes to the Bases of the TS shall be made under appropriate administrative controls and reviews.

5.5.11.b 2. Licensees may make changes to Bases without prior NRC approval provided the changes do not require either of the following:

5.5.11.b.1 a. a change in the TS incorporated in the license; or

5.5.11.b.2 b. a change to the ~~updated~~ UFSAR or Bases that requires NRC approval pursuant to 10 CFR 50.59.

5.5.11.c 3. The Bases Control Program shall contain provisions to ensure that the Bases are maintained consistent with the UFSAR.

5.5.11.b

5.5.11.d 4. Proposed changes that meet the criteria of ~~Specification 6.8.4.j.2.a or 6.8.4.j.2.b,~~ above, shall be reviewed and approved by the NRC prior to implementation. Changes to the Bases implemented without prior NRC approval shall be provided to the NRC on a frequency consistent with 10 CFR 50.71(e).

5.5.8 k. Ventilation Filter Testing Program (VFTP)

in accordance with

A program shall be established to implement the following required testing of Engineered Safety Feature (ESF) filter ventilation systems ~~at the frequencies specified in~~ Regulatory Guide 1.52, Revision 3~~.~~ , ASME N510-1989 and ASTM D3803-1989, as described herein.

A06

5.5.8.a 1. Demonstrate for each of the ESF systems that an inplace test of the high efficiency particulate air (HEPA) filters shows a penetration and system bypass ~~less than the value specified below~~ when tested in accordance with ASME N510-1989 at the system flowrate specified below.

≤ 0.05%

± 10%

ESF Ventilation System	Penetration	Flowrate
Control Room Emergency Air Cleanup	~~≤ 0.05%~~	2000 ~~± 200 cfm~~
Shield Building Ventilation System	~~≤ 0.05%~~	6000 ~~± 600 cfm~~
~~ECCS~~ Area Ventilation System	~~≤ 0.05%~~	30,000 ~~± 3000 cfm~~

System (CREVS)

SBVS

Emergency Core Cooling System (ECCS)

5.5.8.b 2. Demonstrate for each of the ESF systems that an inplace test of the charcoal adsorber shows a penetration and system bypass ~~less than the value specified~~ below when tested in accordance with ASME N510-1989 at the system flowrate specified below.

≤ 0.05%

± 10%

ESF Ventilation System	Penetration	Flowrate
~~Control Room Emergency Air Cleanup~~	~~≤ 0.05%~~	2000 ~~± 200 cfm~~
~~Shield Building Ventilation System~~	~~≤ 0.05%~~	6000 ~~± 600 cfm~~
ECCS Area Ventilation System	~~≤ 0.05%~~	30,000 ~~± 3000 cfm~~

CREVS

SBVS

5.5.8.c

3. Demonstrate for each of the ESF systems that a laboratory test of a sample of the charcoal adsorber, when obtained as described in Regulatory Guide 1.52, Revision 3, shows the methyl iodide penetration less than the value specified below when tested in accordance with ASTM D3803-1989 at a temperature of 30°C (86°F) and ~~the~~ relative humidity ~~specified below~~. ≤ 95% a

ESF Ventilation System	Penetration	~~RH~~
CREVS → ~~Control Room Emergency Air Cleanup~~	≤ 0.175%	~~95%~~
SBVS → ~~Shield Building Ventilation System~~	≤ 2.5%	~~95%~~
ECCS Area Ventilation System	≤ 2.5%	~~95%~~

5.5.8.d

4. For the ~~Control Room Emergency Air Cleanup System~~ (CREVS) and the ECCS Area Ventilation System, demonstrate that the pressure drop across the combined HEPA filters and charcoal adsorbers is less than the value specified below when tested at the system flowrate specified below. For the ~~Shield Building Ventilation System~~ (SBVS), demonstrate that the pressure drop across the combined demisters, electric heaters, HEPA filters and charcoal adsorbers is less than the value specified below when tested at the system flowrate specified below.

ESF Ventilation System	Delta P	Flowrate
CREVS → ~~Control Room Emergency Air Cleanup~~	< 7.4" W.G.	2000 ~~± 200 cfm~~
SBVS → ~~Shield Building Ventilation System~~	< 8.5" W.G.	6000 ~~± 600 cfm~~
ECCS Area Ventilation System	< 4.35" W.G.	30,000 ~~± 3000 cfm~~

5.5.8.f

5. ~~At least once per 18 months~~ At a frequency in accordance with the Surveillance Frequency Control Program, demonstrate that the heaters for each of the ESF systems dissipate the value specified below when tested in accordance with ASME N510-1989. LA01

ESF Ventilation System	Wattage
SBVS → ~~Shield Building Ventilation System~~	
Main Heaters	30 ± 3 kW
Auxiliary Heaters	1.5 ± 0.25 kW

The provisions of SR ~~4~~.0.2 and SR ~~4~~.0.3 are applicable to the VFTP test frequencies. 3

5.5.6

l. Steam Generator (SG) Program

1. A SG Program shall be established and implemented for the replacement SGs to ensure that SG tube integrity is maintained. In addition, the SG Program shall include the following provisions:

5.5.6.a

a. Provisions for condition monitoring assessments. Condition monitoring assessment means an evaluation of the "as found" condition of the tubing with respect to the performance criteria for structural integrity and accident induced leakage. The "as found" condition refers to the condition of the tubing during an SG inspection outage, as determined from the inservice inspection results or by other means, prior to the plugging of tubes. Condition monitoring assessments shall be conducted during each outage during which the SG tubes are inspected or plugged to confirm that the performance criteria are being met.

ADMINISTRATIVE CONTROLS (continued)

l. Steam Generator (SG) Program (continued)

5.5.6

1. (continued)

5.5.6.b

b. Performance criteria for SG tube integrity. SG tube integrity shall be maintained by meeting the performance criteria for tube structural integrity, accident induced leakage, and operational leakage.

1. Structural integrity performance criterion: All in-service SG tubes shall retain structural integrity over the full range of normal operating conditions (including startup, operation in the power range, hot standby, and cooldown and all anticipated transients included in the design specification) and design basis accidents. This includes retaining a safety factor of 3.0 against burst under normal steady state full power operation primary-to-secondary pressure differential and a safety factor of 1.4 against burst applied to the design basis accident primary-to-secondary pressure differentials. Apart from the above requirements, additional loading conditions associated with the design basis accidents, or combination of accidents in accordance with the design and licensing basis, shall also be evaluated to determine if the associated loads contribute significantly to burst or collapse. In the assessment of tube integrity, those loads that do significantly affect burst or collapse shall be determined and assessed in combination with the loads due to pressure with a safety factor of 1.2 on the combined primary loads and 1.0 on axial secondary loads.

2. Accident induced leakage performance criterion: The primary-to-secondary accident induced leakage rate for any design basis accident, other than a SG tube rupture, shall not exceed the leakage rate assumed in the accident analysis in terms of total leakage rate for all SGs and leakage rate for an individual SG. Leakage is not to exceed 0.5 gallons per minute total through all SGs and 0.25 gallons per minute through any one SG.

3. The operational leakage performance criterion is specified in LCO ~~3.4.6.2.c~~, "Reactor Coolant System Operational Leakage."

3.4.13

ADMINISTRATIVE CONTROLS (continued)

5.5.6 l. Steam Generator (SG) Program (continued)

1. (continued)

plugging

A07

5.5.6.c c. Provisions for SG tube ~~repair~~ criteria. Tubes found by inservice inspection to contain flaws with a depth equal to or exceeding 40% of the nominal tube wall thickness shall be plugged.

5.5.6.d d. Provisions for SG tube inspections. Periodic SG tube inspections shall be performed. The number and portions of the tubes inspected and methods of inspection shall be performed with the objective of detecting flaws of any type (e.g., volumetric flaws, axial and circumferential cracks) that may be present along the length of the tube, from the tube-to-tubesheet weld at the tube inlet to the tube-to-tubesheet weld at the tube outlet, and that may satisfy the applicable tube ~~repair~~ criteria. The tube-to-tubesheet weld is not part of the tube. In addition to meeting the requirements of d.1, d.2, and d.3 below, the inspection scope, inspection methods, and inspection intervals shall be such as to ensure that SG tube integrity is maintained until the next SG inspection. An assessment of degradation shall be performed to determine the type and location of flaws to which the tubes may be susceptible and, based on this assessment, to determine which inspection methods need to be employed and at what locations.

plugging

A07

5.5.6.d.1 1. Inspect 100% of the tubes in each SG during the first refueling outage following SG replacement.

5.5.6.d.2 2. Inspect 100% of the tubes at ~~sequential periods of 144, 108, 72, and, thereafter, 60~~ 96 effective full power months. The first sequential period shall be considered to begin after the first inservice inspection of the SGs. ~~In addition, inspect 50% of the tubes by the refueling outage nearest the midpoint of the period and the remaining 50% by the refueling outages nearest the end of the period. No SG shall operate for more than 72 effective full power months or three refueling outages (whichever is less) without being inspected.~~

L01

affected and potentially affected

5.5.6.d.3 3. If crack indications are found in any SG tube, then the next inspection for each SG for the degradation mechanism that caused the crack indication shall ~~not exceed 24 effective full power months or one~~ be at the next refueling outage ~~(whichever is less)~~. If definitive information, such as from examination of a pulled tube, diagnostic non-destructive testing, or engineering evaluation indicates that a crack-like indication is not associated with a crack(s), then the indication need not be treated as a crack.

5.5.6.e e. Provisions for monitoring operational primary-to-secondary leakage

~~ADMINISTRATIVE CONTROLS (continued)~~

~~PAGES 6-15g AND 6-15h HAVE BEEN DELETED.~~
~~THE NEXT PAGE IS 6-15i.~~

5.5.15

m. Control Room Envelope Habitability Program

A Control Room Envelope (CRE) Habitability Program shall be established and implemented to ensure that CRE habitability is maintained such that, with an OPERABLE Control Room Emergency Air Cleanup System (CREACS), CRE occupants can control the reactor safely under normal conditions and maintain it in a safe condition following a radiological event, hazardous chemical release, or a smoke challenge. The program shall ensure that adequate radiation protection is provided to permit access and occupancy of the CRE under design basis accident (DBA) conditions without personnel receiving radiation exposures in excess of 5 rem total effective dose equivalent (TEDE) for the duration of the accident.

The program shall include the following elements:

a. The definition of the CRE and the CRE boundary.

b. Requirements for maintaining the CRE boundary in its design condition including configuration control and preventive maintenance.

c. Requirements for (i) determining the unfiltered air inleakage past the CRE boundary into the CRE in accordance with the testing methods and at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, "Demonstrating Control Room Envelope Integrity at Nuclear Power Reactors," Revision 0, May 2003, and (ii) assessing CRE habitability at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, Revision 0.

d. Measurement, at designated locations, of the CRE pressure relative to all external areas adjacent to the CRE boundary during the pressurization mode of operation by one train of the CREACS, operating at the flow rate required by the VFTP, ~~at a Frequency of 36 months on a STAGGERED TEST BASIS~~ in accordance with the Surveillance Frequency Control Program. The results shall be trended and used as part of the 36 month assessment of the CRE boundary. LA01

e. The quantitative limits on unfiltered air inleakage into the CRE. These limits shall be stated in a manner to allow direct comparison to the unfiltered air inleakage measured by the testing described in paragraph c. The unfiltered air inleakage limit for radiological challenges is the inleakage flow rate assumed in the licensing basis analyses of DBA consequences. Unfiltered air inleakage limits for hazardous chemicals must ensure that exposure of CRE occupants to these hazards will be within the assumptions in the licensing basis.

f. The provisions of SR ~~4~~3.0.2 are applicable to the Frequencies for assessing CRE habitability, determining CRE unfiltered inleakage, and measuring CRE pressure and assessing the CRE boundary as required by paragraphs c and d, respectively.

5.5.10 n. Diesel Fuel Oil Testing Program

A diesel fuel oil testing program to implement required testing of both new fuel oil and stored fuel oil shall be established. The program shall include sampling and testing requirements, and acceptance criteria, all in accordance with applicable ASTM Standards. The purpose of the program is to establish the following:

5.5.10.a (i) Acceptability of new fuel oil for use prior to addition to storage tanks by determining that the fuel oil has:

1. An API gravity or an absolute specific gravity within limits,

2. A flash point and kinematic viscosity within limits for ASTM 2D fuel oil, and

3. A clear and bright appearance with proper color or a water and sediment content within limits;

in accordance with the Surveillance Frequency Control Program

5.5.10.b (ii) Other properties for ASTM 2D fuel oil are within limits within 31 days following ~~sampling and~~ addition to storage tanks; and

LA01

5.5.10.c (iii) Total particulate concentration of the fuel oil is ≤ 10 mg/l when tested ~~every 31 days~~.

3 3

The provisions of SR ~~4~~.0.2 and SR ~~4~~.0.3 are applicable to the Diesel Fuel Oil Testing Program test frequencies.

Insert proposed requirements based on RCP flywheel material

L02

5.5.5 o. Reactor Coolant Pump Flywheel Inspection Program

This program shall provide for the inspection of each reactor coolant pump flywheel by either a 100% volumetric inspection of the upper flywheel over the volume from the inner bore of the flywheel to the circle of one-half the outer radius or a surface examination (magnetic particle testing and/or penetrant testing) of exposed surfaces defined by the volume of the disassembled flywheel at least once every 10 years.

~~p. Snubber Testing Program~~ R1

~~This program conforms to the examination, testing and service life monitoring for dynamic restraints (snubbers) in accordance with 10 CFR 50.55a inservice inspection (ISI) requirements for supports. The program shall be in accordance with the following:~~

~~1. This program shall meet 10 CFR 50.55a(g) ISI requirements for supports.~~

~~2. The program shall meet the requirements for ISI of supports set forth in subsequent editions of the Code of Record and addenda of the American Society of Mechanical Engineers (ASME) Boiler and Pressure (BPV) Code and the ASME Code for Operation and Maintenance of Nuclear Power Plants (OM Code) that are incorporated by reference in 10 CFR 50.55a(b) subject to limitations and modifications listed in 10 CFR 50.55a(b) and subject to Commission approval.~~

LA08

~~3. The program shall, as required by 10 CFR 50.55a(b)(3)(v)(B), meet Subsection ISTA, "General Requirements" and Subsection ISTD, "Preservice and Inservice Examination and Testing of Dynamic Restraints (Snubbers) in Light-Water Reactor Nuclear Power Plants".~~

~~4. The 120-month program updates shall be made in accordance with 10 CFR 50.55a(g)(4), 10 CFR 50.55a(g)(3)(v) and 10 CFR 50.55a(b) (including 10 CFR 50.55a(b)(3)(v)(B)) subject to the limitations and modifications listed therein.~~

ADMINISTRATIVE CONTROLS

5.5.16 q. Surveillance Frequency Control Program

This program provides controls for Surveillance Frequencies. The program shall ensure that Surveillance Requirements specified in the Technical Specifications are performed at intervals sufficient to assure the associated Limiting Conditions for Operation are met.

a. The Surveillance Frequency Control Program shall contain a list of frequencies of those Surveillance Requirements for which the frequency is controlled by the program.

b. Changes to the frequencies listed in the Surveillance Frequency Control Program shall be made in accordance with NEI 04-10, "Risk-Informed Method for Control of Surveillance Frequencies," Revision 1.

SR 3.0.2 SR 3.0.3

c. The provisions of ~~Surveillance Requirements 4.0.2~~ and ~~4.0.3~~ are applicable to the frequencies established in the Surveillance Frequency Control Program.

5.5.4 r. Component Cyclic or Transient Limit Program

U

The Program provides controls to track the FSAR, Section 3.9, cyclic and transient occurrences to ensure that components are maintained within the design limits.

5.5.17 s. Risk Informed Completion Time Program

This program provides controls to calculate a Risk Informed Completion Time (RICT) and must be implemented in accordance with NEI 06-09-A, ~~"Risk-Informed Technical Specifications Initiative 4b:~~ Risk-Managed Technical Specifications (RMTS) Guidelines," Revision 0 ~~-A, November 2006~~. The program shall include the following:

a. The RICT may not exceed 30 days;

b. A RICT may only be utilized in MODES 1 and 2;

c. When a RICT is being used, any plant configuration change within the scope of the Configuration Risk Management Program must be considered for the effect on the RICT.

1. For planned changes, the revised RICT must be determined prior to implementation of the change in configuration.

2. For emergent conditions, the revised RICT must be determined within the time limits of the Required Action Completion Time (i.e., not the RICT) or 12 hours after the plant configuration change, whichever is less.

3. Revising the RICT is not required if the plant configuration change would lower plant risk and would result in a longer RICT.

d. Use of a RICT is not permitted for entry into a configuration which represents a loss of a specified safety function or inoperability of all required trains of a system required to be OPERABLE.

ADMINISTRATIVE CONTROLS

5.5.17 e. If the extent of condition evaluation for inoperable structures, systems, or components (SSCs) is not complete prior to exceeding the Completion Time, the RICT shall account for the increased possibility of common cause failure (CCF) by either:

1. Numerically accounting for the increased possibility of CCF in the RICT calculation, or

2. Risk Management Actions (RMAs) not already credited in the RICT calculation shall be implemented that support redundant or diverse SSCs that perform the function(s) of the inoperable SSCs, and, if practicable, reduce the frequency of initiating events that challenge the function(s) performed by the inoperable SSCs.

5.5.12 t. Safety Function Determination Program (SFDP)

limitations and remedial or compensatory

A08

This program ensures loss of safety function is detected and appropriate actions taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other appropriate actions may be taken as a result of the support system inoperability and corresponding exception to entering supported system ~~ACTIONS~~. This program implements the requirements of LCO 3.0.6. The SFDP shall contain the following:

Conditions and Required Actions

A09

a. Provisions for cross train checks to ensure a loss of the capability to perform the safety function assumed in the accident analysis does not go undetected,

b Provisions for ensuring the plant is maintained in a safe condition if a loss of function condition exists,

Completion Time

A09

c. Provisions to ensure that an inoperable supported system's ~~allowed outage time~~ is not inappropriately extended as a result of multiple support system inoperabilites, and

d. Other appropriate limitations and remedial or compensatory actions.

A loss of safety function exists when, assuming no concurrent single failure, no concurrent loss of offsite power, or no concurrent loss of onsite diesel generator(s), a safety function assumed in the accident analysis cannot be performed. For the purpose of this program, a loss of safety function may exist when a support system is inoperable, and:

a. A required system redundant to the system(s) supported by the inoperable support system is also inoperable, or

b. A required system redundant to the system(s) in turn supported by the inoperable supported system is also inoperable, or

c. A required system redundant to the support system(s) for the supported systems (a) and (b) above is also inoperable.

Conditions and Required Actions

A09

The SFDP identifies where a loss of safety function exists. If a loss of safety function is determined to exist by this program, the appropriate ~~ACTIONS~~ of the LCO in which the loss of safety function exists are required to be entered. When a loss of safety function is caused by the inoperability of a single Technical Specification support system, the appropriate ~~ACTIONS~~ to enter are those of the support system.

Conditions and Required Actions

A09

6.13 PROCESS CONTROL PROGRAM (PCP)

Changes to the PCP:

1. Shall be documented and this documentation shall contain:

   a) Sufficient information to support the change together with the appropriate analyses or evaluations justifying the change(s) and

   b. A determination that the change will maintain the overall conformance of the solidified waste product to existing requirements of Federal, State, or other applicable regulations.

2. Shall become effective after the approval of the plant manager.

See CTS 6.0

5.5.1

6.14 OFFSITE DOSE CALCULATION MANUAL (ODCM)

Changes to the ODCM:

and records of reviews performed shall be retained.

M03

5.5.1.a 1. Shall be documented ~~and~~ this documentation shall contain:

5.5.1.a.1 a) Sufficient information to support the change together with the appropriate analyses or evaluations justifying the change(s) and

5.5.1.a.2 b) A determination that the change ~~will~~ maintain the level of radioactive effluent control required by 10 CFR 20.1302, 40 CFR Part 190, 10 CFR 50.36a, and Appendix I to 10 CFR Part 50 and not adversely impact the accuracy or reliability of effluent, dose, or setpoint calculations.

5.5.1.b 2. Shall become effective after the approval of the plant manager.

5.5.1.c 3. Shall be submitted to the Commission in the form of a complete, legible copy of the entire ODCM as part of or concurrent with the ~~Annual~~ Radioactive Effluent Release Report for the period of the report in which any change to the ODCM was made. Each change shall be identified by markings in the margin of the affected pages, clearly indicating the area of the page that was changed, and shall indicate the date (e.g., month/year) the change was implemented.

DEFINITIONS

INSERVICE TESTING PROGRAM

1.16 The INSERVICE TESTING PROGRAM is the licensee program that fulfills the requirements of 10 CFR 50.55a(f).

MEMBER(S) OF THE PUBLIC

1.17 MEMBER OF THE PUBLIC means an individual in a controlled or unrestricted area. However, an individual is not a member of the public during any period in which the individual receives an occupational dose.

OFFSITE DOSE CALCULATION MANUAL (ODCM)

5.5.1.a
5.5.1.b

~~1.18~~ THE OFFSITE DOSE CALCULATION MANUAL (ODCM) shall contain the methodology and parameters used in the calculation of offsite doses resulting from radioactive gaseous and liquid effluents, in the calculation of gaseous and liquid effluent monitoring Alarm/Trip Setpoints, and in the conduct of the Environmental Radiological Monitoring Program. The ODCM shall also contain ~~(1)~~ the Radioactive Effluent Controls and Radiological Environmental Monitoring ~~Programs required by Section 6.8.4~~ and ~~(2)~~ descriptions of the information that should be included in the Annual Radiological Environmental Operating and ~~Annual~~ Radioactive Effluent Release Reports required by Specifications ~~6.9.1.7~~ and ~~6.9.1.8~~.

activities

5.6.1

5.6.2

OPERABLE – OPERABILITY

1.19 A system, subsystem, train, component or device shall be OPERABLE or have OPERABILITY when it is capable of performing its specified function(s), and when all necessary attendant instrumentation, controls, electrical power, cooling or seal water, lubrication or other auxiliary equipment that are required for the system, subsystem, train, component or device to perform its function(s) are also capable of performing their related support function(s).

OPERATIONAL MODE – MODE

1.20 An OPERATIONAL MODE (i.e., MODE) shall correspond to any one inclusive combination of core reactivity condition, power level and average reactor coolant temperature specified in Table 1.2.

PHYSICS TESTS

1.21 PHYSICS TESTS shall be those tests performed to measure the fundamental nuclear characteristics of the reactor core and related instrumentation and (1) described in Chapter 14.0 of the FSAR, (2) authorized under the provisions of 10 CFR 50.59, or (3) otherwise approved by the Commission.

See ITS 1.1

CONTAINMENT SYSTEMS

3/4.6.6 SECONDARY CONTAINMENT

SHIELD BUILDING VENTILATION SYSTEM (SBVS)

See ITS 3.6.9

LIMITING CONDITION FOR OPERATION

3.6.6.1 Two independent Shield Building Ventilation Systems shall be OPERABLE.

APPLICABILITY: At all times in MODES 1, 2, 3, and 4.
In addition, during movement of recently irradiated fuel assemblies or during crane operations with loads over recently irradiated fuel assemblies in the Spent Fuel Storage Pool in MODES 5 and 6.

ACTION:

a. With the SBVS inoperable solely due to loss of the SBVS capability to provide design basis filtered air evacuation from the Spent Fuel Pool area, only ACTION-c is required. If the SBVS is inoperable for any other reason, concurrently implement ACTION-b and ACTION-c.

b. (1) With one SBVS inoperable in MODE 1, 2, 3, or 4, restore the inoperable system to OPERABLE status within 7 days; otherwise, be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

NOTE
Action not applicable when second SBVS intentionally made inoperable.

(2) With both SBVSs inoperable, within 1 hour verify at least one train of containment spray is OPERABLE, and restore at least one SBVS to OPERABLE status within 24 hours; otherwise, be in at least HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours.

c. (1) With one SBVS inoperable in any MODE, restore the inoperable system to OPERABLE status within 7 days; otherwise, suspend movement of recently irradiated fuel assemblies within the Spent Fuel Storage Pool and crane operations with loads over recently irradiated fuel in the Spent Fuel Storage Pool.

(2) With both SBVS inoperable in any MODE, immediately suspend movement of recently irradiated fuel assemblies within the Spent Fuel Storage Pool and crane operations with loads over recently irradiated fuel in the Spent Fuel Storage Pool.

SURVEILLANCE REQUIREMENTS

4.6.6.1 Each Shield Building Ventilation System shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by initiating, from the control room, flow through the HEPA filters and charcoal adsorbers and verifying that the system operates for at least 15 continuous minutes with the heaters on.

5.5.8

In accordance with the frequencies of Regulatory Guide 1.52, Revision 3, except that the testing frequency of "24 months" is required at a frequency in

b. ~~In~~ accordance with the Surveillance Frequency Control Program ~~or (1) after any structural maintenance on the HEPA filter or charcoal adsorber housings, or (2) following painting, fire, or chemical release in any ventilation zone communicating with the system by:~~

A12

~~1. Performing a visual examination of SBVS in accordance with ASME N510-1989.~~

LA07

CONTAINMENT SYSTEMS

SURVEILLANCE REQUIREMENTS (continued)

5.5.8.e

2. Performing airflow distribution to HEPA filters and charcoal adsorbers in accordance with ASME N510-1989. The distribution shall be ± 20% of the average flow per unit.

c. By performing required shield building ventilation system filter testing in accordance with the Ventilation Filter Testing Program.

d. In accordance with the Surveillance Frequency Control Program by:

1. Verifying that the system starts on a Unit 2 containment isolation signal and on a fuel pool high radiation signal.

2. Verifying that the filter cooling makeup and cross connection valves can be manually opened.

3. Verifying that each system produces a negative pressure of greater than or equal to 2.0 inches WG in the annulus within 99 seconds after a start signal.

4. Verifying that each system achieves a negative pressure of greater than 0.125 inch WG in the fuel storage building after actuation of a fuel storage building high radiation test signal.

~~LIMITING CONDITION FOR OPERATION~~

5.5.9.a

3.11.2.5 The concentration of oxygen in the waste gas decay tanks shall be limited ~~to less than or equal to 2% by volume whenever the hydrogen concentration exceeds 4% by volume.~~

~~**APPLICABILITY:** At all times.~~

LA06

~~**ACTION:**~~

~~a. With the concentration of oxygen in the waste gas decay tank greater than 2% by volume but less than or equal to 4% by volume, reduce the oxygen concentration to the above limits within 48 hours.~~

~~b. With the concentration of oxygen in the waste gas decay tank greater than 4% by volume and the hydrogen concentration greater than 2% by volume, immediately suspend all additions of waste gases to the system and immediately commence reduction of the concentration of oxygen to less than or equal to 2% by volume.~~

~~c. The provisions of Specification 3.0.3 are not applicable.~~

SURVEILLANCE REQUIREMENTS

5.5.9 a and b

4.11.2.5.1 The concentration of oxygen in the waste gas decay tank shall be determined to be within the above limits by ~~continuously*~~ monitoring the waste gases in the ~~on service~~ waste gas decay tank.

5.5.9 a and b

4.11.2.5.2 ~~With the oxygen concentration in the on service waste gas decay tank greater than 2% by volume as determined by Specification 4.11.2.5.1,~~ the concentration of hydrogen in the waste gas decay tank shall be determined to be within the above limits ~~by gas partitioner sample at least once per 24 hours.~~

LA06

~~* When continuous monitoring capability is inoperable, waste gases shall be monitored in accordance with the actions specified for the Waste Gas Decay Tanks Explosive Gas Monitoring System in Chapter 13 of the Updated Final Safety Analysis Report.~~

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Explosive Gas and Storage Tank Radioactivity Monitoring Program surveillance frequencies.

A11

~~RADIOACTIVE EFFLUENTS~~

~~GAS STORAGE TANKS~~

Explosive Gas and Storage Tank Radioactivity Monitoring Program

A11

Add proposed ITS 5.5.9 generic program statement

~~LIMITING CONDITION FOR OPERATION~~

5.5.9.a

3.11.2.6 The quantity of radioactivity contained in each gas storage tank ~~shall be limited to less than or equal to 165,000 curies noble gases (considered as Xe-133).~~

LA06

~~**APPLICABILITY:** At all times.~~

~~**ACTION:**~~

~~a. With the quantity of radioactive material in any gas storage tank exceeding the above limit, immediately suspend all additions of radioactive material to the tank.~~

~~b. The provisions of Specification 3.0.3 are not applicable.~~

SURVEILLANCE REQUIREMENTS

5.5.9 a and b

4.11.2.6 The quantity of radioactive material contained in each gas storage tank shall be determined to be within the above limit ~~in accordance with the Surveillance Frequency Control Program when radioactive materials are being added to the tank when reactor coolant system activity exceeds 518.9 µCi/gram DOSE EQUIVALENT XE-133.~~

LA06

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Explosive Gas and Storage Tank Radioactivity Monitoring Program surveillance frequencies.

A11

DISCUSSION OF CHANGES
ITS 5.5, PROGRAMS AND MANUALS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 6.8.4.a contains a program requiring leakage testing of primary coolant sources outside containment. Included in the listing of systems is the Shutdown Cooling System. ITS 5.5.2 requires the same program and has renamed the Shutdown Cooling System to the Low Pressure Safety Injection System. This changes the CTS by renaming the low pressure cooling/injection system.

The purpose of this administrative program is to ensure systems outside containment that have the potential to contain highly radioactive liquid following a design basis accident (DBA) are leakage tested periodically. The Shutdown Cooling System performs the function of normal shutdown decay heat removal and low pressure safety injection. The titles Low Pressure Safety Injection System and Shutdown Cooling System may be used interchangeable when discussing the system. Since the purpose of the program is to ensure leak tight systems following a DBA, it is more appropriately to use the safety injection function nomenclature. This change is consistent with the ISTS. The change is designated as administrative and is acceptable because it does not result in technical changes to the CTS.

A03 CTS 6.8.4.f 2) requires the Radioactive Effluent Controls Program to provide limitations on the concentrations of radioactive material released in liquid effluents to unrestricted areas and references Appendix B of 10 CFR 20.1001 – 20.2401. ITS 5.5.3 contains the same requirement but references Appendix B of 10 CFR 20.1001 – 20.2402 consistent with the ISTS. This changes the CTS by changing the 10 CFR 20 reference from 2401 to 2402. |R1

This change is considered acceptable because the 10 CFR 20 regulation encompasses 1001 – 2402. The change is designated as an administrative change to correct the regulation reference and is acceptable because it does not result in technical change to the CTS programmatic requirement.

A04 **Unit 1 only:** CTS 6.8.4.h contains an exception to Containment Leakage Rate Testing Program requirements required by 10 CFR 50.54(o) and 10 CFR 50 Appendix J in accordance with the guidelines contained in NEI-94-01. CTS 6.8.4.h states, in part, that the next Type A test performed after the December 8, 2005 Type A test shall be performed no later than December 8, 2020. ITS 5.5.13 does not include this Type A test exception. This changes the CTS by removing a 10 CFR 50, Appendix J exception that is no longer applicable.

The Type A test was performed in November 2019. Therefore, this exception to the Type A containment leakage rate testing frequency specified in the regulation and supporting documents is no longer required. The change is designated as administrative and is acceptable because it does not result in technical changes to the CTS.

A05 TS 6.8.4.h states, in part, that the provisions of T.S. 4.0.2 do not apply to test frequencies in the Containment Leak Rate Testing Program. ITS 5.5.13.f states, "Nothing in these Technical Specifications shall be construed to modify the testing Frequencies required by 10 CFR 50, Appendix J." This changes the CTS by exchanging the requirement that CTS 4.0.2 does not apply with the statement to clarify that Containment Leakage Rate Testing Program test frequencies required by a regulation cannot be extended by the use of any Technical Specification allowance, including CTS 4.0.2.

The change is designated as an administrative change to clarify that no generic testing frequency allowance shall be construed to allow modifying a testing Frequency required pursuant to a regulation and is acceptable because it does not result in technical change to the CTS programmatic requirement.

A06 Unit 1 CTS 4.6.6.1.c.1 and 4.7.8.1.c.1 and Unit 2 CTS 4.6.6.1.b.2 require a test to verify airflow distribution to HEPA filters and charcoal adsorbers in accordance with ASME N510-1989 for the Shield Building Ventilation System (SBVS) and the Unit 1 Emergency Core Cooling System (ECCS) Area Ventilation System. Additionally, Unit 1 CTS 4.9.12 provides filter testing requirements for the Fuel Pool Area Ventilation System, which are tested in accordance with ANSI N510-1975 and ASTM D3803-1989, as applicable. ITS includes the Surveillances associated with the ventilation filter testing in the Ventilation Filter Testing Program (ITS 5.5.8). As such, the general program statement has been modified to include, in addition to Regulatory Guide 1.52, the ASME, ANSI, and ASTM Standards applicable to the filter testing and a listing of which Surveillance Frequency requirements are associated with each filter test. This changes the CTS by moving additional ventilation filter testing Surveillances associated with the SBVS, Unit 1 ECCS Area Ventilation System, and Unit 1 Fuel Pool Area Ventilation System to the Ventilation Filter Testing Program.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A07 CTS 6.8.4 l.c, states the provisions for steam generator (SG) tube repair criteria. ITS 5.5.6.c refers to the SG tube plugging criteria. This changes the CTS by referring to SG plugging criteria instead of "repair" criteria.

SG repair applied to the original SGs. However, the unit contains replacement SGs containing Alloy 690TT Tubing. As further stated in CTS 6.8.4.l.c, if SG tube degradation is discovered, the tubes shall be plugged. Therefore, there is no repair criteria, only plugging criteria, defined in CTS. This change is designated as administrative and is acceptable because it does not result in technical changes to the CTS.

A08 Unit 1 CTS 6.8.4.s and Unit 2 CTS 6.8.4.t state that the Safety Function Determination Program (SFDP) ensures loss of safety function is detected and appropriate actions taken, and other appropriate actions may be taken as a result of the support system inoperability. ITS 5.5.12 states that other appropriate limitations and remedial or compensatory actions may be taken as a result of the support system inoperability. The changes the CTS by adding additional clarification on what other appropriate action may be taken; limitation, remedial, or compensatory.

The addition of the description of the type of action that may be taken is acceptable because it is describing the intent of the CTS SFDP purpose. This change is designated as administrative because it does not result in technical changes to the CTS.

A09 Unit 1 CTS 6.8.4.s and Unit 2 CTS 6.8.4.t format regarding the SFDP refers to remedial actions with their associated prescribed period for completion as "ACTION" and "allowed outage time." ITS 5.5.12 format refers to these same remedial action and prescribed completion periods as "Condition and Required Action" and "Completion Time." This changes the CTS by changing how the remedial actions and associated period for action completion is referred to consistent with the ITS format. |R1

The change in format of these remedial action requirements is acceptable because it continues to portray the intent of the CTS. This change is designated as administrative because it does not result in technical changes to the CTS.

A10 **Unit 1 only:** CTS 4.9.12.b.4 requires verifying a system flow rate of 10,350 cfm ± 10% for the required fuel pool area ventilation train during system operation when tested in accordance with ANSI N510-1975. ITS 5.5.8 does not explicitly require this verification because it is duplicative of the flow rate requirement specified in CTS 4.9.12.b.1 and b.2. This changes the CTS by deleting a duplicative requirement to verify fuel pool area ventilation train flowrate while operating the ventilation system. This change is designated as administrative because it does not result in technical changes to the CTS.

A11 The explosive gas mixture requirements in CTS 3.11.2.5 and the gas storage tank requirements of CTS 3.11.2.6 have been placed in a program in the proposed Administrative Controls Chapter 5.0 (ITS 5.5.9). As such, a general program statement has been added. Also, a statement of applicability of ITS SR 3.0.2 and SR 3.0.3 is needed to clarify the allowances for Surveillance Frequency extensions do apply. This changes the CTS by moving the explosive gas mixture and gas storage tank requirements to a program in ITS Section 5.5 and specifically stating the applicability of ITS SR 3.0.2 and SR 3.0.3 in the program.

The addition of the program statement is acceptable because it is describing the intent of the CTS Specification. The addition of ITS SR 3.0.2 and SR 3.0.3 statement is a clarification needed to maintain provisions that are currently allowed in the LCO and SR sections of the CTS, therefore it is considered acceptable. This change is designated as administrative because it does not result in technical changes to the CTS.

A12 **Unit 2 only:** CTS 4.6.6.1.b requires SBVS filter testing, in part, after any structural maintenance on the HEPA filter or charcoal adsorber housings; or following painting, fire, or chemical release in any ventilation zone communicating with the system. ITS 5.5.8 does not include these specific testing frequency requirements for the SBVS filters. CTS 6.8.4.k currently requires filter testing in accordance with Regulatory Guide (RG) 1.52, Revision 3. RG 1.52 contains the similar testing frequency requirements as stated in CTS 4.6.6.1.b. ITS 5.5.8 retains the requirement that the SBVS filter testing be performed, as applicable, in accordance with Regulatory Guide (RG) 1.52, Revision 3. Therefore, CTS 4.6.6.1.b testing frequency requirements specified herein are duplicative to those required by CTS 6.8.4.k (ITS 5.5.8) and are unnecessary to include in the ITS. As a result, this change is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS does not provide administrative controls for reactor RCP flywheel inspections. ITS 5.5.5, "Reactor Coolant Pump (RCP) Flywheel Inspection Program" is added to the ITS. The proposed program will provide for the inspection of each RCP flywheel per the recommendation of Regulatory position c.4.b of Regulatory Guide 1.14, Revision 1, August 1975 except for an RCP flywheel consisting of ASTM A-516-69 (i.e., SA-516) Grade 65 material. For an RCP flywheel composed of ASTM A-516-69 Grade 65 material, the inspection shall consist of either a 100% volumetric inspection of the upper flywheel over the volume from the inner bore of the flywheel to the circle of one-half the outer radius or a surface examination (magnetic particle testing and/or penetrant testing) of exposed surfaces defined by the volume of the disassembled flywheel at least once every 10 years. This changes the CTS by adding an additional administrative control program.

The purpose of the RCP flywheel program is to implement requirements to minimize the potential for failures of the flywheels of RCP motors in light-water-cooled power reactors. At PSL, RCP flywheels are interchanged between Unit 1 and Unit 2 during refurbishment and replacement. Between 2011 and 2017, the Unit 1 RCP flywheels, which consist of ASTM A-516-69, Grade 65 material, were exchanged with the Unit 2 RCP flywheels, which consist of ASTM A543 (three flywheels Class 1, Type B and one flywheel Grade 70) material. RCP flywheels with ASTM A543 material are inspected per Regulatory Guide 1.14, Revision 1, August 1975. As such, the added program will require the Unit 1 RCP flywheels to be inspected per the recommendation of Regulatory position c.4.b of Regulatory Guide 1.14 consistent with the ISTS. Additionally, the requirements specified for the PSL RCP flywheels composed of ASTM A-516-69 Grade 65 material are included in the ITS to support future RCP flywheel exchanges between Unit 1 and Unit 2. These requirements are consistent with the current requirements in Unit 2 CTS 6.8.4.o that were approved in Unit 2 Amendment No. 205, dated November 18, 2020 (ADAMS Accession No. ML20259A298). This change is designated as more restrictive because it imposes additional programmatic requirements in the Technical Specifications.

M02 CTS does not include a requirement for the Battery Monitoring and Maintenance Program. The ITS includes a requirement for this program. This changes the CTS by adding the ITS 5.5.14, "Battery Monitoring and Maintenance Program."

The Battery Monitoring and Maintenance Program is included to provide for battery restoration and maintenance per the guidance of IEEE-450. The specific wording associated with this program may be found in ITS 5.5.14. The Notice of Availability for TSTF-500, Revision 2, "DC Electrical Rewrite - Update to TSTF-360," (*76FR54510*) references the model application and safety evaluation for plant-specific adoption of TSTF–500, Revision 2 (NRC ADAMS Accession No. ML111751792). PSL has verified the applicable information specified in Section 2.2 of the TSTF-500 model application, including applicable UFSAR information. PSL will update the UFSAR, as necessary, to include any UFSAR information listed in Section 2.2 of the TSTF-500 model application that is not currently reflected in the PSL Unit 1 and Unit 2 UFSARs. This change is acceptable because it supports implementation of the requirements of the ITS. This change is designated as more restrictive because it imposes additional programmatic requirements in the Technical Specifications.

M03 CTS 6.14, in part, requires changes to the Offsite Dose Calculation Manual (ODCM) to be documented with a list of items contained in the documentation. ITS 5.5.1 also requires the same documentation and includes a requirement that records of reviews performed shall be retained. This change is necessary to incorporate the guidance related to ODCM changes specified in NRC Generic Letter GL 89-01, which states, "…the staff has concluded that records of licensee reviews performed for changes made to the ODCM… should be documented and retained for the duration of the unit operating license. This approach is in lieu of the current requirements that the reasons for changes to the ODCM… be addressed in the Semiannual Effluent Release Report." This change is designated as more restrictive because it imposes additional programmatic requirements in the Technical Specifications.

M04 Unit 1 CTS 6.8.4.h states, in part, that the peak calculated containment internal pressure for the design basis loss of coolant accident Pa, is 42.8 psig and Unit 2 CTS 6.8.4.h states, in part, that the peak calculated containment internal pressure for the design basis loss of coolant accident Pa, is 43.48 psig. Unit 1 ITS 5.5.13.b states, in part, that the calculated peak containment internal pressure for the design basis loss of coolant accident, Pa is 42.77 psig and Unit 2 ITS 5.5.13.b states, in part, that the calculated peak containment internal pressure for the design basis loss of coolant accident, Pa is 43.43 psig. This changes the CTS by revising the value of Pa to be consistent with the calculated peak containment internal pressure in the Unit 1 and Unit 2 analyses of record. R1

The purpose of the CTS requirement is to provide the plant specific value of Pa as defined in 10 CFR 50, Appendix J. The change is designated as more restrictive because it corrects a non-conservative Technical Specification value with respect to determining the allowable containment leakage limit, La.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 5 – Removal of SR Frequency to the Surveillance Frequency Control Program)* CTS 6.8.4.a contains a program requiring leakage testing of primary coolant sources outside containment with a stated frequency of every 18 months. CTS 6.8.4.k.5 contains a program requiring testing of the Shield Building Ventilation System (SBVS) filter heaters testing every 18 months. CTS 6.8.4.m.d requires measurement, at designated locations, of the control room envelope (CRE) pressure relative to external areas adjacent to the CRE boundary during the pressurization mode of operation of the CREVS, operating at the flow rate required by the VFTP, at a frequency of 36 months on a Staggered Test Basis. CTS 6.8.4.n (iii) requires that total particulate concentration of the diesel generator fuel oil is ≤ 10 mg/l when tested every 31 days. ITS 5.5.2, 5.5.8, 5.5.15, and 5.5.10 contain similar requirements, respectively, but specify the periodic Frequency as "In accordance with the Surveillance Frequency Control Program." This changes the CTS by moving the specified periodic Frequency for these tests to the Surveillance Frequency Control Program.

The purpose of these Surveillances is to assure that the necessary quality of systems and components is maintained. The removal of these details related to Surveillance Requirement Frequencies from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The existing Frequency is removed from Technical Specifications and placed under licensee control pursuant to the methodology described in NEI 04-10. The surveillance test requirements remain in the Technical Specifications. The control of changes to the Surveillance Frequencies is in accordance with the Surveillance Frequency Control Program, which is retained in ITS Section 5.5. The Surveillance Frequency Control Program provides the necessary administrative controls to require that surveillances related to testing, calibration and inspection are conducted at a frequency to assure that the necessary quality of systems and components is maintained, that facility operation will be within safety limits, and that the limiting conditions for operation will be met pursuant to the requirements of 10 CFR 50.36(c)(3). The proposed change to relocate periodic frequencies in the administrative controls section of Technical Specifications has been previously approved for Wolf Creek Generating Station Unit 1 in Amendment 227, dated April 8, 2021 (NRC ADAMS Accession No. ML21053A117), River Bend Station Unit 1 in Amendment 196, dated April 29, 2019 (NRC ADAMS Accession No. ML19066A008), and Grand Gulf Nuclear Station Unit 1 in Amendment 219, dated June 11, 2019 (NRC ADAMS Accession No. ML19094A799). PSL Unit 1 and Unit 2 adopted a Surveillance Frequency Control Program in Amendment Nos. 223 (Unit 1) and 173 (Unit 2) (ADAMS Accession No. ML15127A066) as contained in CTS 6.8.4.o (Unit 1) and 6.8.4.q (Unit 2) (ITS 5.5.16). This change is acceptable because the testing frequencies will be adequately controlled in accordance with the

Surveillance Frequency Control Program requirements retained in ITS, which ensure changes are properly evaluated. This change is designated as a less restrictive removal of detail change, because the Surveillance Frequencies are being removed from the Technical Specifications.

LA02 *(Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program)* CTS 6.8.4.b, "In-Plant Radioiodine Monitoring," describes a program to ensure the capability to accurately determine the airborne iodine concentration in vital areas under accident conditions. ITS 5.5 does not include this program. This changes the CTS by moving the requirements for the In-Plant Radioiodine Monitoring Program to the Technical Requirements Manual (TRM).

The removal of this requirement from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The CTS 6.8.4.b program is designed to minimize radiation exposure to plant personnel in vital areas of the plant after an accident and has no impact on nuclear safety or the health and safety of the public. This change is acceptable because the program requirements will be adequately controlled in the TRM. Changes to the TRM will be controlled by the provisions of 10 CFR 50.59, which ensure changes are properly evaluated. This change is designated as a less restrictive removal of requirement change because requirements are being removed from the Technical Specifications.

LA03 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 6.8.4 contains a Backup Method for Determining Subcooling Margin Program. This program ensures the capability to accurately monitor RCS subcooling margin by training and procedures. ITS 5.5 does not include this administrative program. This changes the CTS by moving administrative procedural detail to the updated Final Safety Analysis Report (UFSAR).

The removal of these administrative procedural details is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement to maintain the post accident monitoring instrument channels OPERABLE in MODES 1, 2, and 3 that are used to determine RCS subcooling margin and provide input into the RCS subcooling margin monitor (e.g. core exit thermocouples, RCS hot and cold leg temperature, and pressurizer pressure). Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA04 *(Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program)* CTS 6.8.4.g, "Radiological Environmental Monitoring Program," describes a program to monitor the radiation and radio-nuclides in the environs of the plant. ITS Section 5.5 does not require this program. This changes the CTS by moving the requirements for the Radiological Environmental Monitoring Program to the ODCM.

The purpose of these program requirements is to provide representative measurements of radioactivity in the highest potential exposure pathways, and verification of the accuracy of the effluent monitoring program and modeling of environmental exposure pathways. The removal of the requirement for this program from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 5.6.2, “Radiological Effluent Release Report,” continues to require an annual report of the quantities of radioactive liquid and gaseous effluents and solid waste released from the unit. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ODCM. Changes to the ODCM are controlled by the ODCM change control process specified in ITS 5.5.1, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of requirement change because the requirements for a program are being removed from the Technical Specifications.

LA05 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS Table 4.8-2 footnote (c) states that the specified individual battery cell voltage limit for each connected cell is corrected for average electrolyte temperature. ITS 5.5.14 does not include the procedural detail regarding corrected cell voltage based on electrolyte temperature. This changes the CTS by moving procedural information from the Specification to the Battery Monitoring and Maintenance Program implementing document.

The removal of these details from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 5.5.14 retains the requirement specifying the individual battery cell voltage limit. Also, this change is acceptable because these types of procedural details will be adequately controlled by the requirements of a program required by ITS Section 5.5. Changes to the program requirements will be controlled by the provisions of 10 CFR 50.59, which ensure changes are properly evaluated. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA06 *(Type 3 - Removing Procedural Detail for Meeting TS Requirements or Reporting Requirements)* CTS 3.11.2.5 includes the details for implementing the requirements for the explosive gas mixture. CTS 3.11.2.6 includes the details for implementing the requirements for the gas storage tanks. The details for implementing these requirements, including the specific limits for the explosive gas mixture and limit for quantity of radioactivity contained the gas storage tanks, are not included in the ITS. The ITS only includes a requirement to maintain a

program for these requirements. This changes the CTS by moving these procedural details for implementing the requirements, including the specific limits, from the Technical Specifications to the TRM.

The removal of these details for the specific explosive gas limits and limits on quantity of radioactivity in the gas storage tanks, including the Applicability, Actions, and Surveillance Requirements, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 5.5.9 retains the requirement to include a program, which provides controls for potentially explosive gas mixtures contained in the waste gas decay tanks and the quantity of radioactivity contained in the gas storage tanks. Also, this change is acceptable because these types of procedural details will be adequately controlled in the TRM. Changes to the TRM will be controlled by the provisions of 10 CFR 50.59, which ensure changes are properly evaluated. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA07 **Unit 2 only:** *(Type 3 – Removing Procedural Details for Meeting TS Requirements and Related Reporting Problems)* CTS 4.6.6.1.b.1 requires a visual examination of the SBVS in accordance with ASME 510-1989. The ITS does not include this requirement. This changes the CTS by moving this requirement to the UFSAR.

The purpose of CTS 4.6.6.1.b is to ensure that in accordance with the Surveillance Frequency Control Program or; after any structural maintenance on the HEPA filter or charcoal adsorber housings; or following painting, fire, or chemical release in any ventilation zone communicating with the system, a visual inspection is performed on the SBVS. This is a good housekeeping practice that should be part of any recovery of a system from maintenance activities and periodically to visually identify gross system anomalies that would indicate the system is degraded. However, this detail is not necessary to be included in the ITS to provide adequate protection of the public health and safety. ITS 3.6.9 and ITS 5.5.8 retains Surveillance requirements and filter testing requirements to ensure the SBVS is OPERABLE. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. Changes to the UFSAR are controlled by 10 CFR 50.59 or 10 CFR 50.71(e), which ensures that any changes to the UFSAR are properly evaluated. This change is designated as a less restrictive removal of detail change because information relating to meeting a TS requirement is being removed from the Technical Specifications.

LA08 (Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program) CTS 6.8.4.p, "Snubber Testing Program," describes a program that implements the 10 CFR 50.55a inservice inspection (ISI) requirements for dynamic restraints (snubbers). ITS Section 5.5 does not require this program. This changes the CTS by moving the requirements for the Snubber Testing Program to the TRM. R1

The removal of these requirements is acceptable because this type of information is not necessary to be included in the Technical Specifications to

provide adequate protection of public health and safety. The Technical Specifications retain the requirements for the affected components supported by the snubbers to be OPERABLE. ITS LCO 3.0.8 addresses the required actions when one or more required snubbers are found to be unable to perform their associated function. This change is acceptable because the program requirements will be adequately controlled in the TRM. Any changes to the TRM are made under 10 CFR 50.59, which ensures the changes are properly evaluated. This change is designated as a less restrictive removal of requirement change because requirements are being removed from the Technical Specifications. R1

LESS RESTRICTIVE CHANGES

L01 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 6.8.4.l.d.2 requires, in part, inspecting 100% of the steam generator (SG) tubes at sequential periods of 144, 108, 72, and thereafter 60 effective full power months (EFPMs) and, in addition, requires inspecting 50% of the tubes by the refueling outage nearest the midpoint of the period and the remaining 50% by the refueling outages nearest the end of the period. No SG shall operate for more than 72 effective full power months or three refueling outages (whichever is less) without being inspected. ITS 5.5.6.d.2 requires inspection of 100% of the tubes in each steam generator at least every 96 EFPMs. CTS 6.8.4.l.d.3 requires additional inspection for each SG when crack indications are found in any tube at a frequency not to exceed 24 EFPMs or one refueling outage (whichever is less). ITS 5.5.6.d.3 requires the additional inspection on each affected and potentially affected SG at the next refueling outage. This changes the CTS by modifying the inspection frequency to a single requirement to inspect 100% of the SG tubes at a maximum frequency of 96 EFPMs and modifying the inspection frequency when crack indications are discovered to the next refueling outage.

The purpose of the inspection frequencies associated with the SG tubes is to ensure appropriate inspections are performed consistent with accepted NRC and industry practice as identified in Nuclear Energy Institute (NEI) 97-06, “Steam Generator Program Guidelines,” and its referenced Electric Power Research Institute SG examination guidelines, which establish the content of the Steam Generator Program. These guidelines minimize the potential of SG tube failures to support maintaining SG and reactor coolant pressure boundary structural integrity.

The proposed changes are consistent with the ISTS and Technical Specification Task Force (TSTF) traveler TSTF-577-A, Revision 1, “Revised Frequencies for Steam Generator Tube Inspections.” PSL Units 1 and 2 SGs contain Alloy 690 thermal treated (TT) tubes. For Alloy 690TT tubing, TSTF-577, which is incorporated in Revision 5 of the ISTS, revised the frequencies related to 100% and 50% inspection of the tubes such that both the maximum time between inspections and the time to inspect 100 percent of the tubes be 96 EFPMs. TSTF-577 also revised the frequency when crack indications are found in any tube to eliminate 24 EFPMs and require the inspection at the next refueling outage. The nuclear industry’s Steam Generator Task Force presented a technical basis supporting the 96 EFPM Alloy 690TT inspection interval during the February 13, 2019 (ADAMS Package Accession No. ML19044A416), and

February 24, 2020 (ADAMS Package Accession No. ML20066E421), public meetings with the NRC staff.

As stated in the NRC Safety Evaluation (SE) accompanying TSTF-577-A, proposed changes in TSTF-577 are acceptable because they continue to ensure SG tube integrity and, therefore, protect the public health and safety. In particular, the structural integrity performance criterion and accident-induced leakage performance criterion will continue to be met with the proposed revised SG inspection intervals (maximum allowable time between SG inspections) and inspection periods (maximum allowable time between 100 percent of SG tubes inspections). That considered, the changes to the SG tube inspection frequencies are acceptable. For Unit 1, inspection of 100% of the tubes in each SG was completed in the Spring 2021 refueling outage. For Unit 2, inspection of 100% of the tubes in each SG was completed for the current inspection period prior to the Fall 2021 refueling outage. Therefore, the 96 EFPM inspection period will begin from these SG tube inspection outages.

TSTF traveler TSTF-577-A incorporated changes to the Standard Technical Specifications (STSs) under the consolidated line item improvement process (CLIIP). TSTF-577-A was approved for use by the NRC as documented in the accompanying SE dated April 14, 2021 (ADAMS Accession No. ML21098A188, ML21096A274). PSL has reviewed the NRC SE and concluded that the justification presented in TSTF-577-A and the SE prepared by the NRC staff are applicable to PSL and justify this change.

This change is designated as less restrictive because the maximum inspection frequencies for the 100% and 50% tube inspections was extended to beyond the current inspection periods.

L02 **Unit 2 only:** (Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria) CTS 6.8.4.o requires administrative controls for reactor coolant pump (RCP) flywheel inspections. ITS 5.5.5 includes the same requirements and includes the CTS 6.8.4.o program requirements that were issued prior to Amendment No. 205 with a distinction on applicability of the two sets of requirements. The proposed program will provide for the inspection of each RCP flywheel per the recommendation of Regulatory position c.4.b of Regulatory Guide 1.14, Revision 1, August 1975 except for an RCP flywheel consisting of ASTM A-516-69 (i.e., SA-516) Grade 65 material. For an RCP flywheel composed of ASTM A-516-69 Grade 65 material, the inspection shall consist of either a 100% volumetric inspection of the upper flywheel over the volume from the inner bore of the flywheel to the circle of one-half the outer radius or a surface examination (magnetic particle testing and/or penetrant testing) of exposed surfaces defined by the volume of the disassembled flywheel at least once every 10 years. This changes the CTS by restoring program requirements that were issued prior to Amendment No. 205 in addition to the current requirements. |R1

The purpose of the RCP flywheel inspection program is to implement requirements to minimize the potential for failures of the flywheels of RCP motors in light-water-cooled power reactors. At PSL, RCP flywheels are interchanged between Unit 1 and Unit 2 during refurbishment and replacement. Between 2011

and 2017, the Unit 2 RCP flywheels, which consist of ASTM A-543 (three flywheels Class 1, Type B and one flywheel Grade 70) material, were exchanged with the Unit 1 RCP flywheels, which consist of ASTM A-516-69, Grade 65 material. Unit 2 CTS 6.8.4.o was modified to relax the RCP flywheel inspection requirements similar to the conclusions specified in the NRC Safety Evaluation of Topical Report SIR-94-080, Revision 1. The relaxed inspection requirements were approved in Amendment No. 205, dated November 18, 2020 (ADAMS Accession No. ML20259A298). Previously, PSL Unit 2 RCP flywheels were inspected per NRC Regulatory Guide 1.14, “Reactor Coolant Pump Flywheel Integrity,” Revision 1 and the requirements were previously contained in the CTS pre-Amendment 205 requirements. NRC Regulatory Guide 1.14 describes a method acceptable to the NRC staff of implementing RCP flywheel inspection requirements and include a recommended inspection schedule. Since the PSL RCP flywheels consisting of ASTM A-543 material were previously inspected per Regulatory Guide 1.14, Revision 1, August 1975 and the requirements were previously approved for use for Unit 2, the pre-Amendment 205 requirements are proposed to be restored in support of future RCP flywheel exchanges between Unit 1 and Unit 2. This change is designated as less restrictive because RCP flywheel inspection requirements, which have been previously approved for use at PSL, have been added.

Improved Standard Technical Specifications (ISTS) Markup and Justification for Deviations (JFDs)

5.0 ADMINISTRATIVE CONTROLS

5.5 Programs and Manuals

The following programs shall be established, implemented, and maintained.

Definition 1.18

5.5.1 Offsite Dose Calculation Manual (ODCM)

a. The ODCM shall contain the methodology and parameters used in the calculation of offsite doses resulting from radioactive gaseous and liquid effluents, in the calculation of gaseous and liquid effluent monitoring alarm and trip setpoints, and in the conduct of the radiological environmental monitoring program and

b. The ODCM shall also contain the radioactive effluent controls and radiological environmental monitoring activities, and descriptions of the information that should be included in the Annual Radiological Environmental Operating, and Radioactive Effluent Release Reports required by Specification [5.6.1] and Specification [5.6.2]. (2)

Licensee initiated changes to the ODCM:

6.14.1 DOC M03

a. Shall be documented and records of reviews performed shall be retained. This documentation shall contain:

1. Sufficient information to support the change(s) together with the appropriate analyses or evaluations justifying the change(s) and

2. A determination that the change(s) maintain the levels of radioactive effluent control required by 10 CFR 20.1302, 40 CFR 190, 10 CFR 50.36a, and 10 CFR 50, Appendix I, and not adversely impact the accuracy or reliability of effluent, dose, or setpoint calculations,

6.14.2 b. Shall become effective after the approval of the plant manager, and

6.14.3 c. Shall be submitted to the NRC in the form of a complete, legible copy of the entire ODCM as a part of or concurrent with the Radioactive Effluent Release Report for the period of the report in which any change in the ODCM was made. Each change shall be identified by markings in the margin of the affected pages, clearly indicating the area of the page that was changed, and shall indicate the date (i.e., month and year) the change was implemented.

5.5 Programs and Manuals

6.8.4.a

5.5.2 Primary Coolant Sources Outside Containment

High Pressure Safety Injection, Containment

This program provides controls to minimize leakage from those portions of systems outside containment that could contain highly radioactive fluids during a serious transient or accident to levels as low as practicable. The systems include [Low Pressure Injection, ~~Reactor Building~~ Spray~~, Makeup and Purification~~, and ~~Hydrogen Recombiner~~]. The program shall include the following:

Safety

Reactor Coolant Sampling

2

a. Preventive maintenance and periodic visual inspection requirements and

b. Integrated leak test requirements for each system at ~~least once per [18] months~~.

a Frequency in accordance with the Surveillance Frequency Control Program

3

The provisions of SR 3.0.2 are applicable.

~~[5.5.3 Post Accident Sampling~~

2

~~REVIEWER'S NOTE~~

~~This program may be eliminated based on the implementation of Topical Report CE NPSD-1157, Rev. 1, "Technical Justification for the Elimination of the Post-Accident Sampling System from the Plant Design and Licensing Basis for CEOG Utilities," and the associated NRC Safety Evaluation dated May 16, 2000, and implementation of the following commitments:~~

~~1. [Licensee] has developed contingency plans for obtaining and analyzing highly radioactive samples of reactor coolant, containment sump, and containment atmosphere. The contingency plans will be contained in emergency plan implementing procedures and implemented with the implementation of the License amendment. Establishment of contingency plans is considered a regulatory commitment.~~

~~2. The capability for classifying fuel damage events at the Alert level threshold has been established for [PLANT] at radioactivity levels of 300 mCi/cc dose equivalent iodine. This capability may utilize the normal sampling system and/or correlations of sampling or letdown line dose rates to coolant concentrations. This capability will be described in emergency plan implementing procedures and implemented with the implementation of the License amendment. The capability for classifying fuel damage events is considered a regulatory commitment.~~

~~3. [Licensee] has established the capability to monitor radioactive iodines that have been released to offsite environs. This capability is described in our emergency plan implementing procedures. The capability to monitor radioactive iodines is considered a regulatory commitment..~~

~~This program provides controls that ensure the capability to obtain and analyze reactor coolant, radioactive gases, and particulates in plant gaseous effluents~~

5.5 Programs and Manuals

~~5.5.3 Post Accident Sampling (continued)~~

~~and containment atmosphere samples under accident conditions. The program shall include the following:~~

~~a. Training of personnel,~~

~~b. Procedures for sampling and analysis, and~~

~~c. Provisions for maintenance of sampling and analysis equipment.]~~

2
4

6.8.4.f

5.5.~~4~~ Radioactive Effluent Controls Program

3

4

This program conforms to 10 CFR 50.36a for the control of radioactive effluents and for maintaining the doses to members of the public from radioactive effluents as low as reasonably achievable. The program shall be contained in the ODCM, shall be implemented by procedures, and shall include remedial actions to be taken whenever the program limits are exceeded. The program shall include the following elements:

a. Limitations on the functional capability of radioactive liquid and gaseous monitoring instrumentation including surveillance tests and setpoint determination in accordance with the methodology in the ODCM,

b. Limitations on the concentrations of radioactive material released in liquid effluents to unrestricted areas, conforming to ten times the concentration values in Appendix B, Table 2, Column 2 to 10 CFR 20.1001-20.2402,

c. Monitoring, sampling, and analysis of radioactive liquid and gaseous effluents in accordance with 10 CFR 20.1302 and with the methodology and parameters in the ODCM,

d. Limitations on the annual and quarterly doses or dose commitment to a member of the public from radioactive materials in liquid effluents released from each unit to unrestricted areas, conforming to 10 CFR 50, Appendix I,

e. Determination of cumulative dose contributions from radioactive effluents for the current calendar quarter and current calendar year in accordance with the methodology and parameters in the ODCM at least every 31 days. Determination of projected dose contributions from radioactive effluents in accordance with the methodology in the ODCM at least every 31 days,

f. Limitations on the functional capability and use of the liquid and gaseous effluent treatment systems to ensure that appropriate portions of these systems are used to reduce releases of radioactivity when the projected doses in a period of 31 days would exceed 2% of the guidelines for the annual dose or dose commitment, conforming to 10 CFR 50, Appendix I,

5.5 Programs and Manuals

6.8.4.f 5.5.~~4~~ Radioactive Effluent Controls Program (continued) 4

3

g. Limitations on the dose rate resulting from radioactive material released in gaseous effluents from the site to areas at or beyond the site boundary shall be in accordance with the following:

1. For noble gases: a dose rate ≤ 500 mrem/yr to the whole body and a dose rate ≤ 3000 mrem/yr to the skin and

2. For iodine-131, iodine-133, tritium, and all radionuclides in particulate form with half-lives greater than 8 days: a dose rate ≤ 1500 mrem/yr to any organ,

h. Limitations on the annual and quarterly air doses resulting from noble gases released in gaseous effluents from each unit to areas beyond the site boundary, conforming to 10 CFR 50, Appendix I,

i. Limitations on the annual and quarterly doses to a member of the public from iodine-131, iodine-133, tritium, and all radionuclides in particulate form with half lives > 8 days in gaseous effluents released from each unit to areas beyond the site boundary, conforming to 10 CFR 50, Appendix I, and

j. Limitations on the annual dose or dose commitment to any member of the public, beyond the site boundary, due to releases of radioactivity and to radiation from uranium fuel cycle sources, conforming to 40 CFR 190.

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Radioactive Effluent Controls Program surveillance frequency.

6.8.4.q 5.5.~~5~~ Component Cyclic or Transient Limit

4

U 1 4 2 5.2

This program provides controls to track the FSAR, Section [~~ ~~], cyclic and transient occurrences to ensure that components are maintained within the design limits.

~~[5.5.6 Pre-Stressed Concrete Containment Tendon Surveillance Program~~ 2 4

~~This program provides controls for monitoring any tendon degradation in pre-stressed concrete containments, including effectiveness of its corrosion protection medium, to ensure containment structural integrity. The program shall include baseline measurements prior to initial operations. The Tendon Surveillance Program, inspection frequencies, and acceptance criteria shall be in accordance with Section XI, Subsection IWL of the ASME Boiler and Pressure Vessel Code and applicable addenda as required by 10CFR 50.55a, except where an alternative, exemption, or relief has been authorized by the NRC.~~

~~The provisions of SR 3.0.3 are applicable to the Tendon Surveillance Program inspection frequencies.]~~

5

5.5.~~8~~ Steam Generator (SG) Program

4

6

6.8.4.l An SG Program shall be established and implemented to ensure that SG tube integrity is maintained. In addition, the SG Program shall include the following:

6.8.4.l.a a. Provisions for condition monitoring assessments. Condition monitoring assessment means an evaluation of the "as found" condition of the tubing with respect to the performance criteria for structural integrity and accident induced leakage. The "as found" condition refers to the condition of the tubing during an SG inspection outage, as determined from the inservice inspection results or by other means, prior to the plugging ~~[or repair]~~ of tubes. Condition monitoring assessments shall be conducted during each outage during which the SG tubes are inspected, plugged, ~~[~~or ~~repaired]~~ to confirm that the performance criteria are being met.

2

6.8.4.l.b b. Performance criteria for SG tube integrity. SG tube integrity shall be maintained by meeting the performance criteria for tube structural integrity, accident induced leakage, and operational LEAKAGE.

6.8.4.l.b.1 1. Structural integrity performance criterion: All in-service SG tubes shall retain structural integrity over the full range of normal operating conditions (including startup, operation in the power range, hot standby, and cool down), all anticipated transients included in the design specification, and design basis accidents. This includes retaining a safety factor of 3.0 against burst under normal steady state full power operation primary-to-secondary pressure differential and a safety factor of 1.4 against burst applied to the design basis accident primary-to-secondary pressure differentials. Apart from the above requirements, additional loading conditions associated with the design basis accidents, or combination of accidents in accordance with the design and licensing basis, shall also be evaluated to determine if the associated loads contribute significantly to burst or collapse. In the assessment of tube integrity, those loads that do significantly affect burst or collapse shall be determined and assessed in combination with the loads due to pressure with a safety factor of 1.2 on the combined primary loads and 1.0 on axial secondary loads.

6.8.4.l.b.2 2. Accident induced leakage performance criterion: The primary to secondary accident induced leakage rate for any design basis accident, other than a SG tube rupture, shall not exceed the leakage rate assumed in the accident analysis in terms of total leakage rate for

CTS

5

Insert 1

DOC M01 , except for an RCP flywheel consisting of ASTM A-516-69 (i.e., SA-516) Grade 65 material.

For an RCP flywheel composed of ASTM A-516-69 Grade 65 material, the inspection shall consist of either a 100% volumetric inspection of the upper flywheel over the volume from the inner bore of the flywheel to the circle of one-half the outer radius or a surface examination (magnetic particle testing and/or penetrant testing) of exposed surfaces defined by the volume of the disassembled flywheel at least once every 10 years.

5.5 Programs and Manuals

5.5.~~8~~ 6 Steam Generator (SG) Program (continued) 4

6.8.4.l all SGs and leakage rate for an individual SG. Leakage is not to exceed ~~[1 gpm] per~~ SG. ~~[, except for specific types of degradation at specific locations as described in paragraph c of the SG Program.]~~

0.5 gpm total through all SGs and 0.25 gpm through any one

6.8.4.l.b.3 3. The operational LEAKAGE performance criterion is specified in LCO 3.4.13, "RCS Operational LEAKAGE."

6.8.4.l.c c. Provisions for SG tube plugging ~~[or repair]~~ criteria. Tubes found by inservice inspection to contain flaws with a depth equal to or exceeding ~~[~~40%~~]~~ of the nominal tube wall thickness shall be plugged ~~[or repaired]~~.

~~REVIEWER'S NOTE~~

~~Alternate tube plugging [or repair] criteria currently permitted by plant technical specifications are listed here. The description of these alternate tube plugging [or repair] criteria should be equivalent to the descriptions in current technical specifications and should also include any allowed accident induced leakage rates for specific types of degradation at specific locations associated with tube plugging [or repair] criteria.~~ 6

~~[The following alternate tube plugging [or repair] criteria may be applied as an alternative to the 40% depth based criteria:~~ 2

~~1. . . .]~~

~~REVIEWER'S NOTE~~

~~The bracketed phrase in Paragraph d regarding exempt portions of the tube is only applicable to SGs with Alloy 600 thermally treated tubing.~~ 6

6.8.4.l.d d. Provisions for SG tube inspections. Periodic SG tube inspections shall be performed. The number and portions of the tubes inspected and methods of inspection shall be performed with the objective of detecting flaws of any type (e.g., volumetric flaws, axial and circumferential cracks) that may be present along the length of the tube, from the tube-to-tubesheet weld at the tube inlet to the tube-to-tubesheet weld at the tube outlet ~~[except for any portions of the tube that are exempt from inspection by alternate repair criteria]~~, and that may satisfy the applicable tube plugging ~~[or repair]~~ criteria. The tube-to-tubesheet weld is not part of the tube. In addition to meeting the requirements of d.1, d.2, and d.3 below, the inspection scope, inspection methods, and inspection intervals shall be such as to ensure that SG tube integrity is maintained until the next SG inspection. A degradation assessment shall be performed to determine the type and location of flaws to which the tubes may be susceptible and, based on this assessment, to determine which inspection methods need to be employed and at what locations.

5.5 Programs and Manuals

5.5.~~8~~ 6 Steam Generator (SG) Program (continued) 4

~~REVIEWER'S NOTE~~

~~Plants are to include the appropriate Frequency (e.g., select the appropriate Item 2.) for their SG design. The first Item 2 is applicable to SGs with Alloy 600 mill annealed tubing. The second Item 2 is applicable to SGs with Alloy 600 thermally treated tubing. The third Item 2 is applicable to SGs with Alloy 690 thermally treated tubing.~~ 6

6.8.4.l.d.1

1. Inspect 100% of the tubes in each SG during the first refueling outage following SG installation.

~~[2. After the first refueling outage following SG installation, inspect 100% of the tubes in each SG at least every 24 effective full power months, which defines the inspection period.]~~

~~[2. After the first refueling outage following SG installation, inspect 100% of the tubes in each SG at least every 54 effective full power months, which defines the inspection period. If none of the SG tubes have ever experienced cracking other than in regions that are exempt from inspection by alternate repair criteria and the SG inspection was performed with enhanced probes, the inspection period may be extended to 72 effective full power months. Enhanced probes have a capability to detect flaws of any type equivalent to or better than array probe technology. The enhanced probes shall be used from the tube-to-tubesheet weld at the tube inlet to the tube-to-tubesheet weld at the tube outlet except any portions of the tube that are exempt from inspection by alternate repair criteria. If there are regions where enhanced probes cannot be used, the tube inspection techniques shall be capable of detecting all forms of existing and potential degradation in that region.]~~

6.8.4.l.d.2
DOC L01

~~[~~2. After the first refueling outage following SG installation, inspect 100% of the tubes in each SG at least every 96 effective full power months, which defines the inspection period. ~~]~~ 2

~~REVIEWER'S NOTE~~

~~The bracketed phrases in Paragraph 3 are only applicable to SGs with Alloy 600 thermally treated tubing.~~ 6

6.8.4.l.d.3

DOC L01

3. If crack indications are found in any SG tube ~~[excluding any region that is exempt from inspection by alternate repair criteria]~~, then the next inspection for each ~~affected and potentially affected~~ SG for the degradation mechanism that caused the crack indication shall be at the next refueling outage ~~[, but may be deferred to the following refueling~~ 2 1

5.5 Programs and Manuals

4.9.12.b.2
4.9.12.d

g. Demonstrate for the Fuel Pool Area Ventilation System that an inplace test of the HEPA filters shows a removal efficiency of ≥ 99% of dioctyl phthalate when tested in accordance with ANSI N510-1975 at a system flowrate of 10,350 cfm ± 10%.

4.9.12.b.1
4.9.12.e

h. Demonstrate for the Fuel Pool Area Ventilation System that an inplace test of the charcoal adsorbers shows a removal efficiency ≥ 99% of a halogenated hydrocarbon refrigerant test gas when tested in accordance with ANSI N510-1975 at a system flowrate of 10,350 cfm ± 10%.

4.9.12.b.3

i. Demonstrate for the Fuel Pool Area Ventilation System that a laboratory test of a sample of the charcoal adsorber, when obtained as described herein, shows a removal efficiency of ≥ 85% for radioactive methyl iodide when tested in accordance with ASTM D3803-1989 at a temperature of 30°C (86°F) and relative humidity of 95%.

A carbon sample shall be obtained from either one test canister or two carbon samples removed from one of the charcoal adsorbers. Carbon samples not obtained from test canisters shall be prepared by emptying:

4.9.12.b.3 a)

1. one entire bed from a removed adsorber tray, mixing the adsorbent thoroughly, and obtaining samples at least two inches in diameter and with a length equal to the thickness of the bed, or

4.9.12.b.3 b)

2. a longitudinal sample from an adsorber tray, mixing the adsorbent thoroughly, and obtaining samples at least two inches in diameter and with a length equal to the thickness of the bed.

4.9.12.c.1

j. Demonstrate for the Fuel Pool Area Ventilation System that the pressure drop across the combined HEPA filters and the charcoal adsorbers is < 4.15 inches water gauge when tested at a system flowrate of 10,350 cfm ± 10%.

4.9.12.c.2

k. Demonstrate for the Fuel Pool Area Ventilation System that the air flow distribution across HEPA filters and charcoal adsorbers is uniform within 20% when tested in accordance with ANSI N510-1975.

5.5 Programs and Manuals

5.5.~~11~~ Explosive Gas and Storage Tank Radioactivity Monitoring Program

This program provides controls for potentially explosive gas mixtures contained in the ~~[Waste Gas Holdup System], [~~the quantity of radioactivity contained in gas storage tanks ~~or fed into the offgas treatment system, and the quantity of radioactivity contained in unprotected outdoor liquid storage tanks]~~. ~~The gaseous radioactivity quantities shall be determined following the methodology in [Branch Technical Position (BTP) ETSB 11-5, "Postulated Radioactive Release due to Waste Gas System Leak or Failure"]. The liquid radwaste quantities shall be determined in accordance with [Standard Review Plan, Section 15.7.3, "Postulated Radioactive Release due to Tank Failures"].~~
The program shall include:

a. The limits for concentrations of hydrogen and oxygen in the ~~[Waste Gas Holdup System]~~ and a surveillance program to ensure the limits are maintained. Such limits shall be appropriate to the system's design criteria (i.e., whether or not the system is designed to withstand a hydrogen explosion),

b. A surveillance program to ensure that the quantity of radioactivity contained in ~~[~~each gas storage tank ~~and fed into the offgas treatment system]~~ is less than the amount that would result in a whole body exposure of ≥ 0.5 rem to any individual in an unrestricted area, in the event of ~~[~~an uncontrolled release of the tanks' contents~~]~~, and

~~c. A surveillance program to ensure that the quantity of radioactivity contained in all outdoor liquid radwaste tanks that are not surrounded by liners, dikes, or walls, capable of holding the tanks' contents and that do not have tank overflows and surrounding area drains connected to the [Liquid Radwaste Treatment System] is less than the amount that would result in concentrations less than the limits of 10 CFR 20, Appendix B, Table 2, Column 2, at the nearest potable water supply and the nearest surface water supply in an unrestricted area, in the event of an uncontrolled release of the tanks' contents.~~

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Explosive Gas and Storage Tank Radioactivity Monitoring Program surveillance frequencies.

5.5 Programs and Manuals

5.5.~~12~~ Diesel Fuel Oil Testing Program

4

10

6.8.4.n

A diesel fuel oil testing program to implement required testing of both new fuel oil and stored fuel oil shall be established. The program shall include sampling and testing requirements, and acceptance criteria, all in accordance with applicable ASTM Standards. The purpose of the program is to establish the following:

6.8.4.n (i)

a. Acceptability of new fuel oil for use prior to addition to storage tanks by determining that the fuel oil has:

1. An API gravity or an absolute specific gravity within limits,

2. A flash point and kinematic viscosity within limits for ASTM 2D fuel oil, and

3. A clear and bright appearance with proper color or a water and sediment content within limits,

6.8.4.n (ii)

b. Within 31 days following addition of the new fuel oil to storage tanks, verify that the properties of the new fuel oil, other than those addressed in a., above, are within limits for ASTM 2D fuel oil, and

6.8.4.n (iii)

c. Total particulate concentration of the fuel oil is ≤ 10 mg/l when tested ~~every 31 days~~ at a Frequency in accordance with the Surveillance Frequency Control Program.

3

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Diesel Fuel Oil Testing Program test frequencies.

6.8.4.j

5.5.~~13~~ Technical Specifications (TS) Bases Control Program

4

11

This program provides a means for processing changes to the Bases of these Technical Specifications.

6.8.4.j.1

a. Changes to the Bases of the TS shall be made under appropriate administrative controls and reviews.

6.8.4.j.2

b. Licensees may make changes to Bases without prior NRC approval provided the changes do not require either of the following:

6.8.4.j.2.a

1. A change in the TS incorporated in the license or

1

U

6.8.4.j.2.b

2. A change to the ~~updated~~ FSAR or Bases that requires NRC approval pursuant to 10 CFR 50.59.

U

1

6.8.4.j.3

c. The Bases Control Program shall contain provisions to ensure that the Bases are maintained consistent with the FSAR.

5.5 Programs and Manuals

6.8.4.j 5.5.~~13~~ 11 Technical Specifications (TS) Bases Control Program (continued) 4

6.8.4.j.4 d. Proposed changes that meet the criteria of 5.5.~~13~~11.b above shall be reviewed and approved by the NRC prior to implementation. Changes to the Bases implemented without prior NRC approval shall be provided to the NRC on a frequency consistent with 10 CFR 50.71(e).

5.5.~~14~~ 12 Safety Function Determination Program (SFDP) 4

6.8.4.s This program ensures loss of safety function is detected and appropriate actions taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other appropriate limitations and remedial or compensatory actions may be identified to be taken as a result of the support system inoperability and corresponding exception to entering supported system Condition and Required Actions. This program implements the requirements of LCO 3.0.6. The SFDP shall contain the following:

a. Provisions for cross train checks to ensure a loss of the capability to perform the safety function assumed in the accident analysis does not go undetected,

b. Provisions for ensuring the plant is maintained in a safe condition if a loss of function condition exists,

c. Provisions to ensure that an inoperable supported system's Completion Time is not inappropriately extended as a result of multiple support system inoperabilities, and

d. Other appropriate limitations and remedial or compensatory actions.

A loss of safety function exists when, assuming no concurrent single failure, no concurrent loss of offsite power, or no concurrent loss of onsite diesel generator(s), a safety function assumed in the accident analysis cannot be performed. For the purpose of this program, a loss of safety function may exist when a support system is inoperable, and

a. A required system redundant to the system(s) supported by the inoperable support system is also inoperable, or

b. A required system redundant to the system(s) in turn supported by the inoperable supported system is also inoperable, or

c. A required system redundant to the support system(s) for the supported systems (a) and (b) above is also inoperable.

5.5 Programs and Manuals

6.8.4.s 5.5.~~14~~ 12 Safety Function Determination Program (SFDP) (continued) 4

The SFDP identifies where a loss of safety function exists. If a loss of safety function is determined to exist by this program, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered. When a loss of safety function is caused by the inoperability of a single Technical Specification support system, the appropriate Conditions and Required Actions to enter are those of the support system.

6.8.4.h 5.5.~~15~~ 13 Containment Leakage Rate Testing Program 4

~~[OPTION A]~~

~~a. A program shall establish the leakage rate testing of the containment as required by 10 CFR 50.54(o) and 10 CFR 50, Appendix J, Option A, as modified by approved exemptions.~~

~~b. The maximum allowable containment leakage rate, L_a at P_a, shall be [ ]% of containment air weight per day.~~

~~c. Leakage rate acceptance criteria are:~~

~~1. Containment leakage rate acceptance criterion is ≤ 1.0 L_a. During the first unit startup following testing in accordance with this program, the leakage rate acceptance criteria are < 0.60 L_a for the Type B and C tests and < 0.75 L_a for Type A tests.~~ 8

~~2. Air lock testing acceptance criteria are:~~

~~a) Overall air lock leakage rate is ≤ [0.05 L_a] when tested at ≥ P_a.~~

~~b) For each door, leakage rate is ≤ [0.01 L_a] when pressurized to [≥ 10 psig].~~

~~d. The provisions of SR 3.0.3 are applicable to the Containment Leakage Rate Testing Program.~~

~~e. Nothing in these Technical Specifications shall be construed to modify the testing Frequencies required by 10 CFR 50, Appendix J.~~

5.5.~~16~~ Battery Monitoring and Maintenance Program

14

4

~~REVIEWER'S NOTE~~

~~This program and the corresponding requirements in LCO 3.8.4, LCO 3.8.5, and LCO 3.8.6 require providing the information and verifications requested in the Notice of Availability for TSTF-500, Revision 2, "DC Electrical Rewrite - Update to TSTF-360," (76FR54510).~~

6

DOC M02

This Program provides controls for battery restoration and maintenance. The program shall be in accordance with IEEE Standard (Std) 450-~~2002~~2010, "IEEE Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications," as endorsed by Regulatory Guide 1.129, Revision ~~2 (RG), with RG exceptions and program provisions as identified below:~~ 3.

~~a. The program allows the following RG 1.129, Revision 2 exceptions:~~

~~1. Battery temperature correction may be performed before or after conducting discharge tests.~~

~~2. RG 1.129, Regulatory Position 1, Subsection 2, "References," is not applicable to this program.~~

9

5.5 Programs and Manuals

5.5.~~16~~ Battery Monitoring and Maintenance Program (continued) 4

14

~~3. In lieu of RG 1.129, Regulatory Position 2, Subsection 5.2, "Inspections," the following shall be used: "Where reference is made to the pilot cell, pilot cell selection shall be based on the lowest voltage cell in the battery."~~

~~4 In Regulatory Guide 1.129, Regulatory Position 3, Subsection 5.4.1, "State of Charge Indicator," the following statements in paragraph (d) may be omitted: "When it has been recorded that the charging current has stabilized at the charging voltage for three consecutive hourly measurements, the battery is near full charge. These measurements shall be made after the initially high charging current decreases sharply and the battery voltage rises to approach the charger output voltage."~~

~~5. In lieu of RG 1.129, Regulatory Position 7, Subsection 7.6, "Restoration," the following may be used: "Following the test, record the float voltage of each cell of the string."~~ 9

~~b.~~ The program shall include the following provisions:

Table 4.8-2

a. ~~1.~~ Actions to restore battery cells with float voltage < ~~[~~2.13~~]~~ V;

Table 4.8-2

b. ~~2.~~ Actions to determine whether the float voltage of the remaining battery cells is ≥ ~~[~~2.13~~]~~ V when the float voltage of a battery cell has been found to be < ~~[~~2.13~~]~~ V; 2

c. ~~3.~~ Actions to equalize and test battery cells that had been discovered with electrolyte level below the top of the plates;

d. ~~4.~~ Limits on average electrolyte temperature, battery connection resistance, and battery terminal voltage; and

~~5. A requirement to obtain specific gravity readings of all cells at each discharge test, consistent with manufacturer recommendations.~~ 9

5.5 Programs and Manuals

6.8.4.m 5.5.~~17~~ 15 Control Room Envelope (CRE) Habitability Program 4

A Control Room Envelope (CRE) Habitability Program shall be established and implemented to ensure that CRE habitability is maintained such that, with an OPERABLE Control Room Emergency ~~Air Cleanup~~ System (CRE~~AC~~S), CRE occupants can control the reactor safely under normal conditions and maintain it in a safe condition following a radiological event, hazardous chemical release, or a smoke challenge. The program shall ensure that adequate radiation protection is provided to permit access and occupancy of the CRE under design basis accident (DBA) conditions without personnel receiving radiation exposures in excess of ~~[5 rem whole body or its equivalent to any part of the body] [~~5 rem total effective dose equivalent (TEDE)~~]~~ for the duration of the accident. The program shall include the following elements:

Ventilation V 1 2

a. The definition of the CRE and the CRE boundary.

b. Requirements for maintaining the CRE boundary in its design condition including configuration control and preventive maintenance.

c. Requirements for (i) determining the unfiltered air inleakage past the CRE boundary into the CRE in accordance with the testing methods and at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, "Demonstrating Control Room Envelope Integrity at Nuclear Power Reactors," Revision 0, May 2003, and (ii) assessing CRE habitability at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, Revision 0.

~~[The following are exceptions to Sections C.1 and C.2 of Regulatory Guide 1.197, Revision 0:~~

~~1. ;and]~~ 2

d. Measurement, at designated locations, of the CRE pressure relative to all external areas adjacent to the CRE boundary during the pressurization mode of operation by one train of the ~~CRE~~ACS, operating at the flow rate required by the VFTP, at a Frequency ~~of [18] months on a STAGGERED TEST BASIS~~. The results shall be trended and used as part of the ~~[18]~~ month assessment of the CRE boundary.

CREVS | R1 3

in accordance with the Surveillance Frequency Control Program. 36 2

5.5 Programs and Manuals

6.8.4.m 5.5.~~17~~ Control Room Envelope (CRE) Habitability Program (continued) 4

15

e. The quantitative limits on unfiltered air inleakage into the CRE. These limits shall be stated in a manner to allow direct comparison to the unfiltered air inleakage measured by the testing described in paragraph c. The unfiltered air inleakage limit for radiological challenges is the inleakage flow rate assumed in the licensing basis analyses of DBA consequences. Unfiltered air inleakage limits for hazardous chemicals must ensure that exposure of CRE occupants to these hazards will be within the assumptions in the licensing basis.

f. The provisions of SR 3.0.2 are applicable to the Frequencies for assessing CRE habitability, determining CRE unfiltered inleakage, and measuring CRE pressure and assessing the CRE boundary as required by paragraphs c and d, respectively.

~~[5.5.18 Setpoint Control Program~~

~~REVIEWER'S NOTE~~

~~Adoption of a Setpoint Control Program requires changes to other technical specifications. See TSTF-493, Revision 4, "Clarify Application of Setpoint Methodology for LSSS Functions," Option B, for guidance (Agencywide Documents Access and Management System (ADAMS) Accession Number ML101160026).~~

~~This program shall establish the requirements for ensuring that setpoints for automatic protective devices are initially within and remain within the assumptions of the applicable safety analyses, provides a means for processing changes to instrumentation setpoints, and identifies setpoint methodologies to ensure instrumentation will function as required. The program shall ensure that testing of automatic protective devices related to variables having significant safety functions as delineated by 10 CFR 50.36(c)(1)(ii)(A) verifies that instrumentation will function as required.~~

10

~~a. The program shall list the Functions in the following specifications to which it applies:~~

~~1. LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation - Operating [(Analog)] [(Digital)];"~~

5.5 Programs and Manuals

5.5.18 Setpoint Control Program (continued)

2. LCO 3.3.2, "Reactor Protective System (RPS) Instrumentation - Shutdown [(Analog)] [(Digital)];"
3. LCO [3.3.3, "Control Element Assembly Calculators (CEACs) (Digital)];"
4. [LCO 3.3.4,"Engineered Safety Features Actuation System (ESFAS) Instrumentation (Analog);"] [LCO 3.3.5, "Engineered Safety Features Actuation System (ESFAS) Instrumentation (Digital);"]
5. [LCO 3.3.6, "Diesel Generator (DG) - Loss of Voltage Start (LOVS) (Analog);"] [LCO 3.3.7, "Diesel Generator (DG) - Loss of Voltage Start (LOVS) (Digital);"]
6. [LCO 3.3.7, "Containment Purge Isolation Signal (CPIS) (Analog);"] [LCO 3.3.8, "Containment Purge Isolation Signal (CPIS) (Digital);"]
7. [LCO 3.3.8, "Control Room Isolation Signal (CRIS) (Analog);"] [LCO 3.3.9, "Control Room Isolation Signal (CRIS) (Digital);"];
8. [LCO 3.3.9, "Chemical and Volume Control System (CVCS) Isolation Signal (Analog);"]
9. [LCO 3.3.10, "Fuel Handling Isolation Signal (FHIS) (Digital);"]
10. LCO 3.3.13, "[Logarithmic] Power Monitoring Channels [(Analog)."] [(Digital)."]

b. The program shall require the [Limiting Trip Setpoint (LTSP)], [Nominal Trip Setpoint (NTSP)], Allowable Value (AV), As-Found Tolerance (AFT), and As-Left Tolerance (ALT) (as applicable) of the Functions described in paragraph a. are calculated using the NRC approved setpoint methodology, as listed below. In addition, the program shall contain the value of the [LTSP], [NTSP], AV, AFT, and ALT (as applicable) for each Function described in paragraph a. and shall identify the setpoint methodology used to calculate these values.

---------- Reviewer's Note ----------
List the NRC safety evaluation report by letter, date, and ADAMS accession number (if available) that approved the setpoint methodologies.
---

1. [Insert reference to NRC safety evaluation that approved the setpoint methodology.]

c. The program shall establish methods to ensure that Functions described in paragraph a. will function as required by verifying the as-left and as-found settings are consistent with those established by the setpoint methodology.

5.5 Programs and Manuals

5.5.18 Setpoint Control Program (continued)

d. ----------REVIEWER'S NOTE----------
A license amendment request to implement a Setpoint Control Program must list the instrument functions to which the program requirements of paragraph d. will be applied. Paragraph d. shall apply to all Functions in the Reactor Protection System and Engineered Safety Feature Actuation System specifications unless one or more of the following exclusions apply:

1. Manual actuation circuits, automatic actuation logic circuits or to instrument functions that derive input from contacts which have no associated sensor or adjustable device, e.g., limit switches, breaker position switches, manual actuation switches, float switches, proximity detectors, etc. are excluded. In addition, those permissives and interlocks that derive input from a sensor or adjustable device that is tested as part of another TS function are excluded.

2. Settings associated with safety relief valves are excluded. The performance of these components is already controlled (i.e., trended with as-left and as-found limits) under the ASME Code for Operation and Maintenance of Nuclear Power Plants testing program.

3. Functions and Surveillance Requirements which test only digital components are normally excluded. There is no expected change in result between SR performances for these components. Where separate as-left and as-found tolerance is established for digital component SRs, the requirements would apply.

The program shall identify the Functions described in paragraph a. that are automatic protective devices related to variables having significant safety functions as delineated by 10 CFR 50.36(c)(1)(ii)(A). The [LTSP] of these Functions are Limiting Safety System Settings. These Functions shall be demonstrated to be functioning as required by applying the following requirements during CHANNEL CALIBRATIONS and CHANNEL FUNCTIONAL TESTS that verify the [LTSP or NTSP].

1. The as-found value of the instrument channel trip setting shall be compared with the previous as-left value or the specified [LTSP or NTSP].

2. If the as-found value of the instrument channel trip setting differs from the previous as-left value or the specified [LTSP or NTSP] by more than the pre-defined test acceptance criteria band (i.e., the specified AFT), then the instrument channel shall be evaluated before declaring the SR met and returning the instrument channel to service. This condition shall be entered in the plant corrective action program.

5.5 Programs and Manuals

~~5.5.18 Setpoint Control Program (continued)~~

~~3. If the as-found value of the instrument channel trip setting is less conservative than the specified AV, then the SR is not met and the instrument channel shall be immediately declared inoperable.~~

~~4. The instrument channel setpoint shall be reset to a value that is within the as-left tolerance around the [LTSP or NTSP] at the completion of the surveillance test; otherwise, the channel is inoperable (setpoints may be more conservative than the [LTSP or NTSP] provided that the as-found and as-left tolerances apply to the actual setpoint used to confirm channel performance).~~

10

~~e. The program shall be specified in [insert the facility FSAR reference or the name of any document incorporated into the facility FSAR by reference].]~~

~~[~~ 5.5.~~19~~

16

6.8.4.o

Surveillance Frequency Control Program

2

10

This program provides controls for Surveillance Frequencies. The program shall ensure that Surveillance Requirements specified in the Technical Specifications are performed at intervals sufficient to assure the associated Limiting Conditions for Operation are met.

a. The Surveillance Frequency Control Program shall contain a list of Frequencies of those Surveillance Requirements for which the Frequency is controlled by the program.

b. Changes to the Frequencies listed in the Surveillance Frequency Control Program shall be made in accordance with NEI 04-10, "Risk-Informed Method for Control of Surveillance Frequencies," Revision 1.

c. The provisions of Surveillance Requirements 3.0.2 and 3.0.3 are applicable to the Frequencies established in the Surveillance Frequency Control Program. ~~]~~

6.8.4.r

Risk Informed Completion Time Program

2

10

This program provides controls to calculate a Risk Informed Completion Time (RICT) and must be implemented in accordance with NEI 06-09-A, Revision 0, "Risk-Managed Technical Specifications (RMTS) Guidelines." The program shall include the following:

a. The RICT may not exceed 30 days;

5.5 Programs and Manuals

6.8.4.r 5.5.~~20~~ Risk Informed Completion Time Program (continued)

17

10

~~REVIEWER'S NOTE~~

~~The Risk Informed Completion Time is only applicable in MODES supported by the licensee's PRA. Licensees applying the RICT Program to MODES other than MODES 1 and 2 must demonstrate that they have the capability to calculate a RICT in those MODES or that the risk indicated by their MODE 1 and 2 PRA model is bounding with respect to the lower MODE conditions.~~

6

MODES 1 and 2

b. A RICT may only be utilized in ~~MODE 1, 2 [, and 3, and MODE 4 while relying on steam generators for heat removal]~~;

2

c. When a RICT is being used, any change to the plant configuration~~, as defined in NEI 06-09-A, Appendix A,~~ must be considered for the effect on the RICT.

within the scope of the Risk Informed Completion Time Program

1

1. For planned changes, the revised RICT must be determined prior to implementation of the change in configuration.

2. For emergent conditions, the revised RICT must be determined within the time limits of the Required Action Completion Time (i.e., not the RICT) or 12 hours after the plant configuration change, whichever is less.

3. Revising the RICT is not required if the plant configuration change would lower plant risk and would result in a longer RICT.

e

d. ~~For emergent conditions,~~ If the extent of condition evaluation for inoperable structures, systems, or components (SSCs) is not complete prior to exceeding the Completion Time, the RICT shall account for the increased possibility of common cause failure (CCF) by either:

1

1. Numerically accounting for the increased possibility of CCF in the RICT calculation; or

2. Risk Management Actions (RMAs) not already credited in the RICT calculation shall be implemented that support redundant or diverse SSCs that perform the function(s) of the inoperable SSCs, and, if practicable, reduce the frequency of initiating events that challenge the function(s) performed by the inoperable SSCs.

d. Use of a RICT is not permitted for entry into a configuration which represents a loss of a specified safety function or inoperability of all required trains of a system required to be OPERABLE.

1

5.5 Programs and Manuals

5.5.20 Risk Informed Completion Time Program (continued)

e. The risk assessment approaches and methods shall be acceptable to the NRC. The plant PRA shall be based on the as-built, as-operated, and maintained plant; and reflect the operating experience at the plant, as specified in Regulatory Guide 1.200, Revision 2. Methods to assess the risk from extending the Completion Times must be PRA methods used to support this license amendment, or other methods approved by the NRC for generic use; and any change in the PRA methods to assess risk that are outside these approval boundaries require prior NRC approval.] 1

[5.5.21 Spent Fuel Storage Rack Neutron Absorber Monitoring Program

This Program provides controls for monitoring the condition of the neutron absorber used in the spent fuel pool storage racks to verify the Boron-10 areal density is consistent with the assumptions in the spent fuel pool criticality analysis. The program shall be in accordance with NEI 16-03-A, "Guidance for Monitoring of Fixed Neutron Absorbers in Spent Fuel Pools," Revision 0, May 2017 [, with the following exceptions:

1. . . .].] 2

5.0 ADMINISTRATIVE CONTROLS

5.5 Programs and Manuals

The following programs shall be established, implemented, and maintained.

Definition 1.18

5.5.1 Offsite Dose Calculation Manual (ODCM)

a. The ODCM shall contain the methodology and parameters used in the calculation of offsite doses resulting from radioactive gaseous and liquid effluents, in the calculation of gaseous and liquid effluent monitoring alarm and trip setpoints, and in the conduct of the radiological environmental monitoring program and

b. The ODCM shall also contain the radioactive effluent controls and radiological environmental monitoring activities, and descriptions of the information that should be included in the Annual Radiological Environmental Operating, and Radioactive Effluent Release Reports required by Specification ~~[~~5.6.1~~]~~ and Specification ~~[~~5.6.2~~]~~. (2)

Licensee initiated changes to the ODCM:

6.14.1 DOC M03

a. Shall be documented and records of reviews performed shall be retained. This documentation shall contain:

1. Sufficient information to support the change(s) together with the appropriate analyses or evaluations justifying the change(s) and

2. A determination that the change(s) maintain the levels of radioactive effluent control required by 10 CFR 20.1302, 40 CFR 190, 10 CFR 50.36a, and 10 CFR 50, Appendix I, and not adversely impact the accuracy or reliability of effluent, dose, or setpoint calculations,

6.14.2 b. Shall become effective after the approval of the plant manager, and

6.14.3 c. Shall be submitted to the NRC in the form of a complete, legible copy of the entire ODCM as a part of or concurrent with the Radioactive Effluent Release Report for the period of the report in which any change in the ODCM was made. Each change shall be identified by markings in the margin of the affected pages, clearly indicating the area of the page that was changed, and shall indicate the date (i.e., month and year) the change was implemented.

5.5 Programs and Manuals

6.8.4.a

5.5.2 Primary Coolant Sources Outside Containment

High Pressure Safety Injection, Containment

This program provides controls to minimize leakage from those portions of systems outside containment that could contain highly radioactive fluids during a serious transient or accident to levels as low as practicable. The systems include [Low Pressure Injection, ~~Reactor Building~~ Spray~~, Makeup and Purification~~, and ~~Hydrogen Recombiner~~]. The program shall include the following:

Safety

Reactor Coolant Sampling

2

a. Preventive maintenance and periodic visual inspection requirements and

b. Integrated leak test requirements for each system at ~~least once per [18] months~~.

a Frequency in accordance with the Surveillance Frequency Control Program

3

The provisions of SR 3.0.2 are applicable.

~~[5.5.3 Post Accident Sampling~~

2

~~REVIEWER'S NOTE~~

~~This program may be eliminated based on the implementation of Topical Report CE NPSD-1157, Rev. 1, "Technical Justification for the Elimination of the Post-Accident Sampling System from the Plant Design and Licensing Basis for CEOG Utilities," and the associated NRC Safety Evaluation dated May 16, 2000, and implementation of the following commitments:~~

~~1. [Licensee] has developed contingency plans for obtaining and analyzing highly radioactive samples of reactor coolant, containment sump, and containment atmosphere. The contingency plans will be contained in emergency plan implementing procedures and implemented with the implementation of the License amendment. Establishment of contingency plans is considered a regulatory commitment.~~

~~2. The capability for classifying fuel damage events at the Alert level threshold has been established for [PLANT] at radioactivity levels of 300 mCi/cc dose equivalent iodine. This capability may utilize the normal sampling system and/or correlations of sampling or letdown line dose rates to coolant concentrations. This capability will be described in emergency plan implementing procedures and implemented with the implementation of the License amendment. The capability for classifying fuel damage events is considered a regulatory commitment.~~

~~3. [Licensee] has established the capability to monitor radioactive iodines that have been released to offsite environs. This capability is described in our emergency plan implementing procedures. The capability to monitor radioactive iodines is considered a regulatory commitment..~~

~~This program provides controls that ensure the capability to obtain and analyze reactor coolant, radioactive gases, and particulates in plant gaseous effluents~~

5.5 Programs and Manuals

~~5.5.3 Post Accident Sampling (continued)~~

~~and containment atmosphere samples under accident conditions. The program shall include the following:~~

~~a. Training of personnel,~~

~~b. Procedures for sampling and analysis, and~~

~~c. Provisions for maintenance of sampling and analysis equipment.]~~

2
4

6.8.4.f

5.5.~~4~~ Radioactive Effluent Controls Program

3

4

This program conforms to 10 CFR 50.36a for the control of radioactive effluents and for maintaining the doses to members of the public from radioactive effluents as low as reasonably achievable. The program shall be contained in the ODCM, shall be implemented by procedures, and shall include remedial actions to be taken whenever the program limits are exceeded. The program shall include the following elements:

a. Limitations on the functional capability of radioactive liquid and gaseous monitoring instrumentation including surveillance tests and setpoint determination in accordance with the methodology in the ODCM,

b. Limitations on the concentrations of radioactive material released in liquid effluents to unrestricted areas, conforming to ten times the concentration values in Appendix B, Table 2, Column 2 to 10 CFR 20.1001-20.2402,

c. Monitoring, sampling, and analysis of radioactive liquid and gaseous effluents in accordance with 10 CFR 20.1302 and with the methodology and parameters in the ODCM,

d. Limitations on the annual and quarterly doses or dose commitment to a member of the public from radioactive materials in liquid effluents released from each unit to unrestricted areas, conforming to 10 CFR 50, Appendix I,

e. Determination of cumulative dose contributions from radioactive effluents for the current calendar quarter and current calendar year in accordance with the methodology and parameters in the ODCM at least every 31 days. Determination of projected dose contributions from radioactive effluents in accordance with the methodology in the ODCM at least every 31 days,

f. Limitations on the functional capability and use of the liquid and gaseous effluent treatment systems to ensure that appropriate portions of these systems are used to reduce releases of radioactivity when the projected doses in a period of 31 days would exceed 2% of the guidelines for the annual dose or dose commitment, conforming to 10 CFR 50, Appendix I,

5.5 Programs and Manuals

6.8.4.f 5.5.~~4~~ Radioactive Effluent Controls Program (continued) 4

3

g. Limitations on the dose rate resulting from radioactive material released in gaseous effluents from the site to areas at or beyond the site boundary shall be in accordance with the following:

1. For noble gases: a dose rate ≤ 500 mrem/yr to the whole body and a dose rate ≤ 3000 mrem/yr to the skin and

2. For iodine-131, iodine-133, tritium, and all radionuclides in particulate form with half-lives greater than 8 days: a dose rate ≤ 1500 mrem/yr to any organ,

h. Limitations on the annual and quarterly air doses resulting from noble gases released in gaseous effluents from each unit to areas beyond the site boundary, conforming to 10 CFR 50, Appendix I,

i. Limitations on the annual and quarterly doses to a member of the public from iodine-131, iodine-133, tritium, and all radionuclides in particulate form with half lives > 8 days in gaseous effluents released from each unit to areas beyond the site boundary, conforming to 10 CFR 50, Appendix I, and

j. Limitations on the annual dose or dose commitment to any member of the public, beyond the site boundary, due to releases of radioactivity and to radiation from uranium fuel cycle sources, conforming to 40 CFR 190.

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Radioactive Effluent Controls Program surveillance frequency.

6.8.4.r 5.5.~~5~~ Component Cyclic or Transient Limit 1 4 2

4

U

3.9

This program provides controls to track the FSAR, Section [~~ ~~], cyclic and transient occurrences to ensure that components are maintained within the design limits.

~~[5.5.6 Pre-Stressed Concrete Containment Tendon Surveillance Program~~ 2 4

~~This program provides controls for monitoring any tendon degradation in pre-stressed concrete containments, including effectiveness of its corrosion protection medium, to ensure containment structural integrity. The program shall include baseline measurements prior to initial operations. The Tendon Surveillance Program, inspection frequencies, and acceptance criteria shall be in accordance with Section XI, Subsection IWL of the ASME Boiler and Pressure Vessel Code and applicable addenda as required by 10CFR 50.55a, except where an alternative, exemption, or relief has been authorized by the NRC.~~

~~The provisions of SR 3.0.3 are applicable to the Tendon Surveillance Program inspection frequencies.]~~

5.5 Programs and Manuals

5.5.~~7~~ Reactor Coolant Pump Flywheel Inspection Program

6.8.4.o
DOC L02

This program shall provide for the inspection of each ~~reactor coolant pump~~ flywheel per the recommendation of Regulatory position c.4.b of Regulatory Guide 1.14, Revision 1, August 1975.

5.5.~~8~~ Steam Generator (SG) Program

6.8.4.l

An SG Program shall be established and implemented to ensure that SG tube integrity is maintained. In addition, the SG Program shall include the following:

6.8.4.l.a

a. Provisions for condition monitoring assessments. Condition monitoring assessment means an evaluation of the "as found" condition of the tubing with respect to the performance criteria for structural integrity and accident induced leakage. The "as found" condition refers to the condition of the tubing during an SG inspection outage, as determined from the inservice inspection results or by other means, prior to the plugging ~~[or repair]~~ of tubes. Condition monitoring assessments shall be conducted during each outage during which the SG tubes are inspected, plugged, ~~[~~or ~~repaired]~~ to confirm that the performance criteria are being met.

6.8.4.l.b

b. Performance criteria for SG tube integrity. SG tube integrity shall be maintained by meeting the performance criteria for tube structural integrity, accident induced leakage, and operational LEAKAGE.

6.8.4.l.b.1

1. Structural integrity performance criterion: All in-service SG tubes shall retain structural integrity over the full range of normal operating conditions (including startup, operation in the power range, hot standby, and cool down), all anticipated transients included in the design specification, and design basis accidents. This includes retaining a safety factor of 3.0 against burst under normal steady state full power operation primary-to-secondary pressure differential and a safety factor of 1.4 against burst applied to the design basis accident primary-to-secondary pressure differentials. Apart from the above requirements, additional loading conditions associated with the design basis accidents, or combination of accidents in accordance with the design and licensing basis, shall also be evaluated to determine if the associated loads contribute significantly to burst or collapse. In the assessment of tube integrity, those loads that do significantly affect burst or collapse shall be determined and assessed in combination with the loads due to pressure with a safety factor of 1.2 on the combined primary loads and 1.0 on axial secondary loads.

6.8.4.l.b.2

2. Accident induced leakage performance criterion: The primary to secondary accident induced leakage rate for any design basis accident, other than a SG tube rupture, shall not exceed the leakage rate assumed in the accident analysis in terms of total leakage rate for

CTS

5

Insert 1

6.8.4.o
DOC L02

, except for an RCP flywheel consisting of ASTM A-516-69 (i.e., SA-516) Grade 65 material.

For an RCP flywheel composed of ASTM A-516-69 Grade 65 material, the inspection shall consist of either a 100% volumetric inspection of the upper flywheel over the volume from the inner bore of the flywheel to the circle of one-half the outer radius or a surface examination (magnetic particle testing and/or penetrant testing) of exposed surfaces defined by the volume of the disassembled flywheel at least once every 10 years.

5.5 Programs and Manuals

5.5.~~8~~ 6 Steam Generator (SG) Program (continued) 4

6.8.4.l all SGs and leakage rate for an individual SG. Leakage is not to exceed ~~[1 gpm] per~~ SG. ~~[, except for specific types of degradation at specific locations as described in paragraph c of the SG Program.]~~

0.5 gpm total through all SGs and 0.25 gpm through any one

6.8.4.l.b.3 3. The operational LEAKAGE performance criterion is specified in LCO 3.4.13, "RCS Operational LEAKAGE."

6.8.4.l.c c. Provisions for SG tube plugging ~~[or repair]~~ criteria. Tubes found by inservice inspection to contain flaws with a depth equal to or exceeding ~~[~~40%~~]~~ of the nominal tube wall thickness shall be plugged ~~[or repaired]~~.

~~REVIEWER'S NOTE~~

~~Alternate tube plugging [or repair] criteria currently permitted by plant technical specifications are listed here. The description of these alternate tube plugging [or repair] criteria should be equivalent to the descriptions in current technical specifications and should also include any allowed accident induced leakage rates for specific types of degradation at specific locations associated with tube plugging [or repair] criteria.~~ 6

~~[The following alternate tube plugging [or repair] criteria may be applied as an alternative to the 40% depth based criteria:~~ 2

~~1. . . .]~~

~~REVIEWER'S NOTE~~

~~The bracketed phrase in Paragraph d regarding exempt portions of the tube is only applicable to SGs with Alloy 600 thermally treated tubing.~~ 6

6.8.4.l.d d. Provisions for SG tube inspections. Periodic SG tube inspections shall be performed. The number and portions of the tubes inspected and methods of inspection shall be performed with the objective of detecting flaws of any type (e.g., volumetric flaws, axial and circumferential cracks) that may be present along the length of the tube, from the tube-to-tubesheet weld at the tube inlet to the tube-to-tubesheet weld at the tube outlet ~~[except for any portions of the tube that are exempt from inspection by alternate repair criteria]~~, and that may satisfy the applicable tube plugging ~~[or repair]~~ criteria. The tube-to-tubesheet weld is not part of the tube. In addition to meeting the requirements of d.1, d.2, and d.3 below, the inspection scope, inspection methods, and inspection intervals shall be such as to ensure that SG tube integrity is maintained until the next SG inspection. A degradation assessment shall be performed to determine the type and location of flaws to which the tubes may be susceptible and, based on this assessment, to determine which inspection methods need to be employed and at what locations.

5.5 Programs and Manuals

5.5.~~8~~ 6 Steam Generator (SG) Program (continued) 4

6.8.4.l

~~REVIEWER'S NOTE~~

~~Plants are to include the appropriate Frequency (e.g., select the appropriate Item 2.) for their SG design. The first Item 2 is applicable to SGs with Alloy 600 mill annealed tubing. The second Item 2 is applicable to SGs with Alloy 600 thermally treated tubing. The third Item 2 is applicable to SGs with Alloy 690 thermally treated tubing.~~ 6

6.8.4.l.d.1

1. Inspect 100% of the tubes in each SG during the first refueling outage following SG installation.

~~[2. After the first refueling outage following SG installation, inspect 100% of the tubes in each SG at least every 24 effective full power months, which defines the inspection period.]~~

~~[2. After the first refueling outage following SG installation, inspect 100% of the tubes in each SG at least every 54 effective full power months, which defines the inspection period. If none of the SG tubes have ever experienced cracking other than in regions that are exempt from inspection by alternate repair criteria and the SG inspection was performed with enhanced probes, the inspection period may be extended to 72 effective full power months. Enhanced probes have a capability to detect flaws of any type equivalent to or better than array probe technology. The enhanced probes shall be used from the tube-to-tubesheet weld at the tube inlet to the tube-to-tubesheet weld at the tube outlet except any portions of the tube that are exempt from inspection by alternate repair criteria. If there are regions where enhanced probes cannot be used, the tube inspection techniques shall be capable of detecting all forms of existing and potential degradation in that region.]~~

6.8.4.l.d.2
DOC L01

~~[~~2. After the first refueling outage following SG installation, inspect 100% of the tubes in each SG at least every 96 effective full power months, which defines the inspection period. ~~]~~ 2

~~REVIEWER'S NOTE~~

~~The bracketed phrases in Paragraph 3 are only applicable to SGs with Alloy 600 thermally treated tubing.~~ 6

6.8.4.l.d.3

DOC L01

3. If crack indications are found in any SG tube ~~[excluding any region that is exempt from inspection by alternate repair criteria]~~, then the next inspection for each affected and potentially affected SG for the degradation mechanism that caused the crack indication shall be at the next refueling outage ~~[, but may be deferred to the following refueling~~ 2 1

5.5 Programs and Manuals

5.5.~~8~~ 6 Steam Generator (SG) Program (continued)

~~outage if the 100% inspection of all SGs was performed with enhanced probes as described in paragraph d.2~~]. If definitive information, such as from examination of a pulled tube, diagnostic non-destructive testing, or engineering evaluation indicates that a crack-like indication is not associated with a crack(s), then the indication need not be treated as a crack.

6.8.4.l.d.3

6.8.4.l.e

e. Provisions for monitoring operational primary to secondary LEAKAGE.

~~[f. Provisions for SG tube repair methods. SG tube repair methods shall provide the means to reestablish the RCS pressure boundary integrity of SG tubes without removing the tube from service. For the purposes of these Specifications, tube plugging is not a repair. All acceptable tube repair methods are listed below.~~

~~REVIEWER'S NOTE~~

~~Tube repair methods currently permitted by plant technical specifications are to be listed here. The description of these tube repair methods should be equivalent to the descriptions in current technical specifications. If there are no approved tube repair methods, this section should not be used.~~

~~1. . . .]~~

6.8.4.c 5.5.~~9~~ 7 Secondary Water Chemistry Program

This program provides controls for monitoring secondary water chemistry to inhibit SG tube degradation ~~and low pressure turbine disc stress corrosion cracking~~. The program shall include:

6.8.4.c (i)

a. Identification of a sampling schedule for the critical variables and control points for these variables,

6.8.4.c (ii)

b. Identification of the procedures used to measure the values of the critical variables,

6.8.4.c (iii)

c. Identification of process sampling points, which shall include monitoring the discharge of the condensate pumps for evidence of condenser in leakage,

6.8.4 (iv)

d. Procedures for the recording and management of data,

6.8.4 (v)

e. Procedures defining corrective actions for all off control point chemistry conditions, and

5.5 Programs and Manuals

5.5.~~9~~ 7 Secondary Water Chemistry Program (continued) 4

6.8.4 (vi) f. A procedure identifying the authority responsible for the interpretation of the data and the sequence and timing of administrative events, which is required to initiate corrective action.

5.5.~~10~~ 8 Ventilation Filter Testing Program (VFTP)

6.8.4 k A program shall be established to implement the following required testing of Engineered Safety Feature (ESF) filter ventilation systems ~~at the frequencies specified in [Regulatory Guide], and~~ in accordance with ~~[~~Regulatory Guide 1.52, Revision ~~2, ASME N510-1989, and AG-1] at the system flowrate specified below [± 10%]~~. 4 2 1

Insert 2

5.5.~~11~~ Explosive Gas and Storage Tank Radioactivity Monitoring Program

This program provides controls for potentially explosive gas mixtures contained in the ~~[Waste Gas Holdup System], [~~the quantity of radioactivity contained in gas storage tanks ~~or fed into the offgas treatment system, and the quantity of radioactivity contained in unprotected outdoor liquid storage tanks]~~. ~~The gaseous radioactivity quantities shall be determined following the methodology in [Branch Technical Position (BTP) ETSB 11-5, "Postulated Radioactive Release due to Waste Gas System Leak or Failure"]. The liquid radwaste quantities shall be determined in accordance with [Standard Review Plan, Section 15.7.3, "Postulated Radioactive Release due to Tank Failures"].~~
The program shall include:

a. The limits for concentrations of hydrogen and oxygen in the ~~[Waste Gas Holdup System]~~ and a surveillance program to ensure the limits are maintained. Such limits shall be appropriate to the system's design criteria (i.e., whether or not the system is designed to withstand a hydrogen explosion),

b. A surveillance program to ensure that the quantity of radioactivity contained in ~~[~~each gas storage tank ~~and fed into the offgas treatment system]~~ is less than the amount that would result in a whole body exposure of ≥ 0.5 rem to any individual in an unrestricted area, in the event of ~~[~~an uncontrolled release of the tanks' contents~~]~~, and

~~c. A surveillance program to ensure that the quantity of radioactivity contained in all outdoor liquid radwaste tanks that are not surrounded by liners, dikes, or walls, capable of holding the tanks' contents and that do not have tank overflows and surrounding area drains connected to the [Liquid Radwaste Treatment System] is less than the amount that would result in concentrations less than the limits of 10 CFR 20, Appendix B, Table 2, Column 2, at the nearest potable water supply and the nearest surface water supply in an unrestricted area, in the event of an uncontrolled release of the tanks' contents.~~

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Explosive Gas and Storage Tank Radioactivity Monitoring Program surveillance frequencies.

5.5 Programs and Manuals

5.5.~~12~~ Diesel Fuel Oil Testing Program

10

4

6.8.4.n

A diesel fuel oil testing program to implement required testing of both new fuel oil and stored fuel oil shall be established. The program shall include sampling and testing requirements, and acceptance criteria, all in accordance with applicable ASTM Standards. The purpose of the program is to establish the following:

6.8.4.n (i)

a. Acceptability of new fuel oil for use prior to addition to storage tanks by determining that the fuel oil has:

1. An API gravity or an absolute specific gravity within limits,

2. A flash point and kinematic viscosity within limits for ASTM 2D fuel oil, and

3. A clear and bright appearance with proper color or a water and sediment content within limits,

6.8.4.n (ii)

b. Within 31 days following addition of the new fuel oil to storage tanks, verify that the properties of the new fuel oil, other than those addressed in a., above, are within limits for ASTM 2D fuel oil, and

6.8.4.n (iii)

c. Total particulate concentration of the fuel oil is ≤ 10 mg/l when tested ~~every 31 days~~ at a Frequency in accordance with the Surveillance Frequency Control Program.

3

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Diesel Fuel Oil Testing Program test frequencies.

6.8.4.j

5.5.~~13~~ Technical Specifications (TS) Bases Control Program

11

4

This program provides a means for processing changes to the Bases of these Technical Specifications.

6.8.4.j.1

a. Changes to the Bases of the TS shall be made under appropriate administrative controls and reviews.

6.8.4.j.2

b. Licensees may make changes to Bases without prior NRC approval provided the changes do not require either of the following:

6.8.4.j.2.a

1. A change in the TS incorporated in the license or

1

U

6.8.4.j.2.b

2. A change to the ~~updated~~ FSAR or Bases that requires NRC approval pursuant to 10 CFR 50.59.

U

1

6.8.4.j.3

c. The Bases Control Program shall contain provisions to ensure that the Bases are maintained consistent with the FSAR.

5.5 Programs and Manuals

6.8.4.j 5.5.~~13~~ 11 Technical Specifications (TS) Bases Control Program (continued) 4

6.8.4.j.4 d. Proposed changes that meet the criteria of 5.5.~~13~~11.b above shall be reviewed and approved by the NRC prior to implementation. Changes to the Bases implemented without prior NRC approval shall be provided to the NRC on a frequency consistent with 10 CFR 50.71(e).

5.5.~~14~~ 12 Safety Function Determination Program (SFDP) 4

6.8.4.t This program ensures loss of safety function is detected and appropriate actions taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other appropriate limitations and remedial or compensatory actions may be identified to be taken as a result of the support system inoperability and corresponding exception to entering supported system Condition and Required Actions. This program implements the requirements of LCO 3.0.6. The SFDP shall contain the following:

a. Provisions for cross train checks to ensure a loss of the capability to perform the safety function assumed in the accident analysis does not go undetected,

b. Provisions for ensuring the plant is maintained in a safe condition if a loss of function condition exists,

c. Provisions to ensure that an inoperable supported system's Completion Time is not inappropriately extended as a result of multiple support system inoperabilities, and

d. Other appropriate limitations and remedial or compensatory actions.

A loss of safety function exists when, assuming no concurrent single failure, no concurrent loss of offsite power, or no concurrent loss of onsite diesel generator(s), a safety function assumed in the accident analysis cannot be performed. For the purpose of this program, a loss of safety function may exist when a support system is inoperable, and

a. A required system redundant to the system(s) supported by the inoperable support system is also inoperable, or

b. A required system redundant to the system(s) in turn supported by the inoperable supported system is also inoperable, or

c. A required system redundant to the support system(s) for the supported systems (a) and (b) above is also inoperable.

5.5 Programs and Manuals

6.8.4.t 5.5.~~14~~ 12 Safety Function Determination Program (SFDP) (continued) 4

The SFDP identifies where a loss of safety function exists. If a loss of safety function is determined to exist by this program, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered. When a loss of safety function is caused by the inoperability of a single Technical Specification support system, the appropriate Conditions and Required Actions to enter are those of the support system.

6.8.4.h 5.5.~~15~~ 13 Containment Leakage Rate Testing Program 4

~~[OPTION A]~~

~~a. A program shall establish the leakage rate testing of the containment as required by 10 CFR 50.54(o) and 10 CFR 50, Appendix J, Option A, as modified by approved exemptions.~~

~~b. The maximum allowable containment leakage rate, L_a at P_a, shall be [ ]% of containment air weight per day.~~

~~c. Leakage rate acceptance criteria are:~~

~~1. Containment leakage rate acceptance criterion is ≤ 1.0 L_a. During the first unit startup following testing in accordance with this program, the leakage rate acceptance criteria are < 0.60 L_a for the Type B and C tests and < 0.75 L_a for Type A tests.~~ 8

~~2. Air lock testing acceptance criteria are:~~

~~a) Overall air lock leakage rate is ≤ [0.05 L_a] when tested at ≥ P_a.~~

~~b) For each door, leakage rate is ≤ [0.01 L_a] when pressurized to [≥ 10 psig].~~

~~d. The provisions of SR 3.0.3 are applicable to the Containment Leakage Rate Testing Program.~~

~~e. Nothing in these Technical Specifications shall be construed to modify the testing Frequencies required by 10 CFR 50, Appendix J.~~

~~5.5.15 Containment Leakage Rate Testing Program (continued)~~

~~d. Leakage rate acceptance criteria are:~~

~~1. Containment leakage rate acceptance criterion is $\leq$ 1.0 L_a. During the first unit startup following testing in accordance with this program, the leakage rate acceptance criteria are $<$ 0.60 L_a for the Type B and C tests and [$<$ 0.75 L_a for Option A Type A tests] [$\leq$ 0.75 L_a for Option B Type A tests].~~

~~2. Air lock testing acceptance criteria are:~~

~~a) Overall air lock leakage rate is $\leq$ [0.05 L_a] when tested at $\geq P_a$.~~

~~b) For each door, leakage rate is $\leq$ [0.01 L_a] when pressurized to [$\geq$ 10 psig].~~

~~e. The provisions of SR 3.0.3 are applicable to the Containment Leakage Rate Testing Program.~~

~~f. Nothing in these Technical Specifications shall be construed to modify the testing Frequencies required by 10 CFR 50, Appendix J.~~

8

5.5.~~16~~ Battery Monitoring and Maintenance Program

14

4

~~REVIEWER'S NOTE~~

~~This program and the corresponding requirements in LCO 3.8.4, LCO 3.8.5, and LCO 3.8.6 require providing the information and verifications requested in the Notice of Availability for TSTF-500, Revision 2, "DC Electrical Rewrite - Update to TSTF-360," (76FR54510).~~

6

DOC M02

This Program provides controls for battery restoration and maintenance. The program shall be in accordance with IEEE Standard (Std) 450-~~2002~~2010, "IEEE Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications," as endorsed by Regulatory Guide 1.129, Revision ~~2 (RG), with RG exceptions and program provisions as identified below:~~ 3.

~~a. The program allows the following RG 1.129, Revision 2 exceptions:~~

~~1. Battery temperature correction may be performed before or after conducting discharge tests.~~

~~2. RG 1.129, Regulatory Position 1, Subsection 2, "References," is not applicable to this program.~~

9

5.5 Programs and Manuals

5.5.~~16~~ Battery Monitoring and Maintenance Program (continued)

14

4

~~3. In lieu of RG 1.129, Regulatory Position 2, Subsection 5.2, "Inspections," the following shall be used: "Where reference is made to the pilot cell, pilot cell selection shall be based on the lowest voltage cell in the battery."~~

~~4 In Regulatory Guide 1.129, Regulatory Position 3, Subsection 5.4.1, "State of Charge Indicator," the following statements in paragraph (d) may be omitted: "When it has been recorded that the charging current has stabilized at the charging voltage for three consecutive hourly measurements, the battery is near full charge. These measurements shall be made after the initially high charging current decreases sharply and the battery voltage rises to approach the charger output voltage."~~

~~5. In lieu of RG 1.129, Regulatory Position 7, Subsection 7.6, "Restoration," the following may be used: "Following the test, record the float voltage of each cell of the string."~~

9

~~b.~~ The program shall include the following provisions:

Table 4.8-2

a. ~~1.~~ Actions to restore battery cells with float voltage < ~~[~~2.13~~]~~ V;

Table 4.8-2

b. ~~2.~~ Actions to determine whether the float voltage of the remaining battery cells is ≥ ~~[~~2.13~~]~~ V when the float voltage of a battery cell has been found to be < ~~[~~2.13~~]~~ V;

2

c. ~~3.~~ Actions to equalize and test battery cells that had been discovered with electrolyte level below the top of the plates;

d. ~~4.~~ Limits on average electrolyte temperature, battery connection resistance, and battery terminal voltage; and

~~5. A requirement to obtain specific gravity readings of all cells at each discharge test, consistent with manufacturer recommendations.~~

9

5.5 Programs and Manuals

6.8.4.m 5.5.~~17~~ 15 Control Room Envelope (CRE) Habitability Program 4

A Control Room Envelope (CRE) Habitability Program shall be established and implemented to ensure that CRE habitability is maintained such that, with an OPERABLE Control Room Emergency ~~Air Cleanup~~ System (CRE~~AC~~S), CRE occupants can control the reactor safely under normal conditions and maintain it in a safe condition following a radiological event, hazardous chemical release, or a smoke challenge. The program shall ensure that adequate radiation protection is provided to permit access and occupancy of the CRE under design basis accident (DBA) conditions without personnel receiving radiation exposures in excess of ~~[5 rem whole body or its equivalent to any part of the body] [~~5 rem total effective dose equivalent (TEDE)~~]~~ for the duration of the accident. The program shall include the following elements:

Ventilation V 1 2

a. The definition of the CRE and the CRE boundary.

b. Requirements for maintaining the CRE boundary in its design condition including configuration control and preventive maintenance.

c. Requirements for (i) determining the unfiltered air inleakage past the CRE boundary into the CRE in accordance with the testing methods and at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, "Demonstrating Control Room Envelope Integrity at Nuclear Power Reactors," Revision 0, May 2003, and (ii) assessing CRE habitability at the Frequencies specified in Sections C.1 and C.2 of Regulatory Guide 1.197, Revision 0.

~~[The following are exceptions to Sections C.1 and C.2 of Regulatory Guide 1.197, Revision 0:~~

~~1. ;and]~~ 2

d. Measurement, at designated locations, of the CRE pressure relative to all external areas adjacent to the CRE boundary during the pressurization mode of operation by one train of the ~~CREACS~~, operating at the flow rate required by the VFTP, at a Frequency ~~of [18] months on a STAGGERED TEST BASIS~~. The results shall be trended and used as part of the ~~[18]~~ month assessment of the CRE boundary. 36

in accordance with the Surveillance Frequency Control Program.

CREVS | R1 3 2

5.5 Programs and Manuals

6.8.4.m 5.5.~~17~~ Control Room Envelope (CRE) Habitability Program (continued) 4

15

e. The quantitative limits on unfiltered air inleakage into the CRE. These limits shall be stated in a manner to allow direct comparison to the unfiltered air inleakage measured by the testing described in paragraph c. The unfiltered air inleakage limit for radiological challenges is the inleakage flow rate assumed in the licensing basis analyses of DBA consequences. Unfiltered air inleakage limits for hazardous chemicals must ensure that exposure of CRE occupants to these hazards will be within the assumptions in the licensing basis.

f. The provisions of SR 3.0.2 are applicable to the Frequencies for assessing CRE habitability, determining CRE unfiltered inleakage, and measuring CRE pressure and assessing the CRE boundary as required by paragraphs c and d, respectively.

~~[5.5.18 Setpoint Control Program~~

~~REVIEWER'S NOTE~~

~~Adoption of a Setpoint Control Program requires changes to other technical specifications. See TSTF-493, Revision 4, "Clarify Application of Setpoint Methodology for LSSS Functions," Option B, for guidance (Agencywide Documents Access and Management System (ADAMS) Accession Number ML101160026).~~

~~This program shall establish the requirements for ensuring that setpoints for automatic protective devices are initially within and remain within the assumptions of the applicable safety analyses, provides a means for processing changes to instrumentation setpoints, and identifies setpoint methodologies to ensure instrumentation will function as required. The program shall ensure that testing of automatic protective devices related to variables having significant safety functions as delineated by 10 CFR 50.36(c)(1)(ii)(A) verifies that instrumentation will function as required.~~

10

~~a. The program shall list the Functions in the following specifications to which it applies:~~

~~1. LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation - Operating [(Analog)] [(Digital)];"~~

5.5 Programs and Manuals

5.5.18 Setpoint Control Program (continued)

2. LCO 3.3.2, "Reactor Protective System (RPS) Instrumentation - Shutdown [(Analog)] [(Digital)];"
3. LCO [3.3.3, "Control Element Assembly Calculators (CEACs) (Digital)];"
4. [LCO 3.3.4,"Engineered Safety Features Actuation System (ESFAS) Instrumentation (Analog);"] [LCO 3.3.5, "Engineered Safety Features Actuation System (ESFAS) Instrumentation (Digital);"]
5. [LCO 3.3.6, "Diesel Generator (DG) - Loss of Voltage Start (LOVS) (Analog);"] [LCO 3.3.7, "Diesel Generator (DG) - Loss of Voltage Start (LOVS) (Digital);"]
6. [LCO 3.3.7, "Containment Purge Isolation Signal (CPIS) (Analog);"] [LCO 3.3.8, "Containment Purge Isolation Signal (CPIS) (Digital);"]
7. [LCO 3.3.8, "Control Room Isolation Signal (CRIS) (Analog);"] [LCO 3.3.9, "Control Room Isolation Signal (CRIS) (Digital);"];
8. [LCO 3.3.9, "Chemical and Volume Control System (CVCS) Isolation Signal (Analog);"]
9. [LCO 3.3.10, "Fuel Handling Isolation Signal (FHIS) (Digital);"]
10. LCO 3.3.13, "[Logarithmic] Power Monitoring Channels [(Analog)."] [(Digital)."]

b. The program shall require the [Limiting Trip Setpoint (LTSP)], [Nominal Trip Setpoint (NTSP)], Allowable Value (AV), As-Found Tolerance (AFT), and As-Left Tolerance (ALT) (as applicable) of the Functions described in paragraph a. are calculated using the NRC approved setpoint methodology, as listed below. In addition, the program shall contain the value of the [LTSP], [NTSP], AV, AFT, and ALT (as applicable) for each Function described in paragraph a. and shall identify the setpoint methodology used to calculate these values.

---------- Reviewer's Note ----------
List the NRC safety evaluation report by letter, date, and ADAMS accession number (if available) that approved the setpoint methodologies.
---

1. [Insert reference to NRC safety evaluation that approved the setpoint methodology.]

c. The program shall establish methods to ensure that Functions described in paragraph a. will function as required by verifying the as-left and as-found settings are consistent with those established by the setpoint methodology.

5.5 Programs and Manuals

5.5.18 Setpoint Control Program (continued)

d. ----------REVIEWER'S NOTE----------
A license amendment request to implement a Setpoint Control Program must list the instrument functions to which the program requirements of paragraph d. will be applied. Paragraph d. shall apply to all Functions in the Reactor Protection System and Engineered Safety Feature Actuation System specifications unless one or more of the following exclusions apply:

1. Manual actuation circuits, automatic actuation logic circuits or to instrument functions that derive input from contacts which have no associated sensor or adjustable device, e.g., limit switches, breaker position switches, manual actuation switches, float switches, proximity detectors, etc. are excluded. In addition, those permissives and interlocks that derive input from a sensor or adjustable device that is tested as part of another TS function are excluded.

2. Settings associated with safety relief valves are excluded. The performance of these components is already controlled (i.e., trended with as-left and as-found limits) under the ASME Code for Operation and Maintenance of Nuclear Power Plants testing program.

3. Functions and Surveillance Requirements which test only digital components are normally excluded. There is no expected change in result between SR performances for these components. Where separate as-left and as-found tolerance is established for digital component SRs, the requirements would apply.

The program shall identify the Functions described in paragraph a. that are automatic protective devices related to variables having significant safety functions as delineated by 10 CFR 50.36(c)(1)(ii)(A). The [LTSP] of these Functions are Limiting Safety System Settings. These Functions shall be demonstrated to be functioning as required by applying the following requirements during CHANNEL CALIBRATIONS and CHANNEL FUNCTIONAL TESTS that verify the [LTSP or NTSP].

1. The as-found value of the instrument channel trip setting shall be compared with the previous as-left value or the specified [LTSP or NTSP].

2. If the as-found value of the instrument channel trip setting differs from the previous as-left value or the specified [LTSP or NTSP] by more than the pre-defined test acceptance criteria band (i.e., the specified AFT), then the instrument channel shall be evaluated before declaring the SR met and returning the instrument channel to service. This condition shall be entered in the plant corrective action program.

5.5 Programs and Manuals

~~5.5.18 Setpoint Control Program (continued)~~

~~3. If the as-found value of the instrument channel trip setting is less conservative than the specified AV, then the SR is not met and the instrument channel shall be immediately declared inoperable.~~

~~4. The instrument channel setpoint shall be reset to a value that is within the as-left tolerance around the [LTSP or NTSP] at the completion of the surveillance test; otherwise, the channel is inoperable (setpoints may be more conservative than the [LTSP or NTSP] provided that the as-found and as-left tolerances apply to the actual setpoint used to confirm channel performance).~~

10

~~e. The program shall be specified in [insert the facility FSAR reference or the name of any document incorporated into the facility FSAR by reference].]~~

~~[~~ 5.5.~~19~~

16

6.8.4.q

Surveillance Frequency Control Program

2

10

This program provides controls for Surveillance Frequencies. The program shall ensure that Surveillance Requirements specified in the Technical Specifications are performed at intervals sufficient to assure the associated Limiting Conditions for Operation are met.

a. The Surveillance Frequency Control Program shall contain a list of Frequencies of those Surveillance Requirements for which the Frequency is controlled by the program.

b. Changes to the Frequencies listed in the Surveillance Frequency Control Program shall be made in accordance with NEI 04-10, "Risk-Informed Method for Control of Surveillance Frequencies," Revision 1.

c. The provisions of Surveillance Requirements 3.0.2 and 3.0.3 are applicable to the Frequencies established in the Surveillance Frequency Control Program. ~~]~~

2

~~[~~ 5.5.~~20~~

17

6.8.4.s

Risk Informed Completion Time Program

2

10

This program provides controls to calculate a Risk Informed Completion Time (RICT) and must be implemented in accordance with NEI 06-09-A, Revision 0, "Risk-Managed Technical Specifications (RMTS) Guidelines." The program shall include the following:

a. The RICT may not exceed 30 days;

5.5 Programs and Manuals

6.8.4.s 5.5.~~20~~ Risk Informed Completion Time Program (continued)

17

10

~~REVIEWER'S NOTE~~

~~The Risk Informed Completion Time is only applicable in MODES supported by the licensee's PRA. Licensees applying the RICT Program to MODES other than MODES 1 and 2 must demonstrate that they have the capability to calculate a RICT in those MODES or that the risk indicated by their MODE 1 and 2 PRA model is bounding with respect to the lower MODE conditions.~~

6

MODES 1 and 2

b. A RICT may only be utilized in ~~MODE 1, 2 [, and 3, and MODE 4 while relying on steam generators for heat removal]~~;

2

c. When a RICT is being used, any change to the plant configuration~~, as defined in NEI 06-09-A, Appendix A,~~ must be considered for the effect on the RICT.

within the scope of the Risk Informed Completion Time Program

1

1. For planned changes, the revised RICT must be determined prior to implementation of the change in configuration.

2. For emergent conditions, the revised RICT must be determined within the time limits of the Required Action Completion Time (i.e., not the RICT) or 12 hours after the plant configuration change, whichever is less.

3. Revising the RICT is not required if the plant configuration change would lower plant risk and would result in a longer RICT.

d. ~~For emergent conditions,~~ If the extent of condition evaluation for inoperable structures, systems, or components (SSCs) is not complete prior to exceeding the Completion Time, the RICT shall account for the increased possibility of common cause failure (CCF) by either:

e

1

1. Numerically accounting for the increased possibility of CCF in the RICT calculation; or

2. Risk Management Actions (RMAs) not already credited in the RICT calculation shall be implemented that support redundant or diverse SSCs that perform the function(s) of the inoperable SSCs, and, if practicable, reduce the frequency of initiating events that challenge the function(s) performed by the inoperable SSCs.

d. Use of a RICT is not permitted for entry into a configuration which represents a loss of a specified safety function or inoperability of all required trains of a system required to be OPERABLE.

1

5.5 Programs and Manuals

5.5.20 Risk Informed Completion Time Program (continued)

e. The risk assessment approaches and methods shall be acceptable to the NRC. The plant PRA shall be based on the as-built, as-operated, and maintained plant; and reflect the operating experience at the plant, as specified in Regulatory Guide 1.200, Revision 2. Methods to assess the risk from extending the Completion Times must be PRA methods used to support this license amendment, or other methods approved by the NRC for generic use; and any change in the PRA methods to assess risk that are outside these approval boundaries require prior NRC approval.] 1

[5.5.21 Spent Fuel Storage Rack Neutron Absorber Monitoring Program

This Program provides controls for monitoring the condition of the neutron absorber used in the spent fuel pool storage racks to verify the Boron-10 areal density is consistent with the assumptions in the spent fuel pool criticality analysis. The program shall be in accordance with NEI 16-03-A, "Guidance for Monitoring of Fixed Neutron Absorbers in Spent Fuel Pools," Revision 0, May 2017 [, with the following exceptions:

1. . . .].] 2

JUSTIFICATION FOR DEVIATIONS
ITS 5.5, PROGRAMS AND MANUALS

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. ISTS 5.5.2.b requires integrated leak test requirements for each system at least once per [18] months. ISTS 5.5.12.c requires total particulate sampling every 31 days. ISTS 5.5.17.d requires control room envelope pressure measurement testing relative to external adjacent areas to be performed at a frequency of [18] months on a STAGGERED TEST BASIS. St. Lucie Plant (PSL) controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per Unit 1 CTS 6.8.4.o and Unit 2 CTS 6.8.4.q. Therefore, ITS 5.5.2.b, 5.5.10.c, and 5.5.15.d will be performed at a Frequency in accordance with the Surveillance Frequency Control Program.

4. ISTS 5.6.3, Post Accident Sampling, and ISTS 5.5.6, Pre-Stressed Concrete Containment Tendon Surveillance Program are not included in the ITS. The Post Accident Sampling requirements were deleted from the Unit 1 and Unit 2 CTS in March 27, 2001 by Amendments 174, and 114, respectively (ADAMS Accession No. ML011140017). Additionally, the containment design at PSL Unit 1 and Unit 2 does not include tendons. Subsequent Specifications are renumbered as a result of this deletion.

5. ISTS 5.5.7, Reactor Coolant Pump Flywheel Inspection Program, is changed to the PSL Unit 2 current licensing basis for flywheels composed of ASTM A-516-69 Grade 65 material and retains the ISTS requirement for flywheels composed of materials other than ASTM A-516-69 Grade 65. By letter dated October 9, 2019 (Agencywide Documents Access and Management System (ADAMS) Accession No. ML19282D338), as supplemented by letters dated April 30, 2020, and June 26, 2020 (ADAMS Accession Nos. ML20121A170 and ML20178A463, respectively), FPL submitted to the NRC, a license amendment request (LAR) to revise Technical Specification (TS) 6.8.4.o, “Reactor Coolant Pump Flywheel Inspection Program,” for PSL Unit 2. As discussed in Section 3.1 of this safety evaluation (SE), the licensee proposed to modify the St. Lucie Unit 2 Reactor Coolant Pump (RCP) Flywheel Inspection Program requirements to be consistent with the conclusions and limitations specified in the NRC’s May 21, 1997, SE of Topical Report SIR-94-080, Revision 1, “Relaxation of Reactor Coolant Pump Flywheel Inspection Requirements” (ADAMS Accession No. ML20013C086). The proposed change to Unit 2 CTS 6.8.4.o. was approved in NRC SE, dated November 18, 2020 (ADAMS Accession No. ML20259A298). Unit 1 is incorporating an RCP Flywheel Inspection Program as a more restrictive programmatic requirement and, therefore, is including the same frequency requirement in Unit 1 ITS as Unit 2 ITS to allow RCP flywheel exchanges between Unit 1 and Unit 2.

6. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

7. The program details of the Explosive Gas and Storage Tank Radioactivity Monitoring Program are described in ISTS 5.5.11.a and 5.5.11.b (ITS 5.5.9.a and 5.5.9.b). Therefore, the sentence in the introductory paragraph that specifies a method to determine the explosive gas and storage tank radioactivity is not necessary. Additionally, the requirements specified in ISTS 5.5.11.c do not apply to PSL Unit 1 or Unit 2. UFSAR Chapter 15 states that a waste gas decay tank release is not a credible accident and that the dose will remain within the regulatory guidelines. This is also consistent with the CTS.

8. PSL Unit 1 and Unit 2 comply with Option B of 10 CFR 50, Appendix J. Therefore, the Option A and combined Option A and B provisions of ISTS 5.5.15 are not included in the ITS.

9. ISTS 5.5.16 is modified in ITS 5.5.14 to reference IEEE 450-2010 and Revision 3 of Regulatory Guide (RG) 1.129 instead of IEEE-450-2002 and Revision 2 of RG 1.129. RG 1.129, Revision 3 endorses the use of IEEE 450-2010 and eliminates the need for the exceptions specified in ISTS 5.5.16.a. Therefore, the exceptions of ISTS 5.5.16.a are not included in ITS 5.5.14. Section 5.4.2 of IEEE 450-2010 states, in part, that specific gravity readings are not recommended to be taken on a regular basis. PSL batteries are lead-calcium type batteries and therefore, specific gravities are not required to be obtained at each discharge test. Therefore, ISTS 5.5.16.b.5 is not included in ITS 5.5.14. Use of IEEE 450-2010 and RG 1.129, Revision 3 in the Battery Monitoring and Maintenance Program has been previously approved in Donald C. Cook Nuclear Plant Amendments 343 and 325 dated February 5, 2019 for Units 1 and 2, respectively (NRC ADAMS Accession No. ML18346A358).

10. PSL Unit 1 and Unit 2 CTS do not use a Setpoint Control Program for the control of instrumentation setpoints for automatic protective devices. Therefore, ISTS 5.5.18, Setpoint Control Program, is not included in the ITS. Subsequent Specifications are renumbered as a result of this deletion.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 5.5, PROGRAMS AND MANUALS

10 CFR 50.92 EVALUATION
FOR
MORE RESTRICTIVE CHANGE M01 – UNIT 1
LESS RESTRICTIVE CHANGE L02 – UNIT 2

Florida Power & Light Company (FPL) is converting the St. Lucie Plant (PSL) Unit 1 and Unit 2 Technical Specifications to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, "Standard Technical Specifications, Combustion Engineering Plants," Revision 5. The proposed change involves making the Unit 1 Current Technical Specifications (CTS) more restrictive and the Unit 2 CTS less restrictive. Below is the description of the change and the determination of No Significant Hazards Considerations for conversion to NUREG-1432.

Unit 1 CTS does not provide administrative controls for reactor RCP flywheel inspections. ITS 5.5.5, “Reactor Coolant Pump (RCP) Flywheel Inspection Program” is added to the Unit 1 ITS equivalent to the proposed Unit 2 program requirements. Unit 2 CTS requires administrative controls for RCP flywheel inspections. ITS 5.5.5 includes the same requirements and, in addition, includes program requirements for the Unit 2 CTS that were issued prior to Amendment No. 205, which are also consistent with the requirements specified in NUREG-1432, with a distinction on applicability of the two sets of requirements. The proposed program for both units will provide for the inspection of each RCP flywheel per the recommendation of Regulatory position c.4.b of Regulatory Guide 1.14, Revision 1, August 1975 except for an RCP flywheel consisting of ASTM A 516 69 (i.e., SA-516) Grade 65 material. For an RCP flywheel composed of ASTM A 516-69 Grade 65 material, the inspection shall consist of either a 100% volumetric inspection of the upper flywheel over the volume from the inner bore of the flywheel to the circle of one-half the outer radius or a surface examination (magnetic particle testing and/or penetrant testing) of exposed surfaces defined by the volume of the disassembled flywheel at least once every 10 years. This changes the CTS by adding an additional administrative program to the Unit 1 CTS and restoring program requirements that were issued prior to Amendment No. 205 to the Unit 2 CTS, in addition to the current requirements.

The purpose of the RCP flywheel inspection program is to implement requirements to minimize the potential for failures of the flywheels of RCP motors in light-water-cooled power reactors. At PSL, RCP flywheels are interchanged between Unit 1 and Unit 2 during refurbishment and replacement. Between 2011 and 2017, the Unit 2 RCP flywheels, which consist of ASTM A-543 (three flywheels Class 1, Type B and one flywheel Grade 70) material, were exchanged with the Unit 1 RCP flywheels, which consist of ASTM A-516-69, Grade 65 material. Unit 2 CTS was modified to relax the RCP flywheel inspection requirements similar to the conclusions specified in the NRC Safety Evaluation of Topical Report SIR-94-080, Revision 1. The relaxed inspection requirements were approved in Unit 2 CTS Amendment No. 205, dated November 18, 2020 (ADAMS Accession No. ML20259A298). Previously, PSL Unit 2 RCP flywheels were inspected per NRC Regulatory Guide 1.14, “Reactor Coolant Pump Flywheel Integrity,” Revision 1 and the requirements were previously contained in the CTS pre-Amendment 205 requirements. NRC Regulatory Guide 1.14 describes a method acceptable to the NRC staff of implementing the RCP flywheel inspection program requirements and include a recommended inspection schedule. Since the PSL RCP flywheels consisting of ASTM A 543 material were previously inspected per Regulatory Guide 1.14, Revision 1, August 1975 and the requirements were previously approved for

use for Unit 2, the pre-Amendment 205 requirements are proposed to be restored in support of future RCP flywheel exchanges between Unit 1 and Unit 2.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. Does the proposed change involve a significant increase in the probability or consequences of any accident previously evaluated?

Response: No.

The proposed license amendment would add RCP flywheel inspection program requirements to the Unit 1 Technical Specifications and revise the Unit 2 RCP flywheel inspection program by restoring previously NRC approved inspection requirements in addition to the current requirements. Adding an administrative program and restoring previously NRC approved inspection requirements neither affects the design of any plant structure, system or component (SSC), nor the manner in which the SSCs are operated and controlled. No changes are proposed to the facility or to any accident analysis assumptions, inputs or expected outcomes. Providing RCP flywheel inspection frequencies based on the flywheel metallurgical properties in the applicable Unit 2 administrative program and adding an equivalent administrative program to Unit 1 is acceptable because, for the flywheel metallurgical properties that satisfy the criteria specified in the NRC safety evaluation for topical report SIR-94-080, the increase inspection frequency has been determined acceptable by the NRC and approved for use at PSL Unit 2. Flywheels with other metallurgical properties will continue to be inspected using the methods and inspection schedule in accordance with the methods described in Regulatory Guide 1.14, “Reactor Coolant Pump Flywheel Integrity,” Revision 1. Compliance with the SIR-94-080 NRC safety evaluation and the NRC regulatory guide cannot adversely affect the likelihood or outcome of any design basis accident.

Therefore, the proposed changes do not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any previously evaluated?

Response: No

The proposed addition of RCP flywheel inspection program requirements to the Unit 1 Technical Specifications and revision of the Unit 2 RCP flywheel inspection program requirements does not affect RCP capability to provide adequate core cooling in the event of a power loss and thereby cannot create new inputs or assumptions associated with any accident analyses. The proposed change neither installs new plant equipment nor modifies the manner in which existing equipment is operated and controlled, and therefore cannot introduce new failure modes. Providing RCP flywheel inspection frequencies based on the flywheel metallurgical properties in the applicable Unit 2 administrative program and adding an equivalent administrative program to Unit 1 is acceptable because, for the flywheel metallurgical properties that satisfy the criteria specified in the NRC safety evaluation for topical report SIR-94-080, the increase inspection frequency has been determined acceptable by the NRC and approved for use

at PSL Unit 2. Flywheels with other metallurgical properties will continue to be inspected using the methods and inspection schedule in accordance with NRC Regulatory Guide 1.14. Compliance with the SIR-94-080 NRC safety evaluation and the NRC regulatory guide cannot create new or different kinds of accidents.

Therefore, operation of the facility in accordance with this proposed change will not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in the margin of safety?

Response: No.

The proposed addition of RCP flywheel inspection program requirements to the Unit 1 Technical Specifications and revision of the Unit 2 RCP flywheel inspection program requirements do not involve changes to any safety analyses, safety limits or limiting safety system settings. The proposed change does not adversely impact plant operating margins or the reliability of equipment credited in safety analyses. Providing RCP flywheel inspection frequencies based on the flywheel metallurgical properties in the applicable Unit 2 administrative program and adding an equivalent administrative program to Unit 1 is acceptable because, for the flywheel metallurgical properties that satisfy the criteria specified in the NRC safety evaluation for topical report SIR-94-080, the increase inspection frequency has been determined acceptable by the NRC and approved for use at PSL Unit 2. Flywheels with other metallurgical properties will continue to be inspected using the methods and inspection schedule in accordance with NRC Regulatory Guide 1.14. Compliance with the SIR-94-080 NRC safety evaluation and the NRC regulatory guide cannot result in a reduction in the margin of safety.

Therefore, the proposed changes do not involve a significant reduction in a margin of safety.

Based upon the above analysis, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and accordingly, a finding of no significant hazards consideration is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 5.5, PROGRAMS AND MANUALS

10 CFR 50.92 EVALUATION
FOR
REMOVE DETAIL CHANGE LA01

Florida Power & Light Company (FPL) is converting the St. Lucie Plant (PSL) Unit 1 and Unit 2 Technical Specifications to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, "Standard Technical Specifications, Combustion Engineering Plants," Revision 5. The proposed change involves making the Current Technical Specifications (CTS) less restrictive. Below is the description of the change and the determination of No Significant Hazards Considerations for conversion to NUREG-1432. |R1

CTS contains periodic testing frequencies in administrative program requirements for: leakage testing of primary coolant sources outside containment; testing of the Shield Building Ventilation System filter heaters; total particulate concentration testing of the diesel generator fuel oil; measurement, and at designated locations, of the control room envelope (CRE) pressure relative to external areas adjacent to the CRE boundary during the pressurization mode of operation of the Control Room Emergency Ventilation System. ITS specifies the periodic Frequency for these tests as "In accordance with the Surveillance Frequency Control Program." This changes the CTS by moving the specified periodic Frequency for these tests to the Surveillance Frequency Control Program.

The purpose of these Surveillances is to assure that the necessary quality of systems and components is maintained. The removal of these details related to surveillance requirement frequencies from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The existing frequency is removed from Technical Specifications and placed under licensee control pursuant to the methodology described in Nuclear Energy Institute (NEI) 04-10, "Risk-Informed Technical Specifications Initiative 5b, Risk-Informed Method for Control of Surveillance Frequencies," Revision 1, dated April 2007 (ADAMS Accession No. ML071360456). The surveillance test requirements remain in the Technical Specifications. The control of changes to the surveillance frequencies is in accordance with the Surveillance Frequency Control Program, which is retained in the ITS. The Surveillance Frequency Control Program provides the necessary administrative controls to require that surveillances related to testing, calibration and inspection are conducted at a frequency to assure that the necessary quality of systems and components is maintained, that facility operation will be within safety limits, and that the limiting conditions for operation will be met. The proposed change to relocate periodic frequencies in the administrative controls section of Technical Specifications has been previously approved for Wolf Creek Generating Station Unit 1 in Amendment 227, dated April 8, 2021 (NRC ADAMS Accession No. ML21053A117), River Bend Station Unit 1 in Amendment 196, dated April 29, 2019 (NRC ADAMS Accession No. ML19066A008), and Grand Gulf Nuclear Station Unit 1 in Amendment 219, dated June 11, 2019 (NRC ADAMS Accession No. ML19094A799). PSL Unit 1 and Unit 2 adopted a Surveillance Frequency Control Program in Amendment Nos. 223 (Unit 1) and 173 (Unit 2) (ADAMS Accession No. ML15127A066). This change is acceptable because the testing frequencies will be adequately controlled in accordance with the Surveillance Frequency Control Program requirements retained in ITS, which ensure changes are properly evaluated.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 5.5, PROGRAMS AND MANUALS

FPL has reviewed the proposed no significant hazards consideration (NSHC) determination published in *Federal Register 74 FR 32000* dated July 6, 2009. FPL has concluded that the proposed NSHC presented in the Federal Register notice is applicable to the proposed relocation of the periodic testing frequencies specified herein.

As required by 10 CFR 50.91(a), the FPL analysis of the issue of no significant hazards consideration is presented below:

1. Does the proposed change involve a significant increase in the probability or consequences of any accident previously evaluated?

Response: No.

The proposed change relocates the specified frequencies for periodic surveillance requirements to licensee control under a new Surveillance Frequency Control Program. Surveillance frequencies are not an initiator to any accident previously evaluated. As a result, the probability of any accident previously evaluated is not significantly increased. The systems and components required by the technical specifications for which the surveillance frequencies are relocated are still required to be operable, meet the acceptance criteria for the surveillance requirements, and be capable of performing any mitigation function assumed in the accident analysis. As a result, the consequences of any accident previously evaluated are not significantly increased.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any previously evaluated?

Response: No

No new or different accidents result from utilizing the proposed change. The changes do not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed) or a change in the methods governing normal plant operation. In addition, the changes do not impose any new or different requirements. The changes do not alter assumptions made in the safety analysis. The proposed changes are consistent with the safety analysis assumptions and current plant operating practice.

Therefore, operation of the facility in accordance with this proposed change will not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in the margin of safety?

Response: No.

The design, operation, testing methods, and acceptance criteria for systems, structures, and components (SSCs), specified in applicable codes and standards (or alternatives approved for use by the NRC) will continue to be met as described in the plant licensing basis (including the updated final safety analysis report and bases to technical specifications), since these are not affected by changes to the surveillance frequencies.

Similarly, there is no impact to safety analysis acceptance criteria as described in the plant licensing basis. To evaluate a change in the relocated ·surveillance frequency, FPL will perform a probabilistic risk evaluation using the guidance contained in NRC approved NEI 04-10, Rev. 1 in accordance with the Technical Specification Surveillance Frequency Control Program. NEI 04-10, Rev. 1, methodology provides reasonable acceptance guidelines and methods for evaluating the risk increase of proposed changes to surveillance frequencies consistent with Regulatory Guide 1.177, “An Approach for Plant-Specific, Risk-Informed Decisionmaking: Technical Specifications.”

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based upon the above analysis, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and accordingly, a finding of no significant hazards consideration is justified.

ATTACHMENT 6

ITS 5.6 Section, Reporting Requirements

Current Technical Specifications (CTS) Markup and Discussion of Changes (DOCs)

A01

ADMINISTRATIVE CONTROLS (continued)

A loss of safety function exists when, assuming no concurrent single failure, no concurrent loss of offsite power, or no concurrent loss of onsite diesel generator(s), a safety function assumed in the accident analysis cannot be performed. For the purpose of this program, a loss of safety function may exist when a support system is inoperable, and:

See ITS 5.5

a. A required system redundant to the system(s) supported by the inoperable support system is also inoperable, or

b. A required system redundant to the system(s) in turn supported by the inoperable supported system is also inoperable, or

c. A required system redundant to the support system(s) for the supported systems (a) and (b) above is also inoperable.

The SFDP identifies where a loss of safety function exists. If a loss of safety function is determined to exist by this program, the appropriate ACTIONS of the LCO in which the loss of safety function exists are required to be entered. When a loss of safety function is caused by the inoperability of a single Technical Specification support system, the appropriate ACTIONS to enter are those of the support system.

6.9 REPORTING REQUIREMENTS

~~ROUTINE REPORTS~~

5.6

~~6.9.1~~ In addition to the applicable reporting requirements of Title 10, Code of Federal Regulations, the following reports shall be submitted to the NRC ~~in accordance with 10 CFR 50.4~~.

A02

~~STARTUP REPORT~~

~~6.9.1.1 A summary report of plant startup and power escalation testing shall be submitted following:~~

~~(1) receipt of an operating license,~~

~~(2) amendment of the license involving a planned increase in power level,~~

L01

~~(3) installation of fuel that has a different design or has been manufactured by a different fuel supplier, and~~

~~(4) modifications that may have significantly altered the nuclear, thermal or hydraulic performance of the plant.~~

ADMINISTRATIVE CONTROLS

6.9.1.2 The startup report shall address each of the tests identified in the FSAR and shall include a description of the measured values of the operating conditions or characteristics obtained during the test program and a comparison of these values with design predictions and specifications. Any corrective actions that were required to obtain satisfactory operation shall also be described. Any additional specific details required in license conditions based on other commitments shall be included in this report.

L01

6.9.1.3 Startup reports shall be submitted within (1) 90 days following completion of the startup test program, (2) 90 days following resumption or commencement of commercial power operation, or (3) 9 months following initial criticality, whichever is earliest. If the Startup Report does not cover all three events (i.e., initial criticality, completion of startup test program, and resumption or commencement of commercial operation), supplementary reports shall be submitted at least every three months until all three events have been completed.

ANNUAL REPORTS 1/

6.9.1.4 Annual reports covering the activities of the unit as described below for the previous calendar year shall be submitted prior to March 1 of each year. The initial report shall be submitted prior to March 1 of the year following initial criticality.

6.9.1.5 Annual reports shall include the results of specific activity analysis in which the primary coolant exceeded the limits of Specification 3.4.8. The following information shall be included: (1) Reactor power history starting 48 hours prior to the first sample in which the limit was exceeded; (2) Results of the last

L02

1/ A single submittal may be made for a multiple unit station. The submittal should combine those sections that are common to all units at the station.

~~isotopic analysis for radioiodine performed prior to exceeding the limit, results of analysis while the limit was exceeded and results of one analysis after the radioiodine activity was reduced to less than the limit. Each result should include date and time of sampling and the radioiodine concentrations; (3) Clean-up system flow history starting 48 hours prior to the first sample in which the limit was exceeded; (4) Graph of the I-131 concentration and one other radioiodine isotope concentration in microcuries per gram as a function of time for the duration of the specific activity above the steady-state level; and (5) The time duration when the specific activity of the primary coolant exceeded the radioiodine limit.~~

L02

ADMINISTRATIVE CONTROLS

ANNUAL RADIOLOGICAL ENVIRONMENTAL OPERATING REPORT**

The Annual Radiological Environmental Operating Report shall include the results of analyses of all radiological environmental samples and of all environmental radiation measurements taken during the period pursuant to the locations specified in the table and figures in the ODCM, as well as summarized and tabulated results of these analyses and measurements in the format of the table in the Radiological Assessment Branch Technical Position, Revision 1, November 1979. In the event that some individual results are not available for inclusion with the report, the report shall be submitted noting and explaining the reasons for the missing results. The missing data shall be submitted in a supplementary report as soon as possible.

M01

5.6.1

~~6.9.1.8~~ The Annual Radiological Environmental Operating Report covering the operation of the unit during the previous calendar year shall be submitted ~~before May 1~~ by May 15 of each year. The report shall include summaries, interpretations, and analysis of trends of the results of the Radiological Environmental Monitoring Program for the reporting period. The material provided shall be consistent with the objectives outlined in ~~(1)~~ the ~~ODCM~~ in Offsite Dose Calculation Manual (ODCM) and ~~(2)~~ Sections IV.B.2, IV.B.3, and IV.C ~~of~~ Appendix I ~~to~~ 10 CFR Part 50.

L03

5.6.1 Note

** A single submittal may be made for a multiple unit station.

The submittal should combine sections common to all units at the station.

A01

ACTION 15 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirement, either restore the inoperable Channel(s) to OPERABLE status within 72 hours, or:

See ITS 3.3.9

5.6.4
ITS 3.3.9
Action F

~~1)~~ ~~Initiate the~~ preplanned alternate method of monitoring the appropriate parameter(s),and

R1

When a report is required by Condition B or F of LCO 3.3.9, "Post Accident Monitoring (PAM) Instrumentation,"

~~2)~~ Prepare and submit a ~~Special~~ Report ~~to the Commission pursuant to Specification6.9.2~~ within 14 days following the event outlining the ~~action taken~~, the cause of the inoperability and the plans and schedule for restoring the ~~system~~ to OPERABLE status.

A01

instrumentation channels of the Function

ACTION 16 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirements, comply with the ACTION requirements of Specification 3.9.9.

See ITS 3.3.6

ACTION 17 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirement, within 1 hour initiate and maintain operation of the control room emergency ventilation system in the recirculation mode of operation. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

See ITS 3.3.7

~~TABLE 3.3-11~~ (continued)

~~ACTION STATEMENTS~~

ACTION 1 - With the number of OPERABLE channels less than the Total No. of Channels shown in Table 3.3-11, either restore the inoperable channel(s) to OPERABLE status within 30 days or be in HOT STANDBY in 6 hours and HOT SHUTDOWN in 12 hours.

ACTION 2 - With position indication inoperable, restore the inoperable indicator to OPERABLE status or close the associated PORV block valve and remove power from its operator within 48 hours or be in HOT STANDBY in 6 hours and HOT SHUTDOWN in 12 hours.

See ITS 3.3.9

ACTION 3 - With any individual valve position indicator inoperable, obtain quench tank temperature, level and pressure information once per shift to determine valve position.

ACTION 4 - With the number of OPERABLE Channels one less than the Total Number of Channels shown in Table 3.3-11, either restore the inoperable channel to OPERABLE status within 7 days if repairs are feasible without shutting down or prepare and submit a ~~Special~~ Report ~~to the Commission pursuant to the specification 6.9.2~~ within ~~30~~ days following the event outlining the ~~action taken~~, the cause of the inoperability and the plans and schedule for restoring the ~~system~~ to OPERABLE status.

When a report is required by Condition B or F of LCO 3.3.9, "Post Accident Monitoring (PAM) Instrumentation,"

5.6.4 preplanned alternate method of monitoring

instrumentation channels of the Function

14

M03

ACTION 5 - With the number of OPERABLE Channels less than the Minimum Channels OPERABLE requirements of Table 3.3-11, either restore the inoperable channel(s) to OPERABLE status within 48 hours if repairs are feasible without shutting down or:

See ITS 3.3.9

5.6.4
ITS 3.3.9
Action F

1. ~~Initiate an~~ alternate method of monitoring the reactor vessel inventory; and

R1

When a report is required by Condition B or F of LCO 3.3.9, "Post Accident Monitoring (PAM) Instrumentation,"

2. ~~2.~~ Prepare and submit a ~~Special~~ Report ~~to the Commission pursuant to Specification 6.9.2~~ within ~~30~~ days following the event outlining the ~~action taken~~, the cause of the inoperability and the plans and schedule for restoring the ~~system~~ to OPERABLE status; and

14

M03

instrumentation channels of the Function

3. Restore the Channel to OPERABLE status at the next scheduled refueling.

ACTION 6 - With the number of OPERABLE accident monitoring channels less than the Minimum Channels OPERABLE requirements of Table 3.3-11, either restore the inoperable channel(s) to OPERABLE status within 48 hours or be in HOT STANDBY in 6 hours and HOT SHUTDOWN in 12 hours.

See ITS 3.3.9

ACTION 7 - With the number of OPERABLE accident monitoring channels less than the Minimum Channels OPERABLE requirements of Table 3.3-11, either restore the inoperable channel(s) to OPERABLE status within 72 hours or be in HOT STANDBY in 6 hours and HOT SHUTDOWN in 12 hours.

A01

ADMINISTRATIVE CONTROLS

6.9 REPORTING REQUIREMENTS

~~ROUTINE REPORTS~~

5.6

~~6.9.1~~ In addition to the applicable reporting requirements of Title 10, Code of Federal Regulations, the following reports shall be submitted to the NRC. in accordance with 10 CFR 50.4 A02

~~STARTUP REPORT~~

~~6.9.1.1 A summary report of plant startup and power escalation testing shall be submitted following (1) receipt of an operating license, (2) amendment to the license involving a planned increase in power level, (3) installation of fuel that has a different design or has been manufactured by a different fuel supplier; and (4) modifications that may have significantly altered the nuclear, thermal or hydraulic performance of the plant.~~

~~6.9.1.2 The startup report shall address each of the tests identified in the FSAR and shall include a description of the measured values of the operating conditions or characteristics obtained during the test program and a comparison of these values with design predictions and specifications. Any corrective actions that were required to obtain satisfactory operation shall also be described. Any additional specific details required in license conditions based on other commitments shall be included in this report.~~

L01

~~6.9.1.3 Startup reports shall be submitted within (1) 90 days following completion of the startup test program, (2) 90 days following resumption or commencement of commercial power operation, or (3) 9 months following initial criticality, whichever is earliest. If the Startup Report does not cover all three events (i.e., initial criticality, completion of startup test program, and resumption or commencement of commercial operation), supplementary reports shall be submitted at least every three months until all three events have been completed.~~

ADMINISTRATIVE CONTROLS

~~ANNUAL REPORTS~~ ~~1/~~

~~6.9.1.4 Annual reports covering the activities of the unit as described below for the previous calendar year shall be submitted prior to March 1 of each year. The initial report shall be submitted prior to March 1 of the year following initial criticality.~~

~~6.9.1.5 Reports required on an annual basis shall include the results of specific activity analysis in which the primary coolant exceeded the limits of Specification 3.4.8. The following information shall be included: (1) Reactor power history starting 48 hours prior to the first sample in which the limit was exceeded; (2) Results of the last isotopic analysis for radioiodine performed prior to exceeding the limit, results of analysis while the limit was exceeded and results of one analysis after the radioiodine activity was reduced to less than the limit. Each result should include date and time of sampling and the radioiodine concentrations; (3) Clean-up system flow history starting 48 hours prior to the first sample in which the limit was exceeded; (4) Graph of the I-131 concentration and one other radioiodine isotope concentration in microcuries per gram as a function of time for the duration of the specific activity above the steady-state level; and (5) The time duration when the specific activity of the primary coolant exceeded the radioiodine limit.~~

L02

~~MONTHLY OPERATING REPORTS~~

A01

~~6.9.1.6 Deleted~~

~~1/ A single submittal may be made for a multiple unit station. The submittal should combine those sections that are common to all units at the station.~~

L02

A01

ADMINISTRATIVE CONTROLS

~~ANNUAL~~ RADIOACTIVE EFFLUENT RELEASE REPORT*

A01

5.6.2 ~~6.9.1.7~~ The ~~Annual~~ Radioactive Effluent Release Report covering the operation of the unit ~~during the previous 12 months of operation~~ shall be submitted ~~within 60 days after January 1 of each year~~. The report shall include a summary of the quantities of radioactive liquid and gaseous effluents and solid waste released from the unit. The material provided shall be (1) consistent with the objectives outlined in the ODCM and PCP and (2) in conformance with 10 CFR 50.36a and Section IV.B.1 of Appendix I to 10 CFR Part 50.

prior to May 1 of each year in accordance with 10 CFR 50.36a

L03

5.6.2 Note * A single submittal may be made for a multiple unit station. The submittal shall ~~should~~ combine ~~those~~ sections ~~that are~~ common to all units at the station; however, for units with separate radwaste systems, the submittal shall specify the releases of radioactive material from each unit.

A01

ADMINISTRATIVE CONTROLS

ANNUAL RADIOLOGICAL ENVIRONMENTAL OPERATING REPORT**

5.6.1 ~~6.9.1.8~~ The Annual Radiological Environmental Operating Report covering the operation of the unit during the previous calendar year shall be submitted ~~before May 1~~ by May 15 of each year. The report shall include summaries, interpretations, and analysis of trends of the results of the Radiological Environmental Monitoring Program for the reporting period. The material provided shall be consistent with the objectives outlined in ~~(1)~~ the ~~ODCM~~ Offsite Dose Calculation Manual (ODCM) and ~~(2)~~ Sections IV.B.2, IV.B.3, and IV.C ~~of~~ Appendix I ~~to~~ 10 CFR Part 50.

L03

in

The Annual Radiological Environmental Operating Report shall include the results of analyses of all radiological environmental samples and of all environmental radiation measurements taken during the period pursuant to the locations specified in the table and figures in the ODCM, as well as summarized and tabulated results of these analyses and measurements in the format of the table in the Radiological Assessment Branch Technical Position, Revision 1, November 1979. In the event that some individual results are not available for inclusion with the report, the report shall be submitted noting and explaining the reasons for the missing results. The missing data shall be submitted in a supplementary report as soon as possible.

M01

** A single submittal may be made for a multiple unit station.

The submittal should combine sections common to all units at the station.

A01

A01

ADMINISTRATIVE CONTROLS

~~ANNUAL RADIOLOGICAL ENVIRONMENTAL OPERATING REPORT~~ ~~(continued)~~

~~6.9.1.9~~ ~~At least once every 5 years, an estimate of the actual population within 10 miles of the plant shall be prepared and submitted to the NRC.~~

~~6.9.1.10~~ ~~At least once every 10 years, an estimate of the actual population within 50 miles of the plant shall be prepared and submitted to the NRC.~~

LA01

5.6.3 ~~6.9.1.11~~ CORE OPERATING LIMITS REPORT (COLR)

5.6.3.a a. Core operating limits shall be established prior to each reload cycle, or prior to any remaining portion of a reload cycle, and shall be documented in the COLR for the following:

5.6.3.a
Document List
ITS Specifications

Specification 3.1.1.1	Shutdown Margin – T_{avg} Greater than 200°F
Specification 3.1.1.2	Shutdown Margin – T_{avg} Less Than or Equal to 200°F
Specification 3.1.1.4	Moderator Temperature Coefficient
Specification 3.1.3.1	Movable Control Assemblies – CEA Position
Specification 3.1.3.6	Regulating CEA Insertion Limits
Specification 3.2.1	Linear Heat Rate
Specification 3.2.3	Total Integrated Radial Peaking Factors – F_r^T
Specification 3.2.5	DNB Parameters
Specification 3.9.1	Refueling Operations – Boron Concentration

5.6.3.b b. The analytical methods used to determine the core operating limits shall be those previously reviewed and approved by the NRC, ~~as~~ specifically those described in the following documents or any approved Revisions and Supplements thereto:

5.6.3.b
Document List

SPECIAL REPORTS

STEAM GENERATOR TUBE INSPECTION REPORT

MODE 4

5.6.5 ~~6.9.1.12~~ A report shall be submitted within 180 days after the initial entry into ~~HOT SHUTDOWN~~ following completion of an inspection of the replacement SGs performed in accordance with Specification ~~6.8.4.l.1~~. The report shall include:

5.5.6

5.6.5 a a. The scope of inspections performed on each SG,

Add proposed ITS 5.6.5.b

M02

5.6.5 c b. ~~Active~~ degradation mechanisms found,

5.6.5 c.1 c. Nondestructive examination techniques utilized for each degradation mechanism,

A03

5.6.5 c.2 d. Location, orientation (if linear), and measured sizes (if available) of service induced indications, and voltage response for each indication. For tube wear at support structures less than 20 percent through-wall, only the total number of indications needs to be reported;

5.6.5 c.4 e. Number of tubes plugged during the inspection outage for each active degradation mechanism; found

Add proposed ITS 5.6.5.d

M02

The

5.6.5.e f. ~~Total~~ number and percentage of tubes plugged to date,

and

5.6.5.c.3 g. The results of condition monitoring~~, including the results of tube pulls and in-situ testing,~~

5.6.5.e h. The effective plugging percentage ~~for all plugging~~ in each SG.

~~6.9.2 Special reports shall be submitted to the NRC within the time period specified for each report.~~

A01

Add proposed ITS 5.6.5.f

M02

~~**6.10 DELETED**~~

including the margin to the tube integrity performance criteria and comparison with the margin predicted to exist at the inspection by the previous forward-looking tube integrity assessment;

A03

~~TABLE 3.3-6 (Continued)~~

~~ACTION STATEMENTS~~

ACTION 22 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirement, perform area surveys of the monitored area with portable monitoring instrumentation at least once per 24 hours.

See ITS 3.3.8

ACTION 23 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirement, comply with the ACTION requirements of Specification 3.4.6.1.

See ITS 3.4.15

ACTION 24 - DELETED

ACTION 25 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirement, comply with the ACTION requirements of Specification 3.9.9.

See ITS 3.3.6

ACTION 26 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirements, within 1 hour initiate and maintain operation of the control room emergency ventilation system in the recirculation mode of operation. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

See ITS 3.3.7

ACTION 27 - With the number of OPERABLE Channels less than required by the Minimum Channels OPERABLE requirement, either restore the inoperable Channel(s) to OPERABLE status within 72 hours, or:

See ITS 3.3.9

5.6.4
ITS 3.3.9
Action F

When a report is required by Condition B or F of LCO 3.3.9, "Post Accident Monitoring (PAM) Instrumentation,"

1) ~~Initiate the~~ preplanned alternate method of monitoring the appropriate parameter(s), and

R1

2) Prepare and submit a ~~Special~~ Report ~~to the Commission pursuant to Specification 6.9.2~~ within 14 days following the event outlining the ~~action taken~~, the cause of the inoperability and the plans and schedule for restoring the ~~system~~ to OPERABLE status.

A01

instrumentation channels of the Function

INSTRUMENTATION

ACCIDENT MONITORING INSTRUMENTATION

LIMITING CONDITION FOR OPERATION

3.3.3.6 The accident monitoring instrumentation channels shown in Table 3.3-10 shall be OPERABLE.

See ITS 3.3.9

APPLICABILITY: MODES 1, 2 and 3.

ACTION:

a.* With the number of OPERABLE accident monitoring channels less than the Required Number of Channels shown in Table 3.3-10, either restore the inoperable channel to OPERABLE status within 7 days, or be in HOT STANDBY in 6 hours and HOT SHUTDOWN in 12 hours.

b.* With the number of OPERABLE accident monitoring channels less than the Minimum Channels OPERABLE requirements of Table 3.3-10, either restore the inoperable channels to OPERABLE status within 48 hours or be in HOT STANDBY in 6 hours and HOT SHUTDOWN in 12 hours.

When a report is required by Condition B or F of LCO 3.3.9, "Post Accident Monitoring (PAM) Instrumentation,"

c.** With the number of OPERABLE Channels one less than the Total Number of Channels shown in Table 3.3-10, either restore the inoperable channel to OPERABLE status within 7 days if repairs are feasible without shutting down or prepare and submit a ~~Special~~ Report ~~to the Commission pursuant to Specification 6.9.2~~ within ~~30~~ days following the event outlining the ~~action taken~~, the cause of the inoperability and the plans and schedule for restoring the ~~system~~ to OPERABLE status.

5.6.4 preplanned alternate method of monitoring

14

M03

instrumentation channels of the Function

See ITS 3.3.9

d.** With the number of OPERABLE Channels less than the Minimum Channels OPERABLE requirements of Table 3.3-10, either restore the inoperable channel(s) to OPERABLE status within 48 hours if repairs are feasible without shutting down or:

5.6.4
ITS 3.3.9
Action F

When a report is required by Condition B or F of LCO 3.3.9, "Post Accident Monitoring (PAM) Instrumentation,"

1. ~~Initiate an~~ alternate method of monitoring the reactor vessel inventory; and | R1

2. Prepare and submit a ~~Special~~ Report ~~to the Commission pursuant to Specification 6.9.2~~ within ~~30~~ days following the event outlining the ~~action taken~~, the cause of the inoperability and the plans and schedule for restoring the ~~system~~ to OPERABLE status, ~~and~~

instrumentation channels of the Function

14

M03

3. Restore the Channel to OPERABLE status at the next scheduled refueling.

See ITS 3.3.9

* Action statements do not apply to Reactor Vessel Level Monitoring System, Containment Sump Water Level (narrow range) and Containment Sump Water Level (wide range) instruments.

** Action statements apply only to Reactor Vessel Level Monitoring System, Containment Sump Water Level (narrow range) and Containment Sump Water Level (wide range) instruments.

DISCUSSION OF CHANGES
ITS 5.6, REPORTING REQUIREMENTS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 6.9.1 specifies in addition to the applicable reporting requirements of 10 CFR, the reports that must be submitted to the NRC. ITS 5.6 requires that reports be submitted in accordance with 10 CFR 50.4. This changes the CTS by adding the 10 CFR 50.4 requirement.

10 CFR 50.4 provides distribution requirements for written communications to the NRC. This change is acceptable because the 10 CFR 50.4 distribution requirements already apply to each report to be submitted to the NRC. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 CTS 6.9.1.12 provides requirements for the Steam Generator (SG) Tube Inspection Report and lists items to include in the report, including the requirement to provide location, orientation, and measured sizes of each degradation mechanism found, and the results of condition monitoring including the results of tube pulls and in situ testing. ITS 5.6.5 also provides requirements for the SG Tube Inspection Report and a list of items to include in the report the requirement to provide location, orientation, and measured sizes of each degradation mechanism found, and the results of condition monitoring. ITS 5.6.5.c.2 and c.3 include additional detail on what to include in the report. ITS 5.6.5.c.2 clarifies that for any tube degradation mechanisms found, the report must include voltage response for each indication and, for tube wear at support structures less than 20 percent through-wall, only the total number of indications needs to be reported. ITS 5.6.5.c.3 clarifies that the description of the condition monitoring assessment and results must include the margin to the tube integrity performance criteria and comparison with the margin predicted to exist at the inspection by the previous forward-looking tube integrity assessment. The purpose of the report is to advise the NRC of results of SG tube inspections performed in accordance with the plant's steam generator program, which monitors and manages tube degradation and degradation precursors. These changes are consistent with the ISTS and approved for use by the NRC as specified in the safety evaluation associated with TSTF-577-A, Revision 1, dated April 14, 2021 (NRC ADAMS Accession No. ML21098A188). The NRC staff reviewed the proposed changes to the ISTS SG Tube Inspection Report and determined that they are acceptable because they will provide additional detailed information to allow the NRC staff to better understand the overall condition of the SGs. This change solely provides clarification detail on reporting requirements currently listed in the CTS. These clarifications to what must be provided in the SG Tube Inspection Report for the CTS items specified herein do

not result in a technical change to the CTS and, therefore, the change is designated as administrative.

MORE RESTRICTIVE CHANGES

M01 The second paragraph of ITS 5.6.1 includes details required to be included in the Annual Radiological Environmental Operating Report. CTS 6.9.1.8 does not contain this level of detail. This changes the CTS by requiring additional detail to be included in the Annual Radiological Environmental Operating Report.

The purpose of the second paragraph of ITS 5.6.1 is to specify details to be included in the Annual Radiological Environmental Operating Report. This change is acceptable because the content requirements are consistent with the objectives outlined in the Offsite Dose Calculation Manual. This change is designated more restrictive because it adds new reporting requirements to the Technical Specifications.

M02 CTS 6.9.1.12 provides requirements for the SG Tube Inspection Report and lists items to include in the report. ITS 5.6.5 also provides requirements for the SG Tube Inspection Report and a list of items to include in the report. ITS 5.6.5 additionally requires the report to include: 1) the nondestructive examination techniques utilized for tubes with increased degradation susceptibility (ITS 5.6.5.b); 2) an analysis summary of the tube integrity conditions predicted to exist at the next scheduled inspection (the forward-looking tube integrity assessment) relative to the applicable performance criteria, including the analysis methodology, inputs, and results (ITS 5.6.5.d); and 3) the results of any SG secondary side inspections (ITS 5.6.5.f). This changes the CTS by requiring additional items to be included in the SG Tube Inspection Report that is submitted to the NRC.

The purpose of the report is to advise the NRC of results of SG tube inspections performed in accordance with the plant's steam generator program, which monitors and manages tube degradation and degradation precursors. These changes are consistent with the ISTS and approved for use by the NRC as specified in the safety evaluation associated with TSTF-577-A, Revision 1, dated April 14, 2021 (NRC ADAMS Accession No. ML21098A188). The NRC staff reviewed the proposed changes to the ISTS SG Tube Inspection Report and determined that they are acceptable because they will provide additional detailed information to allow the NRC staff to better understand the overall condition of the SGs. The proposed change is designated more restrictive because additional items are required in the ITS to be included in the SG Tube Inspection Report than required in the CTS.

M03 Unit 1 CTS Table 3.3-11 Actions 4 and 5, and Unit 2 CTS 3.3.3.6 Actions c and d contain a requirement that becomes applicable if the applicable channels are not restored to operable status within the allowed time. These actions require submittal of a Special Report to the Commission within 30 days outlining the action taken, the cause of the inoperability and the plans and schedule to restore the associated parameter to OPERABLE status. ITS Specification 5.6.4 requires the same report to be submitted within 14 days. This changes the CTS by

requiring a more timely NRC report to be submitted when channel(s) are not restored to OPERABLE status within the specified Completion Time.

The purpose of the CTS (and ITS) Actions is to advise the NRC regarding the failure to restore the required post accident monitoring channels to OPERABLE status in the allowed time. The CTS requirement allows the NRC report to be submitted within 30 days. The proposed change is acceptable because it provides a more timely report to the NRC. The proposed change does not impose an undue burden on plant personnel nor does the proposed change adversely affect the safe operation of the plant. The proposed change is designated more restrictive because a more timely report is required in the ITS than in the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 6.9.1.9 and CTS 6.9.1.10 require reporting for estimates of actual population within 10 miles of the plant every 5 years, and within 50 miles of the plant every 10 years, respectively. ITS 5.6 does not contain this requirement. This changes the CTS by removing the population reporting requirements from the CTS and relocating them to the UFSAR, which contains these population reporting requirements.

Unit 1 UFSAR, Section 2.1.3.9 and Unit 2 UFSAR, Section 2.1.3.3 provide requirements for periodic update of population data. The UFSAR states, in part, that commencing in April 1993 and at least every 5 years thereafter, FPL will prepare and submit to the NRC an estimate of the actual population within 10 miles of the plant. In addition, commencing in April 1993 and at least every 10 years thereafter, FPL will prepare and submit to the NRC an estimate of the actual population within 50 miles of the plant.

The removal of these details for making reports from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. Also, this change is acceptable because these types of procedural details are adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because reporting requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 9 – Deletion of Reporting Requirements)* CTS 6.9.1.1, CTS 6.9.1.2, and CTS 6.9.1.3 contain requirements for submitting a report of plant startup and power escalation testing following receipt of an operating license; amendments to

the license involving planned increase in power level; installation of fuel that has a different design or has been manufactured by a different fuel supplier; and modifications that may have significantly altered the nuclear, thermal, or hydraulic performance of the unit. The ITS does not contain such reporting requirements. This changes the CTS by deleting the requirements of CTS 6.9.1.1, CTS 6.9.1.2, and CTS 6.9.1.3.

The purpose of CTS 6.9.1.1, CTS 6.9.1.2 and CTS 6.9.1.3 is to provide a summary of plant startup and power escalation testing following the four specified conditions as verification that the unit operated as expected. This change is acceptable because the regulations provide adequate reporting requirements. If there were any unit conditions outside the expected parameters during unit startup, they would be reported to the NRC if they met the reporting requirements in the regulations. Otherwise, the reports would document that the unit operated as expected and already approved by the NRC, as required by regulations. This change is designated as less restrictive because reports that would be submitted under the CTS will not be required under the ITS.

L02 *(Category 9 - Deletion of Reporting Requirements)* CTS 6.9.1.4 requires the annual reports of CTS 6.9.1.5 regarding any instances when the specific activity limit of Specification 3.4.8 is exceeded, to be submitted prior to March 31 of each year. ITS 5.6 does not contain any requirements for such a report. This changes the CTS by not including the requirements for the annual reporting of instances when the Technical Specification specific activity limit for the primary coolant is exceeded.

The purpose of CTS 6.9.1.4 and CTS 6.9.1.5 is to specify the requirements for submitting information regarding any instances when the Technical Specification specific activity of Specification 3.4.8 is exceeded in an annual report. This change is acceptable because the regulations provide adequate details of reporting requirements, and the reporting of exceeding the 1-131 specific activity limit does not affect continued plant operation. Operations or conditions prohibited by the plant's Technical Specifications are required to be reported in accordance with 10 CFR 50.73. Subsequent reports would be provided if necessary, without requiring a specific annual report. This change is designated as less restrictive because the reports that would be submitted under the CTS will not be required under the ITS.

L03 *(Category 1 – Relaxation of LCO Requirements)* CTS 6.9.1.7 requires the Radioactive Effluent Release Report to be submitted within 60 days after January 1 of each year. ITS 5.6.1 requires the Radioactive Effluent Release Report to be submitted prior to May 1 of each year in accordance with 10 CFR 50.36a. CTS 6.9.1.8 requires the Annual Radiological Environmental Operating Report to be submitted before May 1 of each year. ITS 5.6.1 requires the Annual Radiological Environmental Operating Report to be submitted by May 15 of each year. This changes the CTS by allowing an additional time to submit these reports each year.

The purpose of the due date for submitting the Radioactive Effluent Release Report and Annual Radiological Environmental Operating Report is to ensure that the reports are provided in a reasonable period of time to the NRC for

review. This change is acceptable because the reports are still required to be submitted in a reasonable time frame. Given that the reports are still required to be provided to the NRC on or before May 1 or May 15, respectively, and cover the previous calendar year, report completion and submittal is clearly not necessary to assure operation in a safe manner for the interval between March 1 and April 30, and May 1 and May 15, respectively. Additionally, there is no requirement for the NRC to approve the reports. This change is designated as less restrictive because it allows more time to prepare and submit the reports to the NRC.

Improved Standard Technical Specifications (ISTS) Markup and Justification for Deviations (JFDs)

5.0 ADMINISTRATIVE CONTROLS

5.6 Reporting Requirements

The following reports shall be submitted in accordance with 10 CFR 50.4.

6.9.1.8

5.6.1 Annual Radiological Environmental Operating Report

----------NOTE----------

6.9.1.8 Footnote **

~~[~~A single submittal may be made for a multiple unit station. The submittal should combine sections common to all units at the station.~~]~~

2

The Annual Radiological Environmental Operating Report covering the operation of the unit during the previous calendar year shall be submitted by May 15 of each year. The report shall include summaries, interpretations, and analyses of trends of the results of the Radiological Environmental Monitoring Program for the reporting period. The material provided shall be consistent with the objectives outlined in the Offsite Dose Calculation Manual (ODCM), and in 10 CFR 50, Appendix I, Sections IV.B.2, IV.B.3, and IV.C.

DOC M01

The Annual Radiological Environmental Operating Report shall include the results of analyses of all radiological environmental samples and of all environmental radiation measurements taken during the period pursuant to the locations specified in the table and figures in the ODCM, as well as summarized and tabulated results of these analyses and measurements ~~[in the format of the table in the Radiological Assessment Branch Technical Position, Revision 1, November 1979]~~. In the event that some individual results are not available for inclusion with the report, the report shall be submitted noting and explaining the reasons for the missing results. The missing data shall be submitted in a supplementary report as soon as possible.

2

6.9.1.7

5.6.2 Radiological Effluent Release Report

----------NOTE----------

6.9.1.7 Footnote *

~~[~~A single submittal may be made for a multiple unit station. The submittal shall combine sections common to all units at the station; however, for units with separate radwaste systems, the submittal shall specify the releases of radioactive material from each unit.~~]~~

2

The Radioactive Effluent Release Report covering the operation of the unit in the previous year shall be submitted prior to May 1 of each year in accordance with 10 CFR 50.36a. The report shall include a summary of the quantities of radioactive liquid and gaseous effluents and solid waste released from the unit. The material provided shall be consistent with the objectives outlined in the ODCM and Process Control Program and in conformance with 10 CFR 50.36a and 10 CFR Part 50, Appendix I, Section IV.B.1.

5.6 Reporting Requirements

6.9.1.11 **5.6.3 CORE OPERATING LIMITS REPORT**

a. Core operating limits shall be established prior to each reload cycle, or prior to any remaining portion of a reload cycle, and shall be documented in the COLR for the following:, including approved revisions and supplements, as specified thereto (1)

INSERT 1 → ~~[The individual specifications that address core operating limits must be referenced here.]~~ (2)

b. The analytical methods used to determine the core operating limits shall be those previously reviewed and approved by the NRC, specifically those described in the following documents:

~~----------REVIEWER'S NOTE----------~~
~~Licensees that have received prior NRC approval to relocate Topical Report revision numbers and dates to licensee control need only list the number and title of the Topical Report, and the COLR will contain the complete identification for each of the Technical Specification referenced Topical Reports used to prepare the COLR (i.e., report number, title, revision, date, and any supplements). See NRC ADAMS Accession No: ML110660285 for details.~~
~~----------~~ (3)

INSERT 2 → ~~[Identify the Topical Report(s) by number, title, date, and NRC staff approval document or identify the staff Safety Evaluation Report for a plant specific methodology by NRC letter and date.]~~ (2)

c. The core operating limits shall be determined assuming operation up to RATED THERMAL POWER such that all applicable limits (e.g., fuel thermal mechanical limits, core thermal hydraulic limits, Emergency Core Cooling System (ECCS) limits, nuclear limits such as SDM, transient analysis limits, and accident analysis limits) of the safety analysis are met.

d. The COLR, including any midcycle revisions or supplements, shall be provided upon issuance for each reload cycle to the NRC.

~~5.6.4 Reactor Coolant System (RCS) PRESSURE AND TEMPERATURE LIMITS REPORT~~

~~a. RCS pressure and temperature limits for heat up, cooldown, low temperature operation, criticality, and hydrostatic testing as well as heatup and cooldown rates shall be established and documented in the PTLR for the following:~~

~~[The individual specifications that address RCS pressure and temperature limits must be referenced here.]~~ (4)

2

INSERT 1

LCO 3.1.1	SHUTDOWN MARGIN (SDM)
LCO 3.1.3	Moderator Temperature Coefficient (MTC)
LCO 3.1.4	Control Element Assembly (CEA) Alignment
LCO 3.1.6	Regulating Control Element Assembly (CEA) Insertion Limits
LCO 3.2.1	Linear Heat Rate (LHR)
LCO 3.2.2	Total Integrated Radial Peaking Factor (F_r^T)
LCO 3.2.4	AXIAL SHAPE INDEX (ASI)
LCO 3.4.1	RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits
LCO 3.9.1	Boron Concentration

5.6 Reporting Requirements

5.6.4 RCS Pressure and Temperature Limits Report (continued)

b. The analytical methods used to determine the RCS pressure and temperature limits shall be those previously reviewed and approved by the NRC, specifically those described in the following documents:

----------REVIEWER'S NOTE----------
Licensees that have received prior NRC approval to relocate Topical Report revision numbers and dates to licensee control need only list the number and title of the Topical Report, and the PTLR will contain the complete identification for each of the Technical Specification referenced Topical Reports used to prepare the PTLR (i.e., report number, title, revision, date, and any supplements). See NRC ADAMS Accession No: ML110660285 for details.

[Identify the NRC staff approval document by date.]

c. The PTLR shall be provided to the NRC upon issuance for each reactor vessel fluence period and for any revision or supplement thereto.

----------REVIEWER'S NOTE----------
The methodology for the calculation of the P-T limits for NRC approval should include the following provisions:

1. The methodology shall describe how the neutron fluence is calculated (reference new Regulatory Guide when issued).

2. The Reactor Vessel Material Surveillance Program shall comply with Appendix H to 10 CFR 50. The reactor vessel material irradiation surveillance specimen removal schedule shall be provided, along with how the specimen examinations shall be used to update the PTLR curves.

3. Low Temperature Overpressure Protection (LTOP) System lift setting limits for the Power Operated Relief Valves (PORVs), developed using NRC-approved methodologies may be included in the PTLR.

4. The adjusted reference temperature (ART) for each reactor beltline material shall be calculated, accounting for radiation embrittlement, in accordance with Regulatory Guide 1.99, Revision 2.

5. The limiting ART shall be incorporated into the calculation of the pressure and temperature limit curves in accordance with NUREG-0800 Standard Review Plan 5.3.2, Pressure-Temperature Limits.

6. The minimum temperature requirements of Appendix G to 10 CFR Part 50 shall be incorporated into the pressure and temperature limit curves.

4

5.6 Reporting Requirements

~~5.6.4 RCS Pressure and Temperature Limits Report (continued)~~

~~7. Licensees who have removed two or more capsules should compare for each surveillance material the measured increase in reference temperature (RT_{NDT}) to the predicted increase in RT_{NDT}; where the predicted increase in RT_{NDT} is based on the mean shift in RT_{NDT} plus the two standard deviation value ($2\sigma_{\Delta}$) specified in Regulatory Guide 1.99, Revision 2. If the measured value exceeds the predicted value (increase in RT_{NDT} + $2\sigma_{\Delta}$), the licensee should provide a supplement to the PTLR to demonstrate how the results affect the approved methodology.~~

Table 3.3-11, Actions 4 and 5
DOC M03

5.6.~~5~~ Post Accident Monitoring Report

4

9

When a report is required by Condition B or F of LCO 3.3.~~[11]~~, "Post Accident Monitoring (PAM) Instrumentation," a report shall be submitted within the following 14 days. The report shall outline the preplanned alternate method of monitoring, the cause of the inoperability, and the plans and schedule for restoring the instrumentation channels of the Function to OPERABLE status.

~~5.6.6 Tendon Surveillance Report~~

~~[Any abnormal degradation of the containment structure detected during the tests required by the Pre-stressed Concrete Containment Tendon Surveillance Program shall be reported to the NRC within 30 days. The report shall include a description of the tendon condition, the condition of the concrete (especially at tendon anchorages), the inspection procedures, the tolerances on cracking, and the corrective action taken.]~~

5

1

6.9.1.12

5.6.~~7~~ Steam Generator Tube Inspection Report

5

A report shall be submitted within 180 days after the initial entry into MODE 4 following completion of an inspection performed in accordance with the Specification ~~5.5.9~~ 5.5.6, "Steam Generator (SG) Program." The report shall include:

6.9.1.12.a

a. The scope of inspections performed on each SG;

DOC M02

b. The nondestructive examination techniques utilized for tubes with increased degradation susceptibility;

c. For each degradation mechanism found:

6.9.1.12.c

1. The nondestructive examination techniques utilized;

5

6.9.1.12.d DOC A03

2. The location, orientation (if linear), measured size (if available), and voltage response for each indication. For tube wear at support structures less than 20 percent through-wall, only the total number of indications needs to be reported;

6.9.1.12.g DOC A03

3. A description of the condition monitoring assessment and results, including the margin to the tube integrity performance criteria and comparison with the margin predicted to exist at the inspection by the previous forward-looking tube integrity assessment;

6.9.1.12.e

4. The number of tubes plugged ~~[or repaired]~~ during the inspection outage~~;~~. and

~~[5. The repair methods utilized and the number of tubes repaired by each repair method.]~~ 2

DOC M02

d. An analysis summary of the tube integrity conditions predicted to exist at the next scheduled inspection (the forward-looking tube integrity assessment) relative to the applicable performance criteria, including the analysis methodology, inputs, and results;

6.9.1.12.f 6.9.1.12.h

e. The number and percentage of tubes plugged ~~[or repaired]~~ to date, and the effective plugging percentage in each SG; 2

DOC M02

f. The results of any SG secondary side inspections~~;~~. and

~~[g. Insert any plant-specific reporting requirements, if applicable.]~~ 2

5.0 ADMINISTRATIVE CONTROLS

5.6 Reporting Requirements

The following reports shall be submitted in accordance with 10 CFR 50.4.

6.9.1.8

5.6.1 Annual Radiological Environmental Operating Report

----------NOTE----------

6.9.1.8 Footnote **

~~[~~A single submittal may be made for a multiple unit station. The submittal should combine sections common to all units at the station.~~]~~

2

The Annual Radiological Environmental Operating Report covering the operation of the unit during the previous calendar year shall be submitted by May 15 of each year. The report shall include summaries, interpretations, and analyses of trends of the results of the Radiological Environmental Monitoring Program for the reporting period. The material provided shall be consistent with the objectives outlined in the Offsite Dose Calculation Manual (ODCM), and in 10 CFR 50, Appendix I, Sections IV.B.2, IV.B.3, and IV.C.

DOC M01

The Annual Radiological Environmental Operating Report shall include the results of analyses of all radiological environmental samples and of all environmental radiation measurements taken during the period pursuant to the locations specified in the table and figures in the ODCM, as well as summarized and tabulated results of these analyses and measurements ~~[in the format of the table in the Radiological Assessment Branch Technical Position, Revision 1, November 1979]~~. In the event that some individual results are not available for inclusion with the report, the report shall be submitted noting and explaining the reasons for the missing results. The missing data shall be submitted in a supplementary report as soon as possible.

2

6.9.1.7

5.6.2 Radiological Effluent Release Report

----------NOTE----------

6.9.1.7 Footnote *

~~[~~A single submittal may be made for a multiple unit station. The submittal shall combine sections common to all units at the station; however, for units with separate radwaste systems, the submittal shall specify the releases of radioactive material from each unit.~~]~~

2

The Radioactive Effluent Release Report covering the operation of the unit in the previous year shall be submitted prior to May 1 of each year in accordance with 10 CFR 50.36a. The report shall include a summary of the quantities of radioactive liquid and gaseous effluents and solid waste released from the unit. The material provided shall be consistent with the objectives outlined in the ODCM and Process Control Program and in conformance with 10 CFR 50.36a and 10 CFR Part 50, Appendix I, Section IV.B.1.

5.6 Reporting Requirements

6.9.1.11 **5.6.3 CORE OPERATING LIMITS REPORT**

a. Core operating limits shall be established prior to each reload cycle, or prior to any remaining portion of a reload cycle, and shall be documented in the COLR for the following:, including approved revisions and supplements, as specified thereto (1)

INSERT 1 → ~~[The individual specifications that address core operating limits must be referenced here.]~~ (2)

b. The analytical methods used to determine the core operating limits shall be those previously reviewed and approved by the NRC, specifically those described in the following documents:

~~----------REVIEWER'S NOTE----------~~
~~Licensees that have received prior NRC approval to relocate Topical Report revision numbers and dates to licensee control need only list the number and title of the Topical Report, and the COLR will contain the complete identification for each of the Technical Specification referenced Topical Reports used to prepare the COLR (i.e., report number, title, revision, date, and any supplements). See NRC ADAMS Accession No: ML110660285 for details.~~
~~----------~~ (3)

INSERT 2 → ~~[Identify the Topical Report(s) by number, title, date, and NRC staff approval document or identify the staff Safety Evaluation Report for a plant specific methodology by NRC letter and date.]~~ (2)

c. The core operating limits shall be determined assuming operation up to RATED THERMAL POWER such that all applicable limits (e.g., fuel thermal mechanical limits, core thermal hydraulic limits, Emergency Core Cooling System (ECCS) limits, nuclear limits such as SDM, transient analysis limits, and accident analysis limits) of the safety analysis are met.

d. The COLR, including any midcycle revisions or supplements, shall be provided upon issuance for each reload cycle to the NRC.

~~5.6.4 Reactor Coolant System (RCS) PRESSURE AND TEMPERATURE LIMITS REPORT~~

~~a. RCS pressure and temperature limits for heat up, cooldown, low temperature operation, criticality, and hydrostatic testing as well as heatup and cooldown rates shall be established and documented in the PTLR for the following:~~

~~[The individual specifications that address RCS pressure and temperature limits must be referenced here.]~~ (4)

5.6 Reporting Requirements

5.6.4 RCS Pressure and Temperature Limits Report (continued)

b. The analytical methods used to determine the RCS pressure and temperature limits shall be those previously reviewed and approved by the NRC, specifically those described in the following documents:

----------REVIEWER'S NOTE----------
Licensees that have received prior NRC approval to relocate Topical Report revision numbers and dates to licensee control need only list the number and title of the Topical Report, and the PTLR will contain the complete identification for each of the Technical Specification referenced Topical Reports used to prepare the PTLR (i.e., report number, title, revision, date, and any supplements). See NRC ADAMS Accession No: ML110660285 for details.

[Identify the NRC staff approval document by date.]

c. The PTLR shall be provided to the NRC upon issuance for each reactor vessel fluence period and for any revision or supplement thereto.

----------REVIEWER'S NOTE----------
The methodology for the calculation of the P-T limits for NRC approval should include the following provisions:

1. The methodology shall describe how the neutron fluence is calculated (reference new Regulatory Guide when issued).

2. The Reactor Vessel Material Surveillance Program shall comply with Appendix H to 10 CFR 50. The reactor vessel material irradiation surveillance specimen removal schedule shall be provided, along with how the specimen examinations shall be used to update the PTLR curves.

3. Low Temperature Overpressure Protection (LTOP) System lift setting limits for the Power Operated Relief Valves (PORVs), developed using NRC-approved methodologies may be included in the PTLR.

4. The adjusted reference temperature (ART) for each reactor beltline material shall be calculated, accounting for radiation embrittlement, in accordance with Regulatory Guide 1.99, Revision 2.

5. The limiting ART shall be incorporated into the calculation of the pressure and temperature limit curves in accordance with NUREG-0800 Standard Review Plan 5.3.2, Pressure-Temperature Limits.

6. The minimum temperature requirements of Appendix G to 10 CFR Part 50 shall be incorporated into the pressure and temperature limit curves.

4

5.6 Reporting Requirements

~~5.6.4 RCS Pressure and Temperature Limits Report (continued)~~

~~7. Licensees who have removed two or more capsules should compare for each surveillance material the measured increase in reference temperature (RT_{NDT}) to the predicted increase in RT_{NDT}; where the predicted increase in RT_{NDT} is based on the mean shift in RT_{NDT} plus the two standard deviation value ($2\sigma_{\Delta}$) specified in Regulatory Guide 1.99, Revision 2. If the measured value exceeds the predicted value (increase in RT_{NDT} + $2\sigma_{\Delta}$), the licensee should provide a supplement to the PTLR to demonstrate how the results affect the approved methodology.~~

Table 3.3-6, Action 27
3.3.3.6 Actions c and d
DOC M03

5.6.~~5~~ Post Accident Monitoring Report

4

9

When a report is required by Condition B or F of LCO 3.3.~~[11]~~, "Post Accident Monitoring (PAM) Instrumentation," a report shall be submitted within the following 14 days. The report shall outline the preplanned alternate method of monitoring, the cause of the inoperability, and the plans and schedule for restoring the instrumentation channels of the Function to OPERABLE status.

~~5.6.6 Tendon Surveillance Report~~

~~[Any abnormal degradation of the containment structure detected during the tests required by the Pre-stressed Concrete Containment Tendon Surveillance Program shall be reported to the NRC within 30 days. The report shall include a description of the tendon condition, the condition of the concrete (especially at tendon anchorages), the inspection procedures, the tolerances on cracking, and the corrective action taken.]~~

5

1

6.9.1.12

5.6.~~7~~ Steam Generator Tube Inspection Report

5

A report shall be submitted within 180 days after the initial entry into MODE 4 following completion of an inspection performed in accordance with the Specification ~~5.5.9~~ 5.5.6, "Steam Generator (SG) Program." The report shall include:

6.9.1.12.a

a. The scope of inspections performed on each SG;

DOC M02

b. The nondestructive examination techniques utilized for tubes with increased degradation susceptibility;

c. For each degradation mechanism found:

6.9.1.12.c

1. The nondestructive examination techniques utilized;

5.6 Reporting Requirements

6.9.1.12 5.6.~~7~~ 5 Steam Generator Tube Inspection Report (continued) 1

6.9.1.12.d DOC A03

2. The location, orientation (if linear), measured size (if available), and voltage response for each indication. For tube wear at support structures less than 20 percent through-wall, only the total number of indications needs to be reported;

6.9.1.12.g DOC A03

3. A description of the condition monitoring assessment and results, including the margin to the tube integrity performance criteria and comparison with the margin predicted to exist at the inspection by the previous forward-looking tube integrity assessment;

6.9.1.12.e

4. The number of tubes plugged ~~[or repaired]~~ during the inspection outage~~;~~. and

~~[5. The repair methods utilized and the number of tubes repaired by each repair method.]~~ 2

DOC M02

d. An analysis summary of the tube integrity conditions predicted to exist at the next scheduled inspection (the forward-looking tube integrity assessment) relative to the applicable performance criteria, including the analysis methodology, inputs, and results;

6.9.1.12.f 6.9.1.12.h

e. The number and percentage of tubes plugged ~~[or repaired]~~ to date, and the effective plugging percentage in each SG; 2

DOC M02

f. The results of any SG secondary side inspections~~;~~. and

~~[g. Insert any plant-specific reporting requirements, if applicable.]~~ 2

JUSTIFICATION FOR DEVIATIONS
5.6, REPORTING REQUIREMENTS

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

4. ISTS 5.6.4 provides requirements for the RCS Pressure and Temperature Limits report. PSL is not adopting a Pressure Temperature Limits Report (PTLR) and is retaining the RCS Pressure and Temperature (P/T) limits in the ITS 3.4.3, RCS Pressure and Temperature (P/T) Limits. Therefore, this report is not included in the PSL ITS, consistent with the current licensing basis. Subsequent Specifications are renumbered as a result of this deletion.

5. ISTS 5.6.6 provides requirements for the Tendon Surveillance Report. The Containment design at PSL does not include pre-stressed concrete tendons. Therefore, this report is not included in the PSL ITS, consistent with the current licensing basis. Subsequent Specifications are renumbered as a result of this deletion.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 5.6, REPORTING REQUIREMENTS

There are no specific No Significant Hazards Considerations for this Specification.

ATTACHMENT 7

ITS Section 5.7, High Radiation Area

Current Technical Specifications (CTS) Markup and Discussion of Changes (DOCs)

ADMINISTRATIVE CONTROLS

6.12 HIGH RADIATION AREA

As provided in paragraph 20.1601(c) of 10 CFR Part 20, the following controls shall be applied to high radiation areas in place of the controls

and b

5.7 6.12.1 ~~In lieu of the "control device" or "alarm signal"~~ required by paragraph 20.1601(a) of 10 CFR Part 20, each high radiation area in which the intensity of radiation is greater than 100 mrem/hr but less than 1000 mrem/hr measured at a distance of 30 cm (12 in) shall be barricaded and conspicuously 5.7.1 posted as a high radiation area and entrance thereto shall be controlled by requiring issuance of a Radiation Work Permit (RWP)*. Any individual or group of individuals permitted to enter such areas shall be provided with or accompanied by one or more of the following:

a. A radiation monitoring device which continuously indicates the radiation dose rate in the area.

b. A radiation monitoring device which continuously integrates the radiation dose rate in the area and alarms when a preset integrated dose is received. Entry into such areas with this monitoring device may be made after the dose rate level in the area has been established and personnel have been made knowledgeable of them.

c. An ~~health physics qualified~~ individual ~~(i.e.,~~ qualified in radiation protection procedures~~)~~ with a radiation dose rate monitoring device who is responsible for providing positive control over the activities within the area and shall perform periodic radiation surveillance at the frequency ~~specified by the facility Health Physicist~~ in the RWP.

A02

LA01

LA02 A02

6.12.2 In addition to the requirements of Specification 6.12.1, areas accessible to personnel with radiation levels in excess of 1000 mrem/hr at 30 cm (12 in) and less than 500 rad/hr at 1 meter shall be provided with locked doors to prevent unauthorized entry, and the keys shall be maintained under the administrative control of the ~~Shift Foreman on duty and/or health physics supervision~~. Doors shall remain locked except during periods of access by personnel under an approved RWP which shall specify the dose rate levels in 5.7.2 the immediate work area and the maximum allowable stay time for individuals in that area. For individual areas accessible to personnel with radiation levels in excess of 1000 mrem/hr at 30 cm (12 in) and less than 500 rads/hr at 1 meter that are located within large areas, such as PWR containment, where no enclosure exists for purposes of locking, and no enclosure can be reasonably constructed around the individual areas, then that area shall be roped off, conspicuously posted and a flashing light shall be activated as a warning device. In lieu of the stay time specification of the RWP, direct or remote (such as use of closed circuit TV cameras) continuous surveillance may be made by personnel qualified in radiation protection procedures to provide positive exposure control over the activities within the area.

shift supervisor, radiation protection manager, or his or her designee.

radiation protection

radiation protection

A02

5.7.1 * ~~Health Physics~~ personnel or personnel escorted by ~~Health Physics~~ personnel shall be exempt from the RWP issuance requirement during the performance of their assigned radiation protection duties, provided they are otherwise following plant radiation protection procedures for entry into high radiation areas.

ADMINISTRATIVE CONTROLS

6.12 HIGH RADIATION AREA

As provided in paragraph 20.1601(c) of 10 CFR Part 20, the following controls shall be applied to high radiation areas in place of the controls

5.7 6.12.1 ~~In lieu of the "control device" or "alarm signal"~~ required by paragraph 20.1601(a) of 10 CFR Part 20, each high radiation area in which the intensity of radiation is greater than 100 mrem/hr but less than 1000 mrem/hr measured at a distance of 30 cm (12 in) shall be barricaded and conspicuously 5.7.1 posted as a high radiation area and entrance thereto shall be controlled by requiring issuance of a Radiation Work Permit (RWP)*. Any individual or group of individuals permitted to enter such areas shall be provided with or accompanied by one or more of the following:

a. A radiation monitoring device which continuously indicates the radiation dose rate in the area.

b. A radiation monitoring device which continuously integrates the radiation dose rate in the area and alarms when a preset integrated dose is received. Entry into such areas with this monitoring device may be made after the dose rate level in the area has been established and personnel have bee made knowledgeable of them.

c. An ~~health physics qualified~~ individual ~~(i.e.,~~ qualified in radiation protection procedures~~)~~ with a radiation dose rate monitoring device who is responsible for providing position control over the activities within the area and shall perform periodic radiation surveillance at the frequency specified ~~by the facility Health Physicist~~ in the RWP.

A02 LA01

6.12.2 In addition to the requirements of Specification 6.12.1, areas accessible to personnel with radiation levels in excess of 1000 mrem/hr at 30 cm (12 in) and less than 500 rad/hr at 1 meter shall be provided with locked doors to prevent unauthorized entry, and the keys shall be maintained under the administrative control of the ~~Shift Foreman on duty and/or health physics supervision~~. Doors shall remain locked except during periods of access by personnel under an approved RWP which shall specify the dose rate levels in the immediate work area and the maximum allowable stay time for individuals in 5.7.2 that area. For individual areas accessible to personnel with radiation levels in excess of 1000 mrem/hr at 30 cm (12 in) and less than 500 rads/hr at 1 meter that are located within large areas, such as PWR containment, where no enclosure exists for purposes of locking, and no enclosure can be reasonably constructed around the individual areas, then that area shall be roped off, conspicuously posted and a flashing light shall be activated as a warning device. In lieu of the stay time specification of the RWP, direct or remote (such as use of closed circuit TV cameras) continuous surveillance may be made by personnel qualified in radiation protection procedures to provide positive exposure control over the activities within the area.

shift supervisor, radiation protection manager, or his or her designee.

radiation protection

radiation protection

A02

* ~~Health Physics~~ personnel or personnel escorted by ~~Health Physics~~ personnel 5.7.1 shall be exempt for the RWP issuance requirement during the performance of their assigned radiation protection duties, provided they are otherwise following plant radiation protection procedures for entry into high radiation areas.

DISCUSSION OF CHANGES
ITS 5.7, HIGH RADIATION AREA

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 6.12 specifies “health physics” personnel when referring to radiation protection qualified individuals, supervision, and personnel exempt from radiation work permits (RWPs). PSL does not use the term “health physics” when referring to these personnel but rather uses the term “radiation protection.” ITS 5.7 replaces the term “health physics” with “radiation protection.” This changes the CTS by replacing references to health physics personnel with radiation protection personnel. Specifically, a health physics qualified individual is replaced with an individual qualified in radiation protection procedures; health physics supervision is replaced with radiation protection manager, or his or her designee; and health physics personnel is replaced with radiation protection personnel. These changes are consistent with the ISTS and are designated as administrative because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 (*Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements*) CTS 6.12.1.c, states, in part, that the health physics qualified individual responsible for positive control over the activities within the high radiation area shall also perform periodic radiation surveillance at the frequency specified by the facility Health Physicist in the RWP. ITS 5.7.1.c provides a similar requirement but does not specify that the frequency of radiation monitoring specified in the RWP is specified by the facility Health Physicist. This changes the CTS by moving the procedural detail that the frequency of radiation monitoring is specified by the facility Health Physicist to the Updated Final Safety Analysis Report (UFSAR).

The removal of these details, which are related to who establishes the frequency of radiation monitoring in the RWP, from the Technical Specifications is

acceptable because this type of information is not necessary to be included in Technical Specifications to provide adequate protection of public health and safety. Implementation of radiation work procedures, including RWPs, are the responsibility of the radiation protection manager (i.e., facility Health Physicist). This change is acceptable because the individual qualified in radiation protection procedures (i.e., health physics qualified individual) who is responsible for providing positive control over the activities within the area will continue to be required to perform periodic radiation surveillance at the frequency specified in the RWP independent of who is responsible for establishing the surveillance frequency. This change is also acceptable because the removed information will be adequately controlled in the UFSAR. Any changes to the UFSAR are made pursuant to 10 CFR 50.59 or 10 CFR 50.71(e). These change control processes ensure changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information related to meeting Technical Specification requirements are being removed from the Technical Specifications.

LA02 (*Type 4 – Removal of LCO, SR, or other TS requirements to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program or Surveillance Frequency Control Program*) CTS 6.12.2 uses the title "Shift Foreman." ITS 5.7.2 uses the generic title "shift supervisor." This changes the CTS by moving the specific PSL organizational title to the UFSAR or the Quality Assurance Topical Report (QATR) and replacing it with a generic title.

The removal of these details, which are related to meeting Technical Specification requirements, from the Technical Specifications is acceptable because this type of information is not necessary to be included in Technical Specifications to provide adequate protection of public health and safety. The allowance to relocate the specific PSL organizational titles out of the Technical Specifications is consistent with the NRC letter from C. Grimes to the Owners Groups Technical Specification Committee Chairmen, dated November 10, 1994. The various requirements of the shift supervisor are retained in the ITS. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR or the QATR. Any changes to the UFSAR are made pursuant to 10 CFR 50.59 or 10 CFR 50.71(e) and changes to the QATR are made pursuant to 10 CFR 50.54(a). These change control processes ensure changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information related to meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

None

Improved Standard Technical Specifications (ISTS) Markup and Justification for Deviations (JFDs)

5.0 ADMINISTRATIVE CONTROLS

5.7 High Radiation Area

6.12.1 As provided in paragraph 20.1601(c) of 10 CFR Part 20, the following controls shall be applied to high radiation areas in place of the controls required by paragraph 20.1601(a) and (b) of 10 CFR Part 20:

Insert 1

1

~~5.7.1 High Radiation Areas with Dose Rates Not Exceeding 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation~~

~~a. Each entryway to such an area shall be barricaded and conspicuously posted as a high radiation area. Such barricades may be opened as necessary to permit entry or exit of personnel or equipment.~~

~~b. Access to, and activities in, each such area shall be controlled by means of Radiation Work Permit (RWP) or equivalent that includes specification or radiation dose rates in the immediate work area(s) and other appropriate radiation protection equipment and measurers.~~

~~c. Individuals qualified in radiation protection procedures and personnel continuously escorted by such individuals may be exempted from the requirement for an RWP or equivalent while performing their assigned duties provided that they are otherwise following plant radiation protection procedures for entry to, exit from, and work in such areas.~~

~~d. Each individual or group entering such an area shall possess:~~

~~1. A radiation monitoring device that continuously displays radiation dose rates in the area, or~~

~~2. A radiation monitoring device that continuously integrates the radiation dose rates in the area and alarms when the device's dose alarm setpoint is reached, with an appropriate alarm setpoint, or~~

~~3. A radiation monitoring device that continuously transmits dose rate and cumulative dose information to a remote receiver monitored by radiation protection personnel responsible for controlling personnel radiation exposure within the area, or~~

~~4. A self-reading dosimeter (e.g., pocket ionization chamber or electronic dosimeter) and,~~

1

Insert 1

6.12.1 including footnote*

5.7.1 Each high radiation area in which the intensity of radiation is greater than 100 mrem/hr but less than 1000 mrem/hr measured at a distance of 30 cm (12 in) shall be barricaded and conspicuously posted as a high radiation area and entrance thereto shall be controlled by requiring issuance of a Radiation Work Permit (RWP). Radiation protection personnel or personnel escorted by radiation protection personnel shall be exempt for the RWP issuance requirement during the performance of their assigned radiation protection duties, provided they are otherwise following plant radiation protection procedures for entry into high radiation areas. Any individual or group of individuals permitted to enter such areas shall be provided with or accompanied by one or more of the following:

a. A radiation monitoring device which continuously indicates the radiation dose rate in the area.

b. A radiation monitoring device which continuously integrates the radiation dose rate in the area and alarms when a preset integrated dose is received. Entry into such areas with this monitoring device may be made after the dose rate level in the area has been established and personnel have been made knowledgeable of them.

c. An individual qualified in radiation protection procedures with a radiation dose rate monitoring device who is responsible for providing positive control over the activities within the area and shall perform periodic radiation surveillance at the frequency specified in the RWP.

6.12.2

5.7.2 In addition to the requirements of Specification 5.7.1, areas accessible to personnel with radiation levels in excess of 1000 mrem/hr at 30 cm (12 in) and less than 500 rad/hr at 1 meter shall be provided with locked doors to prevent unauthorized entry, and the keys shall be maintained under the administrative control of the shift supervisor, radiation protection manager, or his or her designee. Doors shall remain locked except during periods of access by personnel under an approved RWP which shall specify the dose rate levels in the immediate work area and the maximum allowable stay time for individuals in that area. For individual areas accessible to personnel with radiation levels in excess of 1000 mrem/hr at 30 cm (12 in) and less than 500 rads/hr at 1 meter that are located within large areas, such as PWR containment, where no enclosure exists for purposes of locking, and no enclosure can be reasonably constructed around the individual areas, then that area shall be roped off, conspicuously posted and a flashing light shall be activated as a warning device. In lieu of the stay time specification of the RWP, direct or remote (such as use of closed circuit TV cameras) continuous surveillance may be made by personnel qualified in radiation protection procedures to provide positive exposure control over the activities within the area.

5.7 High Radiation Area

5.7.1 High Radiation Areas with Dose Rates Not Exceeding 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation (continued) 1

(i) Be under the surveillance, as specified in the RWP or equivalent, while in the area, of an individual qualified in radiation protection procedures, equipped with a radiation monitoring device that continuously displays radiation dose rates in the area; who is responsible for controlling personnel exposure within the area, or

(ii) Be under the surveillance, as specified in the RWP or equivalent, while in the area, by means of closed circuit television, or personnel qualified in radiation protection procedures, responsible for controlling personnel radiation exposure in the area, and with the means to communicate with individuals in the area who are covered by such surveillance.

e. Except for individuals qualified in radiation protection procedures, or personnel continuously escorted by such individuals, entry into such areas shall be made only after dose rates in the area have been determined and entry personnel are knowledgeable of them. These continuously escorted personnel will receive a pre-job briefing prior to entry into such areas. This dose rate determination, knowledge, and pre-job briefing does not require documentation prior to initial entry.

5.7.2 High Radiation Areas with Dose Rates Greater than 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation, but less than 500 rads/hour at 1 Meter from the Radiation Source or from any Surface Penetrated by the Radiation

a. Each entryway to such an area shall be conspicuously posted as a high radiation area and shall be provided with a locked or continuously guarded door or gate that prevents unauthorized entry, and, in addition:

1. All such door and gate keys shall be maintained under the administrative control of the shift supervisor, radiation protection manager, or his or her designee.

2. Doors and gates shall remain locked except during periods of personnel or equipment entry or exit.

b. Access to, and activities in, each such area shall be controlled by means of an RWP or equivalent that includes specification of radiation dose rates in the immediate work area(s) and other appropriate radiation protection equipment and measures.

5.7 High Radiation Area

5.7.2 High Radiation Areas with Dose Rates Greater than 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation, but less than 500 rads/hour at 1 Meter from the Radiation Source or from any Surface Penetrated by the Radiation (continued) 1

c. Individuals qualified in radiation protection procedures my be exempted from the requirement for an RWP or equivalent while performing radiation surveys in such areas provided that they are otherwise following plant radiation protection procedures for entry to, exit from, and work in such areas.

d. Each individual or group entering such an area shall possess:

1. A radiation monitoring device that continuously integrates the radiation rates in the area and alarms when the device's dose alarm setpoint is reached, with an appropriate alarm setpoint, or

2. A radiation monitoring device that continuously transmits dose rate and cumulative dose information to a remote receiver monitored by radiation protection personnel responsible for controlling personnel radiation exposure within the area with the means to communicate with and control every individual in the area, or

3. A self-reading dosimeter (e.g., pocket ionization chamber or electronic dosimeter) and

(i) Be under the surveillance, as specified in the RWP or equivalent, while in the area, of an individual qualified in radiation protection procedures, equipped with a radiation monitoring device that continuously displays radiation dose rates in the area; who is responsible for controlling personnel exposure within the area, or

(ii) Be under the surveillance, as specified in the RWP or equivalent, while in the area, by means of closed circuit television, of personnel qualified in radiation protection procedures, responsible for controlling personnel radiation exposure in the area, and with the means to communicate with and control every individual in the area.

4. In those cases where options (2) and (3), above, are impractical or determined to be inconsistent with the "As Low As is Reasonably Achievable" principle, a radiation monitoring device that continuously displays radiation dose rates in the area.

5.7 High Radiation Area

5.7.2 High Radiation Areas with Dose Rates Greater than 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation, but less than 500 rads/hour at 1 Meter from the Radiation Source or from any Surface Penetrated by the Radiation (continued) 1

e. Except for individuals qualified in radiation protection procedures, or personnel continuously escorted by such individuals, entry into such areas shall be made only after dose rates in the area have been determined and entry personnel are knowledgeable of them. These continuously escorted personnel will receive a pre-job briefing prior to entry into such areas. This dose rate determination, knowledge, and pre-job briefing does not require documentation prior to initial entry.

f. Such individual areas that are within a larger area where no enclosure exists for the purpose of locking and where no enclosure can reasonably be constructed around the individual area need not be controlled by a locked door or gate, nor continuously guarded, but shall be barricaded, conspicuously posted, and a clearly visible flashing light shall be activated at the area as a warning device.

5.0 ADMINISTRATIVE CONTROLS

5.7 High Radiation Area

6.12.1 As provided in paragraph 20.1601(c) of 10 CFR Part 20, the following controls shall be applied to high radiation areas in place of the controls required by paragraph 20.1601(a) and (b) of 10 CFR Part 20:

Insert 1

1

~~5.7.1 High Radiation Areas with Dose Rates Not Exceeding 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation~~

~~a. Each entryway to such an area shall be barricaded and conspicuously posted as a high radiation area. Such barricades may be opened as necessary to permit entry or exit of personnel or equipment.~~

~~b. Access to, and activities in, each such area shall be controlled by means of Radiation Work Permit (RWP) or equivalent that includes specification or radiation dose rates in the immediate work area(s) and other appropriate radiation protection equipment and measurers.~~

~~c. Individuals qualified in radiation protection procedures and personnel continuously escorted by such individuals may be exempted from the requirement for an RWP or equivalent while performing their assigned duties provided that they are otherwise following plant radiation protection procedures for entry to, exit from, and work in such areas.~~

~~d. Each individual or group entering such an area shall possess:~~

~~1. A radiation monitoring device that continuously displays radiation dose rates in the area, or~~

~~2. A radiation monitoring device that continuously integrates the radiation dose rates in the area and alarms when the device's dose alarm setpoint is reached, with an appropriate alarm setpoint, or~~

~~3. A radiation monitoring device that continuously transmits dose rate and cumulative dose information to a remote receiver monitored by radiation protection personnel responsible for controlling personnel radiation exposure within the area, or~~

~~4. A self-reading dosimeter (e.g., pocket ionization chamber or electronic dosimeter) and,~~

1

Insert 1

6.12.1 including footnote*

5.7.1 Each high radiation area in which the intensity of radiation is greater than 100 mrem/hr but less than 1000 mrem/hr measured at a distance of 30 cm (12 in) shall be barricaded and conspicuously posted as a high radiation area and entrance thereto shall be controlled by requiring issuance of a Radiation Work Permit (RWP). Radiation protection personnel or personnel escorted by radiation protection personnel shall be exempt for the RWP issuance requirement during the performance of their assigned radiation protection duties, provided they are otherwise following plant radiation protection procedures for entry into high radiation areas. Any individual or group of individuals permitted to enter such areas shall be provided with or accompanied by one or more of the following:

a. A radiation monitoring device which continuously indicates the radiation dose rate in the area.

b. A radiation monitoring device which continuously integrates the radiation dose rate in the area and alarms when a preset integrated dose is received. Entry into such areas with this monitoring device may be made after the dose rate level in the area has been established and personnel have been made knowledgeable of them.

c. An individual qualified in radiation protection procedures with a radiation dose rate monitoring device who is responsible for providing positive control over the activities within the area and shall perform periodic radiation surveillance at the frequency specified in the RWP.

6.12.2

5.7.2 In addition to the requirements of Specification 5.7.1, areas accessible to personnel with radiation levels in excess of 1000 mrem/hr at 30 cm (12 in) and less than 500 rad/hr at 1 meter shall be provided with locked doors to prevent unauthorized entry, and the keys shall be maintained under the administrative control of the shift supervisor, radiation protection manager, or his or her designee. Doors shall remain locked except during periods of access by personnel under an approved RWP which shall specify the dose rate levels in the immediate work area and the maximum allowable stay time for individuals in that area. For individual areas accessible to personnel with radiation levels in excess of 1000 mrem/hr at 30 cm (12 in) and less than 500 rads/hr at 1 meter that are located within large areas, such as PWR containment, where no enclosure exists for purposes of locking, and no enclosure can be reasonably constructed around the individual areas, then that area shall be roped off, conspicuously posted and a flashing light shall be activated as a warning device. In lieu of the stay time specification of the RWP, direct or remote (such as use of closed circuit TV cameras) continuous surveillance may be made by personnel qualified in radiation protection procedures to provide positive exposure control over the activities within the area.

5.7 High Radiation Area

5.7.1 High Radiation Areas with Dose Rates Not Exceeding 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation (continued) 1

(i) Be under the surveillance, as specified in the RWP or equivalent, while in the area, of an individual qualified in radiation protection procedures, equipped with a radiation monitoring device that continuously displays radiation dose rates in the area; who is responsible for controlling personnel exposure within the area, or

(ii) Be under the surveillance, as specified in the RWP or equivalent, while in the area, by means of closed circuit television, or personnel qualified in radiation protection procedures, responsible for controlling personnel radiation exposure in the area, and with the means to communicate with individuals in the area who are covered by such surveillance.

e. Except for individuals qualified in radiation protection procedures, or personnel continuously escorted by such individuals, entry into such areas shall be made only after dose rates in the area have been determined and entry personnel are knowledgeable of them. These continuously escorted personnel will receive a pre-job briefing prior to entry into such areas. This dose rate determination, knowledge, and pre-job briefing does not require documentation prior to initial entry.

5.7.2 High Radiation Areas with Dose Rates Greater than 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation, but less than 500 rads/hour at 1 Meter from the Radiation Source or from any Surface Penetrated by the Radiation

a. Each entryway to such an area shall be conspicuously posted as a high radiation area and shall be provided with a locked or continuously guarded door or gate that prevents unauthorized entry, and, in addition:

1. All such door and gate keys shall be maintained under the administrative control of the shift supervisor, radiation protection manager, or his or her designee.

2. Doors and gates shall remain locked except during periods of personnel or equipment entry or exit.

b. Access to, and activities in, each such area shall be controlled by means of an RWP or equivalent that includes specification of radiation dose rates in the immediate work area(s) and other appropriate radiation protection equipment and measures.

5.7 High Radiation Area

5.7.2 High Radiation Areas with Dose Rates Greater than 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation, but less than 500 rads/hour at 1 Meter from the Radiation Source or from any Surface Penetrated by the Radiation (continued) 1

c. Individuals qualified in radiation protection procedures my be exempted from the requirement for an RWP or equivalent while performing radiation surveys in such areas provided that they are otherwise following plant radiation protection procedures for entry to, exit from, and work in such areas.

d. Each individual or group entering such an area shall possess:

1. A radiation monitoring device that continuously integrates the radiation rates in the area and alarms when the device's dose alarm setpoint is reached, with an appropriate alarm setpoint, or

2. A radiation monitoring device that continuously transmits dose rate and cumulative dose information to a remote receiver monitored by radiation protection personnel responsible for controlling personnel radiation exposure within the area with the means to communicate with and control every individual in the area, or

3. A self-reading dosimeter (e.g., pocket ionization chamber or electronic dosimeter) and

(i) Be under the surveillance, as specified in the RWP or equivalent, while in the area, of an individual qualified in radiation protection procedures, equipped with a radiation monitoring device that continuously displays radiation dose rates in the area; who is responsible for controlling personnel exposure within the area, or

(ii) Be under the surveillance, as specified in the RWP or equivalent, while in the area, by means of closed circuit television, of personnel qualified in radiation protection procedures, responsible for controlling personnel radiation exposure in the area, and with the means to communicate with and control every individual in the area.

4. In those cases where options (2) and (3), above, are impractical or determined to be inconsistent with the "As Low As is Reasonably Achievable" principle, a radiation monitoring device that continuously displays radiation dose rates in the area.

5.7 High Radiation Area

5.7.2 High Radiation Areas with Dose Rates Greater than 1.0 rem/hour at 30 Centimeters from the Radiation Source or from any Surface Penetrated by the Radiation, but less than 500 rads/hour at 1 Meter from the Radiation Source or from any Surface Penetrated by the Radiation (continued) 1

e. Except for individuals qualified in radiation protection procedures, or personnel continuously escorted by such individuals, entry into such areas shall be made only after dose rates in the area have been determined and entry personnel are knowledgeable of them. These continuously escorted personnel will receive a pre-job briefing prior to entry into such areas. This dose rate determination, knowledge, and pre-job briefing does not require documentation prior to initial entry.

f. Such individual areas that are within a larger area where no enclosure exists for the purpose of locking and where no enclosure can reasonably be constructed around the individual area need not be controlled by a locked door or gate, nor continuously guarded, but shall be barricaded, conspicuously posted, and a clearly visible flashing light shall be activated at the area as a warning device.

JUSTIFICATION FOR DEVIATIONS
ITS 5.7, HIGH RADIATION AREA

1. ISTS 5.7 provides requirements for High Radiation Areas. The brackets are removed and the proper plant specific information/value is provided. ITS 5.5.7 is revised to reflect the St. Lucie Plant Unit 1 and Unit 2 current licensing basis and high radiation area controls The change is consistent with the requirements in CTS 6.12.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 5.7, HIGH RADIATION AREA

There are no specific No Significant Hazards Considerations for this Section.

REMOVED DETAIL CHANGES

LA01 *(Type 6 - Removal of LCO, SR, or other TS requirements to the TRM, UFSAR, ODCM, QAPD, or IIP)* CTS 6.11 provides requirements for the Radiation Protection Program. The ITS does not include these requirements. This changes the CTS by moving the requirements for the Radiation Protection Program to the UFSAR.

The removal of these requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The Radiation Protection Program requires procedures to be prepared for personnel radiation protection consistent with 10 CFR 20. These procedures are for nuclear plant personnel and have no impact on nuclear safety or the health and safety of the public. Requirements to have procedures to implement 10 CFR 20 are contained in 10 CFR 20.1101(b). Periodic review of these procedures is addressed in 10 CFR 20.1101(c). Since the PSL Units 1 and 2 Operating Licenses require compliance with 10 CFR 20, there is no need to repeat the requirements in the ITS. As such, the relocated details are not required to be in the ITS to provide adequate protection of the public health and safety. Also, this change is acceptable because these details will be adequately controlled in the UFSAR. Any changes to the UFSAR are made under 10 CFR 50.59 or 10 CFR 50.71(e), which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because details for meeting Technical Specification and regulatory requirements are being removed from the Technical Specifications.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 6 - Removal of LCO, SR, or other TS requirements to the TRM, UFSAR, ODCM, QAPD, or IIP)* CTS Definition 1.23 contains the definition for the Process Control Program (PCP). CTS 6.13 describes the process for control of changes to the PCP. The ITS does not include these requirements. This changes the CTS by moving the requirements of the PCP to the UFSAR.

The removal of these requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The PCP implements the requirements of 10 CFR 20, 10 CFR 61, and 10 CFR 71. Compliance with these regulations is required by the PSL Units 1 and 2 Operating Licenses, and procedures are the method to ensure compliance with the program. Regulations provide an adequate level of control for the affected requirements and inclusion of this requirement in the Technical Specifications is not necessary. Also, this change is acceptable because these details will be adequately controlled in the UFSAR. Any changes to the UFSAR are made under 10 CFR 50.59 or 10 CFR 50.71(e), which ensures changes are properly evaluated. This change is designated as a less restrictive removal of requirements because details for meeting Technical Specification and regulatory requirements are being removed from the Technical Specifications.

ENCLOSURE 3

LICENSEE IDENTIFIED CHANGES THAT MAY REQUIRE TECHNICAL BRANCH REVIEW

(2 TOTAL PAGES, INCLUDING COVER SHEETS)

LICENSEE IDENTIFIED CHANGES THAT MAY REQUIRE TECHNICAL BRANCH REVIEW

Changes included in the Improved Technical Specifications (ITS) conversion submittal that are not consistent with the Current Technical Specifications (CTS) and are not the result of adopting the Improved Standard Technical Specifications (ISTS) as described in NUREG-1432, Rev. 5.0. The following is a list of changes identified in Enclosure 2 that meet this criterion in the St. Lucie Plant (PSL), Unit 1 and Unit 2 ITS conversion submittal, but do not involve a design change to the plant:

1. Change to Engineered Safety Features Actuation System (ESFAS) Main Steam Isolation Signal (MSIS) manual and automatic actuation logic Applicability and action change to match the supported system's Technical Specifications actions. The change is not technical in nature, but rather aligns the MSIS instrumentation actions with the supported system actions. (Refer to Enclosure 2, Volume 8, ITS Section 3.3.4, Discussion of Change (DOC) L01)

2. Add risk informed completion time (RICT) to Unit 1 ESFAS automatic actuation logic and Unit 2 ESFAS MSIS manual actuation. The change is supported by the existing RICT Program and configuration risk management program previously approved in License Amendments 247 and 199, for Unit 1 and Unit 2, respectively. Unit 2 ESFAS automatic actuation logic already applies RICT and both Unit 1 and Unit 2 already apply RICT to manual actuation channels. (Refer to Enclosure 2, Volume 8, ITS 3.3.4 DOCs L04 and L05)

3. Add previously approved program requirements in the Unit 2 Reactor Coolant Pump (RCP) Flywheel Program in addition to the current requirements based on the RCP Flywheel material. In addition, RCP Flywheel Program are proposed for the Unit 1 Technical Specifications and include the same requirements based on RCP flywheel material. Both testing methods have been previously approved by the NRC for PSL. (Refer to Enclosure 2, Volume 16, ITS 5.5, DOCs M01 and L02)

4. The periodic frequency of selected Surveillances in ITS Section 5.5 are proposed to be relocated to the Surveillance Frequency Control Program (SFCP). This deviation from ISTS Rev. 5 and Technical Specification Task Force (TSTF) Traveler TSTF-425 has been previously approved for at least three (3) plants. PSL currently has an approved SFCP. (Refer to Enclosure 2, Volume 16, ITS 5.5, DOC LA01)

ENCLOSURE 5

REGULATORY COMMITMENTS

(2 TOTAL PAGES, INCLUDING COVER SHEETS)

REGULATORY COMMITMENTS

No.	Commitments for TSTF-500	Due Date/Event
1	Revise or develop plant procedures, as applicable, to address the following: • minimum required procedural time to measure battery float current is at least 30 seconds or as recommended by the float current measurement instrument manufacturer. This minimum float current measurement time is required to provide a more accurate battery float current reading. • routinely monitor battery room temperature such that a room temperature excursion could reasonably expect to be detected and corrected prior to the average battery electrolyte temperature dropping below the minimum electrolyte temperature. • verification of the selection of the pilot cell or cells when performing the Surveillance that verifies the float voltage of each connected battery cell. • ensure that the modified performance discharge test completely encompasses the load profile of the battery service test and that it adequately confirms the intent of the service test to verify the battery capacity to supply the design basis load profile.	Upon Implementation
2	Relocate the following requirements to the Battery Monitoring and Maintenance Program and implementing procedures: • Battery cell resistance limits in existing Surveillance • Monitoring of battery parameters (i.e., specific gravity, electrolyte level, cell temperature, float voltage, connection resistance, and physical condition)	Upon Implementation

LIST OF REQUIRED UPDATED FINAL SAFETY ANALYSIS REPORT (UFSAR) DESCRIPTIONS FOR TSTF 500

(2 TOTAL PAGES, INCLUDING COVER SHEETS)

LIST OF REQUIRED UPDATED FINAL SAFETY ANALYSIS REPORT (UFSAR) DESCRIPTIONS FOR TSTF-500

The following table identifies UFSAR descriptions for the 125 VDC batteries required by St. Lucie Plant (PSL), Units 1 and Unit 2, as part of the adoption of TSTF-500, "DC Electrical Rewrite - Update to TSTF-360," Revision 2. These changes will be included with the required implementation date in the Issuance of Amendment letter.

REQUIRED UFSAR DESCRIPTION	DUE DATE/EVENT
PSL will change or verify that the UFSAR: 1. Describes how a 5 percent design margin for the batteries corresponds to a 2 amp float current value indicating that the battery is 95 percent charged. 2. States that long term battery performance is supported by maintaining a float voltage greater than or equal to the minimum established design limits provided by the battery manufacturer. 3. Describes how the batteries are sized with correction margins that include temperature and aging and how these margins are maintained. 4. States the minimum established design limit for battery terminal float voltage. 5. States the minimum established design limit for electrolyte level. 6. States the minimum established design limit for electrolyte temperature. 7. Describes how each battery is designed with additional capacity above that required by the design duty cycles to allow for temperature variations and other factors. 8. Describes normal DC system operation, i.e., powered from the battery chargers with the batteries floating on the system, and a loss of normal power to the battery charger describing how the DC load is automatically powered from the station batteries.	Upon implementation (applies to all)
