~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~ 3

If the RWT boron concentration is not restored to within limits within the associated Completion Time, the plant must be brought to MODE 3 within 6 hours. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant

BASES

ACTIONS (continued)

systems. Reference 2 demonstrated that is it acceptable to remain in MODE 3 in this condition because the boron concentration limit is based on MODE 1 events which are unlikely in MODE 3, such as a LOCA, and conditions which do not exist in MODE 3, such as a critical core with all rods out. Since the anticipated deviations from the RWT boron concentration requirements are expected to be small and the ability to correct the deficiency is expected to be readily available, entry into MODE 4 or 5 is not necessary.

Required Action B.1 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 3 or MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 3 or MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

C.1

With RWT water temperature not within limits, it must be returned to within limits within 8 hours. In this condition neither the ECCS nor the Containment Spray System can perform their design functions; therefore, prompt action must be taken to restore the tank to OPERABLE condition. The allowed Completion Time of 8 hours to restore the RWT to within limits was developed considering the time required to change water temperature and that the contents of the tank are still available for injection.

D.1 or RWT inoperable for reasons other than boron concentration, borated water temperature, or borated water volume, 1

With RWT borated water volume not within limits, it must be returned to within limits within 1 hour. In this condition, neither the ECCS nor Containment Spray System can perform their design functions; therefore, prompt action must be taken to restore the tank to OPERABLE status or to place the unit in a MODE in which these systems are not required. The allowed Completion Time of 1 hour to restore the RWT to OPERABLE status is based on this condition simultaneously affecting multiple redundant trains.

BASES

ACTIONS (continued)

E.1 and E.2

If the RWT temperature or water volume cannot be restored to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.5.4.1

RWT borated water temperature shall be verified to be within the limits assumed in the accident analysis. ~~[This Frequency of 24 hours has been shown to be sufficient to identify temperature changes that approach either acceptable limit.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 4
~~]~~

The SR is modified by a Note that eliminates the requirement to perform this Surveillance when ambient air temperatures are within the operating temperature limits of the RWT. With ambient temperatures within this range, the RWT temperature should not exceed the limits.

SR 3.5.4.2

Above minimum RWT water volume level shall be verified. This Frequency ensures that a sufficient initial water supply is available for injection and to support continued ESF pump operation on recirculation. ~~[Since the RWT volume is normally stable and is provided with a Low Level Alarm, a 7 day Frequency is appropriate and has been shown to be acceptable through operating experience.~~ 2

~~OR~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~ 2

SR 3.5.4.3

Boron concentration of the RWT shall be verified to be within the required range. This Frequency ensures that the reactor will remain subcritical following a LOCA. Further, it ensures that the resulting sump pH will be maintained in an acceptable range such that boron precipitation in the core will not occur earlier than predicted and the effect of chloride and caustic stress corrosion on mechanical systems and components will be minimized~~. [Since the RWT volume is normally stable, a 7 day sampling Frequency is appropriate and has been shown through operating experience to be acceptable.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.5.4, BASES, REFUELING WATER TANK (RWT)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The Reviewer's Note has been deleted. The Reviewer's Note provides the NRC Reviewer information needed to meet the requirements. This Note is not meant to be retained in the final version of the plant specific submittal.

   CTS 3.5.4 ACTION, states, "With the refueling water tank inoperable, restore the tank to OPERABLE status within 1 hour or be in at least HOT STANDBY within 6 hours and in COLD SHUTDOWN within the following 30 hours." ITS 3.5.4 ACTION A allows 8 hours to restore the RWT to OPERABLE status if the inoperability is due to the RWT boron concentration not within limits. ITS ACTION B requires that with the Required Action and associated Completion Time of Condition A (boron concentration) not met, then be in MODE 3 within 6 hours. The end state of ITS 3.5.4 is MODE 5. In addition, ITS ACTION B includes a NOTE modifying Required Action B.1 that states, "LCO 3.0.4.a is not applicable when entering MODE 3 or MODE 4." This changes CTS by modifying the end state of CTS 3.5.4.b, RWT boron concentration. The modification of the end state from MODE 5 to MODE 3, with respect to RWT boron concentration, is consistent with CE NPSD-1186-A, Revision 00, "Technical Justification for the Risk-Informed Modification to Selected Required Action End States for CEOG Member PWRs," dated October 2001 (ADAMS Accession No. ML110410539) and Technical Specifications Task Force (TSTF) traveler TSTF- 422, Revision 2, "Change in Technical Specifications End States, (CE NPSD-1186)," dated December 22, 2009 (ADAMS Accession No. ML103270197) allowances.

   FPL (PSL Unit 1 and Unit 2) provided the regulatory commitments regarding the implementation of TSTF-422, Revision 2, in License Amendment Request for Adoption of Technical Specifications Task Force (TSTF) Traveler TSTF-422, Revision 2, "Change in Technical Specifications End States, (CE NPSD-1186)," Using the Consolidated Line Item Improvement Process (ADAMS Accession No. ML16118A272). The NRC issued Amendment Nos. 234 and 184 to Renewed Facility Operating License Nos. DPR-67 and NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2, respectively (ADAMS Accession No. ML16210A374).

4. **Unit 2 Only:** The Reviewer's Note has been deleted. The Reviewer's Note provides the NRC Reviewer information needed to meet the requirements. This Note is not meant to be retained in the final version of the plant specific submittal. CTS 4.5.4.b requires verification that RWT borated water temperature is within limits at least once per 24 hours when the outside (i.e., ambient) air temperature is less than 55°F or greater than 100°F. The Surveillance Frequency Control Program was incorporated into the CTS by License Amendment 173, dated June 22, 2015 (ADAMS Accession No. 15127A066). The 24 hour Frequency specified in CTS 4.5.4.b is proposed to be relocated to the Surveillance Frequency Control Program (See Discussion of Change LA01).

SURVEILLANCE REQUIREMENTS

4.5.2 Each ECCS subsystem shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by verifying that the following valves are in the indicated positions with power to the valve operators removed:

See ITS 3.5.2

Valve Number	Valve Function	Valve Position
a. V3733 V3734	a. SIT Vent Valves	a. Locked Closed
b. V3735 V3736	b. SIT Vent Valves	b. Locked Closed
c. V3737 V3738 V3739 V3740	c. SIT Vent Valves	c. Locked Closed

b. In accordance with the Surveillance Frequency Control Program by verifying that each valve (manual, power-operated or automatic) in the flow path that is not locked, sealed, or otherwise secured in position, is in its correct position.*

c. In accordance with the Surveillance Frequency Control Program by verifying ECCS locations susceptible to gas accumulation are sufficiently filled with water.

. d. By a visual inspection which verifies that no loose debris (rags, trash, clothing, etc.) is present in the containment which could be transported to the containment sump and cause restriction of the pump suctions during LOCA conditions. This visual inspection shall be performed:

1. For all accessible areas of the containment prior to establishing CONTAINMENT INTEGRITY, and

2. At least once daily of the areas affected within containment by the containment entry and during the final entry when CONTAINMENT INTEGRITY is established.

f. In accordance with the Surveillance Frequency Control Program, during shutdown, by:

1. Verifying that each automatic valve in the flow paths actuates to its correct position on SIAS and/or RAS test signals.

2. Verifying that each of the following pumps start automatically upon receipt of a Safety Injection Actuation Test Signal:

   a. High-Pressure Safety Injection pumps.

   b. Low-Pressure Safety Injection pumps.

   c. Charging Pumps

3. Verifying that upon receipt of an actual or simulated Recirculation Actuation Signal: each low-pressure safety injection pump stops, each containment sump isolation valve opens, each refueling water tank outlet valve closes, and each safety injection system recirculation valve to the refueling water tank closes.

g. By verifying that each of the following pumps develops the specified total developed head when tested pursuant to the INSERVICE TESTING PROGRAM:

1. High-Pressure Safety Injection pumps.

2. Low-Pressure Safety Injection pumps.

h. By verifying the correct position of each electrical and/or mechanical position stop for the following ECCS throttle valves:

1. During valve stroking operation or following maintenance on the valve and prior to declaring the valve OPERABLE when the ECCS subsystems are required to be OPERABLE.

DISCUSSION OF CHANGES
ITS 3.5.5, TRISODIUM PHOSPHATE (TSP) – UNIT 2 ONLY

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.5.2 requires two ECCS subsystems to be OPERABLE with each subsystem comprised of specific components and flowpaths and is applicable in MODES 1, 2, and 3 with pressurizer pressure ≥ 1750 psia. CTS 4.5.2.e.3 and e.4 provide requirements for trisodium phosphate dodecahydrate (TSP). ITS LCO 3.5.5, "Trisodium Phosphate (TSP)," states that the TSP baskets shall contain ≥ 173 ft^3 of active TSP. The Applicability for this requirement is MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia, consistent with the CTS Applicability. ITS ACTIONS are provided to restore TSP to within limits within 72 hours or place the plant in MODE 3 within 6 hours and reduce pressurizer pressure to < 1750 psia within 12 hours (See Discussion of Change L01 for change to CTS actions). This changes the CTS by providing a separate Specification for TSP requirements.

The purpose of CTS 4.5.2.e.3 and e.4 (TSP Surveillances) is to verify an adequate amount of active TSP is available to maintain pH in the containment sump during a LOCA to promote iodine retention in the sump during the recirculation phase of ECCS and containment spray, thereby limiting radiological consequences. This function is not related to the OPERABILITY of the ECCS trains and is more appropriately addressed by a separate Specification. This change is designated as administrative because providing a separate Specification for TSP requirements does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS SR 4.5.2.e.4 states that when a representative sample of 70.5 + 0.5 grams of TSP from a TSP storage basket is submerged, without agitation, in 10.0 ± 0.1 gallons of 120 ± 10°F borated water representative of the

RWT, the pH of the mixed solution is raised to greater than or equal to 7 within 4 hours. ITS SR 3.5.5.2 requires verification that a sample from the TSP baskets provides adequate pH adjustment of RWT water, and does not retain this detail. This changes the CTS by relocating the details for verification of the TSP sample for pH adjustment.

The removal of these details, that are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS SR 3.5.5.2 retains the requirement to periodically verify a TSP sample for pH adjustment. The removed details that state "a representative sample of 70.5 + 0.5 grams of TSP from a TSP storage basket is submerged, without agitation, in 10.0 $\pm$ 0.1 gallons of 120 $\pm$ 10°F borated water representative of the RWT, the pH of the mixed solution is raised to greater than or equal to 7 within 4 hours," are moved to the ITS Bases. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled.

This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* CTS 3.5.2 does not contain ACTIONS to follow if the TSP Surveillances are not met. Therefore, if the TSP Surveillances are not met, CTS 3.0.3 would be required. CTS 3.0.3 requires action to be initiated within 1 hour and place the unit, as applicable, in hot standby (MODE 3) within the next 6 hours, hot shutdown (MODE 4) within the following 6 hours, and cold shutdown (MODE 5) within the subsequent 24 hours. Since the TSP Surveillances are applicable in MODES 1, 2, and 3 with pressurizer pressure ≥ 1750 psia, upon entry into CTS 3.0.3, the unit would have be placed in MODE 3 within 7 hours from entry and pressurizer pressure reduced below 1750 psia before MODE 4 is required to be reached within 13 hours from entry. ITS 3.5.5 contains ACTIONS to follow if the TSP LCO is not met. If the LCO is not met, 72 hours are provided to restore TSP to within limits. If this action is not completed within the 72 hours, the plant must be placed in MODE 3 within 6 hours and reduce pressurizer pressure to < 1750 psia within 12 hours. This changes the CTS by providing time to restore TSP to within limits before a plant shutdown is required.

The purpose of CTS 4.5.2.e.3 and e.4 (TSP Surveillances) is to verify an adequate amount of active TSP is available to maintain pH in the containment sump during a LOCA. During plant operation the containment sump is not accessible, and corrections may not be possible. However, if possible, this change provides time to restore TSP within limits rather than requiring a plant shutdown. If active TSP is not within the required limit, TSP must be restored

within the required limit in 72 hours. The pH control of the ECCS recirculation and containment spray solution for corrosion protection and iodine removal is reduced in this condition. This change is acceptable because the 72 hour Completion Time takes into account that the condition, which caused the TSP not within limits, would most likely allow the ECCS and Containment Spray System to continue to provide some capability for pH adjustment and iodine removal. The 72-hour Completion Time also considers that the Containment Spray System would continue to be available to remove some iodine from the containment atmosphere in the event of a DBA and the low probability of the worst case DBA occurring during this period. Therefore, allowing time to evaluate the TSP degradation and make any adjustments is acceptable. If TSP cannot be restored to within limits in 72 hours, the unit must be placed in a condition where the LCO no longer applies; MODE 3 with pressurizer pressure < 1750 psia. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.5.5, TRISODIUM PHOSPHATE (TSP) – UNIT 2 ONLY

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.5 Trisodium Phosphate (TSP)

BASES

BACKGROUND

Trisodium phosphate (TSP) is placed on the floor or in the sump of the containment building to ensure that iodine, which may be dissolved in the recirculated reactor cooling water following a loss of coolant accident (LOCA), remains in solution. TSP also helps inhibit stress corrosion cracking (SCC) of austenitic stainless steel components in containment during the recirculation phase following an accident.

Fuel that is damaged during a LOCA will release iodine in several chemical forms to the reactor coolant and to the containment atmosphere. A portion of the iodine in the containment atmosphere is washed to the sump by containment sprays. The emergency core cooling water is borated for reactivity control. This borated water causes the sump solution to be acidic. In a low pH (acidic) solution, dissolved iodine will be converted to a volatile form. The volatile iodine will evolve out of solution into the containment atmosphere, significantly increasing the levels of airborne iodine. The increased levels of airborne iodine in containment contribute to the radiological releases and increase the consequences from the accident due to containment atmosphere leakage.

After a LOCA, the components of the core cooling and containment spray systems will be exposed to high temperature borated water. Prolonged exposure to the core cooling water combined with stresses imposed on the components can cause SCC. The SCC is a function of stress, oxygen and chloride concentrations, pH, temperature, and alloy composition of the components. High temperatures and low pH, which would be present after a LOCA, tend to promote SCC. This can lead to the failure of necessary safety systems or components.

Adjusting the pH of the recirculation solution to levels above 7.0 prevents a significant fraction of the dissolved iodine from converting to a volatile form. The higher pH thus decreases the level of airborne iodine in containment and reduces the radiological consequences from containment atmosphere leakage following a LOCA. Maintaining the solution pH above 7.0 also reduces the occurrence of SCC of austenitic stainless steel components in containment. Reducing SCC reduces the probability of failure of components.

BASES

BACKGROUND (continued)

TSP is employed as a passive form of pH control for post LOCA containment spray and core cooling water. Baskets of TSP are placed on the floor or in the sump of the containment building to dissolve from released reactor coolant water and containment sprays after a LOCA. Recirculation of the water for core cooling and containment sprays then provides mixing to achieve a uniform solution pH. The hydrated form (45-57% moisture) of TSP is used because of the high humidity in the containment building during normal operation. Since the TSP is hydrated, it is less likely to absorb large amounts of water from the humid atmosphere and will undergo less physical and chemical change than the anhydrous form of TSP.

APPLICABLE SAFETY ANALYSES

The LOCA radiological consequences analysis takes credit for iodine retention in the sump solution based on the recirculation water pH being ≥ 7.0. The radionuclide releases from the containment atmosphere and the consequences of a LOCA would be increased if the pH of the recirculation water were not adjusted to 7.0 or above.

TSP satisfies Criterion 3 of the 10 CFR 50.36(c)(2)(ii).

LCO

The TSP is required to adjust the pH of the recirculation water to > 7.0 after a LOCA. A pH > 7.0 is necessary to prevent significant amounts of iodine released from fuel failures and dissolved in the recirculation water from converting to a volatile form and evolving into the containment atmosphere. Higher levels of airborne iodine in containment may increase the release of radionuclides and the consequences of the accident. A pH > 7.0 is also necessary to prevent SCC of austenitic stainless steel components in containment. SCC increases the probability of failure of components.

The required amount of TSP is based upon the extreme cases of water volume and pH possible in the containment sump after a large break LOCA. The minimum required volume is the volume of TSP that will achieve a sump solution pH of ≥ 7.0 when taking into consideration the maximum possible sump water volume and the minimum possible pH. The amount of TSP needed in the containment building is based on the mass of TSP required to achieve the desired pH. However, a required volume is specified, rather than mass, since it is not feasible to weigh the entire amount of TSP in containment. The minimum required volume is based on the manufactured density of TSP. Since TSP can have a tendency to agglomerate from high humidity in the containment building, the density may increase and the volume decrease during normal plant operation. Due to possible agglomeration and increase in density, estimating the minimum volume of TSP in containment is conservative with respect to achieving a minimum required pH.

BASES

APPLICABILITY

with pressurizer pressure ≥ 1750 psia

In MODES 1, 2, and 3, the RCS is at elevated temperature and pressure, providing an energy potential for a LOCA. The potential for a LOCA results in a need for the ability to control the pH of the recirculated coolant. 1

3 with pressurizer pressure < 1750 psia,

In MODES 4, 5, and 6, the potential for a LOCA is reduced or nonexistent, and TSP is not required. 1

ACTIONS

A.1

If it is discovered that the TSP in the containment building sump is not within limits, action must be taken to restore the TSP to within limits. During plant operation the containment sump is not accessible and corrections may not be possible.

The Completion Time of 72 hours is allowed for restoring the TSP within limits, where possible~~, because 72 hours is the same time allowed for restoration of other ECCS components~~. 1

B.1 and B.2

If the TSP cannot be restored within limits within the Completion Time of Required Action A.1, the plant must be brought to a MODE in which the LCO does not apply. The specified Completion Times for reaching MODE~~S~~ 3 and ~~4 are~~ those used throughout the Technical Specifications; they were chosen to allow reaching the specified conditions from full power in an orderly manner and without challenging plant systems. 3

and reducing pressurizer pressure below 1750 psia correspond to

SURVEILLANCE REQUIREMENTS

SR 3.5.5.1

Periodic determination of the volume of TSP in containment must be performed due to the possibility of leaking valves and components in the containment building that could cause dissolution of the TSP during normal operation. A verification is required to determine visually that a minimum of ~~[291]~~ cubic feet is contained in the TSP baskets. This requirement ensures that there is an adequate volume of TSP to adjust the pH of the post LOCA sump solution to a value ≥ 7.0. 2

173

~~[The periodic verification is required every 18 months, since access to the TSP baskets is only feasible during outages, and normal fuel cycles are scheduled for 18 months. Operating experience has shown this Surveillance Frequency acceptable due to the margin in the volume of TSP placed in the containment building.~~ 2

and takes into account that the condition which caused the TSP not within limits would most likely allow the ECCS and Containment Spray System to continue to provide some capability for pH adjustment and iodine removal. The 72 hour Completion Time also considers that the Containment Spray System would continue to be available to remove some iodine from the containment atmosphere in the event of a DBA and the low probability of the worst case DBA occurring during this period.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 2

SR 3.5.5.2

Testing must be performed to ensure the solubility and buffering ability of the TSP after exposure to the containment environment. A representative sample of ~~[~~] ~~]~~ grams of TSP from one of the baskets in containment is submerged in ~~1.0 gal ± 0.05~~ gal of water at a boron concentration ~~of~~ [ ] ppm and at the standard temperature of ~~25°C ± 5°C~~. Without agitation, the solution pH should be raised to ≥ 7 within 4 hours. ~~The representative sample weight is based on the minimum required TSP weight of [ ] kilograms, which at manufactured density corresponds to the minimum volume of [ ] cubic ft, and maximum possible post LOCA sump volume of [ ] gallons, normalized to buffer a 1.0 gal sample.~~ The boron concentration of the test water is representative of the ~~maximum possible~~ boron concentration corresponding to the ~~maximum possible~~ post LOCA sump volume. Agitation of the test solution is prohibited, since an adequate standard for the agitation intensity cannot be specified. The test time ~~of 4 hours~~ is necessary to allow time for the dissolved TSP to naturally diffuse through the sample solution. In the post LOCA containment sump, rapid mixing would occur, significantly decreasing the actual amount of time before the required pH is achieved. This would ensure compliance with the Standard Review Plan requirement of a pH ≥ 7.0 by the onset of recirculation after a LOCA.

R1

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.5 Trisodium Phosphate (TSP)

BASES

BACKGROUND

Trisodium phosphate (TSP) is placed on the floor or in the sump of the containment building to ensure that iodine, which may be dissolved in the recirculated reactor cooling water following a loss of coolant accident (LOCA), remains in solution. TSP also helps inhibit stress corrosion cracking (SCC) of austenitic stainless steel components in containment during the recirculation phase following an accident.

Fuel that is damaged during a LOCA will release iodine in several chemical forms to the reactor coolant and to the containment atmosphere. A portion of the iodine in the containment atmosphere is washed to the sump by containment sprays. The emergency core cooling water is borated for reactivity control. This borated water causes the sump solution to be acidic. In a low pH (acidic) solution, dissolved iodine will be converted to a volatile form. The volatile iodine will evolve out of solution into the containment atmosphere, significantly increasing the levels of airborne iodine. The increased levels of airborne iodine in containment contribute to the radiological releases and increase the consequences from the accident due to containment atmosphere leakage.

After a LOCA, the components of the core cooling and containment spray systems will be exposed to high temperature borated water. Prolonged exposure to the core cooling water combined with stresses imposed on the components can cause SCC. The SCC is a function of stress, oxygen and chloride concentrations, pH, temperature, and alloy composition of the components. High temperatures and low pH, which would be present after a LOCA, tend to promote SCC. This can lead to the failure of necessary safety systems or components.

Adjusting the pH of the recirculation solution to levels above 7.0 prevents a significant fraction of the dissolved iodine from converting to a volatile form. The higher pH thus decreases the level of airborne iodine in containment and reduces the radiological consequences from containment atmosphere leakage following a LOCA. Maintaining the solution pH above 7.0 also reduces the occurrence of SCC of austenitic stainless steel components in containment. Reducing SCC reduces the probability of failure of components.

1

R1

BASES

BACKGROUND (continued)

TSP is employed as a passive form of pH control for post LOCA containment spray and core cooling water. Baskets of TSP are placed on the floor or in the sump of the containment building to dissolve from released reactor coolant water and containment sprays after a LOCA. Recirculation of the water for core cooling and containment sprays then provides mixing to achieve a uniform solution pH. The hydrated form (45-57% moisture) of TSP is used because of the high humidity in the containment building during normal operation. Since the TSP is hydrated, it is less likely to absorb large amounts of water from the humid atmosphere and will undergo less physical and chemical change than the anhydrous form of TSP.

APPLICABLE SAFETY ANALYSES

The LOCA radiological consequences analysis takes credit for iodine retention in the sump solution based on the recirculation water pH being ≥ 7.0. The radionuclide releases from the containment atmosphere and the consequences of a LOCA would be increased if the pH of the recirculation water were not adjusted to 7.0 or above.

TSP satisfies Criterion 3 of the 10 CFR 50.36(c)(2)(ii).

LCO

The TSP is required to adjust the pH of the recirculation water to > 7.0 after a LOCA. A pH > 7.0 is necessary to prevent significant amounts of iodine released from fuel failures and dissolved in the recirculation water from converting to a volatile form and evolving into the containment atmosphere. Higher levels of airborne iodine in containment may increase the release of radionuclides and the consequences of the accident. A pH > 7.0 is also necessary to prevent SCC of austenitic stainless steel components in containment. SCC increases the probability of failure of components.

The required amount of TSP is based upon the extreme cases of water volume and pH possible in the containment sump after a large break LOCA. The minimum required volume is the volume of TSP that will achieve a sump solution pH of ≥ 7.0 when taking into consideration the maximum possible sump water volume and the minimum possible pH. The amount of TSP needed in the containment building is based on the mass of TSP required to achieve the desired pH. However, a required volume is specified, rather than mass, since it is not feasible to weigh the entire amount of TSP in containment. The minimum required volume is based on the manufactured density of TSP. Since TSP can have a tendency to agglomerate from high humidity in the containment building, the density may increase and the volume decrease during normal plant operation. Due to possible agglomeration and increase in density, estimating the minimum volume of TSP in containment is conservative with respect to achieving a minimum required pH.

1

R1

BASES

APPLICABILITY

In MODES 1, 2, and 3, the RCS is at elevated temperature and pressure, providing an energy potential for a LOCA. The potential for a LOCA results in a need for the ability to control the pH of the recirculated coolant.

In MODES 4, 5, and 6, the potential for a LOCA is reduced or nonexistent, and TSP is not required.

ACTIONS

A.1

If it is discovered that the TSP in the containment building sump is not within limits, action must be taken to restore the TSP to within limits. During plant operation the containment sump is not accessible and corrections may not be possible.

The Completion Time of 72 hours is allowed for restoring the TSP within limits, where possible, because 72 hours is the same time allowed for restoration of other ECCS components.

B.1 and B.2

If the TSP cannot be restored within limits within the Completion Time of Required Action A.1, the plant must be brought to a MODE in which the LCO does not apply. The specified Completion Times for reaching MODES 3 and 4 are those used throughout the Technical Specifications; they were chosen to allow reaching the specified conditions from full power in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.5.5.1

Periodic determination of the volume of TSP in containment must be performed due to the possibility of leaking valves and components in the containment building that could cause dissolution of the TSP during normal operation. A verification is required to determine visually that a minimum of [291] cubic feet is contained in the TSP baskets. This requirement ensures that there is an adequate volume of TSP to adjust the pH of the post LOCA sump solution to a value ≥ 7.0.

[The periodic verification is required every 18 months, since access to the TSP baskets is only feasible during outages, and normal fuel cycles are scheduled for 18 months. Operating experience has shown this Surveillance Frequency acceptable due to the margin in the volume of TSP placed in the containment building.

R1

SURVEILLANCE REQUIREMENTS (continued)

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

SR 3.5.5.2

Testing must be performed to ensure the solubility and buffering ability of the TSP after exposure to the containment environment. A representative sample of [ ] grams of TSP from one of the baskets in containment is submerged in 1.0 gal ± 0.05 gal of water at a boron concentration of [ ] ppm and at the standard temperature of 25°C ± 5°C. Without agitation, the solution pH should be raised to ≥ 7 within 4 hours. The representative sample weight is based on the minimum required TSP weight of [ ] kilograms, which at manufactured density corresponds to the minimum volume of [ ] cubic ft, and maximum possible post LOCA sump volume of [ ] gallons, normalized to buffer a 1.0 gal sample. The boron concentration of the test water is representative of the maximum possible boron concentration corresponding to the maximum possible post LOCA sump volume. Agitation of the test solution is prohibited, since an adequate standard for the agitation intensity cannot be specified. The test time of 4 hours is necessary to allow time for the dissolved TSP to naturally diffuse through the sample solution. In the post LOCA containment sump, rapid mixing would occur, significantly decreasing the actual amount of time before the required pH is achieved. This would ensure compliance with the Standard Review Plan requirement of a pH ≥ 7.0 by the onset of recirculation after a LOCA.

[The periodic verification is required every 18 months, since access to the TSP baskets is only feasible during outages, and normal fuel cycles are scheduled for 18 months. Operating experience has shown this Surveillance Frequency acceptable due to the margin in the volume of TSP placed in the containment building.

CONTROLLED LEAKAGE

1.8 CONTROLLED LEAKAGE shall be the seal water flow supplied from the reactor coolant pump seals.

CORE ALTERATION

1.9 CORE ALTERATION shall be the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity within the reactor vessel with the vessel head removed and fuel in the vessel. Exceptions to the above include evolutions performed with the upper guide structure (UGS) in place such as control element assembly (CEA) latching/unlatching or verification of latching/unlatching which do not constitute a CORE ALTERATION. Suspension of CORE ALTERATIONS shall not preclude completion of movement of a component to a safe position.

CORE OPERATING LIMITS REPORT (COLR)

See ITS Chapter 1.0

1.9a THE COLR is the unit-specific document that provides cycle specific parameter limits for the current operating reload cycle. These cycle-specific parameter limits shall be determined for each reload cycle in accordance with Specification 6.9.1.11. Plant operation within these limits is addressed in individual Specifications.

DISCUSSION OF CHANGES
ITS 3.6.1, CONTAINMENT

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3/4.6.1 requires CONTAINMENT VESSEL INTEGRITY. CTS 3.6.1.1 states "CONTAINMENT VESSEL INTEGRITY shall be maintained." Unit 1 CTS 3.6.1.1 ACTION requires, in part, “without CONTAINMENT VESSEL INTEGRITY to restore CONTAINMENT VESSEL INTEGRITY within one hour."

Unit 2 CTS 3/4.6.1 requires PRIMARY CONTAINMENT INTEGRITY. Unit 2 CTS 3.6.1.1 states "Primary CONTAINMENT INTEGRITY shall be maintained." Unit 2 CTS 3.6.1.1 ACTION requires, in part, without primary CONTAINMENT INTEGRITY to restore CONTAINMENT INTEGRITY within 1 hour."

Unit 1 and 2 CTS 4.6.1.2 require containment leakage rates to be demonstrated at the required test schedule and in conformance with Containment Leakage Rate Testing Program criteria. Unit 1 and 2 CTS 3.6.1.2 require containment leakage rates be limited in accordance with the Containment Leakage Rate Testing Program.

Unit 1 CTS 4.6.1.6 requires CONTAINMENT VESSEL STRUCTURAL INTEGRITY to be demonstrated by performance of a visual inspection in accordance with the Containment Leak Rate Testing Program. Unit 2 CTS 4.6.1.6 requires the structural integrity of the containment vessel be determined in accordance with the Containment Leak Rate Testing Program by a visual inspection. CTS 3.6.1.6 requires the structural integrity of the containment to be maintained within specified parameters.

ITS 3.6.1 is the containment specification. ITS LCO 3.6.1 requires the containment to be OPERABLE. ITS 3.6.1 ACTION A requires when containment is inoperable to restore the containment to OPERABLE status within 1 hour. ITS SR 3.6.1.1 requires performance of a visual examination and leak rate testing in accordance with the Containment Leak Rate Testing Program, with an exception for the containment air lock and secondary containment bypass leakage testing.

This changes the Unit 1 and 2 CTS by replacing the specific CONTAINMENT VESSEL INTEGRITY definition and all references to it with the requirement for Containment OPERABILITY. Additionally, it changes the Unit 1 and Unit 2 CTS by combining CTS 3.6.1.1, CTS 3.6.1.2, and CTS 3.6.1.6 into one specification.

The purpose of CTS 3.6.1.1, CTS 3.6.1.2 and CTS 3.6.1.6 is to provide requirements pertaining to containment OPERABILITY. This portion of the

change (combining CTS 3.6.1.1, CTS 3.6.1.2 and 3.6.1.6) is acceptable because moving these requirements into one LCO, ITS LCO 3.6.1, centralizes the requirements. The Unit 1 CTS 3/4.6.1 references to CONTAINMENT VESSEL INTEGRITY and the Unit 2 CTS 3/4.6.1 reference to primary CONTAINMENT INTEGRITY have been deleted because the CTS definition of CONTAINMENT VESSEL INTEGRITY in CTS 1.7 is incorporated into ITS 3.6.1, 3.6.2 and 3.6.3 and is no longer maintained as a separate definition in the ITS. ITS 3.6.1 requires that the containment shall be OPERABLE. The definition of OPERABLE and the subsequent ITS 3.6.1 LCO, ACTIONS, and Surveillance Requirements are sufficient to encompass the applicable requirements of the CTS definition. This change removes any confusion that may exist between the definition and the specific requirements of the LCO and is a presentation preference consistent with NUREG-1432, Rev. 5.0. Because the aspects of the CONTAINMENT VESSEL INTEGRITY definition requirements, along with the remainder of the LCOs in the Containment Systems Primary Containment section (i.e., air locks and containment isolation valves), are maintained in subsequent Specifications of ITS, this change is considered acceptable. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 CTS 3.6.1.6, ACTION, states, "With the structural integrity of the containment vessel not conforming to the above requirements, restore the structural integrity to within the limits prior to increasing the Reactor Coolant System temperature above 200°F." CTS 3.6.1.6 ACTION does not state what action to take if the structural integrity limits are not met while in MODE 1, 2, 3, or 4. Thus, entry into CTS 3.0.3 is required if CTS 3.6.1.6 is not met while in MODE 1, 2, 3, or 4. CTS 3.0.3 allows 1 hour to prepare for a shutdown and requires the unit to be in HOT STANDBY (ITS MODE 3) within the next 6 hours, HOT SHUTDOWN (ITS MODE 4) within the following 6 hours, and Cold Shutdown (similar to ITS MODE 5) within the subsequent 24 hours (37 hours total). ITS 3.6.1 ACTION A requires that if the containment is inoperable, it must be restored to OPERABLE status within 1 hour. ITS 3.6.1 ACTION B requires that if the Required Action and associated Completion Time are not met (i.e., the containment is not restored to OPERABLE status in 1 hour), the unit must be in MODE 3 within 6 hours and MODE 5 within 36 hours (37 hours total). This changes CTS by stating the ACTIONS rather than deferring to CTS 3.0.3. In addition, it deletes the CTS Actions to restore the limits prior to increasing the Reactor Coolant System temperature above 200°F.

The purpose of CTS 3.0.3 is to place the unit outside the MODE of Applicability within a reasonable amount of time in a controlled manner. CTS 3.6.1.6 is silent on these actions, deferring to CTS 3.0.3 for the actions to accomplish this. This change is acceptable because the ACTIONS specified in ITS 3.6.1 adopt ISTS structure for placing the unit outside the MODE of Applicability while changing the time specified to enter MODE 3 and MODE 5 but still within the plants ability to safely shutdown. In addition, deletion of the current Actions of CTS 3.6.1.6 is acceptable, because CTS 4.0.4 (ITS SR 3.0.4) already precludes entering the MODE of Applicability when the LCO is not met. Therefore, it is not necessary to include these requirements as specific actions in ITS 3.6.1. This change is designated as administrative because it does not result in technical changes to the CTS.

A04 CTS 4.6.1.2 requires containment leakage rates be demonstrated in conformance with the criteria specified in the Containment Leakage Rate Testing Program. ITS SR 3.6.1.1 requires the same test but adds an exception for containment air lock testing and secondary containment bypass leakage. This changes the Unit 1 and Unit 2 CTS by excluding containment air lock and secondary containment bypass leakage testing.

This is acceptable because ITS SR 3.6.2.1 requires performance of air lock leakage testing, Unit 1 ITS SR 3.6.3.7 and Unit 2 ITS SR 3.6.3.8 require secondary containment bypass leakage testing. Individual leakage rates specified for the containment air lock (CTS 4.6.1.1.b and 4.6.1.3.a) and secondary bypass leakage (CTS 6.8.4.h) are not specifically part of the acceptance criteria of 10 CFR 50, Appendix J. Therefore, leakage rates exceeding these individual limits only result in the containment being inoperable when the leakage results in exceeding the overall acceptance criteria of 1.0 La. This change is designated as administrative because it does not result in technical changes to the CTS.

A05 CTS 3.6.1.2 Action, in part, requires restoring the overall leakage rate to less than that specified by the Containment Leakage Rate Testing Program prior to increasing the Reactor Coolant System temperature above 200°F (i.e., MODE 4). Although not explicitly stated, if overall leakage rate is not within the limits of the Containment Leakage Rate Testing Program prior to increasing the RCS temperature above 200°F, the LCO is not met and CTS 3.0.4 (ITS LCO 3.0.4) would apply. ITS 3.6.1 ACTIONS do not include an explicit requirement to restoring the overall leakage rate to less than that specified by the Containment Leakage Rate Testing Program prior to increasing the Reactor Coolant System temperature above 200°F because it is inherently required by ITS LCO 3.0.4. This changes the CTS by deleting the Action to restore the LCO prior to increasing RCS temperature above 200°F (i.e., entering MODE 4). R1

This change is acceptable because CTS 3.0.4 (ITS LCO 3.0.4) already precludes entering the MODE of Applicability when the LCO is not met except: a) when the associated ACTIONS to be entered permit continued operation in the MODE or other specified condition in the Applicability for an unlimited period of time; b) after performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering the MODE or other specified condition in the Applicability, and establishment of risk management actions, if appropriate; or c) when an allowance is stated in the individual value, parameter, or other Specification. With overall leakage rate not within the limits specified in the Containment Leakage Rate Testing Program, none of the allowances provided in CTS 3.0.4 apply because the Technical Specification actions do not allow operation in MODE 4 for an unlimited period of time, a risk assessment cannot be performed and managed on a parameter outside limits, and there is no specific allowance stated in the Specification. Therefore, it is not necessary to include explicit requirements to restore the overall leakage rate to less than that specified by the Containment Leakage Rate Testing Program prior to increasing the Reactor Coolant System temperature above 200°F. This change is designated as administrative, because it does not result in a technical change to the CTS.

DISCUSSION OF CHANGES
ITS 3.6.1, CONTAINMENT

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program)* Unit 1 CTS 4.6.1.6 states , "The structural integrity of the containment vessel shall be determined, in accordance with the containment Leakage Rate Testing Program, by a visual inspection of the accessible interior and exterior surfaces of the vessel and verifying no apparent changes in appearance of the surfaces or other abnormal degradation." Unit 2 CTS 4.6.1.6 states , "The structural integrity of the containment vessel shall be determined in accordance with the Containment Leak Rate Testing Program by a visual inspection of the exposed accessible interior and exterior surfaces of the vessel and verifying no apparent changes in appearance of the surfaces or other abnormal degradation."

ITS SR 3.6.1.1 requires the same visual examination in accordance with the Containment Leakage Rate Testing Program but does not include the details of when the testing is performed, what is verified and the acceptance criteria. This changes the CTS by moving the details of the visual examination to the Containment Leakage Rate Testing Program.

The removal of these details associated with the visual examination of the containment vessel is acceptable because this type of information is not necessary to be included in the Technical Specifications in order to provide adequate protection of public health and safety. ITS SR 3.6.1.1 retains the requirement to perform a visual examination in accordance with the Containment Leakage Rate Testing Program. This change is acceptable because these types of procedural details will be adequately controlled in the Containment Leakage Rate Testing Program requirements in ITS Chapter 5. This change is designated as a less restrictive removal of detail change because details associated with performance of the containment vessel visual examination are being removed from the Technical Specifications.

LA02 *(Type 2 – Removing Descriptions of System Operation)* CTS 1.7 states, in part, "CONTAINMENT VESSEL INTEGRITY shall exist when: a. All penetrations required to be closed during accident conditions are either: 1) Capable of being closed by an OPERABLE containment automatic isolation valve system, or 2) Closed by manual valves, blind flanges, or deactivated automatic valves secured in their closed positions, except for valves that are open under administrative control. b. All containment vessel equipment hatches are closed and sealed, c. Each containment vessel air lock is in compliance with the requirements of Specification 3.6.1.3, and e. The sealing mechanism associated

with each penetration (e.g., welds, bellows, or 0-rings) is OPERABLE." ITS 3.6.1 states "Containment shall be OPERABLE." This changes the CTS by moving the reference to penetration and containment vessel equipment hatches and sealing mechanism associated with each penetration to the Bases.

The removal of these details, that are related to system operation, from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for the containment to be OPERABLE and the relocated material describes aspects of OPERABILITY. In addition, the ITS retains the requirement to perform required visual inspections and leakage rate testing in accordance with the Containment Leakage Rate Testing Program in accordance with 10 CFR 50 Appendix J, Part B, that would provide verification that the equipment hatch is closed and sealed and the sealing mechanisms are OPERABLE. Also, this change is acceptable, because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system operation is being removed from the Technical Specifications.

LA03 **Unit 2 only:** *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 3.6.1.1, by footnote, states the APPLICABILITY to require "In MODES 1 and 2, the RCB polar crane shall be rendered inoperable by locking the power supply breaker open." The ITS 3.6.1 APPLICABILITY is "MODES 1, 2, 3, and 4." This changes the CTS by moving the procedural detail to the UFSAR.

The removal of these details, for performing actions, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for the containment to be OPERABLE in MODES 1, 2, 3, and 4 and the relocated material describes procedural requirements of OPERABILITY. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.1, CONTAINMENT

1. The type of Containment (Atmospheric and Dual) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ITS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants or may not be applicable to all Combustion Engineering plants. Since St. Lucie Plant (PSL) Units 1 and 2 do not have containment tendons, ISTS SR 3.6.1.2 is not included in PSL Units 1 and 2 ITS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.1~~B~~ Containment ~~(Dual)~~ 1

BASES

BACKGROUND

The containment is a free standing steel pressure vessel surrounded by a reinforced concrete shield building. The containment vessel, including all its penetrations, is a low leakage steel shell designed to contain radioactive material that may be released from the reactor core following a design basis loss of coolant accident (LOCA). Additionally, the containment and shield building provide shielding from the fission products that may be present in the containment atmosphere following accident conditions.

The containment vessel is a vertical cylindrical steel pressure vessel with hemispherical dome and ellipsoidal bottom, completely enclosed by a reinforced concrete shield building. A 4 ft wide annular space exists between the walls and domes of the steel containment vessel and the concrete shield building to permit inservice inspection and collection of containment outleakage. Dual containments utilize an outer concrete building for shielding and an inner steel containment for leak tightness.

Containment piping penetration assemblies provide for the passage of process, service, sampling, and instrumentation pipelines into the containment vessel while maintaining containment OPERABILITY. The shield building provides biological shielding and allows controlled release of the annulus atmosphere under accident conditions, as well as environmental missile protection for the containment vessel and the Nuclear Steam Supply System.

The inner steel containment and its penetrations establish the leakage limiting boundary of the containment. Maintaining the containment OPERABLE limits the leakage of fission product radioactivity from the containment to the environment. Loss of containment OPERABILITY could cause site boundary doses, in the event of a Design Basis Accident (DBA), to exceed values given in the licensing basis. SR 3.6.1.1 leakage rate requirements comply with 10 CFR 50, Appendix J, Option ~~[A][~~B~~]~~ (Ref. 1), as modified by approved exemptions. 3

The isolation devices for the penetrations in the containment boundary are a part of the containment leak tight barrier. To maintain this leak tight barrier:

BASES

BACKGROUND (continued)

a. All penetrations required to be closed during accident conditions are either:

1. Capable of being closed by an OPERABLE automatic containment isolation system or

2. Closed by manual valves, blind flanges, or de-activated automatic valves secured in their closed positions, except as provided in LCO 3.6.3, "Containment Isolation Valves,"

b. Each air lock is OPERABLE except as provided in LCO 3.6.2, "Containment Air Locks,"

c. All equipment hatches are closed, and

Insert 1

~~[~~d. ~~The pressurized sealing mechanism associated with a penetration, except as provided in LCO 3.6.[ ], is OPERABLE.]~~ 3

APPLICABLE SAFETY ANALYSES

The safety design basis for the containment is that the containment must withstand the pressures and temperatures of the limiting DBA without exceeding the design leakage rate.

The DBAs that result in a release of radioactive material within containment are a LOCA, a main steam line break, and a control element assembly ejection accident (Ref. 2). In the analysis of each of these accidents, it is assumed that containment is OPERABLE such that release of fission products to the environment is controlled by the rate of containment leakage. The containment was designed with an allowable leakage rate of ~~[~~0.50~~]~~% of containment air weight per day (Ref. 3). This leakage rate is defined in 10 CFR 50, Appendix J, Option ~~[A][~~B~~]~~ (Ref. 1), as L_a: the maximum allowable containment leakage rate at the calculated maximum peak containment pressure (P_a) of ~~[42.3]~~ psig, which results from the limiting design basis LOCA (Ref. ~~2~~). 3

42.77

3 2

Satisfactory leakage rate test results are a requirement for the establishment of containment OPERABILITY.

The containment satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

St. Lucie – Unit 1

3 **INSERT 1**

The sealing mechanism associated with each containment penetration (e.g., welds, bellows, or O-rings) is OPERABLE.

BASES

LCO

Containment OPERABILITY is maintained by limiting leakage to ≤ 1.0 L_a, except prior to the first startup after performing a required Containment Leakage Rate Testing Program leakage test. At this time, the applicable leakage limits must be met.

Compliance with this LCO will ensure a containment configuration, including equipment hatches, that is structurally sound and that will limit leakage to those leakage rates assumed in the safety analysis.

Individual leakage rates specified for the containment air lock (LCO 3.6.2) ~~[~~, purge valves with resilient seals, and secondary bypass leakage (LCO 3.6.3)~~]~~ are not specifically part of the acceptance criteria of 10 CFR 50, Appendix J. Therefore, leakage rates exceeding these individual limits only result in the containment being inoperable when the leakage results in exceeding the overall acceptance criteria of 1.0 L_a. 3

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material into containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, containment is not required to be OPERABLE in MODE 5 to prevent leakage of radioactive material from containment. The requirements for containment during MODE 6 refueling operations are addressed in LCO 3.9.3, "Containment Penetrations."

ACTIONS

A.1

In the event that containment is inoperable, it must be restored to OPERABLE status within 1 hour. The 1 hour Completion Time provides a period of time to correct the problem commensurate with the importance of maintaining containment OPERABLE during MODES 1, 2, 3, and 4. This time period also ensures that the probability of an accident (requiring containment OPERABILITY) occurring during periods when containment is inoperable is minimal.

B.1 and B.2

If containment cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.6.1.1

Maintaining containment OPERABLE requires compliance with the visual examinations and leakage rate test requirements of the Containment Leakage Rate Testing Program. The containment ~~concrete~~ visual examinations may be performed during ~~either power operation, e.g., performed concurrently with other containment inspection-related activities such as tendon testing, or during~~ a maintenance or refueling outage. ~~The visual examinations of the steel liner plate inside containment are performed during maintenance or refueling outages since this is the only time the liner plate is fully accessible.~~ 2

Failure to meet air lock and purge valve with resilient seal specific leakage limits specified in LCO 3.6.2 and LCO 3.6.3 does not invalidate the acceptability of these overall leakage determinations unless their contribution to overall Type A, B, and C leakage causes that to exceed limits. As left leakage prior to the first startup after performing a required Containment Leakage Rate Testing Program leakage test is required to be < 0.6 L_a for combined Type B and C leakage, and ~~[< 0.75 L_a for Option A] [~~≤ 0.75 L_a ~~for Option B]~~ for overall Type A leakage. At all other times between required leakage rate tests, the acceptance criteria is based on an overall Type A leakage limit of ≤ 1.0 L_a. At ≤ 1.0 L_a the offsite dose consequences are bounded by the assumptions of the safety analysis. SR Frequencies are as required by the Containment Leakage Rate Testing Program. These periodic testing requirements verify that the containment leakage rate does not exceed the leakage rate assumed in the safety analysis. 3

SR Frequencies are as required by the Containment Leakage Rate Testing Program. These periodic testing requirements verify that the containment leakage rate does not exceed the leakage rate assumed in the safety analysis.

~~REVIEWER'S NOTE~~
~~Regulatory Guide 1.163 and NEI 94-01 include acceptance criteria for as-left and as-found Type A leakage rates and combined Type B and C leakage rates, which may be reflected in the Bases.~~ 4

~~[SR 3.6.1.2~~

~~For ungrouted, post tensioned tendons, this SR ensures that the structural integrity of the containment will be maintained in accordance with the provisions of the Containment Tendon Surveillance Program. B 3.6 CONTAINMENT SYSTEMS

B 3.6.1~~B~~ Containment ~~(Dual)~~ 1

BASES

BACKGROUND

The containment is a free standing steel pressure vessel surrounded by a reinforced concrete shield building. The containment vessel, including all its penetrations, is a low leakage steel shell designed to contain radioactive material that may be released from the reactor core following a design basis loss of coolant accident (LOCA). Additionally, the containment and shield building provide shielding from the fission products that may be present in the containment atmosphere following accident conditions.

The containment vessel is a vertical cylindrical steel pressure vessel with hemispherical dome and ellipsoidal bottom, completely enclosed by a reinforced concrete shield building. A 4 ft wide annular space exists between the walls and domes of the steel containment vessel and the concrete shield building to permit inservice inspection and collection of containment outleakage. Dual containments utilize an outer concrete building for shielding and an inner steel containment for leak tightness.

Containment piping penetration assemblies provide for the passage of process, service, sampling, and instrumentation pipelines into the containment vessel while maintaining containment OPERABILITY. The shield building provides biological shielding and allows controlled release of the annulus atmosphere under accident conditions, as well as environmental missile protection for the containment vessel and the Nuclear Steam Supply System.

The inner steel containment and its penetrations establish the leakage limiting boundary of the containment. Maintaining the containment OPERABLE limits the leakage of fission product radioactivity from the containment to the environment. Loss of containment OPERABILITY could cause site boundary doses, in the event of a Design Basis Accident (DBA), to exceed values given in the licensing basis. SR 3.6.1.1 leakage rate requirements comply with 10 CFR 50, Appendix J, Option ~~[A][~~B~~]~~ (Ref. 1), as modified by approved exemptions. 3

The isolation devices for the penetrations in the containment boundary are a part of the containment leak tight barrier. To maintain this leak tight barrier:

BASES

BACKGROUND (continued)

a. All penetrations required to be closed during accident conditions are either:

1. Capable of being closed by an OPERABLE automatic containment isolation system or

2. Closed by manual valves, blind flanges, or de-activated automatic valves secured in their closed positions, except as provided in LCO 3.6.3, "Containment Isolation Valves,"

b. Each air lock is OPERABLE except as provided in LCO 3.6.2, "Containment Air Locks,"

c. All equipment hatches are closed, and

Insert 1

~~[~~d. ~~The pressurized sealing mechanism associated with a penetration, except as provided in LCO 3.6.[ ], is OPERABLE.]~~ 3

APPLICABLE SAFETY ANALYSES

The safety design basis for the containment is that the containment must withstand the pressures and temperatures of the limiting DBA without exceeding the design leakage rate.

The DBAs that result in a release of radioactive material within containment are a LOCA, a main steam line break, and a control element assembly ejection accident (Ref. 2). In the analysis of each of these accidents, it is assumed that containment is OPERABLE such that release of fission products to the environment is controlled by the rate of containment leakage. The containment was designed with an allowable leakage rate of ~~[~~0.50~~]~~% of containment air weight per day (Ref. 3). This leakage rate is defined in 10 CFR 50, Appendix J, Option ~~[A][~~B~~]~~ (Ref. 1), as L_a: the maximum allowable containment leakage rate at the calculated maximum peak containment pressure (P_a) of ~~[42.3]~~ psig, which results from the limiting design basis LOCA (Ref. ~~2~~). 3

43.43

3 2

Satisfactory leakage rate test results are a requirement for the establishment of containment OPERABILITY.

The containment satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

St. Lucie – Unit 2

3 **INSERT 1**

The sealing mechanism associated with each containment penetration (e.g., welds, bellows, or O-rings) is OPERABLE.

BASES

LCO

Containment OPERABILITY is maintained by limiting leakage to ≤ 1.0 L_a, except prior to the first startup after performing a required Containment Leakage Rate Testing Program leakage test. At this time, the applicable leakage limits must be met.

Compliance with this LCO will ensure a containment configuration, including equipment hatches, that is structurally sound and that will limit leakage to those leakage rates assumed in the safety analysis.

Individual leakage rates specified for the containment air lock (LCO 3.6.2) ~~[~~, purge valves with resilient seals, and secondary bypass leakage (LCO 3.6.3)~~]~~ are not specifically part of the acceptance criteria of 10 CFR 50, Appendix J. Therefore, leakage rates exceeding these individual limits only result in the containment being inoperable when the leakage results in exceeding the overall acceptance criteria of 1.0 L_a. 3

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material into containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, containment is not required to be OPERABLE in MODE 5 to prevent leakage of radioactive material from containment. The requirements for containment during MODE 6 refueling operations are addressed in LCO 3.9.3, "Containment Penetrations."

ACTIONS

A.1

In the event that containment is inoperable, it must be restored to OPERABLE status within 1 hour. The 1 hour Completion Time provides a period of time to correct the problem commensurate with the importance of maintaining containment OPERABLE during MODES 1, 2, 3, and 4. This time period also ensures that the probability of an accident (requiring containment OPERABILITY) occurring during periods when containment is inoperable is minimal.

B.1 and B.2

If containment cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.6.1.1

Maintaining containment OPERABLE requires compliance with the visual examinations and leakage rate test requirements of the Containment Leakage Rate Testing Program. The containment ~~concrete~~ visual examinations may be performed during ~~either power operation, e.g., performed concurrently with other containment inspection-related activities such as tendon testing, or during~~ a maintenance or refueling outage. ~~The visual examinations of the steel liner plate inside containment are performed during maintenance or refueling outages since this is the only time the liner plate is fully accessible.~~ 2

Failure to meet air lock and purge valve with resilient seal specific leakage limits specified in LCO 3.6.2 and LCO 3.6.3 does not invalidate the acceptability of these overall leakage determinations unless their contribution to overall Type A, B, and C leakage causes that to exceed limits. As left leakage prior to the first startup after performing a required Containment Leakage Rate Testing Program leakage test is required to be < 0.6 L_a for combined Type B and C leakage, and ~~[< 0.75 L_a for Option A] [~~≤ 0.75 L_a ~~for Option B]~~ for overall Type A leakage. At all other times between required leakage rate tests, the acceptance criteria is based on an overall Type A leakage limit of ≤ 1.0 L_a. At ≤ 1.0 L_a the offsite dose consequences are bounded by the assumptions of the safety analysis. SR Frequencies are as required by the Containment Leakage Rate Testing Program. These periodic testing requirements verify that the containment leakage rate does not exceed the leakage rate assumed in the safety analysis. 3

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.1 Bases, CONTAINMENT

1. The heading for ISTS 3.6.1 includes the parenthetical expression (Dual) and the Specification designator “B” that are deleted. This identifying information is not included in the St. Lucie Plant (PSL) ITS. This information is provided in the NUREG to assist in identifying the appropriate Specification to be used as a model for a plant specific ITS conversion but serves no purpose in a plant specific implementation. In addition, the Atmospheric Specification Bases (ISTS B 3.6.1A) is not used and not shown.

2. Changes are made (additions, deletions, and/or changes) to the ISTS Bases which reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is changed to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. This bracketed requirement regarding Containment Tendon Surveillance Program is deleted because it is not applicable to PSL Unit 1 and Unit 2. The PSL containments do not utilize containment tendons.

6. The PSL Safety Analysis Report (SAR) is an updated version of the original Final Safety Analysis Report. Therefore, the proper acronym is UFSAR and is changed to reflect the document.

3/4.6.1 PRIMARY CONTAINMENT

CONTAINMENT INTEGRITY

LIMITING CONDITION FOR OPERATION

3.6.1.1 Primary CONTAINMENT INTEGRITY shall be maintained.

APPLICABILITY: MODES 1*, 2*, 3, and 4.

ACTION:

Without primary CONTAINMENT INTEGRITY, restore CONTAINMENT INTEGRITY within 1 hour or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

See ITS 3.6.1

SURVEILLANCE REQUIREMENTS

4.6.1.1 Primary CONTAINMENT INTEGRITY shall be demonstrated:

See ITS 3.6.3

a. In accordance with the Surveillance Frequency Control Program by verifying that all penetrations** not capable of being closed by OPERABLE containment automatic isolation valves and required to be closed during accident conditions are closed by valves, blind flanges, or deactivated automatic valves secured in their positions, except for valves that are open on an intermittent basis under administrative control.

SR 3.6.2.1

b. By verifying that each containment air lock is in compliance with the requirements of Specification 3.6.1.3.

---

* In MODES 1 and 2, the RCB polar crane shall be rendered inoperable by locking the power supply breaker open.

See ITS 3.6.1

** Except valves, blind flanges, and deactivated automatic valves which are located inside the containment and are locked, sealed or otherwise secured in the closed position. These penetrations shall be verified closed during each COLD SHUTDOWN except that such verification need not be performed more often than once per 92 days.

See ITS 3.6.3

DISCUSSION OF CHANGES
ITS 3.6.2, CONTAINMENT AIR LOCKS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.6.1.3 states, in part, "Each containment air lock shall be OPERABLE. ITS LCO 3.6.2 states, "Two containment air locks shall be OPERABLE. This changes the CTS by identifying the total number of airlocks that are required to be OPERABLE.

This change is acceptable because PSL has two containment air locks. Therefore, requiring two containment air locks to be OPERABLE in ITS 3.6.2 is the same as requiring each containment air lock to be OPERABLE in CTS 3.6.1.3. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 CTS 3.6.1.3 states, in part, "Each containment air lock shall be OPERABLE." CTS 3.6.1.3 ACTION a states, in part, "With one containment air lock door inoperable" and specifies ACTIONS to be taken. CTS 3.6.1.3 ACTION b states, in part, "With one or both containment air lock(s) inoperable, except as the result of an inoperable air lock door" and specifies ACTIONS to be taken. ITS 3.6.2 ACTIONS Note 2 states "Separate Condition entry is allowed for each airlock." ITS 3.6.2 ACTION A states "One or more containment air locks with one containment air lock door inoperable." ITS 3.6.2 ACTION C states "One or more containment air locks inoperable for reasons other than Condition A or B." This changes the CTS by clarifying the current intent of applying the CTS Actions to each air lock separately.

The purpose of the Unit 1 CTS 3.6.1.3 is to ensure containment air locks meet their requirements for CONTAINMENT VESSEL INTEGRITY and Unit 2 CTS 3.6.1.3 is to ensure containment air locks meet their requirements for primary CONTAINMENT INTEGRITY. One OPERABLE air lock door in each containment air lock provides a pressure boundary and applying the CTS Actions for an inoperable air lock to each of the air locks separately is appropriate. ITS 3.6.2 ACTIONS Note 2 clearly states this. The Required Actions for each Condition provides appropriate compensatory action for each air lock. This change is acceptable because it clarifies existing requirements and better describes how the requirements are currently used. This change is designated as administrative because it does not result in technical changes to the CTS.

A04 CTS 3.6.1.3 ACTION a.1 states in part, to either restore the inoperable air lock door to OPERABLE status within 24 hours or lock the OPERABLE air lock door closed. ITS 3.6.2 ACTION A does not contain the statement to restore the inoperable air lock door to OPERABLE status. This changes CTS by not

including the statement to restore the inoperable air lock door to OPERABLE status.

This change is acceptable because the technical requirements have not changed. Restoration to compliance with the LCO is always an available Required Action and it is the convention in the ITS to not state such "restore" options explicitly unless it is the only action or is required for clarity. This change is designated as administrative because it does not result in technical changes to the CTS.

A05 CTS 4.6.1.3.a requires demonstrating each containment air lock is OPERABLE by verifying leakage rates are in accordance with the Containment Leakage Rate Testing Program. ITS 3.6.2.1 requires the same test, but adds two Notes (SR 3.6.2.1 Note 1) that states in part than an inoperable air lock door does not invalidate the previous successful performance of the overall air lock leakage test and Note 2) requiring that the results be evaluated against acceptance criteria of ITS SR 3.6.1.1. This changes the CTS by clarifying the validity of the previous overall air lock leakage test results and specifically requiring verification of the air lock leakage rates against the Containment leakage rates.

The purpose of leak rate testing requirements for air lock leakage (Type B leakage test) is to verify that the air lock leakage does not exceed the allowed fraction of the overall containment leakage rate. Evaluating the containment air lock leakage with the containment leakage rates ensures that the air lock leakage is accounted for in determining the combined Type B and C containment leakage rate. In the CTS, this evaluation is performed as part of the Containment Leakage Rate Testing Program, but is not specifically addressed in CTS 4.6.1.3.a. This change is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.6.1.3 ACTION a requires, in part, maintaining at least the OPERABLE air lock door closed when one containment air lock door is inoperable. CTS 3.6.1.3 ACTION b requires, in part, maintaining at least one air lock door closed when the containment air lock is inoperable. ITS 3.6.2 ACTIONS A and C require similar actions (Required Action A.1 and C.2, respectively), and require verifying the door is closed in the affected air lock within 1 hour. This changes the CTS by adding a new Completion Time.

The purpose of ITS 3.6.2 Required Actions A.1 and C.2 is to verify that the overall leakage rate aspect of containment OPERABILITY is met in the event an airlock is inoperable for a reason other than an interlock mechanism being inoperable. An additional purpose of ITS 3.6.2 Required Actions A.1 and C.2 is to minimize, to the extent possible, the leakage through the inoperable air lock. This change is acceptable because if the inoperability is something that could cause the overall containment leakage rate limits to be exceeded, this should be evaluated immediately, commensurate with the importance of the limits. Furthermore, the one hour Completion Time is commensurate with the Completion Time in ITS 3.6.1 (CTS 3.6.1.1) for restoring containment to

OPERABLE status when the containment is inoperable. This change is considered more restrictive because it provides a new Completion Time.

M02 CTS 3.6.1.3 ACTION b requires maintaining at least one air lock door closed and restoration of an inoperable air lock within 24 hours. ITS 3.6.2 ACTION C requires one additional Required Action. When one or more containment air locks are inoperable for reasons other than Condition A or B, ITS 3.6.2 Required Action C.1 requires initiation of action to evaluate overall containment leakage rate per LCO 3.6.1, immediately. This changes the CTS by adding a new Required Action.

The purpose of ITS 3.6.2 Required Action C.1 is to verify that the overall leakage rate aspect of containment OPERABILITY is met in the event an airlock is inoperable for a reason other than one door or an interlock mechanism being inoperable. An additional purpose of ITS 3.6.2 Required Action C.2 is to minimize, to the extent possible, the leakage through the inoperable air lock. This change is acceptable because if the inoperability is something that could cause the overall containment leakage rate limits to be exceeded, this should be evaluated immediately, commensurate with the importance of the limits. This change is considered more restrictive because it provides a new Required Action.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.6.1.3 states each containment air lock shall be OPERABLE with both doors closed except when the air lock is being used for normal transit entry and exit through the containment, then at least one air lock door shall be closed. ITS 3.6.2 does not contain this level of detail. This changes the CTS by moving details concerning what constitutes an OPERABLE containment air lock to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the information and is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* CTS 3.6.1.3 ACTION b states "With one or both containment air lock(s) inoperable, except as the result of an inoperable air lock door, maintain at least one air lock door closed in the affected air lock(s) and restore the inoperable air lock(s) to OPERABLE status within 24 hours or in accordance with the Risk Informed Completion Time Program; otherwise be in at least HOT STANDBY within the next six hours and in COLD SHUTDOWN within the following 6 hours." CTS 3.6.1.3 ACTION Note(s) state in part “If the inner air lock door is inoperable, passage through the OPERABLE outer air lock door is permitted to effect repairs to the inoperable inner air lock door.” ITS 3.6.2 ACTION B provides a separate ACTION for inoperability of the air lock with an air lock interlock mechanism inoperable, ITS 3.6.2 ACTION B allows unlimited operation provided an OPERABLE door in the air lock is closed in 1 hour, locked closed in 24 hours, and verification is performed every 31 days that an OPERABLE air lock door in the air lock remains closed. For air lock doors in high radiation areas, this 31 day verification can be performed by administrative means. In addition, containment entry and exit through the air lock is permissible (i.e., the closed and locked door can be opened) under administrative control. Additionally, a new Note which applies to ITS 3.6.2 ACTIONS A, B, and C has been added. This Note, ITS 3.6.2 ACTIONS Note 1, states entry and exit (i.e., the closed and locked OPERABLE air locks can be opened) is permissible to perform repairs on the affected air lock components. This changes the CTS by allowing unlimited operation, with certain restrictions, for air locks that are inoperable due to an inoperable lock mechanism and allows entry and exit to repair an inoperable door.

The purpose of CTS air lock ACTION b is to ensure the containment is not allowed to operate indefinitely in a condition such that it cannot perform its safety function. The changes are acceptable because the proposed ACTION will still ensure the containment safety function is met. Since there are two redundant doors in each air lock, only one OPERABLE air lock door is needed to be maintained closed to ensure the leak tightness requirements are met. The leak tightness of each door is verified, as required by ITS SR 3.6.2.1, in accordance with the Containment Leakage Rate Testing Program. In addition, the interlock mechanism only ensures that both doors in the air lock are not inadvertently opened at the same time. With either an OPERABLE air lock door locked closed, or a dedicated individual ensuring that only one door at a time is opened, the function of the interlock mechanism is being met. The allowances to open the air lock doors to perform repairs or other reasons is acceptable since the time the door is opened is short and the opening is under administrative controls. Also, for the case where the air lock door is opened for reasons other than to effect repairs, the time period (7 days) is short. These changes are designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.6.1.3 ACTION a states "With one containment air lock inoperable, maintain at least the OPERABLE air lock door closed and either restore the inoperable air lock door to OPERABLE status within 24 hours or lock the OPERABLE air lock door closed” and “Operation may then continue until performance of the next required overall air

lock leakage test provided that the OPERABLE air lock door is verified to be locked closed at least once per 31 days." ITS 3.6.2 ACTION A contains similar requirements, but contains two Required Action Notes stating "Required Actions A.1, A.2, and A.3 are not applicable if both doors in the same air lock are inoperable and Condition C is entered" and "Entry and exit is permissible for 7 days under administrative controls if both air locks are inoperable." Additionally ITS 3.6.2 Required Action A.3 contains a Note stating "Air lock doors in high radiation areas may be verified locked closed by administrative means." This changes the CTS by ensuring that only the Required Actions and associated Completion Times of Condition C are required if both doors in the same air lock are inoperable, allowing use of the air lock for entry and exit for 7 days under administrative controls if both air locks have an inoperable door, and allowing air lock doors in high radiation areas to be verified locked close by administrative means.

The addition of ITS 3.6.2 Condition A, Required Action Note 1 is acceptable since it ensures that only the Required Actions and associated Completion Times of Condition C are performed if both doors in the same air lock are inoperable. This is acceptable since Condition C contains the appropriate remedial actions to take when both doors are inoperable. The addition of ITS 3.6.2 Condition A, Required Action Note 2 is acceptable since it allows entry and exit to perform Technical Specification Surveillance and Required Action as well as other activities on equipment inside containment that are required by Technical Specifications or activities on equipment that support Technical Specification required equipment. This change is acceptable since the time duration is short and the doors are opened under administrative controls. The addition of ITS 3.6.2 Required Action A.3 Note is acceptable since it allows verifying that air lock doors in high radiation areas by administrative means. Additionally, this change is acceptable since access to these areas is typically restricted and the probability of a misalignment of the doors is small. These changes are designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.2, CONTAINMENT AIR LOCKS

1. The type of Containment (Atmospheric and Dual) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ITS which reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.2 Containment Air Locks ~~(Atmospheric and Dual)~~ 1

BASES

BACKGROUND

Containment air locks (i.e., personnel and emergency) form part of the containment pressure boundary and provide a means for personnel access during all MODES of operation.

Each air lock is nominally a right circular cylinder, approximately 9 ~~10~~ ft in diameter for the personnel air lock and approximately 6 ft in diameter for the emergency air lock, with a door at each end. The doors are interlocked to prevent simultaneous opening. During periods when containment is not required to be OPERABLE, the door interlock mechanism may be disabled, allowing both doors of an air lock to remain open for extended periods when frequent containment entry is necessary. Each air lock door has been designed and tested to certify its ability to withstand a pressure in excess of the maximum expected pressure following a Design Basis Accident (DBA) in containment. As such, closure of a single door supports containment OPERABILITY. Each of the doors contains double gasketed seals and local leakage rate testing capability to ensure pressure integrity. To effect a leak tight seal, the air lock design uses pressure seated doors (i.e., an increase in containment internal pressure results in increased sealing force on each door). 2

~~Each personnel air lock is provided with limit switches on both doors that provide control room indication of door position. Additionally, c~~ C ontrol room indication is provided to alert the operator whenever a ~~n~~ personnel air lock ~~door interlock mechanism is defeated~~ equalizing valve is open. 2

The containment air locks form part of the containment pressure boundary. As such, air lock integrity and leak tightness is essential for maintaining the containment leakage rate within limit in the event of a DBA. Not maintaining air lock integrity or leak tightness may result in a leakage rate in excess of that assumed in the unit safety analysis.

APPLICABLE SAFETY ANALYSES

~~[For atmospheric containment, the DBAs that result in a release of radioactive material within containment are a loss of coolant accident (LOCA), a main steam line break (MSLB) and a control element assembly (CEA) ejection accident (Ref. 2). In the analysis of each of these accidents, it is assumed that containment is OPERABLE such that release of fission products to the environment is controlled by the rate of containment leakage. The containment was designed with an allowable leakage rate of [0.10]% of containment air weight per day (Ref. 3). This leakage rate is defined in 10 CFR 50, Appendix J, Option A (Ref. 1), as~~ 3

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~L_a: the maximum allowable containment leakage rate at the calculated [maximum] peak containment pressure (P_a) of [55.7] psig, which results from the limiting design basis LOCA. This allowable leakage rate forms the basis for the acceptance criteria imposed on the SRs associated with the air lock.~~ 3

For dual containment, the DBAs that result in a release of radioactive material within containment are a LOCA, an MSLB, and a CEA ejection accident (Ref. 2). In the analysis of each of these accidents, it is assumed that containment is OPERABLE such that release of fission products to the environment is controlled by the rate of containment leakage. The containment was designed with an allowable leakage rate of ~~[~~0.50~~]~~% of containment air weight per day (Ref. 3). This leakage rate is defined in 10 CFR 50, Appendix J, Option ~~A~~ B (Ref. 1), as L_a: the maximum allowable containment leakage rate at the calculated ~~[maximum]~~ peak containment pressure (P_a) of ~~[42.3]~~ 42.77 psig, which results from the limiting design basis LOCA. This allowable leakage rate forms the basis for the acceptance criteria imposed on the SRs associated with the air lock.~~]~~ 3 2 3

The containment air locks satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Each containment air lock forms part of the containment pressure boundary. As part of the containment pressure boundary, the air lock safety function is related to control of the containment leakage rate resulting from a DBA. Thus, each air lock's structural integrity and leak tightness are essential to the successful mitigation of such an event.

Each air lock is required to be OPERABLE. For the air lock to be considered OPERABLE, the air lock interlock mechanism must be OPERABLE, the air lock must be in compliance with the Type B air lock leakage test, and both air lock doors must be OPERABLE. The interlock allows only one air lock door of an air lock to be opened at one time. This provision ensures that a gross breach of containment does not exist when containment is required to be OPERABLE. Closure of a single door in each air lock is sufficient to provide a leak tight barrier following postulated events. Nevertheless, both doors are kept closed when the air lock is not being used for normal entry into or exit from containment.

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, the containment air locks are not required in MODE 5 to prevent leakage of radioactive material from containment. The requirements for the containment air locks during MODE 6 are addressed in LCO 3.9.3, "Containment Penetrations."

ACTIONS

The ACTIONS are modified by a Note that allows entry and exit to perform repairs on the affected air lock component. If the outer door is inoperable, then it may be easily accessed for most repairs. It is preferred that the air lock be accessed from inside primary containment by entering through the other OPERABLE air lock. However, if this is not practicable, or if repairs on either door must be performed from the barrel side of the door then it is permissible to enter the air lock through the OPERABLE door, which means there is a short time during which the containment boundary is not intact (during access through the OPERABLE door). The ability to open the OPERABLE door, even if it means the containment boundary is temporarily not intact, is acceptable because of the low probability of an event that could pressurize the containment during the short time in which the OPERABLE door is expected to be open. After each entry and exit, the OPERABLE door must be immediately closed. If ALARA conditions permit, entry and exit should be via an OPERABLE air lock.

A second Note has been added to provide clarification that, for this LCO, separate Condition entry is allowed for each air lock. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable air lock. Complying with the Required Actions may allow for continued operation, and a subsequent inoperable air lock is governed by subsequent Condition entry and application of associated Required Actions. A third Note has been included that requires entry into the applicable Conditions and Required Actions of LCO 3.6.1, "Containment," when leakage results in exceeding the overall containment leakage limit.

A.1, A.2, and A.3

With one air lock door inoperable in one or more containment air locks, the OPERABLE door must be verified closed (Required Action A.1) in each affected containment air lock. This ensures that a leak tight containment barrier is maintained by the use of an OPERABLE air lock door. This action must be completed within 1 hour. This specified time period is consistent with the ACTIONS of LCO 3.6.1, which requires containment be restored to OPERABLE status within 1 hour.

BASES

ACTIONS (continued)

In addition, the affected air lock penetration must be isolated by locking closed an OPERABLE air lock door within the 24 hour Completion Time. The 24 hour Completion Time is considered reasonable for locking the OPERABLE air lock door, considering the OPERABLE door of the affected air lock is being maintained closed.

Required Action A.3 verifies that an air lock with an inoperable door has been isolated by the use of a locked and closed OPERABLE air lock door. This ensures that an acceptable containment leakage boundary is maintained. The Completion Time of once per 31 days is based on engineering judgment and is considered adequate in view of the low likelihood of a locked door being mispositioned and other administrative controls. Required Action A.3 is modified by a Note that applies to air lock doors located in high radiation areas and allows these doors to be verified locked closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Therefore, the probability of misalignment of the door, once it has been verified to be in the proper position, is small.

The Required Actions have been modified by two Notes. Note 1 ensures that only the Required Actions and associated Completion Times of Condition C are required if both doors in the same air lock are inoperable. With both doors in the same air lock inoperable, an OPERABLE door is not available to be closed. Required Actions C.1 and C.2 are the appropriate remedial actions. The exception of Note 1 does not affect tracking the Completion Time from the initial entry into Condition A; only the requirement to comply with the Required Actions. Note 2 allows use of the air lock for entry and exit for 7 days under administrative controls if both air locks have an inoperable door. This 7 day restriction begins when the second air lock is discovered inoperable. Containment entry may be required to perform Technical Specifications (TS) Surveillances and Required Actions, as well as other activities on equipment inside containment that are required by TS or activities on equipment that support TS-required equipment. This Note is not intended to preclude performing other activities (i.e., non-TS-required activities) if the containment was entered, using the inoperable air lock, to perform an allowed activity listed above. This allowance is acceptable due to the low probability of an event that could pressurize the containment during the short time that the OPERABLE door is expected to be open.

BASES

ACTIONS (continued)

B.1, B.2, and B.3

With an air lock interlock mechanism inoperable in one or more air locks, the Required Actions and associated Completion Times are consistent with those specified in Condition A.

The Required Actions have been modified by two Notes. Note 1 ensures that only the Required Actions and associated Completion Times of Condition C are required if both doors in the same air lock are inoperable. With both doors in the same air lock inoperable, an OPERABLE door is not available to be closed. Required Actions C.1 and C.2 are the appropriate remedial actions. Note 2 allows entry into and exit from containment under the control of a dedicated individual stationed at the air lock to ensure that only one door is opened at a time (i.e., the individual performs the function of the interlock).

Required Action B.3 is modified by a Note that applies to air lock doors located in high radiation areas and allows these doors to be verified locked closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Therefore, the probability of misalignment of the door, once it has been verified to be in the proper position, is small.

C.1, C.2, and C.3

With one or more air locks inoperable for reasons other than those described in Condition A or B, Required Action C.1 requires action to be initiated immediately to evaluate previous combined leakage rates using current air lock test results. An evaluation is acceptable since it is overly conservative to immediately declare the containment inoperable if both doors in an air lock have failed a seal test or if the overall air lock leakage is not within limits. In many instances (e.g., only one seal per door has failed), containment remains OPERABLE, yet only 1 hour (per LCO 3.6.1) would be provided to restore the air lock door to OPERABLE status prior to requiring a plant shutdown. In addition, even with both doors failing the seal test, the overall containment leakage rate can still be within limits.

Required Action C.2 requires that one door in the affected containment air lock must be verified to be closed. This action must be completed within the 1 hour Completion Time. This specified time period is consistent with the ACTIONS of LCO 3.6.1, which requires that containment be restored to OPERABLE status within 1 hour.

BASES

ACTIONS (continued)

Additionally, the affected air lock(s) must be restored to OPERABLE status within the 24 hour Completion Time ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The specified time period is considered reasonable for restoring an inoperable air lock to OPERABLE status, assuming that at least one door is maintained closed in each affected air lock. 3

D.1 and D.2

~~---------- REVIEWER'S NOTE ----------~~
~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~
~~----------~~ 4

If the inoperable containment air lock cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 4). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action D.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is

BASES

ACTIONS (continued)

not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.6.2.1

Maintaining containment air locks OPERABLE requires compliance with the leakage rate test requirements of the Containment Leakage Rate Testing Program. This SR reflects the leakage rate testing requirements with regard to air lock leakage (Type B leakage tests). The acceptance criteria were established during initial air lock and containment OPERABILITY testing. The periodic testing requirements verify that the air lock leakage does not exceed the allowed fraction of the overall containment leakage rate. The Frequency is required by the Containment Leakage Rate Testing Program.

The SR has been modified by two Notes. Note 1 states that an inoperable air lock door does not invalidate the previous successful performance of the overall air lock leakage test. This is considered reasonable since either air lock door is capable of providing a fission product barrier in the event of a DBA. Note 2 has been added to this SR requiring the results to be evaluated against the acceptance criteria which is applicable to SR 3.6.1.1. This ensures that air lock leakage is properly accounted for in determining the combined Type B and C containment leakage rate.

SR 3.6.2.2

The air lock interlock is designed to prevent simultaneous opening of both doors in a single air lock. Since both the inner and outer doors of an air lock are designed to withstand the maximum expected post accident containment pressure, closure of either door will support containment OPERABILITY. Thus, the door interlock feature supports containment OPERABILITY while the air lock is being used for personnel transit into and out of containment. Periodic testing of this interlock demonstrates that the interlock will function as designed and that simultaneous opening of the inner and outer doors will not inadvertently occur. Due to the purely mechanical nature of this interlock, and given that the interlock mechanism is not normally challenged when the containment airlock door is used for entry and exit (procedures require strict adherence to single door opening), this test is ~~only required to be performed every 24 months~~ performed in accordance with the Surveillance Frequency Control Program. 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[The 24 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage, and the potential for loss of containment OPERABILITY if the Surveillance were performed with the reactor at power. The 24 month Frequency for the interlock is justified based on generic operating experience. The 24 month Frequency is based on engineering judgment and is considered adequate given that the interlock is not challenged during the use of the airlock.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

B 3.6 CONTAINMENT SYSTEMS

B 3.6.2 Containment Air Locks ~~(Atmospheric and Dual)~~

BASES

BACKGROUND

Containment air locks form part of the containment pressure boundary and provide a means for personnel access during all MODES of operation.

Each air lock is nominally a right circular cylinder, ~~10~~ ft in diameter, with a door at each end. The doors are interlocked to prevent simultaneous opening. During periods when containment is not required to be OPERABLE, the door interlock mechanism may be disabled, allowing both doors of an air lock to remain open for extended periods when frequent containment entry is necessary. Each air lock door has been designed and tested to certify its ability to withstand a pressure in excess of the maximum expected pressure following a Design Basis Accident (DBA) in containment. As such, closure of a single door supports containment OPERABILITY. Each of the doors contains double gasketed seals and local leakage rate testing capability to ensure pressure integrity. To effect a leak tight seal, the air lock design uses pressure seated doors (i.e., an increase in containment internal pressure results in increased sealing force on each door).

Each personnel air lock is provided with limit switches ~~on both~~ door~~s~~ that provide control room indication of door position. ~~Additionally, control room indication is provided to alert the operator whenever an air lock door interlock mechanism is defeated.~~

The containment air locks form part of the containment pressure boundary. As such, air lock integrity and leak tightness is essential for maintaining the containment leakage rate within limit in the event of a DBA. Not maintaining air lock integrity or leak tightness may result in a leakage rate in excess of that assumed in the unit safety analysis.

APPLICABLE SAFETY ANALYSES

~~[For atmospheric containment, the DBAs that result in a release of radioactive material within containment are a loss of coolant accident (LOCA), a main steam line break (MSLB) and a control element assembly (CEA) ejection accident (Ref. 2). In the analysis of each of these accidents, it is assumed that containment is OPERABLE such that release of fission products to the environment is controlled by the rate of containment leakage. The containment was designed with an allowable leakage rate of [0.10]% of containment air weight per day (Ref. 3). This leakage rate is defined in 10 CFR 50, Appendix J, Option A (Ref. 1), as~~

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~L_a: the maximum allowable containment leakage rate at the calculated [maximum] peak containment pressure (P_a) of [55.7] psig, which results from the limiting design basis LOCA. This allowable leakage rate forms the basis for the acceptance criteria imposed on the SRs associated with the air lock.~~ 3

For dual containment, the DBAs that result in a release of radioactive material within containment are a LOCA, an MSLB, and a CEA ejection accident (Ref. 2). In the analysis of each of these accidents, it is assumed that containment is OPERABLE such that release of fission products to the environment is controlled by the rate of containment leakage. The containment was designed with an allowable leakage rate of ~~[~~0.50~~]~~% of containment air weight per day (Ref. 3). This leakage rate is defined in 10 CFR 50, Appendix J, Option ~~A~~ B (Ref. 1), as L_a: the maximum allowable containment leakage rate at the calculated ~~[maximum]~~ peak containment pressure (P_a) of ~~[42.3]~~ 43.43 psig, which results from the limiting design basis LOCA. This allowable leakage rate forms the basis for the acceptance criteria imposed on the SRs associated with the air lock.~~]~~ 3 2 3

The containment air locks satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Each containment air lock forms part of the containment pressure boundary. As part of the containment pressure boundary, the air lock safety function is related to control of the containment leakage rate resulting from a DBA. Thus, each air lock's structural integrity and leak tightness are essential to the successful mitigation of such an event.

Each air lock is required to be OPERABLE. For the air lock to be considered OPERABLE, the air lock interlock mechanism must be OPERABLE, the air lock must be in compliance with the Type B air lock leakage test, and both air lock doors must be OPERABLE. The interlock allows only one air lock door of an air lock to be opened at one time. This provision ensures that a gross breach of containment does not exist when containment is required to be OPERABLE. Closure of a single door in each air lock is sufficient to provide a leak tight barrier following postulated events. Nevertheless, both doors are kept closed when the air lock is not being used for normal entry into or exit from containment.

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, the containment air locks are not required in MODE 5 to prevent leakage of radioactive material from containment. The requirements for the containment air locks during MODE 6 are addressed in LCO 3.9.3, "Containment Penetrations."

ACTIONS

The ACTIONS are modified by a Note that allows entry and exit to perform repairs on the affected air lock component. If the outer door is inoperable, then it may be easily accessed for most repairs. It is preferred that the air lock be accessed from inside primary containment by entering through the other OPERABLE air lock. However, if this is not practicable, or if repairs on either door must be performed from the barrel side of the door then it is permissible to enter the air lock through the OPERABLE door, which means there is a short time during which the containment boundary is not intact (during access through the OPERABLE door). The ability to open the OPERABLE door, even if it means the containment boundary is temporarily not intact, is acceptable because of the low probability of an event that could pressurize the containment during the short time in which the OPERABLE door is expected to be open. After each entry and exit, the OPERABLE door must be immediately closed. If ALARA conditions permit, entry and exit should be via an OPERABLE air lock.

A second Note has been added to provide clarification that, for this LCO, separate Condition entry is allowed for each air lock. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable air lock. Complying with the Required Actions may allow for continued operation, and a subsequent inoperable air lock is governed by subsequent Condition entry and application of associated Required Actions. A third Note has been included that requires entry into the applicable Conditions and Required Actions of LCO 3.6.1, "Containment," when leakage results in exceeding the overall containment leakage limit.

A.1, A.2, and A.3

With one air lock door inoperable in one or more containment air locks, the OPERABLE door must be verified closed (Required Action A.1) in each affected containment air lock. This ensures that a leak tight containment barrier is maintained by the use of an OPERABLE air lock door. This action must be completed within 1 hour. This specified time period is consistent with the ACTIONS of LCO 3.6.1, which requires containment be restored to OPERABLE status within 1 hour.

BASES

ACTIONS (continued)

In addition, the affected air lock penetration must be isolated by locking closed an OPERABLE air lock door within the 24 hour Completion Time. The 24 hour Completion Time is considered reasonable for locking the OPERABLE air lock door, considering the OPERABLE door of the affected air lock is being maintained closed.

Required Action A.3 verifies that an air lock with an inoperable door has been isolated by the use of a locked and closed OPERABLE air lock door. This ensures that an acceptable containment leakage boundary is maintained. The Completion Time of once per 31 days is based on engineering judgment and is considered adequate in view of the low likelihood of a locked door being mispositioned and other administrative controls. Required Action A.3 is modified by a Note that applies to air lock doors located in high radiation areas and allows these doors to be verified locked closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Therefore, the probability of misalignment of the door, once it has been verified to be in the proper position, is small.

The Required Actions have been modified by two Notes. Note 1 ensures that only the Required Actions and associated Completion Times of Condition C are required if both doors in the same air lock are inoperable. With both doors in the same air lock inoperable, an OPERABLE door is not available to be closed. Required Actions C.1 and C.2 are the appropriate remedial actions. The exception of Note 1 does not affect tracking the Completion Time from the initial entry into Condition A; only the requirement to comply with the Required Actions. Note 2 allows use of the air lock for entry and exit for 7 days under administrative controls if both air locks have an inoperable door. This 7 day restriction begins when the second air lock is discovered inoperable. Containment entry may be required to perform Technical Specifications (TS) Surveillances and Required Actions, as well as other activities on equipment inside containment that are required by TS or activities on equipment that support TS-required equipment. This Note is not intended to preclude performing other activities (i.e., non-TS-required activities) if the containment was entered, using the inoperable air lock, to perform an allowed activity listed above. This allowance is acceptable due to the low probability of an event that could pressurize the containment during the short time that the OPERABLE door is expected to be open.

BASES

ACTIONS (continued)

B.1, B.2, and B.3

With an air lock interlock mechanism inoperable in one or more air locks, the Required Actions and associated Completion Times are consistent with those specified in Condition A.

The Required Actions have been modified by two Notes. Note 1 ensures that only the Required Actions and associated Completion Times of Condition C are required if both doors in the same air lock are inoperable. With both doors in the same air lock inoperable, an OPERABLE door is not available to be closed. Required Actions C.1 and C.2 are the appropriate remedial actions. Note 2 allows entry into and exit from containment under the control of a dedicated individual stationed at the air lock to ensure that only one door is opened at a time (i.e., the individual performs the function of the interlock).

Required Action B.3 is modified by a Note that applies to air lock doors located in high radiation areas and allows these doors to be verified locked closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Therefore, the probability of misalignment of the door, once it has been verified to be in the proper position, is small.

C.1, C.2, and C.3

With one or more air locks inoperable for reasons other than those described in Condition A or B, Required Action C.1 requires action to be initiated immediately to evaluate previous combined leakage rates using current air lock test results. An evaluation is acceptable since it is overly conservative to immediately declare the containment inoperable if both doors in an air lock have failed a seal test or if the overall air lock leakage is not within limits. In many instances (e.g., only one seal per door has failed), containment remains OPERABLE, yet only 1 hour (per LCO 3.6.1) would be provided to restore the air lock door to OPERABLE status prior to requiring a plant shutdown. In addition, even with both doors failing the seal test, the overall containment leakage rate can still be within limits.

Required Action C.2 requires that one door in the affected containment air lock must be verified to be closed. This action must be completed within the 1 hour Completion Time. This specified time period is consistent with the ACTIONS of LCO 3.6.1, which requires that containment be restored to OPERABLE status within 1 hour.

BASES

ACTIONS (continued)

Additionally, the affected air lock(s) must be restored to OPERABLE status within the 24 hour Completion Time ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The specified time period is considered reasonable for restoring an inoperable air lock to OPERABLE status, assuming that at least one door is maintained closed in each affected air lock.

D.1 and D.2

~~---------- REVIEWER'S NOTE ----------~~
~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~
~~---------- ----------~~

If the inoperable containment air lock cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 4). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action D.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is

BASES

ACTIONS (continued)

not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.6.2.1

Maintaining containment air locks OPERABLE requires compliance with the leakage rate test requirements of the Containment Leakage Rate Testing Program. This SR reflects the leakage rate testing requirements with regard to air lock leakage (Type B leakage tests). The acceptance criteria were established during initial air lock and containment OPERABILITY testing. The periodic testing requirements verify that the air lock leakage does not exceed the allowed fraction of the overall containment leakage rate. The Frequency is required by the Containment Leakage Rate Testing Program.

The SR has been modified by two Notes. Note 1 states that an inoperable air lock door does not invalidate the previous successful performance of the overall air lock leakage test. This is considered reasonable since either air lock door is capable of providing a fission product barrier in the event of a DBA. Note 2 has been added to this SR requiring the results to be evaluated against the acceptance criteria which is applicable to SR 3.6.1.1. This ensures that air lock leakage is properly accounted for in determining the combined Type B and C containment leakage rate.

SR 3.6.2.2

The air lock interlock is designed to prevent simultaneous opening of both doors in a single air lock. Since both the inner and outer doors of an air lock are designed to withstand the maximum expected post accident containment pressure, closure of either door will support containment OPERABILITY. Thus, the door interlock feature supports containment OPERABILITY while the air lock is being used for personnel transit into and out of containment. Periodic testing of this interlock demonstrates that the interlock will function as designed and that simultaneous opening of the inner and outer doors will not inadvertently occur. Due to the purely mechanical nature of this interlock, and given that the interlock mechanism is not normally challenged when the containment airlock door is used for entry and exit (procedures require strict adherence to single door opening), this test is ~~only required to be performed every 24 months~~ performed in accordance with the Surveillance Frequency Control Program. 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[The 24 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage, and the potential for loss of containment OPERABILITY if the Surveillance were performed with the reactor at power. The 24 month Frequency for the interlock is justified based on generic operating experience. The 24 month Frequency is based on engineering judgment and is considered adequate given that the interlock is not challenged during the use of the airlock.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.2 BASES, CONTAINMENT AIR LOCKS

1. The type of Containment (Atmospheric and Dual) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ISTS Bases which reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS Bases contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. The PSL Safety Analysis Report (SAR) is an updated version of the original Final Safety Analysis Report. Therefore, the proper acronym is UFSAR and is changed to reflect the document.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.6.2, CONTAINMENT AIR LOCKS

There are no specific No Significant Hazards Considerations for this Specification.

CONTAINMENT SYSTEMS

3/4.6.3 CONTAINMENT ISOLATION VALVES

LIMITING CONDITION FOR OPERATION

LCO 3.6.3

3.6.3.1 The containment isolation valves shall be OPERABLE:

Applicability

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

Add proposed ACTIONS NOTE 2

A02

NOTE

ACTIONS NOTE 3

1. Enter applicable ACTIONS for systems made inoperable by containment isolation valves.

ACTIONS NOTE 4

2. Enter the ACTION of LCO 3.6.1.2, “Containment Leakage,” when leakage results in exceeding overall containment leakage rate acceptance criteria.

Add proposed ACTION D

L08

With one or more of the isolation valve(s) inoperable, either:

a. ~~Restore the inoperable valve(s) to OPERABLE status within 4 hours or in accordance with the Risk Informed Completion Time Program, or~~

A03

Required Actions A.1, B.1, and C.1

b. Isolate each affected penetration within 4 hours or in accordance with the Risk Informed Completion Time Program by use of at least one deactivated automatic valve secured in the isolation position, or

c. Isolate each affected penetration within 4 hours or in accordance with the Risk Informed Completion Time Program by use of at least one closed manual valve or blind flange; or

or check valve with flow through the valve secured

L02

MODE 3

MODE 4

ACTION E

d. Be in at least ~~HOT STANDBY~~ within ~~the next~~ 6 hours and in ~~HOT SHUTDOWN~~ within ~~the following 6~~ hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

ACTION E NOTE

12

Add Completion Time of 1 hour for ACTION B

M03

Add Completion Time of 72 hours for ACTION C

L01

SURVEILLANCE REQUIREMENTS

~~4.6.3.1.1 The isolation valves shall be demonstrated OPERABLE prior to returning the valve to service after maintenance, repair or replacement work is performed on the valve or its associated actuator, control or power circuit by performance of the cycling test, and verification of isolation time.~~

3/4.6 CONTAINMENT SYSTEMS

3/4.6.1 CONTAINMENT VESSEL

CONTAINMENT VESSEL INTEGRITY

LIMITING CONDITION FOR OPERATION

3.6.1.1 CONTAINMENT VESSEL INTEGRITY shall be maintained.

See ITS 3.6.1

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

ACTION B / ACTION E

Without CONTAINMENT VESSEL INTEGRITY, restore CONTAINMENT VESSEL INTEGRITY within one hour or be in at least HOT STANDBY within the next 6 hours and in ~~COLD~~ ~~SHUTDOWN~~ within ~~the following 30~~ hours.

MODE 4

L10

12

SURVEILLANCE REQUIREMENTS

4.6.1.1 CONTAINMENT VESSEL INTEGRITY shall be demonstrated:

a. In accordance with the Surveillance Frequency Control Program by verifying that:

Add proposed action Required Actions A.2 and C.2 NOTEs 1 and 2; and SRs 3.6.3.2 and SR 3.6.3.3 NOTE

L07

Required Actions A.2 and C.2

SR 3.6.3.2

SR 3.6.3.3

1. All containment vessel penetrations* not capable of being closed by OPERABLE containment automatic isolation valves and required to be closed during accident conditions are closed by valves, blind flanges, or deactivated automatic valves secured in their positions, except for valves that are open on an intermittent basis under administrative control, and

ACTIONS NOTE 1

, or check valve with flow through the valve secured

L02

2. All containment vessel equipment hatches are closed and sealed.

See ITS 3.6.1

b. By verifying that each containment vessel air lock is OPERABLE per Specification 3.6.1.3

See ITS 3.6.2

---

and outside

L07

SR 3.6.3.3

* Except valves, blind flanges, and deactivated automatic valves which are located inside the containment and are locked, sealed or otherwise secured in the closed position. These penetrations shall be verified closed during each COLD SHUTDOWN except that such verification need not be performed more often than once per 92 days.

DEFINITIONS

CHANNEL FUNCTIONAL TEST

1.6 A CHANNEL FUNCTIONAL TEST shall be the injection of a simulated signal into the channel as close to the primary sensor as practicable to verify OPERABILITY including alarm and/or trip functions.

See ITS Chapter 1.0

CONTAINMENT VESSEL INTEGRITY

1.7 CONTAINMENT VESSEL INTEGRITY shall exist when:

a. All containment vessel penetrations required to be closed during accident conditions are either:

LCO 3.6.3

1. Capable of being closed by an OPERABLE containment automatic isolation valve system, or

2. Closed by manual valves, blind flanges, or deactivated automatic valves secured in their closed position except for valves that are open on an intermittent basis under administrative control.

b. All containment vessel equipment hatches are closed and sealed,

See ITS Chapter 3.6.1

c. Each containment vessel air lock is in compliance with the requirements of Specification 3.6.1.3,

See ITS Chapter 3.6.2

d. The containment leakage rates are within the limits of Specification 3.6.1.2, and

e. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.

See ITS Chapter 3.6.1

CONTROLLED LEAKAGE

1.8 CONTROLLED LEAKAGE shall be the seal water flow supplied from the reactor coolant pump seals.

CORE ALTERATION

1.9 CORE ALTERATION shall be the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity within the reactor vessel with the vessel head removed and fuel in the vessel. Exceptions to the above include shared (4 fingered) control element assemblies (CEAs) withdrawn into the upper guide structure (UGS) or evolutions performed with the UGS in place such as CEA latching/unlatching or verification of latching/unlatching which do not constitute a CORE ALTERATION. Suspension of CORE ALTERATIONS shall not preclude completion of movement of a component to a safe position.

See ITS Chapter 1.0

CORE OPERATING LIMITS REPORT (COLR)

1.9a THE COLR is the unit-specific document that provides cycle specific parameter limits for the current operating reload cycle. These cycle-specific parameter limits shall be determined for each reload cycle in accordance with Specification 6.9.1.11. Plant operation within these limits is addressed in individual Specifications.

ADMINISTRATIVE CONTROLS

(2) conform to the guidance of Appendix I to 10 CFR Part 50, and
(3) include the following:

1) Monitoring, sampling, analysis, and reporting of radiation and radionuclides in the environment in accordance with the methodology and parameters in the ODCM.

2) A Land Use Census to ensure that changes in the use of areas at and beyond the SITE BOUNDARY are identified and that modifications to the monitoring program are made if required by the results of this census, and

3) Participation in a Interlaboratory Comparison Program to ensure that independent checks on the precision and accuracy of the measurements of radioactive materials in environmental sample matrices are performed as part of the quality assurance program for environmental monitoring.

See ITS 5.5

h. Containment Leakage Rate Testing Program

A program to implement the leakage rate testing of the containment as required by 10 CFR 50.54(o) and 10 CFR 50 Appendix J, Option B, as modified by approved exemptions. This program is in accordance with the guidelines contained in NEI 94-01, Revision 2-A, "Industry Guideline for Implementing Performance-Based Option of 10 CFR Part 50, Appendix J," except that the next Type A test performed after the December 8, 2005 Type A test shall be performed no later than December 8, 2020.

The peak calculated containment internal pressure for the design basis loss of coolant accident P_a, is 42.8 psig. The containment design pressure is 44 psig.

The maximum allowed containment leakage rate, L_a, at P_a, shall be 0.50% of containment air weight per day.

Leakage rate acceptance criteria are:

a. Containment leakage rate acceptance criterion is $\leq$ 1.0 L_a. During the first unit startup following testing in accordance with this program, the leakage rate acceptance criteria are < 0.60 L_a for the Type B and C tests, $\leq$ 0.75 L_a for Type A tests, and $\leq$ 0.096 L_a for secondary containment bypass leakage paths.

See ITS 5.5

SR 3.6.3.7

Verify the combined leakage rate when pressurized to $\geq$ 42.77 psig

R1

b. Air lock testing acceptance criteria are:

1) Overall air lock leakage rate is $\leq$ 0.05 L_a when tested at $\geq$ P_a.

2) For the personnel air lock door seal, leakage rate is < 0.01 L_a when pressurized to $\geq$ 1.0 P_a.

3) For the emergency air lock door seal, leakage rate is < 0.01 L_a when pressurized to $\geq$ 10 psig.

See ITS 5.5

Add proposed action Required Actions A.2 and C.2 NOTEs 1 and 2; and SRs 3.6.3.3 and SR 3.6.3.4 NOTE

L07

SURVEILLANCE REQUIREMENTS

4.6.1.1 Primary CONTAINMENT INTEGRITY shall be demonstrated:

Required Actions A.2 and C.2
SR 3.6.3.3
SR 3.6.3.4

a. In accordance with the Surveillance Frequency Control Program by verifying that all penetrations** not capable of being closed by OPERABLE containment automatic isolation valves and required to be closed during accident conditions are closed by valves, blind flanges, or deactivated automatic valves secured in their positions, except for valves that are open on an intermittent basis under administrative control.

ACTIONS NOTE 1

, or check valve with flow through the valve secured

L02

b. By verifying that each containment air lock is in compliance with the requirements of Specification 3.6.1.3.

See ITS 3.6.2

---

* In MODES 1 and 2, the RCB polar crane shall be rendered inoperable by locking the power supply breaker open.

See ITS 3.6.1.1

SR 3.6.3.4

** Except valves, blind flanges, and deactivated automatic valves which are located inside the containment and are locked, sealed or otherwise secured in the closed position. These penetrations shall be verified closed during each COLD SHUTDOWN except that such verification need not be performed more often than once per 92 days.

L07

and outside

CONTAINMENT SYSTEMS

CONTAINMENT VENTILATION SYSTEM

LIMITING CONDITION FOR OPERATION

LCO 3.6.3

3.6.1.7 Each containment purge supply and exhaust isolation valve shall be OPERABLE and:

SR 3.6.3.1

a. Each 48-inch containment purge supply and exhaust isolation valve shall be sealed closed.

SR 3.6.3.2

b. The 8-inch containment purge supply and exhaust isolation valves may be open for purging and/or venting as required for safety related purposes such as:

1. Maintaining containment pressure within the limits of Specification 3.6.1.4.

2. Reducing containment atmosphere airborne radioactivity and/or improving air quality to an acceptable level for containment access.

Applicability

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

ACTION A

ACTION F

a. With a 48-inch containment purge supply and/or exhaust isolation valve(s) open or not sealed closed, close and/or seal close the open valve(s) or isolate the penetration(s) within 4 hours, otherwise be in at least HOT STANDBY within the next 6 hours and in ~~COLD SHUTDOWN~~ within ~~the following 30~~ hours.

MODE 4

ACTION A

ACTION F

b. With an 8-inch containment purge supply and/or exhaust isolation valve(s) open for reasons other than those stated in Specification 3.6.1.7.b, close the open 8-inch valve(s) or isolate the penetration(s) within 4 hours, otherwise be in at least HOT STANDBY within the next 6 hours and in ~~COLD SHUTDOWN~~ within ~~the following 30~~ hours.

12

MODE 4

L10

ACTION E

c. With a containment purge supply and/or exhaust isolation valve(s) having a measured leakage rate exceeding the limits of Surveillance Requirements 4.6.1.7.3 and/or 4.6.1.7.4, within 24 hours ~~either restore the inoperable valve(s) to OPERABLE status or~~ isolate the affected penetration flow path by use of at least

A03

ACTION E.1

one closed and de-activated automatic valve with resilient seals or blind flange,

ACTION E.2

verify the affected penetration flowpath is isolated, and perform Surveillance

ACTION E.3

Requirement 4.6.1.7.3 or 4.6.1.7.4 for resilient seated valves closed to isolate the penetration flowpath, otherwise be in at least HOT STANDBY within the next

ACTION F

6 hours and in ~~COLD SHUTDOWN~~ within ~~the following 30~~ hours.

12

MODE 4

L10

ACTION E.3

1. Closed and de-activated automatic valve(s) with resilient seals used to isolate the penetration flowpath(s) shall be tested in accordance with either Surveillance Requirement 4.6.1.7.3 for 48-inch valves at least once per 6 months or Surveillance Requirement 4.6.1.7.4 for 8-inch valves at least once per 92 days.

ACTION E.2
NOTES 1 and 2

NOTE

Verification of isolation devices by administrative means is acceptable when they are located in high radiation areas or they are locked, sealed, or otherwise secured by administrative means.

R1

ACTION E.2

2. Verify the affected penetration flowpath is isolated once per 31 days following isolation for isolation devices outside containment and prior to entering MODE 4 from MODE 5 for isolation devices inside containment if not performed within the previous 92 days.

CONTAINMENT SYSTEMS

CONTAINMENT VENTILATION SYSTEM

LIMITING CONDITION FOR OPERATION (continued)

SURVEILLANCE REQUIREMENTS

SR 3.6.3.1 4.6.1.7.1 Each 48-inch containment purge supply and exhaust isolation valve shall be verified to be sealed-closed in accordance with the Surveillance Frequency Control Program.

except for one purge valve in a penetration flow path while in Condition E of this LCO

L09

~~4.6.1.7.2 Documentation shall be reviewed in accordance with the Surveillance Frequency Control Program to confirm that purging and venting were performed in accordance with Specification 3.6.1.7.b.~~

L11

SR 3.6.3.6 4.6.1.7.3 In accordance with the Surveillance Frequency Control Program each sealed closed 48-inch containment purge supply and exhaust isolation valve with resilient material seals shall be demonstrated OPERABLE by verifying ~~that the measured leakage rate is less than or equal to 0.05 L_a when pressurized to P_a~~.

SR 3.6.3.6 4.6.1.7.4 In accordance with the Surveillance Frequency Control Program, each 8-inch containment purge supply and exhaust isolation valve with resilient material seals shall be demonstrated OPERABLE by verifying ~~that the measured leakage rate is less than or equal to 0.05 L_a when pressurized to P_a~~.

LA02

DEFINITIONS

CHANNEL FUNCTIONAL TEST

1.6 A CHANNEL FUNCTIONAL TEST shall be the injection of a simulated signal into the channel as close to the primary sensor as practicable to verify OPERABILITY including alarm and/or trip functions.

CONTAINMENT VESSEL INTEGRITY

See ITS Chapter 1.0

1.7 CONTAINMENT VESSEL INTEGRITY shall exist when:

a. All containment vessel penetrations required to be closed during accident conditions are either:

LCO 3.6.3

1. Capable of being closed by an OPERABLE containment automatic isolation valve system, or

2. Closed by manual valves, blind flanges, or deactivated automatic valves secured in their closed positions, except for valves that are open on an intermittent basis under administrative control.

b. All containment vessel equipment hatches are closed and sealed,

See ITS Chapter 3.6.1

c. Each containment vessel air lock is in compliance with the requirements of Specification 3.6.1.3,

See ITS Chapter 3.6.2

d. The containment leakage rates are within the limits of Specification 3.6.1.2, and

e. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.

CONTROLLED LEAKAGE

See ITS Chapter 3.6.1

1.8 CONTROLLED LEAKAGE shall be the seal water flow supplied from the reactor coolant pump seals.

CORE ALTERATION

1.9 CORE ALTERATION shall be the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity within the reactor vessel with the vessel head removed and fuel in the vessel. Exceptions to the above include evolutions performed with the upper guide structure (UGS) in place such as control element assembly (CEA) latching/unlatching or verification of latching/unlatching which do not constitute a CORE ALTERATION. Suspension of CORE ALTERATIONS shall not preclude completion of movement of a component to a safe position.

CORE OPERATING LIMITS REPORT (COLR)

1.9a THE COLR is the unit-specific document that provides cycle specific parameter limits for the current operating reload cycle. These cycle-specific parameter limits shall be determined for each reload cycle in accordance with Specification 6.9.1.11. Plant operation within these limits is addressed in individual Specifications.

See ITS Chapter 1.0

ADMINISTRATIVE CONTROLS (Continued)

Leakage rate acceptance criteria are:

a. Containment leakage rate acceptance criterion is $\leq$ 1.0 L_a. During the first unit startup following testing in accordance with this program, the leakage rate acceptance criteria are < 0.60 L_a for the Type B and C tests, $\leq$ 0.75 L_a for Type A tests, and $\leq$ 0.096 L_a for secondary containment bypass leakage paths.

See ITS 5.5

SR 3.6.3.8

Verify the combined leakage rate when pressurized to $\geq$ 43.43 psig

R1

b. Air lock testing acceptance criteria are:

1) Overall air lock leakage is $\leq$ 0.05 L_a when tested at $\geq$ P_a.

2) For each door seal, leakage rate is < 0.01 L_a when pressurized to $\geq$ P_a.

See ITS 5.5

The provisions of T.S. 4.0.2 do not apply to test frequencies in the Containment Leak Rate Testing Program.

The provisions for T.S. 4.0.3 are applicable to the Containment Leak Rate Testing Program.

i. Deleted

DISCUSSION OF CHANGES
ITS 3.6.3, CONTAINMENT ISOLATION VALVES

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.6.3.1 and Unit 2 3.6.3 ACTIONS provide requirements to be taken for each inoperable containment isolation valve. ITS 3.6.3 includes an explicit Note (ACTION Note 2) that states, “Separate Condition entry is allowed for each penetration flow path.” This Note provides instructions for the proper application of the ACTIONS for ITS compliance. This changes the CTS by providing explicit direction for using the ACTIONS when a containment isolation valve is inoperable.

This change is acceptable because the addition of the Note reflects the CTS allowance to take appropriate Actions. This change is designated as administrative since it does not result in a technical change to the CTS.

A03 When one or more containment isolation valves are inoperable, Unit 1 CTS 3.6.3.1 and Unit 2 CTS 3.6.3 Action a requires restoring the inoperable valve(s) to OPERABLE status within 4 hours or taking one of the other specified compensatory actions. In addition, Unit 2 CTS 3.6.1.7 Action c requires restoring the inoperable valve(s) to OPERABLE status. ITS 3.6.3 does not state the requirement to restore an inoperable isolation valve to OPERABLE status but includes other compensatory Required Actions to take within in 4 hours or 72 hours, as applicable. This changes the CTS by not explicitly stating the requirement to restore an inoperable valve to OPERABLE status.

This change is acceptable because the technical requirements have not changed. Restoration of compliance with the LCO is always an available action and it is the convention in the ITS to not state such “restore” options explicitly unless it is the only action or is required for clarity. This change is designated as administrative because it does not result in any technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS 3.6.3.1 does not have specific requirements for the 48 inch purge valves. ITS SR 3.6.3.1 requires verification that each 48 inch purge valve is sealed closed in accordance with the Surveillance Frequency Control Program except for purge valves in a penetration flow path while in Condition D. This changes the CTS by adding a specific Surveillance Requirement to verify each 48 inch purge valve is sealed closed in MODES 1, 2, 3, and 4. Actions are also added for excessive leakage in containment penetration flow paths containing purge valves (Refer to Discussion of Change (DOC) L08).

The purpose of ITS SR 3.6.3.1 is to ensure that a gross breach of containment is not caused by an inadvertent or spurious opening of a 48 inch containment purge valve. A sealed closed valve must have motive power to the valve operator removed. The initial Frequency in accordance with the Surveillance Frequency Control Program will be specified as 31 days consistent with ISTS 3.6.3.1 and based on an NRC initiative, Generic Issue B-24, "Containment Leakage Due to Seal Deterioration." This change is acceptable and is designated as more restrictive since the CTS does not currently require this verification for the 48 inch purge valves.

M02 **Unit 2 only:** CTS 3.6.3 and CTS 3.6.1.7 do not have a specific surveillance requirement to verify each 8 inch purge valve is closed. However, CTS 3.6.1.7.b allows the 8 inch purge supply and exhaust isolation valves to be opened for purging and venting as required with restrictions. This implies that the 8 inch purge valves must be closed at other times during MODES 1, 2, 3 and 4. ITS SR 3.6.3.2 requires verification that each 8 inch purge valve is closed in accordance with the Surveillance Frequency Control Program except when the 8 inch purge valves are open for pressure control, ALARA or air quality considerations for personnel entry, or for Surveillances that require the valves to be open. This changes the CTS by adding a specific Surveillance Requirement to verify each 8 inch purge valve is closed in MODES 1, 2, 3, and 4. |R1

The purpose of ITS SR 3.6.3.2 to ensure that the 8 inch purge valves are closed as required or, if open, it is for an allowable reason. The initial Frequency in accordance with the Surveillance Frequency Control Program will be specified as 31 days consistent with ISTS 3.6.3.2 and based on the Frequency of verifying the position of containment isolation valves. This change is acceptable and is designated as more restrictive since the CTS does not currently require this verification for the 8 inch purge valves.

M03 Unit 1 CTS 3.6.3.1 and Unit 2 CTS 3.6.3 Actions require, in part, with one or more isolation valve(s) inoperable to isolate the affected penetration. CTS Actions b and c allow 4 hours to isolate the affected penetration when one or more containment isolation valves are inoperable. ITS 3.6.3 Required Action B.1 requires 1 hour to isolate the affected penetration flow path when both valves in the same penetration flow path are inoperable. This changes the CTS by prescribing the time allowed to isolate the affected penetration when both containment isolation valves in the same penetration flow path are inoperable.

The purpose of the CTS Actions is to provide compensatory actions for inoperable containment isolation valves. However, when both valves in the same penetration flow path are inoperable, the time allowed to isolate the affected penetration flow path is not prescribed and action must be taken immediately to maintain at least one isolation valve operable. Because the containment isolation valves support the leak tightness of the containment the time allowed to isolate the affected penetration should be the same as that allowed to restore an inoperable containment. The one hour Completion Time is commensurate with the Completion Time in ITS 3.6.1 (CTS 3.6.1.1 (U1) and 3.6.3 (U2)) for restoring the containment to OPERABLE status when the containment is inoperable. This change is considered more restrictive because it provides a new Condition and

associated Required Actions for two inoperable containment isolation valves in the same containment penetration flow path.

M04 **Unit 1 only:** CTS 3.6.3.1 does not have a specific surveillance requirement to perform leakage rate testing for containment purge valves with resilient seals. ITS SR 3.6.3.5 requires leakage rate testing for containment penetration flow paths containing purge valves with resilient seals in accordance with the Surveillance Frequency Control Program. This changes the CTS by adding a specific Surveillance Requirement to perform leakage rate testing for containment penetration flow paths containing purge valves with resilient seals. Actions are also added for excessive leakage in containment penetration flow paths containing purge valves (Refer to DOC L08).

The purpose of ITS SR 3.6.3.5 to perform additional leakage rate testing beyond the 10 CFR 50, Appendix J requirements to ensure OPERABILITY. Operating experience has demonstrated that this type of seal has the potential to degrade in a shorter period of time than do other seal types. The initial Frequency in accordance with the Surveillance Frequency Control Program will be specified as 184 days consistent with ISTS SR 3.6.3.6 and based on the Frequency established as part of the NRC resolution of Generic Issue B-20, "Containment Leakage Due to Seal Deterioration." This change is acceptable and is designated as more restrictive since the CTS does not currently require this Surveillance.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 4.6.3.1.2.a states that each containment isolation valve shall be demonstrated OPERABLE by verifying that on “a Containment Isolation test signal, and/or SIAS Test” signal actuates to its isolation position. Unit 2 CTS 4.6.3.2.a states that on “a Containment Isolation test signal (CIAS) and/or a Safety Injection test signal (SIAS)” actuates to its isolation position and Unit 2 CTS 4.6.3.2.b. states that on “a Containment Radiation High test signal” each containment purge valve actuates to its isolation position. Unit 1 ITS 3.6.3.6 and Unit 2 ITS SR 3.6.3.7 require verification that each automatic containment isolation valve that is not locked, sealed, or otherwise secured in position, actuates to the isolation position on an actual or simulated actuation signal. This changes the CTS by moving the detail concerning what type of signals are used to conduct the Surveillance Requirement to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement to verify that the required valve automatically actuate. Also, this change is acceptable because the removed information will be adequately controlled in the

ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 **Unit 2 only:** *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.6.1.7.3 and 4.6.1.7.4 require the containment purge and exhaust valve leakage rate to be less than or equal to 0.05 La when pressurized to Pa. ITS SR 3.6.3.6 does not include this requirement. This changes the CTS by moving the specific acceptance criteria to the Bases.

The removal of these details, which provide specific leakage acceptance criteria for purge valve leakage, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS SR 3.6.3.6 retains the requirement to perform leakage rate testing for containment penetration flow paths containing purge valves with resilient seals. Also, this change is acceptable because these types of details will be adequately controlled by the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirement are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 3 – Relaxation of Completion Time)* Unit 1 CTS 3.6.3.1 and Unit 2 CTS 3.6.3 Actions b and c state that with one or more of the containment isolation valve(s) inoperable, isolate each affected penetration within 4 hours by use of one deactivated automatic valve secured in the isolation position, closed manual valve, or blind flange. ITS 3.6.3 ACTION C, which only applies to penetration flow paths with only one containment isolation valve and in a closed system, requires that with one or more penetration flow paths with one containment isolation valve inoperable, the penetration flow path be isolated by means similar to those specified in the CTS within 72 hours. This changes the CTS by extending the Completion Time from 4 hours to 72 hours when the inoperable containment isolation valve is in penetration flow path associated with a closed system. This also changes the Unit 2 CTS by providing an Action for a single valve penetration in a closed system, consistent with the Unit 1 CTS, instead of entering CTS 3.0.3.

The purpose of the CTS 3.6.3.1 Actions b and c is to provide a degree of assurance that the penetration flow path with an inoperable containment isolation valve maintains the containment penetration isolation boundary. This change is acceptable because the Completion Time is consistent with safe operation under the specified Condition, the capacity and capability of remaining features (i.e., a closed system), a reasonable time for repairs or replacement of required features, and the low probability of a DBA occurring during the allowed

Completion Time. In the case of a penetration flow path in a closed system with an inoperable valve, 72 hours is a reasonable time period considering the relative stability of the closed system to act as a penetration isolation boundary, or the small diameter of the pipe penetration and the instrument to act as a penetration isolation boundary. This change is designated as less restrictive because additional time is allowed to restore the components to within the LCO limits than was allowed in the CTS.

L02 *(Category 4 - Relaxation of Required Action)* Unit 1 CTS 3.6.3.1 and Unit 2 CTS 3.6.3 Action b. and c. state that with one or more of the containment isolation valve(s) inoperable, isolate each affected penetration by use of at least one deactivated automatic valve secured in the isolation position (Action b), closed manual valve (Action c), or blind flange (Action c). In addition, Unit 1 CTS 4.6.1.1.a.1 and Unit 2 CTS 4.6.1.1.a require a periodic verification that the affected penetration remains isolated by the same methods. When one or more penetration flow paths with one containment isolation valve inoperable, ITS 3.6.3 Required Action A.1 requires that the affected penetration flow path be isolated by use of at least one closed and de-activated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured. In addition, ITS 3.6.3 Required Action A.2 requires a periodic verification that the affected penetration remains isolated by one of the methods required by ITS 3.6.3 Required Action A.1. This changes the CTS by allowing penetration flow paths with two containment isolation valves that have one containment isolation valve inoperable to use a check valve with flow through the valve secured as the means of isolating the penetration flow path.

The purpose of Unit 1 CTS 3.6.3.1 Unit 2 CTS 3.6.3 b and c actions, and Unit 1 CTS 4.6.1.1.a.1 and Unit 2 CTS 4.6.1.1.a Surveillances is to provide assurance that the affected penetration flow path is isolated. This change is acceptable. because the ITS Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The ITS Required Actions are consistent with safe operation under the specified Condition, considering the operability status of the redundant systems of required features, the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of a DBA occurring during the repair period. This change allows the flow path to be isolated by one check valve with flow through the valve secured. The requirement to isolate the flow path is retained and using a check valve with flow through the valve secured is an appropriate method of isolation. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 *(Category 5 – Deletion of Surveillance Requirement)* Unit 1 CTS 4.6.3.1.1 and Unit 2 CTS 4.6.3.1 describe tests that must be performed prior to returning a valve to service after maintenance, repair or replacement work is performed on the valve or its associated actuator, control or power circuit. The ITS does not include these testing requirements. This changes the CTS by deleting this post-maintenance Surveillance.

The purpose of Unit 1 CTS 4.6.3.1.1 and Unit 2 CTS 4.6.3.1 is to verify OPERABILITY of containment isolation valves following their maintenance, repair, or replacement. This change is acceptable because the deleted Surveillance Requirement is not necessary to ensure that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to give confidence that the equipment can perform its assumed safety function. Any time the OPERABILITY of a system or component has been affected by repair, maintenance, modification, or replacement of a component, post-maintenance testing is required to demonstrate the OPERABILITY of the system or component. This is described in the Bases for ITS SR 3.0.1 and required under SR 3.0.1. The OPERABILITY requirements for the containment isolation valves are described in the Bases for ITS 3.6.3. In addition, the requirements of 10 CFR 50, Appendix B, Section XI (Test Control), provide adequate controls for test programs to ensure that testing incorporates applicable acceptance criteria. Compliance with 10 CFR 50, Appendix B, is required under the unit operating license. As a result, post-maintenance testing will continue to be performed and an explicit requirement in the Technical Specifications is not necessary. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

L04 *(Category 7 – Relaxation Of Surveillance Frequency Change)* Unit 1 CTS 4.6.3.1.2 and Unit 2 CTS 4.6.3.2 state, in part, that each containment isolation valve shall be demonstrated Operable during Cold Shutdown or Refueling Mode in accordance with the Surveillance Frequency Control Program by verifying the valve actuates on an isolation signal. Unit 1 ITS SR 3.6.3.6 and Unit 2 ITS SR 3.6.3.7 require verifying each automatic containment isolation valve that is not locked, sealed, or otherwise secured in position, actuates to the isolation position on an actual or simulated signal without requiring the verification be performed in cold shutdown or refueling modes. This changes the CTS by removing the restriction on surveillance performance during specific Modes.

The purpose of the CTS Surveillance is to demonstrate Operability of automatic containment isolation valves. The proposed change is acceptable because it does not change the method of test or frequency of the affected surveillances. The proposed change only deletes the requirement to perform this testing during shutdown or refueling conditions. In addition, allowing this testing to be performed either at refueling, shutdown or at power does not affect the applicable safety analysis conclusions and allows shutdown activities to be planned which will help reduce risk and Increase equipment availability during shutdowns. Thus, the proposed change will continue to provide adequate assurance the required components are routinely tested to ensure system operability while providing some additional flexibility in planning and scheduling the required testing. In addition, due to system designs that allow for safe testing at power, the proposed change will not adversely affect the safe operation of the plant. The proposed change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L05 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.6.3.1.2.a and Unit 2 CTS 4.6.3.2.a. and b. require verification of the

containment isolation valve actuation on specific isolation test signals. ITS SR 3.6.3.6 and Unit 2 ITS SR 3.6.3.7 specify that the signal may be either an "actual" or a simulated actuation signal. This changes the Unit 1 and Unit 2 CTS by allowing the use of either an actual or a simulated signal for the test.

The purpose of CTS Surveillances is to ensure that the containment isolation valves operate correctly upon receipt of an actuation signal. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual," "simulated," or "test" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L06 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.6.3.1.2.a and CTS 4.6.1.1.a.1, and Unit 2 CTS 4.6.3.2.a. and 4.6.1.1.a require verification that each containment isolation valve actuates to its isolation position. Unit 1 ITS SR 3.6.3.6 and Unit 2 ITS SR 3.6.3.7 require verification that each automatic containment isolation valve that is not locked, sealed, or otherwise secured in position, actuates to the isolation position on an actual or simulated actuation signal. This changes the CTS by not requiring automatic valves locked, sealed or otherwise secured in position to be tested to verify that they automatically actuate to their isolation position.

The purpose of CTS Surveillances is to provide assurance that the automatic valves required to actuate in case of a design basis accident (DBA) isolate containment properly. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Automatic valves already in the isolated position and secured are not required to be tested to automatically actuate because, in case of a DBA, they are already in their required position and secured to prevent changing from the required position. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L07 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* CTS 4.6.1.1.a. requires verification that specified containment penetrations are closed. These CTS requirements also contain a note (* Note for Unit 1 and **Note for Unit 2) that exempts testing for valves which are located inside the containment and are locked, sealed or otherwise secured in the closed position. ITS 3.6.3 Required Actions A.2 and C.2, Unit 1 ITS SRs 3.6.3.2 and 3.6.3.3 and Unit 2 SRs 3.6.3.3 and 3.6.3.4 include similar requirements but contain a Note that allows valves and blind flanges in high radiation areas to be verified administratively and except valves, whether inside containment or outside containment, that are required to be closed in an accident and are locked, sealed or otherwise secured in the closed position. In addition, ITS 3.6.3 Required Actions A.2 and C.2

include a second Note that allows verification of isolation devices that are locked, sealed, or otherwise secured to also be performed using administrative means. This changes the CTS by allowing certain valves and blind flanges to not require physical verification.

The purpose of CTS 4.6.1.1.a is to provide assurance that containment penetrations are closed when necessary. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. The position of containment isolation valves and blind flanges in high radiation areas that are required to be closed can be verified administratively, not requiring physical verification. Access to high radiation areas is limited, making access to the valves and blind flanges more difficult, and mispositioning less likely. For those isolation devices, including devices outside containment, that are locked, sealed, or otherwise secured, plant procedures control their operation. Therefore, the potential for inadvertent misalignment of these devices after locking, sealing, or securing is low. In addition, all the isolation devices were verified to be in the correct position (as required by ITS 3.6.3 Required Actions A.2 and C.2) prior to locking, sealing, or otherwise securing. This change is designated as less restrictive because less stringent Surveillance Requirements and Required Actions are being applied in the ITS than were applied in the CTS.

L08 *(Category 3 – Relaxation of Completion Time)* Unit 1 CTS 3.6.3.1 does not have an explicit ACTION for secondary containment bypass leakage or containment penetration flow paths with purge valve leakage not within limits. Unit 2 CTS 3.6.3 does not have an explicit ACTION for secondary containment bypass leakage. Because CTS do not explicitly address these leakage limits, CTS 3.6.1.2 ACTION states, “With the containment leakage rate exceeding the acceptance criteria of the Containment Leakage Rate Testing Program, within 1 hour initiate action to be in HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.” Unit 1 ITS ACTION D requires secondary bypass leakage to be restored within limit in 4 hours and purge valve leakage to be restored within 24 hours. Unit 2 ITS ACTION D requires secondary bypass leakage to be restored within limit in 4 hours and Unit 2 ACTION E requires isolation of the affected penetration flow path when purge valve leakage is not within leakage limits. This changes the CTS by adding an explicit Action time to restore secondary containment bypass and purge valve leakage to within the leakage limits rather than requiring the unit be in Cold Shutdown within 36 hours.

The purpose of Unit 1 and Unit 2 ITS 3.6.3 ACTION D is to restore secondary containment bypass leakage to within the assumptions of the safety analysis. This change is acceptable because the 4 hour Completion Time is reasonable considering the time required to restore the leakage by isolating penetration(s) and the relative importance of secondary containment bypass leakage to the overall containment function. The Unit 1 Required Action D.1 24-hour Completion Time for purge valve leakage is acceptable considering the purge valves remain closed so that a gross breach of containment does not exist. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L09 **Unit 2 only:** *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* CTS 4.6.1.7.1 requires verification that each 48 inch containment purge supply and exhaust isolation valve be verified to be sealed closed in accordance with the Surveillance Frequency Control Program. ITS SR 3.6.3.1 provides the exception for purge valves in a penetration flow path while in Condition E of the LCO. This changes the CTS by not requiring the Surveillance Requirement to be met while in Condition E.

The purpose of CTS 4.6.1.7.1 is to ensure that a gross breach of the containment is not caused by an inadvertent or spurious opening of a 48 inch containment purge valve. The change is acceptable because the relaxed Surveillance Requirement acceptance criteria detail is not necessary for verification that the penetration can meet its required function. The Surveillance Requirement is not required to be met while in Condition E since the penetration flow path would be isolated and verified isolated periodically. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L10 *(Category 4 - Relaxation of Required Action)* CTS 3.6.1.1 requires the plant to be in at least MODE 3 in 6 hours and in MODE 5 within the following 30 hours when containment vessel penetrations not capable of being closed by OPERABLE containment isolation valves required to be closed during accident conditions are isolated by other allowed means (CTS 4.6.1.1).

Unit 2 CTS 3.6.1.7 Actions a, b and c require the plant to be in at least MODE 3 in 6 hours and in MODE 5 within the following 30 hours if the 48 inch containment purge valves are open or not sealed closed and the penetration is not isolated within 4 hours, the 8 inch containment purge valves are open for reasons other than containment pressure control, air quality improvement for containment access or to reduce containment atmosphere airborne radioactivity and the penetration is not isolated within 4 hours; or, the containment purge valve measured leakage exceeds limits and the penetration is not isolated within 24 hours.

Unit 1 ITS 3.6.3 ACTION E and Unit 2 ITS 3.6.3 ACTION F require that the plant be in MODE 3 within 6 hours and MODE 4 within 12 hours. This changes the end state for CTS for the applicable condition.

This change is acceptable because the modification of the end state from MODE 5 to MODE 4 is consistent with CE-NPSD-1186-A, Revision 00, “Technical Justification for the Risk-Informed Modification to Selected Required Action End States for CEOG Member PWRs,” dated October 2001 (ADAMS Accession No. 110410539). This change is designated as less restrictive because instead of requiring the plant to achieve MODE 5 (COLD SHUTDOWN), the ITS end state is MODE 4 (HOT SHUTDOWN) with LCO 3.0.4.a allowances not applicable.

L11 **Unit 2 only:** (*Category 5 – Deletion of Surveillance Requirement*) CTS 4.6.1.7.2 states, “Documentation shall be reviewed in accordance with the Surveillance Frequency Control Program to confirm that purging and venting were performed in accordance with Specification 3.6.1.7.b.” ITS 3.6.3 does not include this

quality assurance detail. This changes the CTS by deleting a documentation review requirement.

The purpose of CTS 4.6.1.7.2 is to confirm that the 8 inch purge valves are opened for the purposes specified in Specification 3.6.1.7.b. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify that the purge valves are Operable and can perform their required functions of supporting the containment and containment isolation. The 8 inch purge supply and exhaust valves continue to be tested in a manner and at a frequency necessary to give confidence that they can perform their intended safety function. This change is acceptable because determining if an activity was properly performed after the activity has been completed is a quality assurance attribute and has no impact to the immediate compliance of the requirement while the activity is performed and, therefore, is unnecessary and not required to ensure the LCO met or the remedial actions performed, as required. The PSL quality assurance program requires that surveillance, inspection and test reports, routine testing and technical specification be controlled under the document control program as quality related products, which provides effective monitoring of activities of this type and provide for corrective actions, if necessary. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.3, CONTAINMENT ISOLATION VALVES

1. The type of Containment (Atmospheric and Dual) is deleted since it is unnecessary (only one Containment Specification is used in the St. Lucie Plant (PSL) Unit 1 and 2 ITS). This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ITS which reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. ISTS SR 3.6.3.6 requires performance of leakage rate testing for containment penetration flow paths containing purge valves with resilient seals within 92 days after opening a valve. Unit 2 ITS SR 3.6.3.6 deletes the 92 day verification requirement based on Unit 2 current licensing basis. The Surveillance is performed in accordance with the Surveillance Frequency Control Program as implemented per Amendment No. 173 (ADAMS Accession No. ML15127A066). Unit 1 ITS SR 3.6.3.5 has been added as a more restrictive requirement (See DOC M04) that deletes the 92 day verification requirement consistent with the PSL Unit 2 Surveillance. The Surveillance is performed at a frequency in accordance with the Surveillance Frequency Control Program.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.3 Containment Isolation Valves ~~(Atmospheric and Dual)~~ 1

BASES

BACKGROUND

The containment isolation valves form part of the containment pressure boundary and provide a means for fluid penetrations not serving accident consequence limiting systems to be provided with two isolation barriers that are closed on an automatic isolation signal. These isolation devices are either passive or active (automatic). Manual valves, de-activated automatic valves secured in their closed position (including check valves with flow through the valve secured), blind flanges, and closed systems are considered passive devices. Check valves, or other automatic valves designed to close without operator action following an accident, are considered active devices. Two barriers in series are provided for each penetration so that no single credible failure or malfunction of an active component can result in a loss of isolation or leakage that exceeds limits assumed in the safety analysis. One of these barriers may be a closed system.

, Safety Injection Actuation Signal

containment high radiation

Containment isolation occurs upon receipt of a high containment pressure signal or a ~~low Reactor Coolant System (RCS) pressure~~ signal. The containment isolation signal closes automatic containment isolation valves in fluid penetrations not required for operation of Engineered Safety Feature systems in order to prevent leakage of radioactive material. Upon actuation of safety injection, automatic containment isolation valves also isolate systems not required for containment or RCS heat removal. Other penetrations are isolated by the use of valves in the closed position or blind flanges. As a result, the containment isolation valves (and blind flanges) help ensure that the containment atmosphere will be isolated in the event of a release of radioactive material to containment atmosphere from the RCS following a Design Basis Accident (DBA). 2

The OPERABILITY requirements for containment isolation valves help ensure that containment is isolated within the time limits assumed in the safety analysis. Therefore, the OPERABILITY requirements provide assurance that the containment function assumed in the accident analysis will be maintained.

~~The purge valves were designed for intermittent operation, providing a means of removing airborne radioactivity caused by minor RCS leakage prior to personnel entry into containment. There are two sets of purge valves: normal purge and exhaust valves and minipurge and exhaust valves.~~ The ~~normal and minipurge~~ supply and exhaust lines are each supplied with inside and outside containment isolation valves but share common supply and exhaust penetration lines. 2

BASES

BACKGROUND (continued)

to provide a means of removing airborne radioactivity following operation of the containment airborne radioactivity removal system and

The ~~normal~~ purge valves are designed ~~for~~ purging the containment atmosphere to the unit stack while introducing filtered makeup from the outside to provide adequate ventilation for personnel comfort when the unit is shut down during refueling operations and maintenance. ~~Motor operated isolation valves are provided inside the containment, and air operated isolation valves are provided outside the containment.~~ The valves are operated manually from the control room. The valves will close automatically upon receipt of a containment ~~purge~~ isolation signal~~.~~ ~~The air operated valves~~ fail closed upon a loss of air. Because of their large size, the ~~normal~~ purge valves ~~in some units~~ are not qualified for automatic closure from their open position under DBA conditions. Therefore, the ~~normal~~ purge valves are normally maintained closed in MODES 1, 2, 3, and 4 to ensure the containment boundary is maintained.

Air operated isolation valves are provided both inside and outside the containment.

and

2

Open ~~normal~~ purge valves~~, or a failure of the minipurge valves to close,~~ following an accident that releases contamination to the containment atmosphere would cause a significant increase in the containment leakage rate. 2

APPLICABLE SAFETY ANALYSES

The containment isolation valve LCO was derived from the assumptions related to minimizing the loss of reactor coolant inventory and establishing the containment boundary during major accidents. As part of the containment boundary, containment isolation valve OPERABILITY supports leak tightness of the containment. Therefore, the safety analysis of any event requiring isolation of containment is applicable to this LCO.

The DBAs that result in a release of radioactive material within containment are a loss of coolant accident (LOCA), a main steam line break, and a control element assembly ejection accident. In the analysis for each of these accidents, it is assumed that containment isolation valves are either closed or function to close within the required isolation time following event initiation. This ensures that potential paths to the environment through containment isolation valves (including containment purge valves) are minimized. The safety analysis assumes that the ~~normal~~ purge valves are closed at event initiation. 2

The DBA analysis assumes that, within 60 seconds after the accident, isolation of the containment is complete and leakage terminated except for the design leakage rate, L_a. The containment isolation total response time of 60 seconds includes signal delay, diesel generator startup (for loss of offsite power), and containment isolation valve stroke times.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The single failure criterion required to be imposed in the conduct of unit safety analyses was considered in the original design of the containment purge valves. Two valves in series on each purge line provide assurance that both the supply and exhaust lines could be isolated even if a single failure occurred. ~~The inboard and outboard isolation valves on each line are provided with diverse power sources, motor operated and pneumatically operated spring closed, respectively.~~ This arrangement was designed to preclude common mode failures from disabling both valves on a purge line. 2

The purge valves may be unable to close in the environment following a LOCA. Therefore, each of the purge valves is required to remain sealed closed during MODES 1, 2, 3, and 4. In this case, the single failure criterion remains applicable to the containment purge valves due to failure in the control circuit associated with each valve. Again, the purge system valve design precludes a single failure from compromising the containment boundary as long as the system is operated in accordance with the subject LCO. ~~The minipurge valves are capable of closing under accident conditions. Therefore, they are allowed to be open for limited periods during power operation.~~ 2

The containment isolation valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Containment isolation valves form a part of the containment boundary. The containment isolation valve safety function is related to minimizing the loss of reactor coolant inventory and establishing the containment boundary during a DBA.

The automatic power operated isolation valves are required to have isolation times within limits and to actuate on an automatic isolation signal. The purge valves must be maintained sealed closed ~~[or have blocks installed to prevent full opening]. [Blocked purge valves also actuate on an automatic signal.]~~ 3 The valves covered by this LCO are listed with their associated stroke times in the FSAR (Ref. 1). 5 U

The normally closed isolation valves are considered OPERABLE when manual valves are closed, automatic valves are de-activated and secured in their closed position, blind flanges are in place, and closed systems are intact. These passive isolation valves or devices are those listed in Reference ~~2~~ 1. 2

BASES

LCO (continued)

Purge valves with resilient seals ~~[~~and secondary containment bypass valves~~]~~ must meet additional leakage rate requirements. The other containment isolation valve leakage rates are addressed by LCO 3.6.1, "Containment," as Type C testing. 3

This LCO provides assurance that the containment isolation valves and purge valves will perform their designed safety functions to minimize the loss of reactor coolant inventory and establish the containment boundary during accidents.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, the containment isolation valves are not required to be OPERABLE in MODE 5. The requirements for containment isolation valves during MODE 6 are addressed in LCO 3.9.3, "Containment Penetrations."

ACTIONS

48

The ACTIONS are modified by a Note allowing penetration flow paths, except for ~~[42]~~ inch purge valve penetration flow paths, to be unisolated intermittently under administrative controls. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way, the penetration can be rapidly isolated when a need for containment isolation is indicated. Due to the size of the containment purge line penetration and the fact that those penetrations exhaust directly from the containment atmosphere to the environment, these valves may not be opened under administrative controls. 3

A second Note has been added to provide clarification that, for this LCO, separate Condition entry is allowed for each penetration flow path. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable containment isolation valve. Complying with the Required Actions may allow for continued operation, and subsequent inoperable containment isolation valves are governed by subsequent Condition entry and application of associated Required Actions.

The ACTIONS are further modified by a third Note, which ensures that appropriate remedial actions are taken, if necessary, if the affected systems are rendered inoperable by an inoperable containment isolation valve.

BASES

ACTIONS (continued)

A fourth Note has been added that requires entry into the applicable Conditions and Required Actions of LCO 3.6.1 when leakage results in exceeding the overall containment leakage limit.

---------- REVIEWER'S NOTE ----------
The bracketed phrase "following isolation" in the Completion Times for Required Actions A.2, B.2, D.2, F.2 and F.3 is only applicable to plants that have adopted a Risk Informed Completion Time Program. 4

A.1 and A.2

In the event one containment isolation valve in one or more penetration flow paths is inoperable, the affected penetration flow path must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic containment isolation valve, a closed manual valve, a blind flange, and a check valve with flow through the valve secured. For penetrations isolated in accordance with Required Action A.1, the device used to isolate the penetration should be the closest available one to containment. Required Action A.1 must be completed within the 4 hour Completion Time [or in accordance with the Risk Informed Completion Time Program]. The 4 hour Completion Time is reasonable, considering the time required to isolate the penetration and the relative importance of supporting containment OPERABILITY during MODES 1, 2, 3, and 4 (Refs. 4 and 5). 2

For affected penetration flow paths that cannot be restored to OPERABLE status within the 4 hour Completion Time and that have been isolated in accordance with Required Action A.1, the affected penetration flow paths must be verified to be isolated on a periodic basis. This is necessary to ensure that containment penetrations required to be isolated following an accident and no longer capable of being automatically isolated will be in the isolation position should an event occur. This Required Action does not require any testing or device manipulation. Rather, it involves verification that those isolation devices outside containment and capable of being mispositioned are in the correct position. The Completion Time of "once per 31 days [following isolation] for isolation devices outside containment" is appropriate considering the fact that the devices are operated under administrative controls and the probability of their misalignment is low. For the isolation devices inside containment, the time period specified as "prior to entering MODE 4 from MODE 5 if not performed within the

BASES

ACTIONS (continued)

~~previous 92 days" is based on engineering judgment and is considered reasonable in view of the inaccessibility of the isolation devices and other administrative controls that will ensure that isolation device misalignment is an unlikely possibility.~~

~~Condition A has been modified by a Note indicating that this Condition is only applicable to [the containment sump supply valves to the ECCS and containment spray pumps].~~

~~REVIEWER'S NOTE~~
~~Condition A is only applicable to the containment isolation valves that do not meet the conditions to extend the Completion Time to 7 days.~~

~~Required Action A.2 is modified by two Notes. Note 1 applies to isolation devices located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned. Therefore, the probability of misalignment of these devices, once they have been verified to be in the proper position, is small.~~

A

[~~B~~.1 and ~~B~~.2

~~REVIEWER'S NOTE~~
~~Adoption of the 7 day Completion Time is contingent on the conditions identified in Reference 4.~~

~~1. Individual licensees requesting CIV Completion Time relaxations should state in their plant-specific application that they have verified that the Joint Applications Report (JAR) results apply to their plant. Licensees should verify that the relaxed Completion Times will only apply to penetrations analyzed to meet the risk guidelines of Regulatory Guide 1.177 and fall within the 14 containment penetration configurations considered in the JAR. Any other containment penetration configurations not analyzed in the JAR must be supported by a plant-specific analysis. Licensee submittals must retain the current Completion Times for the three configurations that~~

BASES

ACTIONS (continued)

~~were not analyzed in the JAR: containment sump supply valves to the ECCS and containment spray systems pumps, valves associated with the main feedwater system, and main steam isolation valves.~~

~~2. Licensees should provide sufficient quantitative or qualitative substantiation to demonstrate that external events will not affect the results of the analysis supporting the extended Completion Times.~~

~~3. Licensees should state that they have verified acceptable PRA quality as described in Regulatory Guide 1.177.~~

~~4. Licensees should require verification of the operability of the remaining CIV(s) in a penetration flow path before entering the extended Completion Time for corrective maintenance. The JAR assumes that the penetrations remain physically intact in MODES in which these valves are to be operable during corrective maintenance. Licensees should describe in their plant specific application how the affected penetration will remain physically intact, or state that the penetration will be isolated so as to not permit a release to the outside environment.~~

~~5. The licensee should consider the additive nature of multiple failed CIVs, and the possibility of entering multiple AOTs and verify that these situations will result in risks consistent with the incremental conditional core damage probability (ICCDP) and incremental large early release probability (ICLERP) guidelines so that defense-in-depth for the safety systems will be maintained.~~

In the event one containment isolation valve in one or more penetration flow paths is inoperable, except for ~~Condition A and for~~ purge valve leakage and ~~shield building~~ bypass leakage not within limit~~]~~, the affected penetration flow path must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic containment isolation valve, a closed manual valve, a blind flange, and a check valve with flow through the valve secured. For penetrations isolated in accordance with Required Action ~~B~~.1, the device used to isolate the penetration should be the closest available one to containment. Required Action ~~B~~.1 must be completed within the ~~[7 day]~~ Completion Time ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The ~~[7 day]~~ Completion Time is reasonable, considering the time required to isolate the penetration and the relative importance of supporting containment OPERABILITY during MODES 1, 2, 3, and 4 ~~(References 3 and 4)~~.

BASES

ACTIONS (continued)

4 hour

For affected penetration flow paths that cannot be restored to OPERABLE status within the ~~[7 day]~~ Completion Time and that have been isolated in accordance with Required Action ~~B~~.1, the affected penetration flow paths must be verified to be isolated on a periodic basis. This is necessary to ensure that containment penetrations required to be isolated following an accident and no longer capable of being automatically isolated will be in the isolation position should an event occur. This Required Action does not require any testing or device manipulation. Rather, it involves verification that those isolation devices outside containment and capable of being mispositioned are in the correct position. The Completion Time of "once per 31 days ~~[~~following isolation~~]~~ for isolation devices outside containment" is appropriate considering the fact that the devices are operated under administrative controls and the probability of their misalignment is low. For the isolation devices inside containment, the time period specified as "prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days" is based on engineering judgment and is considered reasonable in view of the inaccessibility of the isolation devices and other administrative controls that will ensure that isolation device misalignment is an unlikely possibility.

A 3 2

A

Condition ~~B~~ has been modified by a Note indicating that this Condition is only applicable to those penetration flow paths with two ~~[or more]~~ containment isolation valves. For penetration flow paths with only one containment isolation valve and a closed system, Condition ~~D~~ provides appropriate actions.

2 3 2

C

A

Required Action ~~B~~.2 is modified by two Notes. Note 1 applies to isolation devices located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned. Therefore, the probability of misalignment of these devices, once they have been verified to be in the proper position, is small.~~]~~

2 3

BASES

ACTIONS (continued)

B

~~C~~.1

With two ~~[or more]~~ containment isolation valves in one or more penetration flow paths inoperable, ~~[~~except for purge valve leakage and ~~shield building~~ bypass leakage not within limit~~]~~, the affected penetration flow path must be isolated within 1 hour. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic valve, a closed manual valve, and a blind flange. The 1 hour Completion Time is consistent with the ACTIONS of LCO 3.6.1. In the event the affected penetration is isolated in accordance with Required Action ~~C~~.1, the affected penetration must be verified to be isolated on a periodic basis per Required Action ~~B~~.2, which remains in effect. This periodic verification is necessary to assure leak tightness of containment and that penetrations requiring isolation following an accident are isolated. The Completion Time of once per 31 days for verifying each affected penetration flow path is isolated is appropriate considering the fact that the valves are operated under administrative controls and the probability of their misalignment is low.

secondary containment

B

A

B

Condition ~~C~~ is modified by a Note indicating this Condition is only applicable to penetration flow paths with two ~~[or more]~~ containment isolation valves. Condition ~~B~~ of this LCO addresses the condition of one containment isolation valve inoperable in this type of penetration flow path.

A

C

~~D~~.1 and ~~D~~.2

With one or more penetration flow paths with one containment isolation valve inoperable, the inoperable valve must be restored to OPERABLE status or the affected penetration flow path must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic valve, a closed manual valve, and a blind flange. A check valve may not be used to isolate the affected penetration. Required Action ~~D~~.1 must be completed within the ~~[~~72~~]~~ hour Completion Time ~~for those penetrations that do not meet the 7 day Completion Time criteria and [7 days] for penetrations that do meet the 7 day Completion Time criteria~~. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ The specified time period is reasonable, considering the relative stability of the closed system (hence, reliability) to act as a penetration isolation boundary and the relative importance of supporting containment OPERABILITY during

C

BASES

ACTIONS (continued)

MODES 1, 2, 3, and 4. In the event the affected penetration is isolated in accordance with Required Action ~~D~~.1, the affected penetration flow path must be verified to be isolated on a periodic basis. This is necessary to assure leak tightness of containment and that containment penetrations requiring isolation following an accident are isolated. The Completion Time of once per 31 days ~~[~~following isolation~~]~~ for verifying that each affected penetration flow path is isolated is appropriate considering the valves are operated under administrative controls and the probability of their misalignment is low.

Condition ~~D~~ is modified by a Note indicating that this Condition is only applicable to those penetration flow paths with only one containment isolation valve and a closed system. The closed system must meet the requirements of Reference ~~4~~. This Note is necessary since this Condition is written to specifically address those penetration flow paths in a closed system.

Required Action ~~D~~.2 is modified by two Notes. Note 1 applies to valves and blind flanges located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned. Therefore, the probability of misalignment of these valves, once they have been verified to be in the proper position, is small.

~~[E~~. 1

With the secondary containment bypass leakage rate (SR 3.6.3.~~9~~) ~~[~~or purge valve leakage rate (SR 3.6.3.~~6~~)~~]~~ not within limit, the assumptions of the safety analysis are not met. Therefore, the leakage must be restored to within limit. Restoration can be accomplished by isolating the penetration(s) that caused the limit to be exceeded by use of one closed and de-activated automatic valve, closed manual valve, or blind flange. When ~~a~~ penetration is isolated, the leakage rate for the isolated penetration is assumed to be the actual pathway leakage through the isolation device. If two isolation devices are used to isolate the penetration, the leakage rate is assumed to be the lesser actual pathway leakage of the two devices. The 4 hour Completion Time for secondary

BASES

ACTIONS (continued)

containment bypass leakage is reasonable considering the time required to restore the leakage by isolating the penetration(s) and the relative importance of secondary containment bypass leakage to the overall containment function. [The 24 hour Completion Time for purge valve leakage is acceptable considering the purge valves remain closed so that a gross breach of containment does not exist.]

to restore

REVIEWER'S NOTE

[The bracketed options provided in ACTION E reflect options in plant design and options in adopting the associated leakage rate Surveillances.

The options (in both ACTION E and ACTION F for purge valve leakage, are based primarily on the design - if leakage rates can be measured separately for each purge valve, ACTION F is intended to apply. This would be required to be able to implement Required Action F.3. Should the design allow only for leak testing both purge valves simultaneously, then the Completion Time for ACTION E should include the "24 hours for purge valve leakage" and ACTION F should be eliminated.]]

[F.1, F.2, and F.3

In the event one or more containment purge valves in one or more penetration flow paths are not within the purge valve leakage limits, purge valve leakage must be restored to within limits, or the affected penetration must be isolated. The method of isolation must be by the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a [closed and de-activated automatic valve with resilient seals, a closed manual valve with resilient seals, or a blind flange]. A purge valve with resilient seals utilized to satisfy Required Action F.1 must have been demonstrated to meet the leakage requirements of SR 3.6.3.6. The specified Completion Time is reasonable, considering that one containment purge valve remains closed so that a gross breach of containment does not exist.

In accordance with Required Action F.2, this penetration flow path must be verified to be isolated on a periodic basis. The periodic verification is necessary to ensure that containment penetrations required to be isolated following an accident, which are no longer capable of being automatically isolated, will be in the isolation position should an event occur. This Required Action does not require any testing or valve manipulation. Rather, it involves verification that those isolation devices outside

BASES

ACTIONS (continued)

~~containment capable of being mispositioned are in the correct position. For the isolation devices inside containment, the time period specified as "prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days" is based on engineering judgment and is considered reasonable in view of the inaccessibility of the isolation devices and other administrative controls that will ensure that isolation device misalignment is an unlikely possibility.~~

~~For the containment purge valve with resilient seal that is isolated in accordance with Required Action F.1, SR 3.6.3.6 must be performed at least once every [92] days. This assures that degradation of the resilient seal is detected and confirms that the leakage rate of the containment purge valve does not increase during the time the penetration is isolated. The normal Frequency for SR 3.6.3.6, 184 days, is based on an NRC initiative, Generic Issue B-20 (Ref. 6). Since more reliance is placed on a single valve while in this Condition, it is prudent to perform the SR more often. Therefore, a Frequency of once per [92] days was chosen and has been shown to be acceptable based on operating experience.~~

~~Required Action F.2 is modified by two Notes. Note 1 applies to isolation devices located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned.]~~

E

~~G~~.1 and ~~G~~.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

BASES

ACTIONS (continued)

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

If the Required Actions and associated Completion Times are not met, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~7~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action ~~G~~.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

~~[~~SR 3.6.3.1

This Surveillance is designed to ensure that a gross breach of containment is not caused by an inadvertent or spurious opening of a ~~[42]~~ inch containment purge valve. Detailed analysis of the purge valves failed to conclusively demonstrate their ability to close during a LOCA in time to limit offsite doses. Therefore, these valves are required to be in the sealed closed position during MODES 1, 2, 3, and 4. A containment purge valve that is sealed closed must have motive power to the valve operator removed. This can be accomplished by de-energizing the source of electric power or by removing the air supply to the valve operator. In this application, the term "sealed" has no connotation of leak

BASES

SURVEILLANCE REQUIREMENTS (continued)

tightness. ~~[The Frequency of 31 days is a result of an NRC initiative, Generic Issue B-24 (Ref. 8), related to containment purge valve use during unit operations.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

D

This SR is not required to be met while in Condition ~~E~~ of this LCO. This is reasonable since the penetration flow path would be isolated.~~]~~

, the time the leakage is not within limits is restricted, and if the purge valve leakage results in exceeding the overall containment leakage rate acceptance criteria, action will be required in accordance with LCO 3.6.1.

~~SR 3.6.3.2~~

~~This SR ensures that the minipurge valves are closed as required or, if open, open for an allowable reason. If a purge valve is open in violation of this SR, the valve is considered inoperable. If the inoperable valve is not otherwise known to have excessive leakage when closed, it is not considered to have leakage outside of limits. The SR is not required to be met when the purge valves are open for pressure control, ALARA or air quality considerations for personnel entry, or for Surveillances that require the valves to be open. The minipurge valves are capable of closing in the environment following a LOCA. Therefore, these valves are allowed to be open for limited periods of time. [The 31 day Frequency is consistent with other containment isolation valve requirements discussed in SR 3.6.3.3.~~

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.3.~~3~~

This SR requires verification that each containment isolation manual valve and blind flange located outside containment and not locked, sealed, or otherwise secured and required to be closed during accident conditions is closed. The SR helps to ensure that post accident leakage of radioactive fluids or gases outside the containment boundary is within design limits. This SR does not require any testing or valve manipulation. Rather, it involves verification that those containment isolation valves outside containment and capable of being mispositioned are in the correct position. ~~[Since verification of valve position for containment isolation valves outside containment is relatively easy, the 31 day Frequency is based on engineering judgment and was chosen to provide added assurance of the correct positions.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

Containment isolation valves that are open under administrative controls are not required to meet the SR during the time the valves are open. This SR does not apply to valves that are locked, sealed, or otherwise secured in the closed position, since these were verified to be in the correct position upon locking, sealing, or securing.

The Note applies to valves and blind flanges located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted during MODES 1, 2, 3, ~~4~~ and for ALARA reasons. Therefore, the probability of misalignment of these containment isolation valves, once they have been verified to be in the proper position, is small.

SR 3.6.3.~~4~~

This SR requires verification that each containment isolation manual valve and blind flange located inside containment and not locked, sealed,

BASES

SURVEILLANCE REQUIREMENTS (continued)

or otherwise secured and required to be closed during accident conditions is closed. The SR helps to ensure that post accident leakage of radioactive fluids or gases outside the containment boundary is within design limits. For containment isolation valves inside containment, the Frequency of "prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days" is appropriate, since these containment isolation valves are operated under administrative controls and the probability of their misalignment is low. Containment isolation valves that are open under administrative controls are not required to meet the SR during the time that they are open. This SR does not apply to valves that are locked, sealed, or otherwise secured in the closed position, since these were verified to be in the correct position upon locking, sealing, or securing.

The Note allows valves and blind flanges located in high radiation areas to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted during MODES 1, 2, and 3 for ALARA reasons. Therefore, the probability of misalignment of these containment isolation valves, once they have been verified to be in their proper position, is small.

4

SR 3.6.3.~~5~~ 2

Verifying that the isolation time of each automatic power operated containment isolation valve is within limits is required to demonstrate OPERABILITY. The isolation time test ensures the valve will isolate in a time period less than or equal to that assumed in the safety analysis.

~~----------REVIEWER'S NOTE----------~~
~~If the testing is within the scope of the licensee's INSERVICE TESTING PROGRAM, the Frequency "In accordance with the INSERVICE TESTING PROGRAM" should be used. Otherwise, the periodic Frequency of [18 months] or the reference to the Surveillance Frequency Control Program should be used.~~
~~----------~~ 4

~~[~~The Frequency of this SR is in accordance with ~~[~~the INSERVICE TESTING PROGRAM~~]~~ ~~[92 days.~~

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.]]~~ 3

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 3

SR 3.6.3.~~6~~ 5 2

For containment purge valves with resilient seals, additional leakage rate testing beyond the test requirements of 10 CFR 50, Appendix J, Option ~~[A]~~[B~~]~~, (Ref. ~~9~~), is required to ensure OPERABILITY. Operating experience has demonstrated that this type of seal has the potential to degrade in a shorter time period than do other seal types. ~~[Based on this observation and the importance of maintaining this penetration leak tight (due to the direct path between containment and the environment), a Frequency of 184 days was established as part of the NRC resolution of Generic Issue B-20, "Containment Leakage Due to Seal Deterioration" (Ref. 6).~~ 4 2 2 3

Leakage testing of the purge valves in each penetration flow path is performed simultaneously and OPERABILITY is demonstrated by verifying that the measured leakage rate is ≤ 0.05 La when pressurized to Pa.

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 4 3

~~Additionally, this SR must be performed within 92 days after opening the valve. The 92 day Frequency was chosen recognizing that cycling the valve could introduce additional seal degradation (beyond that occurring to a valve that has not been opened). Thus, decreasing the interval is a prudent measure after a valve has been opened.~~ 2

SR 3.6.3.~~7~~ 6 2

Automatic containment isolation valves close on a containment isolation signal to prevent leakage of radioactive material from containment following a DBA. This SR ensures each automatic containment isolation

BASES

SURVEILLANCE REQUIREMENTS (continued)

valve will actuate to its isolation position on a containment isolation actuation signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. ~~[The [18] month Frequency was developed considering it is prudent that this SR be performed only during a unit outage, since isolation of penetrations would eliminate cooling water flow and disrupt normal operation of many critical components. Operating experience has shown that these components usually pass this SR when performed on the [18] month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]]~~

~~[~~ SR 3.6. 3.~~9~~

This SR ensures that the combined leakage rate of all secondary containment bypass leakage paths is less than or equal to the specified leakage rate. This provides assurance that the assumptions in the safety analysis are met. The leakage rate of each bypass leakage path is assumed to be the maximum pathway leakage (leakage through the worse of the two isolation valves) unless the penetration is isolated by use of one closed and de-activated automatic valve, closed manual valve, or blind flange. In this case, the leakage rate of the isolated bypass leakage path is assumed to be the actual pathway leakage through the isolation device. If both isolation valves in the penetration are closed, the actual leakage rate is the lesser leakage rate of the two valves. The Frequency is required by the Containment Leakage Rate Testing Program. This SR simply imposes additional acceptance criteria.

~~[~~Bypass leakage is considered part of L_a. unless specifically exempted.~~]]~~

B 3.6 CONTAINMENT SYSTEMS

B 3.6.3 Containment Isolation Valves ~~(Atmospheric and Dual)~~ 1

BASES

BACKGROUND

The containment isolation valves form part of the containment pressure boundary and provide a means for fluid penetrations not serving accident consequence limiting systems to be provided with two isolation barriers that are closed on an automatic isolation signal. These isolation devices are either passive or active (automatic). Manual valves, de-activated automatic valves secured in their closed position (including check valves with flow through the valve secured), blind flanges, and closed systems are considered passive devices. Check valves, or other automatic valves designed to close without operator action following an accident, are considered active devices. Two barriers in series are provided for each penetration so that no single credible failure or malfunction of an active component can result in a loss of isolation or leakage that exceeds limits assumed in the safety analysis. One of these barriers may be a closed system.

, Safety Injection Actuation Signal

containment high radiation

Containment isolation occurs upon receipt of a high containment pressure signal or a ~~low Reactor Coolant System (RCS) pressure~~ signal. The containment isolation signal closes automatic containment isolation valves in fluid penetrations not required for operation of Engineered Safety Feature systems in order to prevent leakage of radioactive material. Upon actuation of safety injection, automatic containment isolation valves also isolate systems not required for containment or RCS heat removal. Other penetrations are isolated by the use of valves in the closed position or blind flanges. As a result, the containment isolation valves (and blind flanges) help ensure that the containment atmosphere will be isolated in the event of a release of radioactive material to containment atmosphere from the RCS following a Design Basis Accident (DBA). 2

The OPERABILITY requirements for containment isolation valves help ensure that containment is isolated within the time limits assumed in the safety analysis. Therefore, the OPERABILITY requirements provide assurance that the containment function assumed in the accident analysis will be maintained.

8 inch

(48 inch)

8 inch supply

8 inch

The purge valves were designed for intermittent operation, providing a means of removing airborne radioactivity caused by minor RCS leakage prior to personnel entry into containment. There are two sets of purge valves: normal purge and exhaust valves and ~~mini~~purge and exhaust valves. The normal and ~~mini~~purge supply and exhaust lines are each supplied with inside and outside containment isolation valves but share common supply and exhaust penetration lines. 2

BASES

BACKGROUND (continued)

Air operated isolation valves are provided both inside and outside the containment.

The normal purge valves are designed for purging the containment atmosphere to the unit stack while introducing filtered makeup from the outside to provide adequate ventilation for personnel comfort when the unit is shut down during refueling operations and maintenance. ~~Motor operated isolation valves are provided inside the containment, and air operated isolation valves are provided outside the containment.~~ The valves are operated manually from the control room. The valves will close automatically upon receipt of a containment ~~purge~~ isolation signal~~.~~ ~~The air operated valves~~ fail closed upon a loss of air. Because of their large size, the normal purge valves ~~in some units~~ are not qualified for automatic closure from their open position under DBA conditions. Therefore, the normal purge valves are normally maintained closed in MODES 1, 2, 3, and 4 to ensure the containment boundary is maintained. 2

and

8 inch

Open normal purge valves, or a failure of the ~~mini~~purge valves to close, following an accident that releases contamination to the containment atmosphere would cause a significant increase in the containment leakage rate. 2

APPLICABLE SAFETY ANALYSES

The containment isolation valve LCO was derived from the assumptions related to minimizing the loss of reactor coolant inventory and establishing the containment boundary during major accidents. As part of the containment boundary, containment isolation valve OPERABILITY supports leak tightness of the containment. Therefore, the safety analysis of any event requiring isolation of containment is applicable to this LCO.

The DBAs that result in a release of radioactive material within containment are a loss of coolant accident (LOCA), a main steam line break, and a control element assembly ejection accident. In the analysis for each of these accidents, it is assumed that containment isolation valves are either closed or function to close within the required isolation time following event initiation. This ensures that potential paths to the environment through containment isolation valves (including containment purge valves) are minimized. The safety analysis assumes that the normal purge valves are closed at event initiation.

The DBA analysis assumes that, within 60 seconds after the accident, isolation of the containment is complete and leakage terminated except for the design leakage rate, L_a. The containment isolation total response time of 60 seconds includes signal delay, diesel generator startup (for loss of offsite power), and containment isolation valve stroke times.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The single failure criterion required to be imposed in the conduct of unit safety analyses was considered in the original design of the containment purge valves. Two valves in series on each purge line provide assurance that both the supply and exhaust lines could be isolated even if a single failure occurred. ~~The inboard and outboard isolation valves on each line are provided with diverse power sources, motor operated and pneumatically operated spring closed, respectively.~~ This arrangement was designed to preclude common mode failures from disabling both valves on a purge line. 2

The purge valves may be unable to close in the environment following a LOCA. Therefore, each of the purge valves is required to remain sealed closed during MODES 1, 2, 3, and 4. In this case, the single failure criterion remains applicable to the containment purge valves due to failure in the control circuit associated with each valve. Again, the purge system valve design precludes a single failure from compromising the containment boundary as long as the system is operated in accordance with the subject LCO. The ~~mini~~purge valves are capable of closing under accident conditions. Therefore, they are allowed to be open for limited periods during power operation. 8 inch 2

The containment isolation valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Containment isolation valves form a part of the containment boundary. The containment isolation valve safety function is related to minimizing the loss of reactor coolant inventory and establishing the containment boundary during a DBA.

The automatic power operated isolation valves are required to have isolation times within limits and to actuate on an automatic isolation signal. The purge valves must be maintained sealed closed ~~[or have blocks installed to prevent full opening]. [Blocked purge valves also actuate on an automatic signal.]~~ The valves covered by this LCO are listed with their associated stroke times in the FSAR (Ref. 1). 3 5 U

The normally closed isolation valves are considered OPERABLE when manual valves are closed, automatic valves are de-activated and secured in their closed position, blind flanges are in place, and closed systems are intact. These passive isolation valves or devices are those listed in Reference ~~2~~. 2 1

BASES

LCO (continued)

Purge valves with resilient seals ~~[~~and secondary containment bypass valves~~]~~ must meet additional leakage rate requirements. The other containment isolation valve leakage rates are addressed by LCO 3.6.1, "Containment," as Type C testing. 3

This LCO provides assurance that the containment isolation valves and purge valves will perform their designed safety functions to minimize the loss of reactor coolant inventory and establish the containment boundary during accidents.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, the containment isolation valves are not required to be OPERABLE in MODE 5. The requirements for containment isolation valves during MODE 6 are addressed in LCO 3.9.3, "Containment Penetrations."

ACTIONS

48

The ACTIONS are modified by a Note allowing penetration flow paths, except for ~~[42]~~ inch purge valve penetration flow paths, to be unisolated intermittently under administrative controls. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way, the penetration can be rapidly isolated when a need for containment isolation is indicated. Due to the size of the containment purge line penetration and the fact that those penetrations exhaust directly from the containment atmosphere to the environment, these valves may not be opened under administrative controls. 3

A second Note has been added to provide clarification that, for this LCO, separate Condition entry is allowed for each penetration flow path. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable containment isolation valve. Complying with the Required Actions may allow for continued operation, and subsequent inoperable containment isolation valves are governed by subsequent Condition entry and application of associated Required Actions.

The ACTIONS are further modified by a third Note, which ensures that appropriate remedial actions are taken, if necessary, if the affected systems are rendered inoperable by an inoperable containment isolation valve.

BASES

ACTIONS (continued)

A fourth Note has been added that requires entry into the applicable Conditions and Required Actions of LCO 3.6.1 when leakage results in exceeding the overall containment leakage limit.

---------- REVIEWER'S NOTE ----------
The bracketed phrase "following isolation" in the Completion Times for Required Actions A.2, B.2, D.2, F.2 and F.3 is only applicable to plants that have adopted a Risk Informed Completion Time Program. 4

A.1 and A.2

In the event one containment isolation valve in one or more penetration flow paths is inoperable, the affected penetration flow path must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic containment isolation valve, a closed manual valve, a blind flange, and a check valve with flow through the valve secured. For penetrations isolated in accordance with Required Action A.1, the device used to isolate the penetration should be the closest available one to containment. Required Action A.1 must be completed within the 4 hour Completion Time [or in accordance with the Risk Informed Completion Time Program]. The 4 hour Completion Time is reasonable, considering the time required to isolate the penetration and the relative importance of supporting containment OPERABILITY during MODES 1, 2, 3, and 4 (Refs. 4 and 5). 2

For affected penetration flow paths that cannot be restored to OPERABLE status within the 4 hour Completion Time and that have been isolated in accordance with Required Action A.1, the affected penetration flow paths must be verified to be isolated on a periodic basis. This is necessary to ensure that containment penetrations required to be isolated following an accident and no longer capable of being automatically isolated will be in the isolation position should an event occur. This Required Action does not require any testing or device manipulation. Rather, it involves verification that those isolation devices outside containment and capable of being mispositioned are in the correct position. The Completion Time of "once per 31 days [following isolation] for isolation devices outside containment" is appropriate considering the fact that the devices are operated under administrative controls and the probability of their misalignment is low. For the isolation devices inside containment, the time period specified as "prior to entering MODE 4 from MODE 5 if not performed within the

BASES

ACTIONS (continued)

~~previous 92 days" is based on engineering judgment and is considered reasonable in view of the inaccessibility of the isolation devices and other administrative controls that will ensure that isolation device misalignment is an unlikely possibility.~~

~~Condition A has been modified by a Note indicating that this Condition is only applicable to [the containment sump supply valves to the ECCS and containment spray pumps].~~

~~REVIEWER'S NOTE~~
~~Condition A is only applicable to the containment isolation valves that do not meet the conditions to extend the Completion Time to 7 days.~~

~~Required Action A.2 is modified by two Notes. Note 1 applies to isolation devices located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned. Therefore, the probability of misalignment of these devices, once they have been verified to be in the proper position, is small.~~

A

[~~B~~.1 and ~~B~~.2

~~REVIEWER'S NOTE~~
~~Adoption of the 7 day Completion Time is contingent on the conditions identified in Reference 4.~~

~~1. Individual licensees requesting CIV Completion Time relaxations should state in their plant specific application that they have verified that the Joint Applications Report (JAR) results apply to their plant. Licensees should verify that the relaxed Completion Times will only apply to penetrations analyzed to meet the risk guidelines of Regulatory Guide 1.177 and fall within the 14 containment penetration configurations considered in the JAR. Any other containment penetration configurations not analyzed in the JAR must be supported by a plant specific analysis. Licensee submittals must retain the current Completion Times for the three configurations that~~

BASES

ACTIONS (continued)

~~were not analyzed in the JAR: containment sump supply valves to the ECCS and containment spray systems pumps, valves associated with the main feedwater system, and main steam isolation valves.~~

~~2. Licensees should provide sufficient quantitative or qualitative substantiation to demonstrate that external events will not affect the results of the analysis supporting the extended Completion Times.~~

~~3. Licensees should state that they have verified acceptable PRA quality as described in Regulatory Guide 1.177.~~

~~4. Licensees should require verification of the operability of the remaining CIV(s) in a penetration flow path before entering the extended Completion Time for corrective maintenance. The JAR assumes that the penetrations remain physically intact in MODES in which these valves are to be operable during corrective maintenance. Licensees should describe in their plant specific application how the affected penetration will remain physically intact, or state that the penetration will be isolated so as to not permit a release to the outside environment.~~

~~5. The licensee should consider the additive nature of multiple failed CIVs, and the possibility of entering multiple AOTs and verify that these situations will result in risks consistent with the incremental conditional core damage probability (ICCDP) and incremental large early release probability (ICLERP) guidelines so that defense-in-depth for the safety systems will be maintained.~~

In the event one containment isolation valve in one or more penetration flow paths is inoperable, except for ~~Condition A and for~~ purge valve leakage and ~~shield building~~ bypass leakage not within limit~~]~~, the affected penetration flow path must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic containment isolation valve, a closed manual valve, a blind flange, and a check valve with flow through the valve secured. For penetrations isolated in accordance with Required Action ~~B~~.1, the device used to isolate the penetration should be the closest available one to containment. Required Action ~~B~~.1 must be completed within the ~~[7 day]~~ Completion Time ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The ~~[7 day]~~ Completion Time is reasonable, considering the time required to isolate the penetration and the relative importance of supporting containment OPERABILITY during MODES 1, 2, 3, and 4 ~~(References 3 and 4)~~.

BASES

ACTIONS (continued)

For affected penetration flow paths that cannot be restored to OPERABLE status within the ~~[7 day]~~ Completion Time and that have been isolated in accordance with Required Action ~~B~~.1, the affected penetration flow paths must be verified to be isolated on a periodic basis. This is necessary to ensure that containment penetrations required to be isolated following an accident and no longer capable of being automatically isolated will be in the isolation position should an event occur. This Required Action does not require any testing or device manipulation. Rather, it involves verification that those isolation devices outside containment and capable of being mispositioned are in the correct position. The Completion Time of "once per 31 days ~~[~~following isolation~~]~~ for isolation devices outside containment" is appropriate considering the fact that the devices are operated under administrative controls and the probability of their misalignment is low. For the isolation devices inside containment, the time period specified as "prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days" is based on engineering judgment and is considered reasonable in view of the inaccessibility of the isolation devices and other administrative controls that will ensure that isolation device misalignment is an unlikely possibility.

Condition ~~B~~ has been modified by a Note indicating that this Condition is only applicable to those penetration flow paths with two ~~[or more]~~ containment isolation valves. For penetration flow paths with only one containment isolation valve and a closed system, Condition ~~D~~ provides appropriate actions.

Required Action ~~B~~.2 is modified by two Notes. Note 1 applies to isolation devices located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned. Therefore, the probability of misalignment of these devices, once they have been verified to be in the proper position, is small.~~]~~

BASES

ACTIONS (continued)

B

~~C~~.1

With two ~~[or more]~~ containment isolation valves in one or more penetration flow paths inoperable, ~~[~~except for purge valve leakage and ~~shield building~~ bypass leakage not within limit~~]~~, the affected penetration flow path must be isolated within 1 hour. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic valve, a closed manual valve, and a blind flange. The 1 hour Completion Time is consistent with the ACTIONS of LCO 3.6.1. In the event the affected penetration is isolated in accordance with Required Action ~~C~~.1, the affected penetration must be verified to be isolated on a periodic basis per Required Action ~~B~~.2, which remains in effect. This periodic verification is necessary to assure leak tightness of containment and that penetrations requiring isolation following an accident are isolated. The Completion Time of once per 31 days for verifying each affected penetration flow path is isolated is appropriate considering the fact that the valves are operated under administrative controls and the probability of their misalignment is low.

secondary containment

B

A

B

Condition ~~C~~ is modified by a Note indicating this Condition is only applicable to penetration flow paths with two ~~[or more]~~ containment isolation valves. Condition ~~B~~ of this LCO addresses the condition of one containment isolation valve inoperable in this type of penetration flow path.

A

C

~~D~~.1 and ~~D~~.2

With one or more penetration flow paths with one containment isolation valve inoperable, the inoperable valve must be restored to OPERABLE status or the affected penetration flow path must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic valve, a closed manual valve, and a blind flange. A check valve may not be used to isolate the affected penetration. Required Action ~~D~~.1 must be completed within the ~~[~~72~~]~~ hour Completion Time ~~for those penetrations that do not meet the 7 day Completion Time criteria and [7 days] for penetrations that do meet the 7 day Completion Time criteria~~. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ The specified time period is reasonable, considering the relative stability of the closed system (hence, reliability) to act as a penetration isolation boundary and the relative importance of supporting containment OPERABILITY during

C

BASES

ACTIONS (continued)

MODES 1, 2, 3, and 4. In the event the affected penetration is isolated in accordance with Required Action ~~D~~.1, the affected penetration flow path must be verified to be isolated on a periodic basis. This is necessary to assure leak tightness of containment and that containment penetrations requiring isolation following an accident are isolated. The Completion Time of once per 31 days ~~[~~following isolation~~]~~ for verifying that each affected penetration flow path is isolated is appropriate considering the valves are operated under administrative controls and the probability of their misalignment is low.

Condition ~~D~~ is modified by a Note indicating that this Condition is only applicable to those penetration flow paths with only one containment isolation valve and a closed system. The closed system must meet the requirements of Reference ~~4~~. This Note is necessary since this Condition is written to specifically address those penetration flow paths in a closed system.

Required Action ~~D~~.2 is modified by two Notes. Note 1 applies to valves and blind flanges located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned. Therefore, the probability of misalignment of these valves, once they have been verified to be in the proper position, is small.

~~[~~ ~~E~~. 1

With the secondary containment bypass leakage rate (SR 3.6.3.~~9~~) ~~[or purge valve leakage rate (SR 3.6.3.6)]~~ not within limit, the assumptions of the safety analysis are not met. Therefore, the leakage must be restored to within limit. Restoration can be accomplished by isolating the penetration(s) that caused the limit to be exceeded by use of one closed and de-activated automatic valve, closed manual valve, or blind flange. When a penetration is isolated, the leakage rate for the isolated penetration is assumed to be the actual pathway leakage through the isolation device. If two isolation devices are used to isolate the penetration, the leakage rate is assumed to be the lesser actual pathway leakage of the two devices. The 4 hour Completion Time for secondary

BASES

ACTIONS (continued)

containment bypass leakage is reasonable considering the time required to restore the leakage by isolating the penetration(s) and the relative importance of secondary containment bypass leakage to the overall containment function. ~~[The 24 hour Completion Time for purge valve leakage is acceptable considering the purge valves remain closed so that a gross breach of containment does not exist.]~~

~~----------REVIEWER'S NOTE----------~~
~~[The bracketed options provided in ACTION E reflect options in plant design and options in adopting the associated leakage rate Surveillances.~~

~~The options (in both ACTION E and ACTION F for purge valve leakage, are based primarily on the design - if leakage rates can be measured separately for each purge valve, ACTION F is intended to apply. This would be required to be able to implement Required Action F.3. Should the design allow only for leak testing both purge valves simultaneously, then the Completion Time for ACTION E should include the "24 hours for purge valve leakage" and ACTION F should be eliminated.]]~~
~~----------~~

E

[~~F~~.1, ~~F~~.2, and ~~F~~.3

In the event one or more ~~containment purge valves in one or more~~ penetration flow paths are not within the purge valve leakage limits, purge valve leakage must be restored to within limits, or the affected penetration must be isolated. The method of isolation must be by the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a ~~[~~closed and de-activated automatic valve with resilient seals, a closed manual valve with resilient seals, or a blind flange~~]~~. A ~~purge~~ valve with resilient seals utilized to satisfy Required Action ~~F~~.1 must have been demonstrated to meet the leakage requirements of SR 3.6.3.6. The specified Completion Time is reasonable, considering that one ~~containment purge~~ valve remains closed so that a gross breach of containment does not exist.

E

with a resilient seal

E

In accordance with Required Action ~~F~~.2, this penetration flow path must be verified to be isolated on a periodic basis. The periodic verification is necessary to ensure that containment penetrations required to be isolated following an accident, which are no longer capable of being automatically isolated, will be in the isolation position should an event occur. This Required Action does not require any testing or valve manipulation. Rather, it involves verification that those isolation devices outside

BASES

ACTIONS (continued)

containment capable of being mispositioned are in the correct position. For the isolation devices inside containment, the time period specified as "prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days" is based on engineering judgment and is considered reasonable in view of the inaccessibility of the isolation devices and other administrative controls that will ensure that isolation device misalignment is an unlikely possibility.

For the ~~containment purge~~ valve with resilient seal that is isolated in accordance with Required Action ~~F~~.1, SR 3.6.3.6 must be performed at least once every ~~[~~92~~]~~ days. This assures that degradation of the resilient seal is detected and confirms that the leakage rate of the ~~containment purge valve~~ does not increase during the time the penetration is isolated. ~~The normal Frequency for SR 3.6.3.6, 184 days, is based on an NRC initiative, Generic Issue B-20 (Ref. 6).~~ Since more reliance is placed on a single ~~valve~~ while in this Condition, it is prudent to perform the SR more often. Therefore, a Frequency of once per ~~[~~92~~]~~ days was chosen and has been shown to be acceptable based on operating experience.

Required Action ~~F~~.2 is modified by two Notes. Note 1 applies to isolation devices located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Note 2 applies to isolation devices that are locked, sealed, or otherwise secured in position and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since the function of locking, sealing, or securing components is to ensure that these devices are not inadvertently repositioned. ~~]~~

~~G~~.1 and ~~G~~.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

BASES

ACTIONS (continued)

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

If the Required Actions and associated Completion Times are not met, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~7~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action ~~G~~.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

~~[~~SR 3.6.3.1

This Surveillance is designed to ensure that a gross breach of containment is not caused by an inadvertent or spurious opening of a ~~[42]~~ inch containment purge valve. Detailed analysis of the purge valves failed to conclusively demonstrate their ability to close during a LOCA in time to limit offsite doses. Therefore, these valves are required to be in the sealed closed position during MODES 1, 2, 3, and 4. A containment purge valve that is sealed closed must have motive power to the valve operator removed. This can be accomplished by de-energizing the source of electric power or by removing the air supply to the valve operator. In this application, the term "sealed" has no connotation of leak

BASES

SURVEILLANCE REQUIREMENTS (continued)

tightness. ~~[The Frequency of 31 days is a result of an NRC initiative, Generic Issue B-24 (Ref. 8), related to containment purge valve use during unit operations.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

This SR is not required to be met while in Condition E of this LCO. This is reasonable since the penetration flow path would be isolated. ~~]~~

SR 3.6.3.2

8 inch

This SR ensures that the ~~mini~~purge valves are closed as required or, if open, open for an allowable reason. If a purge valve is open in violation of this SR, the valve is considered inoperable. If the inoperable valve is not otherwise known to have excessive leakage when closed, it is not considered to have leakage outside of limits. The SR is not required to be met when the purge valves are open for pressure control, ALARA or air quality considerations for personnel entry, or for Surveillances that require the valves to be open. The ~~mini~~purge valves are capable of closing in the environment following a LOCA. Therefore, these valves are allowed to be open for limited periods of time. ~~[The 31 day Frequency is consistent with other containment isolation valve requirements discussed in SR 3.6.3.3.~~

8 inch

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.3.3

This SR requires verification that each containment isolation manual valve and blind flange located outside containment and not locked, sealed, or otherwise secured and required to be closed during accident conditions is closed. The SR helps to ensure that post accident leakage of radioactive fluids or gases outside the containment boundary is within design limits. This SR does not require any testing or valve manipulation. Rather, it involves verification that those containment isolation valves outside containment and capable of being mispositioned are in the correct position. ~~[Since verification of valve position for containment isolation valves outside containment is relatively easy, the 31 day Frequency is based on engineering judgment and was chosen to provide added assurance of the correct positions.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

Containment isolation valves that are open under administrative controls are not required to meet the SR during the time the valves are open. This SR does not apply to valves that are locked, sealed, or otherwise secured in the closed position, since these were verified to be in the correct position upon locking, sealing, or securing.

The Note applies to valves and blind flanges located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted during MODES 1, 2, 3, and 4 and for ALARA reasons. Therefore, the probability of misalignment of these containment isolation valves, once they have been verified to be in the proper position, is small.

SR 3.6.3.4

This SR requires verification that each containment isolation manual valve and blind flange located inside containment and not locked, sealed,

BASES

SURVEILLANCE REQUIREMENTS (continued)

or otherwise secured and required to be closed during accident conditions is closed. The SR helps to ensure that post accident leakage of radioactive fluids or gases outside the containment boundary is within design limits. For containment isolation valves inside containment, the Frequency of "prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days" is appropriate, since these containment isolation valves are operated under administrative controls and the probability of their misalignment is low. Containment isolation valves that are open under administrative controls are not required to meet the SR during the time that they are open. This SR does not apply to valves that are locked, sealed, or otherwise secured in the closed position, since these were verified to be in the correct position upon locking, sealing, or securing.

The Note allows valves and blind flanges located in high radiation areas to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted during MODES 1, 2, and 3 for ALARA reasons. Therefore, the probability of misalignment of these containment isolation valves, once they have been verified to be in their proper position, is small.

SR 3.6.3.5

Verifying that the isolation time of each automatic power operated containment isolation valve is within limits is required to demonstrate OPERABILITY. The isolation time test ensures the valve will isolate in a time period less than or equal to that assumed in the safety analysis.

~~REVIEWER'S NOTE~~
~~If the testing is within the scope of the licensee's INSERVICE TESTING PROGRAM, the Frequency "In accordance with the INSERVICE TESTING PROGRAM" should be used. Otherwise, the periodic Frequency of [18 months] or the reference to the Surveillance Frequency Control Program should be used.~~

~~[~~The Frequency of this SR is in accordance with ~~[~~the INSERVICE TESTING PROGRAM~~]~~ ~~[92 days~~.

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.]]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 4 3

SR 3.6.3.6

For containment purge valves with resilient seals, additional leakage rate testing beyond the test requirements of 10 CFR 50, Appendix J, Option ~~[A]~~[B~~]~~, (Ref. ~~9~~), is required to ensure OPERABILITY. Operating experience has demonstrated that this type of seal has the potential to degrade in a shorter time period than do other seal types. ~~[~~ Based on this observation and the importance of maintaining this penetration leak tight (due to the direct path between containment and the environment), a Frequency of 184 days was established as part of the NRC resolution of Generic Issue B-20, "Containment Leakage Due to Seal Deterioration" (Ref. 6).~~

4

Leakage testing of the purge valves in each penetration flow path is performed simultaneously and OPERABILITY IS demonstrated by verifying that the measured leakage rate is ≤ 0.05 La when pressurized to Pa.

2 2 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 4 3

~~Additionally, this SR must be performed within 92 days after opening the valve. The 92 day Frequency was chosen recognizing that cycling the valve could introduce additional seal degradation (beyond that occurring to a valve that has not been opened). Thus, decreasing the interval is a prudent measure after a valve has been opened.~~ 2

SR 3.6.3.7

Automatic containment isolation valves close on a containment isolation signal to prevent leakage of radioactive material from containment following a DBA. This SR ensures each automatic containment isolation

BASES

SURVEILLANCE REQUIREMENTS (continued)

valve will actuate to its isolation position on a containment isolation actuation signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. ~~[The [18] month Frequency was developed considering it is prudent that this SR be performed only during a unit outage, since isolation of penetrations would eliminate cooling water flow and disrupt normal operation of many critical components. Operating experience has shown that these components usually pass this SR when performed on the [18] month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4 3

~~[SR 3.6.3.8~~

~~---------- REVIEWER'S NOTE ----------~~
~~This SR is only required for those units with resilient seal purge valves allowed to be open during [MODE 1, 2, 3, or 4] and having blocking devices on the valves that are not permanently installed.~~
~~----------~~

~~Verifying that each [42] inch containment purge valve is blocked to restrict opening to ≤ [50]% is required to ensure that the valves can close under DBA conditions within the times assumed in the analyses of References 1 and 2. If a LOCA occurs, the purge valves must close to maintain containment leakage within the values assumed in the accident analysis. At other times when purge valves are required to be capable of closing (e.g., during movement of [recently] irradiated fuel assemblies), pressurization concerns are not present, thus the purge valves can be fully open. [The [18] month Frequency is appropriate because the blocking devices are typically removed only during a refueling outage.~~ 3

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]]~~

~~[~~ SR 3.6.3.~~9~~

This SR ensures that the combined leakage rate of all secondary containment bypass leakage paths is less than or equal to the specified leakage rate. This provides assurance that the assumptions in the safety analysis are met. The leakage rate of each bypass leakage path is assumed to be the maximum pathway leakage (leakage through the worse of the two isolation valves) unless the penetration is isolated by use of one closed and de-activated automatic valve, closed manual valve, or blind flange. In this case, the leakage rate of the isolated bypass leakage path is assumed to be the actual pathway leakage through the isolation device. If both isolation valves in the penetration are closed, the actual leakage rate is the lesser leakage rate of the two valves. The Frequency is required by the Containment Leakage Rate Testing Program. This SR simply imposes additional acceptance criteria.

~~[~~Bypass leakage is considered part of L_a. unless specifically exempted.~~]]~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.3 BASES, CONTAINMENT ISOLATION VALVES

1. The type of Containment (Atmospheric and Dual) is deleted since it is unnecessary (only one Containment Specification is used in the St. Lucie Plant (PSL)ITS). This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ITS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. The PSL Safety Analysis Report (SAR) is an updated version of the original Final Safety Analysis Report. Therefore, the proper acronym is UFSAR and is changed to reflect the document.

DISCUSSION OF CHANGES
ITS 3.6.4, CONTAINMENT PRESSURE

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.6.1.4 states, "Primary containment internal pressure shall be maintained between -0.490 and +0.5 psig" and Unit 2 CTS 3.6.1.4 states, in part, "Primary containment internal pressure shall be maintained between -0.420 and +0.400 psig." ITS 3.6.4 states "Containment pressure shall be ≥ -0.49 psig and ≤ +0.50 psig (Unit 1) ≥ -0.42 psig and ≤ +0.40 (Unit 2)." Additionally, the title for CTS 3.6.1.4 is "Internal Pressure." The title for ITS 3.6.4 is "Containment Pressure." This changes the CTS by changing the title and changing the presentation of the LCO statement.

This change is a wording preference that does not change the requirements for Containment Pressure. This change is designated as an administrative change and is acceptable because it does not result in technical changes to the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.4, CONTAINMENT PRESSURE

1. The type of Containment (Atmospheric and Dual) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ITS which reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is inserted to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.4~~B~~ Containment Pressure ~~(Dual)~~ 1

BASES

BACKGROUND

The containment pressure is limited, during normal operation, to preserve the initial conditions assumed in the accident analyses for a loss of coolant accident (LOCA) or main steam line break (MSLB). These limits also prevent the containment pressure from exceeding the containment design negative pressure differential, with respect to the ~~outside atmosphere~~ shield building annulus, in the event of inadvertent actuation of the Containment Spray System. 2

Containment pressure is a process variable that is monitored and controlled. The containment pressure limits are derived from the input conditions used in the containment functional analyses and the containment structure external pressure analysis. Should operation occur outside these limits coincident with a Design Basis Accident (DBA), post accident containment pressures could exceed calculated values.

APPLICABLE SAFETY ANALYSES

Containment internal pressure is an initial condition used in the DBA analyses to establish the maximum peak containment internal pressure. The limiting DBAs considered for determining the maximum containment internal pressure (P_a) are the LOCA and MSLB. Double-ended hot leg LOCA A~~n MSLB at 75% RTP~~ 2 results in the highest calculated internal containment pressure of 42.77 ~~42.3~~ psig, which is below the internal design pressure of 44 psig. The postulated DBAs are analyzed assuming degraded containment Engineered Safety Feature (ESF) systems (i.e., assuming the loss of one ESF bus, which is the worst case single active failure, resulting in one train of the Containment Spray System and one train of the Containment Cooling System being rendered inoperable). It is this maximum containment pressure that is used to ensure that the licensing basis dose limitations are met.

The initial pressure condition used in the containment analysis was 15.51 psia ~~[14.7] psig~~. The maximum containment pressure resulting from the limiting DBA, 42.77 ~~[42.3]~~ psig, does not exceed the containment design pressure, ~~[~~44~~]~~ psig. The containment was also designed for an internal pressure equal to 1.04 ~~[0.65]~~ psid below external pressure to withstand the resultant pressure drop from an accidental actuation of the Containment Spray System. The LCO limit of -0.49 psig ~~[27] inches of water~~ ensures that operation within the design limit of -1.04 ~~[-0.65]~~ psid is maintained. The maximum calculated differential pressure that would occur as a result of an inadvertent actuation of the Containment Spray System between the containment and the shield building annulus is ~~[0.49]~~ psid. 3 (Ref. 1)

Containment pressure satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii). 0.9996 2

BASES

LCO

Maintaining containment pressure less than or equal to the LCO upper pressure limit ensures that, in the event of a DBA, the resultant peak containment accident pressure will remain below the containment design pressure. Maintaining containment pressure greater than or equal to the LCO lower pressure limit ensures the containment will not exceed the design negative differential pressure following the inadvertent actuation of the Containment Spray System.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. Since maintaining containment pressure within limits is essential to ensure initial conditions assumed in the accident analysis are maintained, the LCO is applicable in MODES 1, 2, 3, and 4. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES.

ACTIONS

A.1

When containment pressure is not within the limits of the LCO, containment pressure must be restored to within these limits within 1 hour. The Required Action is necessary to return operation to within the bounds of the containment analysis. The 1 hour Completion Time is consistent with the ACTIONS of LCO 3.6.1, "Containment," which requires that containment be restored to OPERABLE status within 1 hour.

B.1 and B.2

~~---------- REVIEWER'S NOTE ----------~~
~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F]3, July 2000.~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~
~~---------- 4~~

If containment pressure cannot be restored to within limits within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this

BASES

ACTIONS (continued)

status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~1~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 2 2

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

B 3.6 CONTAINMENT SYSTEMS

B 3.6.4~~B~~ Containment Pressure ~~(Dual)~~

BASES

BACKGROUND

The containment pressure is limited, during normal operation, to preserve the initial conditions assumed in the accident analyses for a loss of coolant accident (LOCA) or main steam line break (MSLB). These limits also prevent the containment pressure from exceeding the containment design negative pressure differential, with respect to the ~~outside atmosphere~~ shield building annulus, in the event of inadvertent actuation of the Containment Spray System.

Containment pressure is a process variable that is monitored and controlled. The containment pressure limits are derived from the input conditions used in the containment functional analyses and the containment structure external pressure analysis. Should operation occur outside these limits coincident with a Design Basis Accident (DBA), post accident containment pressures could exceed calculated values.

APPLICABLE SAFETY ANALYSES

Containment internal pressure is an initial condition used in the DBA analyses to establish the maximum peak containment internal pressure. The limiting DBAs considered for determining the maximum containment internal pressure (P_a) are the LOCA and MSLB. Double-ended hot leg LOCA ~~An MSLB at 75% RTP~~ results in the highest calculated internal containment pressure of 43.43 ~~42.3~~ psig, which is below the internal design pressure of 44 psig. The postulated DBAs are analyzed assuming degraded containment Engineered Safety Feature (ESF) systems (i.e., assuming the loss of one ESF bus, which is the worst case single active failure, resulting in one train of the Containment Spray System and one train of the Containment Cooling System being rendered inoperable). It is this maximum containment pressure that is used to ensure that the licensing basis dose limitations are met.

The initial pressure condition used in the containment analysis was 15.41 psia ~~[14.7] psig~~. The maximum containment pressure resulting from the limiting DBA, ~~[42.3]~~ psig, does not exceed the containment design pressure, ~~[~~44~~]~~ psig. The containment was also designed for an internal pressure equal to 1.05 ~~[0.65]~~ psid below external pressure to withstand the resultant pressure drop from an accidental actuation of the Containment Spray System. The LCO limit of -0.42 psig ~~[27] inches of water~~ ensures that operation within the design limit of -1.05 ~~[-0.65]~~ psid is maintained. The maximum calculated differential pressure that would occur as a result of an inadvertent actuation of the Containment Spray System is ~~[0.49]~~ psid between the containment and the shield building annulus.

Containment pressure satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii). (Ref. 1) 0.9983

BASES

LCO

Maintaining containment pressure less than or equal to the LCO upper pressure limit ensures that, in the event of a DBA, the resultant peak containment accident pressure will remain below the containment design pressure. Maintaining containment pressure greater than or equal to the LCO lower pressure limit ensures the containment will not exceed the design negative differential pressure following the inadvertent actuation of the Containment Spray System.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. Since maintaining containment pressure within limits is essential to ensure initial conditions assumed in the accident analysis are maintained, the LCO is applicable in MODES 1, 2, 3, and 4. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES.

ACTIONS

A.1

When containment pressure is not within the limits of the LCO, containment pressure must be restored to within these limits within 1 hour. The Required Action is necessary to return operation to within the bounds of the containment analysis. The 1 hour Completion Time is consistent with the ACTIONS of LCO 3.6.1, "Containment," which requires that containment be restored to OPERABLE status within 1 hour.

B.1 and B.2

~~---------- REVIEWER'S NOTE ----------~~
~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F]3, July 2000.~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

~~----------~~ 4

If containment pressure cannot be restored to within limits within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this

BASES

ACTIONS (continued)

status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~1~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 2 2

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.4 BASES, CONTAINMENT PRESSURE

1. The type of Containment (Dual) and the Specification designator "B" are deleted since they are unnecessary (only one Containment Pressure Specification is used in the St. Lucie Plant (PSL) ITS.) This information is provided in NUREG-1432, Rev. 5.0, to assist in indentifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation. In addition, the Atmospheric Containment Pressure Bases (ISTS 3.6.4B) is not used and is not shown.

2. Changes are made (additions, deletions, and/or changes) to the ISTS Bases which reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

DISCUSSION OF CHANGES
ITS 3.6.5, CONTAINMENT AIR TEMPERATURE

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS) and additional Technical Specification Task Force (TSTF) travelers included in this submittal.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 4.6.1.5 requires the primary containment average air temperature to be the arithmetical average of the temperatures at three of four locations identified as containment fan cooler intakes No. 1A (Elevation 45 feet), No. 1B (Elevation 45 feet), No. 1C (Elevation 62 feet), No. 1D (Elevation 45 feet). Unit 2 CTS 4.6.1.5 requires the primary containment average air temperature to be the arithmetical average* of two temperature readings at Elevation 70'. Furthermore, Unit 2 CTS 4.6.1.5 requires the use of the air intake temperature detectors of the operating containment air coolers if one temperature detector is inoperable. R1

ITS SR 3.6.5.1 requires verification that the containment average air temperature is within the limit. This changes the CTS by moving the description of how compliance with the Technical Specification LCO is determined to the Bases.

The removal of these details for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement to verify containment average air temperatures are within limits. Also, this change is acceptable because these types of procedural details will be adequately controlled in the Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural

details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.5 Containment Air Temperature ~~(Atmospheric and Dual)~~

BASES

BACKGROUND

The containment structure serves to contain radioactive material that may be released from the reactor core following a Design Basis Accident (DBA). The containment average air temperature is limited during normal operation to preserve the initial conditions assumed in the accident analyses for a loss of coolant accident (LOCA) or main steam line break (MSLB).

The containment average air temperature limit is derived from the input conditions used in the containment functional analyses and the containment structure external pressure analyses. This LCO ensures that initial conditions assumed in the analysis of containment response to a DBA are not violated during unit operations. The total amount of energy to be removed from containment by the Containment Spray and Cooling systems during post accident conditions is dependent on the energy released to the containment due to the event, as well as the initial containment temperature and pressure. The higher the initial temperature, the more energy that must be removed, resulting in a higher peak containment pressure and temperature. Exceeding containment design pressure may result in leakage greater than that assumed in the accident analysis (Ref. 1). Operation with containment temperature in excess of the LCO limit violates an initial condition assumed in the accident analysis.

APPLICABLE SAFETY ANALYSES

Containment average air temperature is an initial condition used in the DBA analyses that establishes the containment environmental qualification operating envelope for both pressure and temperature. The limit for containment average air temperature ensures that operation is maintained within the assumptions used in the DBA analysis for containment. The accident analyses and evaluations considered both LOCAs and MSLBs for determining the maximum peak containment pressures and temperatures. The worst case MSLB generates larger mass and energy releases than the worst case LOCA. Thus, the MSLB event bounds the LOCA event from the containment peak ~~pressure and~~ temperature standpoint. The initial pre-accident temperature inside containment was assumed to be ~~[~~120~~]~~°F (Ref. ~~2~~).

~~[For atmospheric containment, the initial containment average air temperature condition of [120]°F resulted in a maximum vapor temperature in containment of [413]°F. The temperature of the~~

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~containment steel liner and concrete structure reach approximately 230°F and 220°F, respectively. The containment average air temperature limit of [120]°F ensures that, in the event of an accident, the maximum design temperature for containment, [300]°F, is not exceeded. The consequence of exceeding this design temperature may be the potential for degradation of the containment structure under accident loads.~~

~~For dual containment,~~ the initial containment condition of ~~[~~120~~]~~°F resulted in a maximum vapor temperature in containment of ~~[413.5]~~°F. ~~The~~ temperature of the containment steel pressure vessel ~~also reaches~~ approximately ~~[413.5]~~°F. The containment average temperature limit of ~~[~~120~~]~~°F ensures that, in the event of an accident, the maximum design temperature for containment of ~~[269.3]~~°F during LOCA ~~conditions~~ and ~~[413.5]°F during~~ MSLB conditions is not exceeded. The consequences of exceeding this design temperature may be the potential for degradation of the containment structure under accident loads.~~]~~

Containment average air temperature satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

During a DBA, with an initial containment average air temperature less than or equal to the LCO temperature limit, the resultant accident temperature profile assures that the containment structural temperature is maintained below its design temperature and that required safety related equipment will continue to perform its function.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, maintaining containment average air temperature within the limit is not required in MODE 5 or 6.

ACTIONS

A.1

When containment average air temperature is not within the limit of the LCO, it must be restored to within limit within 8 hours. This Required Action is necessary to return operation to within the bounds of the containment analysis. The 8 hour Completion Time is acceptable considering the sensitivity of the analysis to variations in this parameter and provides sufficient time to correct minor problems.

BASES

ACTIONS (continued)

B.1 and B.2

~~REVIEWER'S NOTE~~
~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F]3, July 2000.~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

4

If the containment average air temperature cannot be restored to within its limit within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the 2 plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~3~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 2

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MOD 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.6.5.1

Verifying that containment average air temperature is within the LCO limit ensures that containment operation remains within the limit assumed for the containment analyses. In order to determine the containment average air temperature, an arithmetic average is calculated using measurements taken at locations within the containment selected to provide a representative sample of the overall containment atmosphere.

~~[The 24 hour Frequency of this SR is considered acceptable based on the observed slow rates of temperature increase within containment as a result of environmental heat sources (due to the large volume of containment). Furthermore, the 24 hour Frequency is considered adequate in view of other indications available in the control room, including alarms, to alert the operator to an abnormal containment temperature condition.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

2

INSERT 1

The arithmetical average is calculated from three of the following locations:

a. Containment fan cooler No. 1A air intake, elevation 45 feet,
b. Containment fan cooler No. 1B air intake, elevation 45 feet,
c. Containment fan cooler No. 1C air intake, elevation 62 feet, and
d. Containment fan cooler No. 1D air intake, elevation 45 feet.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.5 Containment Air Temperature ~~(Atmospheric and Dual)~~ 1

BASES

BACKGROUND

The containment structure serves to contain radioactive material that may be released from the reactor core following a Design Basis Accident (DBA). The containment average air temperature is limited during normal operation to preserve the initial conditions assumed in the accident analyses for a loss of coolant accident (LOCA) or main steam line break (MSLB).

The containment average air temperature limit is derived from the input conditions used in the containment functional analyses and the containment structure external pressure analyses. This LCO ensures that initial conditions assumed in the analysis of containment response to a DBA are not violated during unit operations. The total amount of energy to be removed from containment by the Containment Spray and Cooling systems during post accident conditions is dependent on the energy released to the containment due to the event, as well as the initial containment temperature and pressure. The higher the initial temperature, the more energy that must be removed, resulting in a higher peak containment pressure and temperature. Exceeding containment design pressure may result in leakage greater than that assumed in the accident analysis (Ref. 1). Operation with containment temperature in excess of the LCO limit violates an initial condition assumed in the accident analysis.

APPLICABLE SAFETY ANALYSES

Containment average air temperature is an initial condition used in the DBA analyses that establishes the containment environmental qualification operating envelope for both pressure and temperature. The limit for containment average air temperature ensures that operation is maintained within the assumptions used in the DBA analysis for containment. The accident analyses and evaluations considered both LOCAs and MSLBs for determining the maximum peak containment pressures and temperatures. The worst case MSLB generates larger mass and energy releases than the worst case LOCA. Thus, the MSLB event bounds the LOCA event from the containment peak ~~pressure and~~ temperature standpoint. The initial pre-accident temperature inside containment was assumed to be ~~[~~120~~]~~°F (Ref. ~~2~~). 2 3 1 2

~~[For atmospheric containment, the initial containment average air temperature condition of [120]°F resulted in a maximum vapor temperature in containment of [413]°F. The temperature of the~~ 3

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~containment steel liner and concrete structure reach approximately 230°F and 220°F, respectively. The containment average air temperature limit of [120]°F ensures that, in the event of an accident, the maximum design temperature for containment, [300]°F, is not exceeded. The consequence of exceeding this design temperature may be the potential for degradation of the containment structure under accident loads.~~

~~For dual containment,~~ the initial containment condition of ~~[~~120~~]~~°F resulted in a maximum vapor temperature in containment of ~~[413.5]~~°F. ~~The~~ temperature of the containment steel pressure vessel ~~also reaches~~ approximately ~~[413.5]~~°F. The containment average temperature limit of ~~[~~120~~]~~°F ensures that, in the event of an accident, the maximum design temperature for containment of ~~[269.3]~~°F during LOCA ~~conditions~~ and ~~[413.5]°F during~~ MSLB conditions is not exceeded. The consequences of exceeding this design temperature may be the potential for degradation of the containment structure under accident loads.~~]~~

Containment average air temperature satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

During a DBA, with an initial containment average air temperature less than or equal to the LCO temperature limit, the resultant accident temperature profile assures that the containment structural temperature is maintained below its design temperature and that required safety related equipment will continue to perform its function.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, maintaining containment average air temperature within the limit is not required in MODE 5 or 6.

ACTIONS

A.1

When containment average air temperature is not within the limit of the LCO, it must be restored to within limit within 8 hours. This Required Action is necessary to return operation to within the bounds of the containment analysis. The 8 hour Completion Time is acceptable considering the sensitivity of the analysis to variations in this parameter and provides sufficient time to correct minor problems.

BASES

ACTIONS (continued)

B.1 and B.2

~~REVIEWER'S NOTE~~
~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F]3, July 2000.~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

4

If the containment average air temperature cannot be restored to within its limit within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the 2 plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~3~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 2

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MOD 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.6.5.1

Verifying that containment average air temperature is within the LCO limit ensures that containment operation remains within the limit assumed for the containment analyses. In order to determine the containment average air temperature, an arithmetic average is calculated using measurements taken at locations within the containment selected to provide a representative sample of the overall containment atmosphere.

~~[The 24 hour Frequency of this SR is considered acceptable based on the observed slow rates of temperature increase within containment as a result of environmental heat sources (due to the large volume of containment). Furthermore, the 24 hour Frequency is considered adequate in view of other indications available in the control room, including alarms, to alert the operator to an abnormal containment temperature condition.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

2

INSERT 1

The arithmetical average is calculated from the following containment temperature detectors:

a. TE-07-3A NW RCB Elevation 70', and
b. TE-07-3B SW RCB Elevation 70'.

When one of the two temperature detectors is not functional, the air intake temperature of the operating containment air coolers may be used.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.5 BASES, CONTAINMENT AIR TEMPERATURE

1. The type of Containment (Atmospheric and Dual) is deleted since it is unnecessary (only one Containment Specification is used in the St. Lucie Plant (PSL) ITS). This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ITS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. The PSL Safety Analysis Report (SAR) is an updated version of the original Final Safety Analysis Report. Therefore, the proper acronym is UFSAR and is changed to reflect the document.

DISCUSSION OF CHANGES
ITS 3.6.6, CONTAINMENT SPRAY AND COOLING SYSTEMS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.6.2.1 Actions 1.a, 1.b, 1.d, and 1.e require in part, “otherwise be in… MODE 4...” when containment spray trains or cooling trains cannot be restored to OPERABLE status within the required time. ITS 3.6.6 Required Action F.2 requires, when the Required Actions and associated Completion Times are not met, reducing pressurizer pressure to < 1750 psia. This changes the end states in CTS 3.6.2.1 Action 1 from MODE 4 to MODE 3 with pressurizer pressure < 1750 psia.

The purpose of CTS 3.6.2.1 Action 1 is to place the plant in a condition in which the equipment is no longer required. CTS 3.6.2.1 Action 1 provides appropriate actions to take for the containment spray and containment cooling trains when the unit is in MODE 1, 2, or 3 when pressurizer pressure is ≥ 1750 psia. CTS 3.6.2.1 Action 2 provides appropriate actions to take for the containment cooling trains when the unit is in MODE 3 when pressurizer pressure is < 1750 psia. The Containment Spray System is not required to be OPERABLE when pressurizer pressure is < 1750 psia. Therefore, in accordance with CTS 3.0.2 (ITS LCO 3.0.2), when pressurizer pressure is < 1750 psia, the requirements to be in MODE 4 in CTS 3.6.2.1 Action 1 are no longer required to be completed. For the Containment Spray System, with pressurizer pressure below 1750 psia, the system is no longer required to be OPERABLE. For the Containment Cooling System, CTS 3.6.2.1 Action 2 applies and provides the appropriate actions while in MODE 3 with pressurizer pressure < 1750 psia.

These changes are designated as administrative changes and are acceptable because they maintain the current requirement to place the unit in a condition in which the applicable trains are no longer required consistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2) and, therefore, do not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.6.2.1 Action 1.a states in part, “otherwise be in… MODE 4 within the following 54 hours.” ITS 3.6.6 Required Action F.2, when the Required Actions and associated Completion Times are not met, requires reducing pressurizer pressure to < 1750 psia within 12 hours. This change reduces the time within which the plant must be placed in a condition where the containment spray trains are no longer required from 54 hours to 12 hours.

The purpose of CTS 3.6.2.1 Action 1.a is to place the plant in a condition in which the equipment is no longer required. The containment spray trains are only required to be OPERABLE when pressurizer pressure is ≥ 1750 psia. Therefore, in accordance with CTS 3.0.2 (ITS LCO 3.0.2), when pressurizer pressure is < 1750 psia, the requirements to be in MODE 4 in CTS 3.6.2.1 Action 1 are no longer required to be completed. This effectively allows 54 hours following entry into MODE 3 to reduce pressurizer pressure below 1750 psia. A Completion Time of 12 hours is a reasonable time to reach the required condition in an orderly manner without challenging plant systems. In addition, the 12 hour time is consistent with similar ITS Completion Times (e.g., Required Action C.2 of ISTS 3.5.1 and 3.5.2). The change is designated as more restrictive because it reduces a Required Action time to place the unit in a condition where the LCO does not apply.

RELOCATED SPECIFICATIONS

LA01 *(Type 2 – Removing Descriptions of System Operation)* CTS 4.6.2.1.a requires verification that each valve in the containment spray system is "positioned to take suction from the RWT on a Containment Pressure - - High-High test signal." ITS SR 3.6.6.1 requires verification that the valves are "in the correct position." This changes the CTS my moving the specific detail of system operation to the Bases.

The removal of these details, that are related to system operation, from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for the containment spray system to be demonstrated OPERABLE and the relocated material describes system operation and aspects of OPERABILITY. This change is acceptable because the removed information will be adequately controlled by the Technical Specification Bases Control Program in ITS Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system operation is being removed from the Technical Specification.

LA02 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 4.6.2.1.d.3 and Unit 2 CTS 4.6.2.1.c.2 require "that upon a recirculation actuation signal, the containment sump isolation valves open and that a recirculation mode flow path via an OPERABLE shutdown cooling heat exchanger is established." ITS SR 3.6.6.4 requires verification that each automatic valve in the recirculation mode flow path actuates to the correct position on an actual or simulated actuation signal. This changes the CTS by moving the system detail of the recirculation mode alignment to the Bases. | R1

The removal of these details related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement to verify that an automatic alignment of containment spray to the containment sump occurs on actual or simulated actuation signal. Also, this change is acceptable because the

removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specifications Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* CTS 3.6.2.1 ACTION 1.a for MODE 3 ≥ 1750 psia requires the restoration of a single inoperable containment spray train to OPERABLE status within 72 hours or in accordance with the Risk Informed Completion Time Program otherwise be in MODE 3 within 6 hours and MODE 4 within the following 54 hours. ITS 3.6.6 ACTION A requires restoration of the inoperable containment spray train to OPERABLE status within 7 days or in accordance with the Risk Informed Completion Time Program otherwise ITS 3.6.6 ACTION F (discussed in DOCs A02 and M01) requires the plant to be in MODE 3 within 6 hours and pressurizer pressure reduced to <1750 psia within 12 hours. This changes the CTS by allowing 7 days or a period determined in accordance with the Risk Informed Completion Time Program to restore the inoperable containment spray train. | R1

This change is acceptable because the proposed time will still ensure the containment cooling safety function for Units 1 and 2 and the iodine removal safety function for Unit 1 are met. Unit 2 accident analyses does not credit containment spray for fission product removal. Each containment spray train is capable of satisfying at least 50% of the accident heat removal requirements and for Unit 1 100% of the post-accident iodine removal spray requirements. A redundant OPERABLE containment spray train in conjunction with two redundant 50% capacity containment cooling trains ensures a heat removal capability of at least 150% and iodine removal capability (Unit 1 only) of 100% for the 7 day duration. The 7 day period is consistent with the restoration time for an inoperable containment cooling train that is also capable of satisfying at least 50% of the accident heat removal requirements.

The 72 hour containment spray train restoration criterion is retained in ITS 3.6.6 ACTION D when the inoperable containment spray train occurs concurrent with an inoperable containment cooling train. In this condition, the capability of 100% accident containment heat and iodine removal (Unit 1 only) requirements are satisfied by the combination of one OPERABLE containment spray and one containment cooling train.

CTS ACTION 1.c. states, “With one containment spray train and one containment cooling train inoperable, concurrently implement ACTIONS a. and b. The completion intervals for ACTION a. and ACTION b. shall be tracked separately for each train starting from the time each train was discovered

inoperable." CTS ACTION 1.c. does not provide a specific time period requirement, instead relying on the times specified in CTS ACTION 1.a and CTS ACTION 1.b for the respective train inoperability. Because the inoperability of containment spray is the limiting component in CTS ACTION 1.c, (72 hours from CTS ACTION 1.a) restoration of the inoperable containment cooling train would necessarily have to be restored also within the 72 hours or less from the time the concurrent condition occurred to satisfy the CTS 1.c. ACTION requirement. The 7 days allowed in CTS ACTION 1.b is inconsequential if the available allowed time for restoration of an inoperable containment cooling train in accordance with CTS ACTION 1.b is (i.e., containment cooling train inoperable preceding the concurrent condition) $\geq$ 72 hours. If the available allowed time for restoration of the inoperable containment cooling train is < 72 hours the restoration time is limited by that remaining time. ITS ACTION D requires when one containment spray train and one containment cooling train are inoperable concurrently that one of the inoperable trains be restored to OPERABLE status within 72 hours or in accordance with the Risk Informed Completion Time Program. Therefore, in effect there is no change to the CTS ACTION 1.c. restoration time requirement for an inoperable containment cooling train when the inoperability is concurrent with an inoperable containment spray train.

ITS ACTION F requires the plant be in MODE 3 in 6 hours and pressurizer pressure reduced to < 1750 psia in 12 hours if ITS 3.6.6 ACTIONS A, B, C, D, or E requirements are not met. This is consistent with the change to CTS discussed in DOC A03.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.6.2.1 ACTION 2.a for MODE 3 < 1750 psia requires, "With one containment cooling train inoperable, restore the inoperable cooling train to OPERABLE status within 72 hours otherwise be in MODE 4 within the next 6 hours." ITS 3.6.6 ACTION H requires the plant to be in MODE 4 in 12 hours if an inoperable containment cooling train cannot be restored to OPERABLE status within 72 hours. This changes the CTS by allowing 12 hours to be in MODE 4.

This change is acceptable because based on operating experience a period of 12 hours to reach MODE 4 in an orderly manner and without challenging plant systems is reasonable and is consistent with similar Required Action Completion Times throughout the ITS (e.g., Required Action B.2 of ITS 3.6.4 and 3.6.5).

L03 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.6.2.1.d.1 and Unit 2 CTS 4.6.2.1.a.1 require verification that each automatic valve in the flow path actuates to its correct position on a CSAS test signal. ITS SR 3.6.6.7 requires verification that each automatic valve in the flow path actuates to the correct position except for valves that are locked, sealed, or otherwise secured in the actuated position. This changes the CTS by excluding

those valves that are locked, sealed, or otherwise secured in the actuated position from verification.

The purpose of Unit 1 CTS 4.6.2.1.d.1 and Unit 2 CTS 4.6.2.1.c.2 is to provide assurance that if an event occurred requiring actuation of the containment spray system, then those valves requiring automatic actuation would actuate to their correct position. Those automatic valves that are locked, sealed, or otherwise secured in position are not required to actuate on a containment spray actuation signal in order to perform their safety function because they are already in the required position. Testing such valves would not provide any additional assurance of OPERABILITY. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS. | R1

L04 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.6.2.1.d.1, CTS 4.6.2.1.d.2 and CTS 4.6.2.1.1.b and Unit 2 CTS 4.6.2.1.c.1, 4.6.2.1.c.3 and 4.6.2.1.1.b require verification that the containment spray system and containment cooling trains start automatically on a Containment Spray Actuation Signal (CSAS) test signal or Safety Injection Actuation Signal (SIAS), as applicable. ITS SR 3.6.6.7, ITS SR 3.6.6.8, and ITS SR 3.6.6.9 require verification that systems or components actuate on an actual or simulated actuation signal. This changes the CTS by explicitly allowing the use of either an actual or simulated signal for the tests. | R1

The purpose of Unit 1 CTS 4.6.2.1.d.1, CTS 4.6.2.1.d.2 and CTS 4.6.2.1.1.b and Unit 2 CTS 4.6.2.1.c.1, 4.6.2.1.c.3 and 4.6.2.1.1.b is to ensure the containment spray system and containment cooling trains start automatically on a Containment Spray Actuation Signal (CSAS) test signal or Safety Injection Actuation Signal (SIAS), as applicable. This change is acceptable because it has been determined that the current Surveillance Requirement acceptance criteria are not the only method that can be used for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual" or "simulated" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L05 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.6.2.1.d.3 and Unit 2 CTS 4.6.2.1.c.2 require verification that the containment spray system automatically aligns to the containment sump upon receipt of an RAS actuation signal. ITS SR 3.6.6.4 requires verification that each automatic valve in the recirculation mode flow path that is not locked, sealed, or otherwise secured in position actuates to the correct position on an actual or simulated actuation signal. This changes the CTS by explicitly allowing the use of either an actual or simulated signal for the tests.

The purpose of Unit 1 CTS 4.6.2.1.d.3 and Unit 2 CTS 4.6.2.1.c.2 is to ensure the containment spray system actuates to align the containment spray system to

the containment sump upon receipt of an RAS signal. This change is acceptable because it has been determined that the current Surveillance Requirement acceptance criteria are not the only method that can be used for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual" or "simulated" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L06 *(Category 8 – Deletion of Surveillance Requirement Shutdown Performance Requirements)* Unit 1 CTS 4.6.2.1.d, Unit 1 CTS 4.6.2.1.1.b, Unit 2 CTS 4.6.2.1.c and Unit 2 CTS 4.6.2.1.1.b state, in part, “In accordance with the Surveillance Frequency Control Program, during shutdown.” ITS surveillances state “In accordance with the Surveillance Frequency Control Program”. This changes the CTS by deleting the SR requirement to perform the Surveillances during shutdown.

This change is acceptable because the new Surveillance Frequency has been evaluated to ensure that it provides an acceptable level of equipment reliability. The proposed Surveillance does not include the restriction on unit conditions. The Surveillance Requirements could be performed in other than shutdown conditions, without jeopardizing safe plant operations. The control of the unit conditions appropriate to perform the test is an issue for procedures and scheduling and has been determined by the NRC Staff to be unnecessary as a Technical Specification restriction. As indicated in Generic Letter 91-04, allowing this control is consistent with the vast majority of other Technical Specification Surveillances that do not dictate unit conditions for the Surveillance. This change is designated as less restrictive because the Surveillance may be performed at plant conditions other than shutdown.

St. Lucie Unit 2

Amendment XXX

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.6, CONTAINMENT SPRAY AND COOLING SYSTEMS

1. The type of Containment (Atmospheric and Dual), Specification designator "A" and the descriptor (credit taken for iodine removal by the Containment Spray System) are deleted since they are unnecessary (only one Containment Specification type is used in the St. Lucie Plant (PSL) Unit 1 and 2 ITS). ISTS 3.6.6A is used for PSL Unit 1 and Unit 2. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ITS which reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. The LCO 3.0.4.a Note to ISTS 3.6.6 Required Action F.2 is not applicable to the PSL ITS because the ITS 3.6.6 Applicability does not include MODE 4 rendering the Note unnecessary. Therefore, the Note has been removed.

5. The Control Room Emergency Air Cleanup System (ISTS 3.7.11) is renumbered and relabeled as ITS 3.7.10, "Control Room Emergency Ventilation System (CREVS)," because the PSL ITS does not include ISTS 3.7.10, "Essential Chilled Water (ECW) System.

6. PSL Current Technical Specifications only require the Containment Spray System to be OPERABLE in MODES 1, 2 and 3 when pressurizer pressure is ≥ 1750 psia. The Applicability of ISTS 3.6.6 reflects this current licensing basis. In addition, the actions associated with containment cooling trains are different based on pressurizer pressure above or below 1750 psia. The Condition qualifiers added to ISTS 3.6.6, Conditions B, D, E, F, and G (ITS Condition I) reflect Conditions that apply when pressurizer pressure is ≥ 1750 psia and the new ACTIONS provided in Insert 1 reflect Conditions that apply when pressurizer pressure is < 1750 psia.

   The change made to Required Action F.2 reflects the end state for Conditions that apply when in MODE 1, 2, or MODE 3 with pressurizer pressure is ≥ 1750 psia. The new ITS 3.6.6 Condition I reflects the end state for Conditions that apply when in MODE 3 with pressurizer pressure is < 1750 psia. Conditions and Required Actions are renumerated to reflect the added ITS ACTIONS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.6~~A~~ Containment Spray and Cooling Systems ~~(Atmospheric and Dual)~~
~~(Credit taken for iodine removal by the Containment Spray System)~~

BASES

BACKGROUND

The Containment Spray and Containment Cooling systems provide containment atmosphere cooling to limit post accident pressure and temperature in containment to less than the design values. Reduction of containment pressure and the iodine removal capability of the spray reduce the release of fission product radioactivity from containment to the environment, in the event of a Design Basis Accident (DBA), to within limits. The Containment Spray and Containment Cooling systems are designed to the requirements of 10 CFR 50, Appendix A, GDC 38, "Containment Heat Removal," GDC 39, "Inspection of Containment Heat Removal Systems," GDC 40, "Testing of Containment Heat Removal Systems," GDC 41, "Containment Atmosphere Cleanup," GDC 42, "Inspection of Containment Atmosphere Cleanup Systems," and GDC 43, "Testing of Containment Atmosphere Cleanup Systems" (Ref. 1), or other documents that were appropriate at the time of licensing (identified on a unit specific basis).

The Containment Cooling System and Containment Spray System are Engineered Safety Feature (ESF) systems. They are designed to ensure that the heat removal capability required during the post accident period can be attained. The Containment Spray System and the Containment Cooling System provide redundant methods to limit and maintain post accident conditions to less than the containment design values.

Containment Spray System

The Containment Spray System consists of two separate trains of equal capacity, each capable of meeting the design bases. Each train includes a containment spray pump, spray header~~s~~, nozzles, valves, and piping. Each train is powered from a separate ESF bus. The refueling water tank (RWT) supplies borated water to the containment spray during the injection phase of operation. In the recirculation mode of operation, containment spray pump suction is transferred from the RWT to the containment sump(s).

shutdown heat exchanger,

The Containment Spray System provides a spray of cold borated water mixed with sodium hydroxide from the spray additive tank into the upper regions of containment to reduce containment pressure and temperature and to reduce the concentration of fission products in the containment atmosphere during a DBA. The RWT solution temperature is an

BASES

BACKGROUND (continued)

important factor in determining the heat removal capability of the Containment Spray System during the injection phase. In the recirculation mode of operation, heat is removed from the containment sump water by the shutdown cooling heat exchangers. Each train of the Containment Spray System provides adequate spray coverage to meet 50% of the system design requirements for containment heat removal and 100% of the iodine removal design bases.

The Spray Additive System injects a ~~hydrazine (N_2H_4)~~ sodium hydroxide (NaOH) solution into the spray. The resulting alkaline pH of the spray enhances its ability to scavenge fission products from the containment atmosphere. The ~~N_2H_4~~ NaOH added to the spray also ensures an alkaline pH for the solution recirculated in the containment sump. The alkaline pH of the containment sump water minimizes the evolution of iodine and minimizes the occurrence of chloride and caustic stress corrosion on mechanical systems and components exposed to the fluid.

The Containment Spray System is actuated either automatically by a containment High-High pressure signal coincident with a safety injection actuation signal (SIAS) or manually. An automatic actuation opens the containment spray pump discharge valves, starts the two Containment Spray System pumps, and begins the injection phase. The containment spray header isolation valves open upon a containment spray actuation signal. A manual actuation of the Containment Spray System is available on the main control board to begin the same sequence. The injection phase continues until an RWT level Low signal is received. The Low level for the RWT generates a recirculation actuation signal that aligns valves from the containment spray pump suction to the containment sump. The Containment Spray System in recirculation mode maintains an equilibrium temperature between the containment atmosphere and the recirculated sump water. Operation of the Containment Spray System in the recirculation mode is controlled by the operator in accordance with the emergency operating procedures.

Containment Cooling System

Two trains of containment cooling, each of sufficient capacity to supply 50% of the design cooling requirement, are provided. Two trains with two fan units each are supplied with cooling water from ~~a separate train of service water cooling~~ redundant essential cooling headers through normally open valves. All four fans are required to furnish the design cooling capacity. ~~Air is drawn into the coolers through the fans and discharged to the steam generator compartments and pressurizer compartment.~~

BASES

BACKGROUND (continued)

During normal operation, all four containment fan coolers are in operation. If a fan were to be idle, it would automatically be started on receipt of an SIAS.

~~In post accident operation following a containment cooling actuation signal (CCAS), all four Containment Cooling System fans are designed to start automatically in slow speed. Cooling is shifted from the chilled water cooled coils to the service water cooled coils.~~ The temperature of the ~~service~~ component cooling water and intake cooling water is an important factor in the heat removal capability of the fan units.

APPLICABLE SAFETY ANALYSES

The Containment Spray System and Containment Cooling System limit the temperature and pressure that could be experienced following a DBA. The limiting DBAs considered relative to containment temperature and pressure are the loss of coolant accident (LOCA) and the main steam line break (MSLB). The DBA LOCA and MSLB are analyzed using computer codes designed to predict the resultant containment pressure and temperature transients. No DBAs are assumed to occur simultaneously or consecutively. The postulated DBAs are analyzed with regard to containment ESF systems, assuming the loss of one ESF bus, which is the worst case single active failure, resulting in one train of the Containment Spray System and one train of the Containment Cooling System being rendered inoperable.

The analysis and evaluation show that under the worst case scenario, the highest peak containment pressure is 42.77 ~~[55.7]~~ psig (experienced during a LOCA ~~n MSLB~~). The analysis shows that the peak containment vapor temperature is 387 ~~[413]~~ °F (experienced during an MSLB). Both results are within the design. (See the Bases for Specifications 3.6.4~~A and 3.6.4B~~, "Containment Pressure," and 3.6.5, "Containment Air Temperature," for a detailed discussion.) The analyses and evaluations assume a power level of 100.3 ~~[102]~~% RTP, one containment spray train and one containment cooling train operating, and initial (pre-accident) conditions of ~~[~~120~~]~~°F and 15.51 ~~[14.7]~~ psia. The analyses also assume a response time delayed initiation in order to provide a conservative calculation of peak containment pressure and temperature responses.

The effect of an inadvertent containment spray actuation has been analyzed. An inadvertent spray actuation results in an annulus to ~~reduces the~~ containment pressure of 0.9996 psid ~~to [-2.8] psig~~ differential due to the sudden cooling effect in the interior of the air tight containment. Additional discussion is provided in the Bases for Specifications 3.6.4~~A, 3.6.4B~~, and 3.6.~~12~~ 8, "Vacuum Relief Valves."

The modeled Containment Spray System actuation from the containment analysis is based upon a response time associated with exceeding the containment High-High pressure setpoint coincident with an SIAS to achieve full flow through the containment spray nozzles. The

BASES

APPLICABLE SAFETY ANALYSES (continued)

Containment Spray System total response time of ~~[60]~~ seconds includes diesel generator startup (for loss of offsite power), block loading of equipment, containment spray pump startup, and spray line filling (Ref. 2).

The performance of the containment cooling train for post accident conditions is given in Reference ~~3~~. The result of the analysis is that each train can provide 50% of the required peak cooling capacity during the post accident condition. The train post accident cooling capacity under varying containment ambient conditions, required to perform the accident analyses, is also shown in Reference ~~4~~.

The modeled Containment Cooling System actuation from the containment analysis is based upon the unit specific response time associated with exceeding the ~~CCAS~~ to achieve full Containment Cooling System air and safety grade cooling water flow.

The Containment Spray System and the Containment Cooling System satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

During a DBA, a minimum of two containment cooling trains or two containment spray trains, or one of each, is required to maintain the containment peak pressure and temperature below the design limits (Ref. ~~5~~). Additionally, one containment spray train is also required to remove iodine from the containment atmosphere and maintain concentrations below those assumed in the safety analysis. To ensure that these requirements are met, two containment spray trains and two containment cooling units must be OPERABLE. Therefore, in the event of an accident, the minimum requirements are met, assuming that the worst case single active failure occurs.

Each Containment Spray System includes a spray pump, spray header~~s~~, nozzles, valves, piping, instruments, and controls to ensure an OPERABLE flow path capable of taking suction from the RWT upon an ESF actuation signal and automatically transferring suction to the containment sump. Management of gas voids is important to Containment Spray System OPERABILITY.

Each Containment Cooling System includes ~~demisters,~~ cooling coils, ~~dampers,~~ fans, instruments, and controls to ensure an OPERABLE flow path.

APPLICABILITY

In MODES 1, 2, ~~3,~~ and ~~4~~, a DBA could cause a release of radioactive material to containment and an increase in containment pressure and temperature, requiring the operation of the containment spray trains and containment cooling trains.

Containment spray trains are not required to be OPERABLE when pressurizer pressure is < 1750 psia.

BASES

APPLICABILITY (continued)

In MODES ~~5~~ and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Thus, the ~~Containment Spray and~~ Containment Cooling ~~systems are~~ not required to be OPERABLE in MODES ~~5~~ and 6.

ACTIONS

A.1

~~REVIEWER'S NOTE~~

~~Utilization of the 7 day Completion Time for Required Action A.1 is dependent on the licensee adopting CE NPSD-1045-A (Ref. 6) and meeting the requirements of the Topical Report and the associated Safety Evaluation including the following commitment: "[LICENSEE] has enhanced its Configuration Risk Management Program, as implemented under 10 CFR 50.65(a)(4), the Maintenance Rule, to include a Large Early Release Fraction assessment to support this application." Otherwise, a 72 hour Completion Time applies.~~

With one containment spray train inoperable, the inoperable containment spray train must be restored to OPERABLE status within ~~[~~7~~]~~ days ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. In this Condition, the remaining OPERABLE spray and cooling trains are adequate to perform the iodine removal and containment cooling functions. The ~~[~~7~~]~~ day Completion Time takes into account the redundant heat removal capability afforded by the Containment Spray System, reasonable time for repairs, and the findings of Ref. ~~6~~.

B.1

With one required containment cooling train inoperable, the inoperable containment cooling train must be restored to OPERABLE status within 7 days ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The components in this degraded condition are capable of providing greater than 100% of the heat removal needs (for the condition of one containment cooling train inoperable) after an accident. The 7 day Completion Time was developed based on the same reasons as those for Required Action A.1.

BASES

ACTIONS (continued)

C.1

and pressurizer pressure ≥ 1750 psia

With two required containment spray trains inoperable~~,~~ at least one of the required containment spray trains must be restored to OPERABLE status within 24 hours. Both trains of containment cooling must be OPERABLE or Condition ~~C~~ is also entered. The Condition is modified by a Note stating it is not applicable if the second containment spray train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one train is inoperable for any reason and the second train is discovered to be inoperable, or if both trains are discovered to be inoperable at the same time. In addition, LCO 3.7.~~11~~, "~~CREACS~~," must be verified to be met within 1 hour. The components in this degraded condition are capable of providing greater than 100% of the heat removal needs after an accident. The Completion Time is based on Reference ~~7~~ which demonstrated that the 24 hour Completion Time is acceptable based on the redundant heat removal capabilities afforded by the Containment Cooling System, the iodine removal capability of ~~the Control Room Emergency Air Cleanup System~~, the infrequent use of the Required Action, and the small incremental effect on plant risk.

D.1 and D.2

with pressurizer pressure ≥ 1750 psia

With one containment spray train and one containment cooling train inoperable~~,~~ one of the required containment spray or containment cooling trains must be restored to OPERABLE status within 72 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The components in this degraded condition provide iodine removal capabilities and are capable of providing at least 100% of the heat removal needs after an accident. The 72 hour Completion Time was developed taking into account the redundant heat removal capabilities afforded by combinations of the Containment Spray System and Containment Cooling System, the iodine removal function of the Containment Spray System, and the low probability of a DBA occurring during this period.

E.1

and pressurizer pressure ≥ 1750 psia

With two required containment cooling trains inoperable~~,~~ one of the required containment cooling trains must be restored to OPERABLE status within 72 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The components in this degraded condition provide iodine removal capabilities and are capable of providing at least 100% of the heat removal needs after an accident. The 72 hour

BASES

ACTIONS (continued)

Completion Time was developed taking into account the redundant heat removal capabilities afforded by ~~combinations of~~ the Containment Spray System ~~and Containment Cooling System~~, the iodine removal function of the Containment Spray System, and the low probability of a DBA occurring during this period.

F.1 and F.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

condition where the requirements do not apply. Containment spray trains are not required to be OPERABLE when pressurizer pressure is below 1750 psia and other Conditions apply when containment cooling trains are inoperable with pressurizer pressure below 1750 psia.

of Condition A, B, C, D, or E

If the Required Actions and associated Completion Times are not met, the plant must be brought to a ~~MODE in which overall plant risk is minimized~~. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and ~~to MODE 4~~ within 12 hours.

reduce pressurizer pressure to < 1750 psia

~~Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 8). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.~~

If one or more containment cooling trains remain inoperable once pressurizer pressure is < 1750 psia, the Conditions (i.e., Conditions G and I) must be entered, as applicable, and Required Actions performed within the associated Completion Times.

~~Required Action F.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the~~

BASES

ACTIONS (continued)

~~results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.~~

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

Insert 1

I

~~C~~.1

with pressurizer pressure ≥ 1750 psia

With any combination of three or more Containment Spray System and Containment Cooling System trains inoperable, the unit is in a condition outside the accident analysis. Therefore, LCO 3.0.3 must be entered immediately.

Insert 2

SURVEILLANCE REQUIREMENTS

SR 3.6.6~~A~~.1

Verifying the correct alignment for manual, power operated, and automatic valves in the containment spray flow path provides assurance that the proper flow paths will exist for Containment Spray System operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position since these were verified to be in the correct position prior to being secured. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves.

This SR does not require any testing or valve manipulation. Rather, it involves verifying that those valves outside containment and capable of potentially being mispositioned are in the correct position.

~~[The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

7

INSERT 1

G.1

With one required containment cooling train inoperable in MODE 3 with pressurizer pressure < 1750 psia, the inoperable containment cooling train must be restored to OPERABLE status within 72 hours. The remaining OPERABLE containment cooling train can provide sufficient heat removal needs after an accident when in MODE 3 and pressurizer pressure < 1750 psia. The 72 hours Completion Time was developed considering the reduced heat removal needs and the low probability of a DBA occurring during this period.

H.1

If the Required Action and associated Completion Time of Condition G are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 4 within 12 hours. The allowed Completion Time is reasonable, based on operating experience, to reach the required plant condition in an orderly manner.

7

INSERT 2

Additionally, with two containment cooling trains inoperable with pressurizer pressure < 1750 psia the containment cooling function may be lost since the Containment Spray System is not required to be OPERABLE below 1750 psia.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

The Surveillance is modified by a Note which exempts system vent flow paths opened under administrative control. The administrative control should be proceduralized and include stationing a dedicated individual at the system vent flow path who is in continuous communication with the operators in the control room. This individual will have a method to rapidly close the system vent flow path if directed.

SR 3.6.6~~A~~.2

Operating each containment cooling train fan unit for ≥ 15 minutes ensures that all trains are OPERABLE and that all associated controls are functioning properly. It also ensures that blockage, fan or motor failure, or excessive vibration can be detected and corrective action taken. ~~[The 31 day Frequency of this SR was developed considering the known reliability of the fan units and controls, the two train redundancy available, and the low probability of a significant degradation of the containment cooling train occurring between surveillances and has been shown to be acceptable through operating experience.~~

This surveillance verifies that each automatic valve in the recirculation mode flow path actuates to the correct position on an actual or simulated actuation signal. The surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.6~~A~~.5 1

Containment Spray System piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the required containment spray trains and may also prevent water hammer and pump cavitation.

Selection of Containment Spray System locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

The Containment Spray System is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. If accumulated gas is discovered that exceeds the acceptance criteria for the susceptible location (or the volume of accumulated gas at one or more susceptible locations exceeds an acceptance criteria for gas volume at the suction or discharge of a pump), the Surveillance is not met. If the accumulated gas is eliminated or brought within the acceptance criteria limits during performance of the Surveillance, the Surveillance is met and past system OPERABILITY is evaluated under the Corrective Action Program. If it is determined by subsequent evaluation that the Containment Spray System is not rendered inoperable by the accumulated gas (i.e., the system is sufficiently filled with water), the Surveillance may be declared met. Accumulated gas should be eliminated or brought within the acceptance criteria limits. | R1

Containment Spray System locations susceptible to gas accumulation are monitored and, if gas is found, the gas volume is compared to the acceptance criteria for the location. Susceptible locations in the same system flow path which are subject to the same gas intrusion mechanisms may be verified by monitoring a representative sub-set of susceptible locations. Monitoring may not be practical for locations that are inaccessible due to radiological or environmental conditions, the plant configuration, or personnel safety. For these locations alternative methods (e.g., operating parameters, remote monitoring) may be used to monitor the susceptible location. Monitoring is not required for susceptible locations where the maximum potential accumulated gas void

BASES

SURVEILLANCE REQUIREMENTS (continued)

volume has been evaluated and determined to not challenge system OPERABILITY. The accuracy of the method used for monitoring the susceptible locations and trending of the results should be sufficient to assure system OPERABILITY during the Surveillance interval.

~~[The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the Containment Spray System piping and the procedural controls governing system operation.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. The Surveillance Frequency may vary by location susceptible to gas accumulation.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

SR 3.6.6~~A~~.6

Verifying that each containment spray pump's developed head at the flow test point is greater than or equal to the required developed head ensures that spray pump performance has not degraded during the cycle. Flow and differential pressure are normal tests of centrifugal pump performance required by the ASME Code (Ref. ~~9~~). Since the containment spray pumps cannot be tested with flow through the spray headers, they are tested on recirculation flow. This test confirms one point on the pump design curve and is indicative of overall performance. Such inservice inspections confirm component OPERABILITY, trend performance, and detect incipient failures by indicating abnormal performance. The Frequency of this SR is in accordance with the INSERVICE TESTING PROGRAM.

SR 3.6.6~~A~~.7 and SR 3.6.6~~A~~.8

These SRs verify that each automatic containment spray valve actuates to its correct position and that each containment spray pump starts upon receipt of an actual or simulated actuation signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. ~~[The [18] month~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~Frequency is based on the need to perform these Surveillances under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillances were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillances when performed at the [18] month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

B 3.6 CONTAINMENT SYSTEMS

B 3.6.6~~A~~ Containment Spray and Cooling Systems ~~(Atmospheric and Dual)~~ 1
~~(Credit taken for iodine removal by the Containment Spray System)~~

BASES

BACKGROUND

The Containment Spray and Containment Cooling systems provide containment atmosphere cooling to limit post accident pressure and temperature in containment to less than the design values. Reduction of containment pressure and the iodine removal capability of the spray reduce the release of fission product radioactivity from containment to the environment, in the event of a Design Basis Accident (DBA), to within limits. The Containment Spray and Containment Cooling systems are designed to the requirements of 10 CFR 50, Appendix A, GDC 38, "Containment Heat Removal," GDC 39, "Inspection of Containment Heat Removal Systems," GDC 40, "Testing of Containment Heat Removal Systems," GDC 41, "Containment Atmosphere Cleanup," GDC 42, "Inspection of Containment Atmosphere Cleanup Systems," and GDC 43, "Testing of Containment Atmosphere Cleanup Systems" (Ref. 1), or other documents that were appropriate at the time of licensing (identified on a unit specific basis).

The Containment Cooling System and Containment Spray System are Engineered Safety Feature (ESF) systems. They are designed to ensure that the heat removal capability required during the post accident period can be attained. The Containment Spray System and the Containment Cooling System provide redundant methods to limit and maintain post accident conditions to less than the containment design values.

Containment Spray System

The Containment Spray System consists of two separate trains of equal capacity, each capable of meeting the design bases. Each train includes a containment spray pump, spray header~~s~~, nozzles, valves, and piping. Each train is powered from a separate ESF bus. The refueling water tank (RWT) supplies borated water to the containment spray during the injection phase of operation. In the recirculation mode of operation, containment spray pump suction is transferred from the RWT to the containment sump(s).

shutdown heat exchanger, 2

The Containment Spray System provides a spray of cold borated water ~~mixed with sodium hydroxide from the spray additive tank~~ into the upper regions of containment to reduce containment pressure and temperature and to reduce the concentration of fission products in the containment atmosphere during a DBA. The RWT solution temperature is an 8

BASES

BACKGROUND (continued)

important factor in determining the heat removal capability of the Containment Spray System during the injection phase. In the recirculation mode of operation, heat is removed from the containment sump water by the shutdown cooling heat exchangers. Each train of the Containment Spray System provides adequate spray coverage to meet 50% of the system design requirements for containment heat removal ~~and 100% of the iodine removal design bases~~.

~~The Spray Additive System injects a hydrazine (N_2H_4) solution into the spray. The resulting alkaline pH of the spray enhances its ability to scavenge fission products from the containment atmosphere. The N_2H_4 added to the spray also ensures an alkaline pH for the solution recirculated in the containment sump. The alkaline pH of the containment sump water minimizes the evolution of iodine and minimizes the occurrence of chloride and caustic stress corrosion on mechanical systems and components exposed to the fluid.~~

The Containment Spray System is actuated either automatically by a containment High-High pressure signal coincident with a safety injection actuation signal (SIAS) or manually. An automatic actuation opens the containment spray ~~pump discharge~~ valves, starts the two Containment Spray System pumps, and begins the injection phase. The containment spray header isolation valves open upon a containment spray actuation signal. A manual actuation of the Containment Spray System is available on the main control board to begin the same sequence. The injection phase continues until an RWT level Low signal is received. The Low level for the RWT generates a recirculation actuation signal that aligns valves from the containment spray pump suction to the containment sump. The Containment Spray System in recirculation mode maintains an equilibrium temperature between the containment atmosphere and the recirculated sump water. Operation of the Containment Spray System in the recirculation mode is controlled by the operator in accordance with the emergency operating procedures.

isolation

Containment Cooling System

redundant essential cooling headers through normally open valves

Two trains of containment cooling, each of sufficient capacity to supply 50% of the design cooling requirement, are provided. Two trains with two fan units each are supplied with cooling water from ~~a separate train of service water cooling~~. All four fans are required to furnish the design cooling capacity. ~~Air is drawn into the coolers through the fans and discharged to the steam generator compartments and pressurizer compartment.~~

component

BASES

BACKGROUND (continued)

Each train is supplied with component cooling water from redundant essential cooling headers through normally open valves.

SIAS

In post accident operation following a ~~containment cooling~~ actuation ~~signal (CCAS),~~ all four Containment Cooling System fans are designed to start automatically in slow speed. ~~Cooling is shifted from the chilled water cooled coils to the service water cooled coils.~~ The temperature of the ~~service~~ water is an important factor in the heat removal capability of the fan units.

component cooling water and intake cooling

APPLICABLE SAFETY ANALYSES

The Containment Spray System and Containment Cooling System limit the temperature and pressure that could be experienced following a DBA. The limiting DBAs considered relative to containment temperature and pressure are the loss of coolant accident (LOCA) and the main steam line break (MSLB). The DBA LOCA and MSLB are analyzed using computer codes designed to predict the resultant containment pressure and temperature transients. No DBAs are assumed to occur simultaneously or consecutively. The postulated DBAs are analyzed with regard to containment ESF systems, assuming the loss of one ESF bus, which is the worst case single active failure, resulting in one train of the Containment Spray System and one train of the Containment Cooling System being rendered inoperable.

43.43

The analysis and evaluation show that under the worst case scenario, the highest peak containment pressure is ~~[55.7]~~ psig (experienced during a~~n~~ ~~MSLB~~). The analysis shows that the peak containment vapor temperature is ~~[413]~~ °F (experienced during an MSLB). Both results are within the design. (See the Bases for Specifications 3.6.4~~A and 3.6.4B~~, "Containment Pressure," and 3.6.5, "Containment Air Temperature," for a detailed discussion.) The analyses and evaluations assume a power level of ~~[102]~~% RTP, one containment spray train and one containment cooling train operating, and initial (pre-accident) conditions of ~~[~~120~~]~~°F and ~~[14.7]~~ psia. The analyses also assume a response time delayed initiation in order to provide a conservative calculation of peak containment pressure and temperature responses.

LOCA

377

100.3

15.41

The effect of an inadvertent containment spray actuation has been analyzed. An inadvertent spray actuation ~~reduces the~~ containment pressure ~~to [2.8] psig~~ due to the sudden cooling effect in the interior of the air tight containment. Additional discussion is provided in the Bases for Specifications 3.6.4~~A, 3.6.4B~~, and 3.6.~~12~~, "Vacuum Relief Valves."

results in an annulus to

of 0.9983 psid

differential

8

The modeled Containment Spray System actuation from the containment analysis is based upon a response time associated with exceeding the containment High-High pressure setpoint coincident with an SIAS to achieve full flow through the containment spray nozzles. The

BASES

APPLICABLE SAFETY ANALYSES (continued)

Containment Spray System total response time of ~~[60]~~ seconds includes diesel generator startup (for loss of offsite power), block loading of equipment, containment spray pump startup, and spray line filling (Ref. 2).

The performance of the containment cooling train for post accident conditions is given in Reference ~~3~~. The result of the analysis is that each train can provide 50% of the required peak cooling capacity during the post accident condition. The train post accident cooling capacity under varying containment ambient conditions, required to perform the accident analyses, is also shown in Reference ~~4~~.

The modeled Containment Cooling System actuation from the containment analysis is based upon the unit specific response time associated with exceeding the ~~CCAS~~ to achieve full Containment Cooling System air and safety grade cooling water flow.

The Containment Spray System and the Containment Cooling System satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

During a DBA, a minimum of two containment cooling trains or two containment spray trains, or one of each, is required to maintain the containment peak pressure and temperature below the design limits (Ref. ~~5~~). Additionally, one containment spray train is also required to remove iodine from the containment atmosphere and maintain concentrations below those assumed in the safety analysis. To ensure that these requirements are met, two containment spray trains and two containment cooling units must be OPERABLE. Therefore, in the event of an accident, the minimum requirements are met, assuming that the worst case single active failure occurs.

Each Containment Spray System includes a spray pump, spray header~~s~~, nozzles, valves, piping, instruments, and controls to ensure an OPERABLE flow path capable of taking suction from the RWT upon an ESF actuation signal and automatically transferring suction to the containment sump. Management of gas voids is important to Containment Spray System OPERABILITY.

Each Containment Cooling System includes ~~demisters,~~ cooling coils, ~~dampers,~~ fans, instruments, and controls to ensure an OPERABLE flow path.

APPLICABILITY

In MODES 1, 2, ~~3,~~ and ~~4~~, a DBA could cause a release of radioactive material to containment and an increase in containment pressure and temperature, requiring the operation of the containment spray trains and containment cooling trains.

Containment spray trains are not required to be OPERABLE when pressurizer pressure is < 1750 psia.

BASES

APPLICABILITY (continued)

In MODES ~~5~~ and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Thus, the ~~Containment Spray and~~ Containment Cooling ~~systems are~~ not required to be OPERABLE in MODES ~~5~~ and 6.

ACTIONS

A.1

~~REVIEWER'S NOTE~~

~~Utilization of the 7 day Completion Time for Required Action A.1 is dependent on the licensee adopting CE NPSD-1045-A (Ref. 6) and meeting the requirements of the Topical Report and the associated Safety Evaluation including the following commitment: "[LICENSEE] has enhanced its Configuration Risk Management Program, as implemented under 10 CFR 50.65(a)(4), the Maintenance Rule, to include a Large Early Release Fraction assessment to support this application." Otherwise, a 72 hour Completion Time applies.~~

With one containment spray train inoperable, the inoperable containment spray train must be restored to OPERABLE status within ~~[~~7~~]~~ days ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. In this Condition, the remaining OPERABLE spray and cooling trains are adequate to perform the iodine removal and containment cooling functions. The ~~[~~7~~]~~ day Completion Time takes into account the redundant heat removal capability afforded by the Containment Spray System, reasonable time for repairs, and the findings of Ref. ~~6~~.

B.1

With one required containment cooling train inoperable, the inoperable containment cooling train must be restored to OPERABLE status within 7 days ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The components in this degraded condition are capable of providing greater than 100% of the heat removal needs (for the condition of one containment cooling train inoperable) after an accident. The 7 day Completion Time was developed based on the same reasons as those for Required Action A.1.

BASES

ACTIONS (continued)

C.1

and pressurizer pressure ≥ 1750 psia

With two required containment spray trains inoperable~~,~~ at least one of the required containment spray trains must be restored to OPERABLE status within 24 hours. Both trains of containment cooling must be OPERABLE or Condition ~~C~~ is also entered. The Condition is modified by a Note stating it is not applicable if the second containment spray train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one train is inoperable for any reason and the second train is discovered to be inoperable, or if both trains are discovered to be inoperable at the same time. In addition, LCO 3.7.~~11~~, "~~CREACS~~," must be verified to be met within 1 hour. The components in this degraded condition are capable of providing greater than 100% of the heat removal needs after an accident. The Completion Time is based on Reference ~~7~~ which demonstrated that the 24 hour Completion Time is acceptable based on the redundant heat removal capabilities afforded by the Containment Cooling System, the iodine removal capability of ~~the Control Room Emergency Air Cleanup System~~, the infrequent use of the Required Action, and the small incremental effect on plant risk.

D.1 and D.2

with pressurizer pressure ≥ 1750 psia

With one containment spray train and one containment cooling train inoperable~~,~~ one of the required containment spray or containment cooling trains must be restored to OPERABLE status within 72 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The components in this degraded condition provide iodine removal capabilities and are capable of providing at least 100% of the heat removal needs after an accident. The 72 hour Completion Time was developed taking into account the redundant heat removal capabilities afforded by combinations of the Containment Spray System and Containment Cooling System, the iodine removal function of the Containment Spray System, and the low probability of a DBA occurring during this period.

E.1

and pressurizer pressure ≥ 1750 psia

With two required containment cooling trains inoperable~~,~~ one of the required containment cooling trains must be restored to OPERABLE status within 72 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The components in this degraded condition provide iodine removal capabilities and are capable of providing at least 100% of the heat removal needs after an accident. The 72 hour

BASES

ACTIONS (continued)

Completion Time was developed taking into account the redundant heat removal capabilities afforded by ~~combinations of~~ the Containment Spray System ~~and Containment Cooling System~~, the iodine removal function of the Containment Spray System, and the low probability of a DBA occurring during this period.

F.1 and F.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

condition where the requirements do not apply. Containment spray trains are not required to be OPERABLE when pressurizer pressure is below 1750 psia and other Conditions apply when containment cooling trains are inoperable with pressurizer pressure below 1750 psia.

of Condition A, B, C, D, or E

If the Required Actions and associated Completion Times are not met, the plant must be brought to a ~~MODE in which overall plant risk is minimized~~. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and ~~to MODE 4~~ within 12 hours.

reduce pressurizer pressure to < 1750 psia

~~Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 8). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.~~

If one or more containment cooling trains remain inoperable once pressurizer pressure is < 1750 psia, the Conditions (i.e., Conditions G and I) must be entered, as applicable, and Required Actions performed within the associated Completion Times.

~~Required Action F.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the~~

BASES

ACTIONS (continued)

~~results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.~~

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

Insert 1

I

~~G~~.1

with pressurizer pressure ≥ 1750 psia

With any combination of three or more Containment Spray System and Containment Cooling System trains inoperable, the unit is in a condition outside the accident analysis. Therefore, LCO 3.0.3 must be entered immediately.

Insert 2

SURVEILLANCE REQUIREMENTS

SR 3.6.6~~A~~.1

Verifying the correct alignment for manual, power operated, and automatic valves in the containment spray flow path provides assurance that the proper flow paths will exist for Containment Spray System operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position since these were verified to be in the correct position prior to being secured. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves.

This SR does not require any testing or valve manipulation. Rather, it involves verifying that those valves outside containment and capable of potentially being mispositioned are in the correct position.

~~[The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

7

INSERT 1

G.1

With one required containment cooling train inoperable in MODE 3 with pressurizer pressure < 1750 psia, the inoperable containment cooling train must be restored to OPERABLE status within 72 hours. The remaining OPERABLE containment cooling train can provide sufficient heat removal needs after an accident when in MODE 3 and pressurizer pressure < 1750 psia. The 72 hours Completion Time was developed considering the reduced heat removal needs and the low probability of a DBA occurring during this period.

H.1

If the Required Action and associated Completion Time of Condition G are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 4 within 12 hours. The allowed Completion Time is reasonable, based on operating experience, to reach the required plant condition in an orderly manner.

7

INSERT 2

Additionally, with two containment cooling trains inoperable with pressurizer pressure < 1750 psia the containment cooling function may be lost since the Containment Spray System is not required to be OPERABLE below 1750 psia.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

The Surveillance is modified by a Note which exempts system vent flow paths opened under administrative control. The administrative control should be proceduralized and include stationing a dedicated individual at the system vent flow path who is in continuous communication with the operators in the control room. This individual will have a method to rapidly close the system vent flow path if directed.

SR 3.6.6~~A~~.2

Operating each containment cooling train fan unit for ≥ 15 minutes ensures that all trains are OPERABLE and that all associated controls are functioning properly. It also ensures that blockage, fan or motor failure, or excessive vibration can be detected and corrective action taken. ~~[The 31 day Frequency of this SR was developed considering the known reliability of the fan units and controls, the two train redundancy available, and the low probability of a significant degradation of the containment cooling train occurring between surveillances and has been shown to be acceptable through operating experience.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.6~~A~~.3

cooling

1200

Verifying a ~~service~~ water flow rate of ≥ ~~[2000]~~ gpm to each cooling unit provides assurance that the design flow rate assumed in the safety analyses will be achieved (Ref. 2). ~~[Also considered in selecting the Frequency of 31 days were the known reliability of the Cooling Water System, the two train redundancy, and the low probability of a significant degradation of flow occurring between surveillances.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

~~[~~ SR 3.6.6~~A~~.4

~~Verifying that the containment spray header piping is full of water to the [100] ft level minimizes the time required to fill the header. This ensures that spray flow will be admitted to the containment atmosphere within the time frame assumed in the containment analysis. [The 31 day Frequency is based on the static nature of the fill header and the low probability of a significant degradation of water level in the piping occurring between surveillances.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]]~~

This surveillance verifies that each automatic valve in the recirculation mode flow path actuates to the correct position on an actual or simulated actuation signal. The surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.6~~A~~.5 1

Containment Spray System piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the required containment spray trains and may also prevent water hammer and pump cavitation.

Selection of Containment Spray System locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

The Containment Spray System is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. If accumulated gas is discovered that exceeds the acceptance criteria for the susceptible location (or the volume of accumulated gas at one or more susceptible locations exceeds an acceptance criteria for gas volume at the suction or discharge of a pump), the Surveillance is not met. If the accumulated gas is eliminated or brought within the acceptance criteria limits during performance of the Surveillance, the Surveillance is met and past system OPERABILITY is evaluated under the Corrective Action Program. If it is determined by subsequent evaluation that the Containment Spray System is not rendered inoperable by the accumulated gas (i.e., the system is sufficiently filled with water), the Surveillance may be declared met. Accumulated gas should be eliminated or brought within the acceptance criteria limits. | R1

Containment Spray System locations susceptible to gas accumulation are monitored and, if gas is found, the gas volume is compared to the acceptance criteria for the location. Susceptible locations in the same system flow path which are subject to the same gas intrusion mechanisms may be verified by monitoring a representative sub-set of susceptible locations. Monitoring may not be practical for locations that are inaccessible due to radiological or environmental conditions, the plant configuration, or personnel safety. For these locations alternative methods (e.g., operating parameters, remote monitoring) may be used to monitor the susceptible location. Monitoring is not required for susceptible locations where the maximum potential accumulated gas void

BASES

SURVEILLANCE REQUIREMENTS (continued)

volume has been evaluated and determined to not challenge system OPERABILITY. The accuracy of the method used for monitoring the susceptible locations and trending of the results should be sufficient to assure system OPERABILITY during the Surveillance interval.

~~[The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the Containment Spray System piping and the procedural controls governing system operation.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. The Surveillance Frequency may vary by location susceptible to gas accumulation.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

SR 3.6.6~~A~~.6

Verifying that each containment spray pump's developed head at the flow test point is greater than or equal to the required developed head ensures that spray pump performance has not degraded during the cycle. Flow and differential pressure are normal tests of centrifugal pump performance required by the ASME Code (Ref. ~~9~~). Since the containment spray pumps cannot be tested with flow through the spray headers, they are tested on recirculation flow. This test confirms one point on the pump design curve and is indicative of overall performance. Such inservice inspections confirm component OPERABILITY, trend performance, and detect incipient failures by indicating abnormal performance. The Frequency of this SR is in accordance with the INSERVICE TESTING PROGRAM.

SR 3.6.6~~A~~.7 and SR 3.6.6~~A~~.8

These SRs verify that each automatic containment spray valve actuates to its correct position and that each containment spray pump starts upon receipt of an actual or simulated actuation signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. ~~[The [18] month~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~Frequency is based on the need to perform these Surveillances under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillances were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillances when performed at the [18] month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

The surveillance of containment sump isolation valves is also required by SR 3.5.2.~~5~~. A single surveillance may be used to satisfy both requirements.

SR 3.6.6~~A~~.9

This SR verifies that each containment cooling train actuates upon receipt of an actual or simulated actuation signal. ~~[The [18] month Frequency is based on engineering judgment and has been shown to be acceptable through operating experience. See SR 3.6.6A.7 and SR 3.6.6A.8, above, for further discussion of the basis for the [18] month Frequency.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.6~~A~~.10

With the containment spray inlet valves closed and the spray header drained of any solution, low pressure air or smoke can be blown through test connections. Performance of this SR demonstrates that each spray nozzle is unobstructed and provides assurance that spray coverage of the containment during an accident is not degraded. ~~[~~Due to the passive design of the nozzle, a test ~~at [the first refueling and at] 10 year intervals~~ is considered adequate to detect obstruction of the spray nozzles following maintenance that could result in nozzle blockage.

Foreign material introduced as a result of maintenance, although unlikely, is the most likely potential cause for future spray nozzle obstruction. Therefore, verification conducted to confirm that potentially affected nozzles are free of blockage following maintenance activities that could result in nozzle blockage, is sufficient to confirm that the nozzles are free of obstruction.

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.6 BASES, CONTAINMENT SPRAY AND COOLING SYSTEMS

1. The type of Containment (Atmospheric and Dual), Specification designator “A” and the descriptor (credit taken for iodine removal by the Containment Spray System) are deleted since they are unnecessary (only one Containment Specification type is used in the St. Lucie (PSL) Plant ITS). ISTS 3.6.6A is used for PSL Unit 1 and Unit 2. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ITS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. The PSL design does not include Essential Chilled Water (ECW). Therefore, ISTS 3.7.10 is not included in the PSL ITS. The Control Room Emergency Air Cleanup System (ISTS 3.7.11) is renumbered as ITS 3.7.10.

6. The LCO 3.0.4.a NOTE is not applicable for the PSL Unit 1 and 2 and has been removed.

7. Concomitant Bases changes made to reflect changes to the ISTS Specification regarding change to Applicability and ACTIONS to include different Containment Spray and Containment Cooling System requirements in MODE 3 based on pressurizer pressure.

8. **Unit 2 only:** “St. Lucie Plant, Unit No. 2 – Issuance of Amendment No. 201 Regarding Technical Specification Changes to Eliminate the Requirements of the Iodine Removal System,” dated November 20, 2019 (ADAMS Accession No. ML19248C238) approved the elimination of Iodine Removal System requirements for the Technical Specifications. Hydrazine is not credited for maintaining post-LOCA sump pH, nor is it credited in managing post-accident iodine in the radiological consequences of design-basis accidents. Reference to the iodine removal system and hydrazine are removed.

4.6.6.3 The structural integrity of the shield building shall be determined, in accordance with the Containment Leakage Rate Testing Program, by a visual inspection of the accessible interior and exterior surfaces of the shield building ~~and verifying no apparent changes in appearance of the concrete surfaces or other abnormal degradation~~.

LA01

CONTAINMENT SYSTEMS

3/4.6.6 SECONDARY CONTAINMENT

SHIELD BUILDING VENTILATION SYSTEM

LIMITING CONDITION FOR OPERATION

3.6.6.1 Two independent shield building ventilation systems shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

a. With one shield building ventilation system inoperable, restore the inoperable system to OPERABLE status within 7 days or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

See ITS 3.6.9

NOTE
Action not applicable when second shield building ventilation system intentionally made inoperable.

b. With two shield building ventilation systems inoperable, within 1 hour verify at least one train of containment spray is OPERABLE, and restore at least one shield building ventilation system to OPERABLE status within 24 hours; otherwise, be in at least HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.6.6.1 Each shield building ventilation system shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by initiating, from the control room, flow through the HEPA filter and charcoal adsorber train and verifying that the train operates for at least 15 continuous minutes with the heaters on.

See ITS 3.6.9

b. By performing required shield building ventilation system filter testing in accordance with the Ventilation Filter Testing Program.

SR 3.6.7.3

c. In accordance with the Surveillance Frequency Control Program by:

1. Verifying that the air flow distribution is uniform within 20% across HEPA filters and charcoal adsorbers when tested in accordance with ASME N510-1989.

See ITS 5.5.8

2. Verifying that the filtration system starts automatically on a Containment Isolation Signal (CIS).

3. Verifying that the filter cooling makeup air and cross connection valves can be manually opened.

See ITS 3.6.9

SR 3.6.7.3

4. Verifying that ~~each~~ system produces a negative pressure of ≥ 2.0 inches W.G. in the annulus within 2 minutes after a Containment Isolation Signal (CIS).

L02 | R1

DEFINITIONS

RATED THERMAL POWER

1.25 RATED THERMAL POWER shall be a total reactor core heat transfer rate to the reactor coolant of 3020 MWt.

REACTOR TRIP SYSTEM RESPONSE TIME

1.26 The REACTOR TRIP SYSTEM RESPONSE TIME shall be the time interval from when the monitored parameter exceeds its trip setpoint at the channel sensor until electrical power to the CEA drive mechanism is interrupted. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC.

See ITS Chapter 1.0

REPORTABLE EVENT

1.27 A REPORTABLE EVENT shall be any of those conditions specified in Section 50.73 to 10 CFR Part 50.

~~SHIELD BUILDING INTEGRITY~~

1.28 SHIELD BUILDING INTEGRITY shall exist when:

SR 3.6.7.1

a. Each door is closed except when the access opening is being used for normal transit entry and exit;

b. The shield building ventilation system is in compliance with Specification 3.6.6.1, and

See ITS

~~c. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.~~

LA02

SHUTDOWN MARGIN

1.29 SHUTDOWN MARGIN shall be the instantaneous amount of reactivity by which the reactor is subcritical or would be subcritical from its present condition assuming all full-length control element assemblies (shutdown and regulating) are fully inserted except for the single assembly of highest reactivity worth which is assumed to be fully withdrawn.

SITE BOUNDARY

1.30 SITE BOUNDARY means that line beyond which the land or property is not owned, leased, or otherwise controlled by the licensee.

See ITS Chapter 1.0

SOURCE CHECK

1.31 A SOURCE CHECK shall be the qualitative assessment of channel response when the channel sensor is exposed to a radioactive source.

CONTAINMENT SYSTEMS

SHIELD BUILDING ~~INTEGRITY~~

LIMITING CONDITION FOR OPERATION

LCO 3.6.7 3.6.6.2 SHIELD BUILDING ~~INTEGRITY~~ shall be ~~maintained~~ OPERABLE.

Applicability **APPLICABILITY:** MODES 1, 2, 3, and 4.

ACTION:

ACTION A Without SHIELD BUILDING INTEGRITY, restore SHIELD BUILDING INTEGRITY within 24 hours or be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within

ACTION B the following 6 hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

Required Action B.2 NOTE

SURVEILLANCE REQUIREMENTS

SR 3.6.7.1 4.6.6.2 SHIELD BUILDING INTEGRITY shall be demonstrated in accordance with the Surveillance Frequency Control Program by verifying that the door in each access opening is closed except when the access opening is being used for normal transit

LCO 3.6.7 NOTE entry and exit.

CONTAINMENT SYSTEMS

SHIELD BUILDING ~~STRUCTURAL~~ INTEGRITY

LIMITING CONDITION FOR OPERATION

LCO 3.6.7

3.6.6.3 ~~The structural integrity of the shield building shall be maintained at a level consistent with the acceptance criteria in Specification 4.6.6.3.~~

A02

APPLICABILITY: ~~MODES 1, 2, 3, and 4.~~

ACTION:

ACTION A

With the structural integrity of the shield building not conforming to the above requirements, restore the structural integrity to within the limits within 24 hours or be in at least HOT STANDBY within the next 6 hours ~~and in COLD SHUTDOWN within the following 30 hours.~~

L01

SURVEILLANCE REQUIREMENTS

SR 3.6.7.2

4.6.6.3 The structural integrity of the shield building shall be determined, in accordance with the Containment Leakage Rate Testing Program, by a visual inspection of the exposed accessible interior and exterior surfaces of the shield building ~~and verifying no apparent changes in appearance of the concrete surfaces or other abnormal degradation~~.

LA01

CONTAINMENT SYSTEMS

SURVEILLANCE REQUIREMENTS (continued)

2. Performing airflow distribution to HEPA filters and charcoal adsorbers in accordance with ASME N510-1989. The distribution shall be ± 20% of the average flow per unit.

See ITS 5.5.8

c. By performing required shield building ventilation system filter testing in accordance with the Ventilation Filter Testing Program.

d. In accordance with the Surveillance Frequency Control Program by:

See ITS 3.6.9

1. Verifying that the system starts on a Unit 2 containment isolation signal and on a fuel pool high radiation signal.

2. Verifying that the filter cooling makeup and cross connection valves can be manually opened.

SR 3.6.7.3

3. Verifying that ~~each~~ system produces a negative pressure of greater than or equal to 2.0 inches WG in the annulus within 99 seconds after a start signal.

A04 | R1

4. Verifying that each system achieves a negative pressure of greater than 0.125 inch WG in the fuel storage building after actuation of a fuel storage building high radiation test signal.

See ITS 3.6.9

DEFINITIONS

PRESSURE BOUNDARY LEAKAGE

1.22 PRESSURE BOUNDARY LEAKAGE shall be leakage (except primary-to-secondary leakage) through a non-isolable fault in a Reactor Coolant System component body, pipe wall or vessel wall.

PROCESS CONTROL PROGRAM (PCP)

1.23 The PROCESS CONTROL PROGRAM (PCP) shall contain the current formulas, sampling, analyses, test, and determinations to be made to ensure that processing and packaging of solid radioactive wastes based on demonstrated processing of actual or simulated wet solid wastes will be accomplished in such a way as to assure compliance with 10 CFR Parts 20, 61, and 71, State regulations, burial ground requirements, and other requirements governing the disposal of solid radioactive waste.

PURGE – PURGING

1.24 PURGE or PURGING is the controlled process of discharging air or gas from a confinement to maintain temperature, pressure, humidity, concentration or other operating condition, in such a manner that replacement air or gas is required to purify the confinement.

RATED THERMAL POWER

See ITS Chapter 1.0

1.25 RATED THERMAL POWER shall be a total reactor core heat transfer rate to the reactor coolant of 3020 MWt.

REACTOR TRIP SYSTEM RESPONSE TIME

1.26 The REACTOR TRIP SYSTEM RESPONSE TIME shall be the time interval from when the monitored parameter exceeds its trip setpoint at the channel sensor until electrical power to the CEA drive mechanism is interrupted. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC.

REPORTABLE EVENT

1.27 A REPORTABLE EVENT shall be any of those conditions specified in Section 50.73 to 10 CFR Part 50.

~~SHIELD BUILDING INTEGRITY~~

See ITS Chapter 1.0

1.28 SHIELD BUILDING INTEGRITY shall exist when:

See ITS 3.6.7

SR 3.6.7.1

a. Each door is closed except when the access opening is being used for normal transit entry and exit;

b. The shield building ventilation system is in compliance with Specification 3.6.6.1, and

See ITS 3.6.9

~~c. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.~~

LA02

DISCUSSION OF CHANGES
ITS 3.6.7, SHIELD BUILDING

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.6.6.2 states “SHIELD BUILDING INTEGRITY shall be maintained.” CTS 3.6.6.3 requires the structural integrity of the shield building to be maintained as determined by a visual inspection in accordance with the Containment Leakage Rate Testing Program.

ITS 3.6.7 is the shield building specification. ITS LCO 3.6.7 requires the shield building to be OPERABLE. ITS 3.6.7 ACTION A requires when the shield building is inoperable to restore the shield building to OPERABLE status with 24 hours. ITS SR 3.6.7.2 requires performance of a visual inspection of the interior and exterior surfaces of the shield building. This changes the CTS by replacing the specific SHIELD BUILDING INTEGRITY definition and all references to it with the requirement for Shield Building OPERABILITY. Additionally, it changes the CTS by combining CTS 3.6.6.2 and CTS 3.6.6.3 into one specification.

The purpose of CTS 3.6.6.2 and CTS 3.6.6.3 is to provide requirements pertaining to shield building OPERABILITY. This portion of the change (combining CTS 3.6.6.2 and CTS 3.6.6.3) is acceptable because moving these requirements into one LCO, ITS 3.6.7 centralizes the requirements. The CTS 3.6.6.2 references to SHIELD BUILDING INTEGRITY have been deleted because the CTS definition of SHIELD BUILDING INTEGRITY in CTS 1.28 is incorporated into ITS 3.6.7 and ITS 3.6.9 and is no longer maintained as a separate definition in the ITS. ITS 3.6.7 requires that the shield building shall be OPERABLE. The definition of OPERABLE and the subsequent ITS 3.6.7 LCO, ACTIONS, and Surveillance Requirements are sufficient to encompass the applicable requirements of the CTS definition. This change removes any confusion that may exist between the definition and the specific requirements of the LCO and is a presentation preference consistent with NUREG-1432, Rev. 5.0. Because the aspects of SHIELD BUILDING INTEGRITY definition requirements are maintained within the Specifications of ITS, this change is considered acceptable.

This change is designated as administrative, because it does not result in technical changes to the CTS.

A03 Unit 1 CTS 3.6.6.3 does not provide an ACTION to take if the shield building is inoperable while in MODE 1, 2, 3, or 4; it only includes a requirement that the shield building be restored to OPERABLE status prior to increasing Reactor Coolant System temperature above 200°F (i.e., MODE 4). Although not explicitly stated, if these requirements are not met the shield building integrity

requirements are not met and the CTS 3.6.2.2 actions would apply. When the shield building is inoperable and not restored to an OPERABLE status within the specified Completion Time ITS 3.6.7 ACTION B requires the unit be in MODE 3 within 6 hours and MODE 4 within 12 hours. This changes the CTS by stating the ACTIONS within the Specification rather than deferring to CTS 3.6.2.2 and deletes the Action to restore the LCO prior to entering MODE 4. In addition, it combines CTS 3.6.6.2 and CTS 3.6.6.3 into one specification.

This change is acceptable because the ACTIONS specified in ITS 3.6.7 adopt ISTS structure for placing the unit outside the MODE of Applicability without changing the time specified to enter MODE 3 and MODE 4. In addition, deletion of the current Action of CTS 3.6.6.3 is acceptable because CTS 3.0.4 (ITS LCO 3.0.4) already precludes entering the MODE of Applicability when the LCO is not met. Therefore, it is not necessary to include these requirements as specific actions in ITS 3.6.7. This change is designated as administrative, because it does not result in technical changes to the CTS.

A04 **Unit 2 Only** CTS 4.6.1.1.d.3 requires a drawdown of the shield building annulus by each Shield Building Ventilation System (SBVS) train to within limits in accordance with the Surveillance Frequency Control Program. The Frequency in accordance with the Surveillance Frequency Control Program for PSL Unit 2 is “at least once per 36 months on a Staggered Test Basis.” ITS SR 3.6.7.3 requires a drawdown of the shield building to within limits using one SBVS train." R1

The purpose of CTS 4.6.6.1.c.4 is to verify the integrity of the shield building boundary by ensuring the shield building annulus can be rapidly drawn to a negative pressure of at least -2.0 inches water gauge. Staggering use of the SBVS train every 18 months (i.e., 36 months total) will ensure both trains are capable of producing the proper negative pressure in the shield building annulus. The specified Surveillance Frequency “on a Staggered Test Basis" continues to require each SBVS train to be tested. Therefore, this change is designated as administrative.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 4 – Removal of LCO, SR, or other TS Requirements to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program)* CTS 4.6.6.3 requires the structural integrity of the shield building to be determined by a visual inspection of the accessible shield building interior and exterior surfaces and verifying no apparent changes in concrete surface appearance or other abnormal degradation. ITS SR 3.6.7.2 includes the shield building structural integrity visual inspection verification of exposed interior and exterior surfaces but does not

include the details of what the inspection entails. This changes the CTS by moving the details of the shield building inspection to the TS Bases.

The removal of these details, which are related to methods of surveillance test performance, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirements for verifying integrity of the shield building. Also, this changes is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specifications Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to methods of surveillance test performance is being removed from the Technical Specifications.

LA02 *(Type 2 – Removing Descriptions of System Operation)* CTS 1.28 states, in part, "SHIELD BUILDING INTEGRITY shall exist when: c. The sealing mechanism associated with each penetration (e.g., welds, bellows, or 0-rings) is OPERABLE. ITS 3.6.7 states "The shield building shall be OPERABLE." This changes the CTS by moving the reference to penetration sealing mechanism requirements to the Bases.

The removal of these details, which are related to system operation, from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for the shield building to be OPERABLE and the relocated material describes aspects of OPERABILITY. In addition, the ITS retains the requirement to perform a shield building annulus drawdown test, which would provide verification that the penetration sealing mechanisms are OPERABLE. Also, this change is acceptable, because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system operation is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 **Unit 2 Only** *(Category 4 – Relaxation of Required Action)* Unit 2 CTS 3.6.6.3, ACTION, states, "With the structural integrity of the shield building not conforming to the above requirements, restore the structural integrity to within the limits within 24 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. ITS 3.6.7 ACTION A requires that if the shield building is inoperable, it must be restored to OPERABLE status within 24 hours. ITS 3.6.7 is the shield building specification. ITS 3.6.7 combines CTS 3.6.6.2 and CTS 3.6.6.3 to address shield building OPERABILITY (see DOC A02). The end state of ITS 3.6.7 is MODE 4. ITS 3.6.7 ACTION B requires that if the Required Action and associated Completion Time

are not met (i.e., the shield building is not restored to OPERABLE status in 24 hours), the unit must be in MODE 3 within 6 hours and MODE 4 within 12 hours. In addition, ITS ACTION B includes a NOTE modifying Required Action B.2 that states, “LCO 3.0.4.a is not applicable when entering MODE 4.” This changes CTS by modifying the end state of CTS 3.6.6.3.

This change is acceptable because the modification of the end state from MODE 5 to MODE 4, with respect to shield building OPERABILITY, is consistent with CE NPSD-1186-A, Revision 00, “Technical Justification for the Risk-Informed Modification to Selected Required Action End States for CEOG Member PWRs,” dated October 2001 (ADAMS Accession No. 110410539) and Technical Specifications Task Force (TSTF) traveler TSTF- 422, Revision 2, “Change in Technical Specifications End States, (CE NPSD-1186),“ dated December 22, 2009 (ADAMS Accession No. ML103270197) allowances.

This change is designated as less restrictive because instead of requiring the plant to achieve COLD SHUTDOWN (MODE 5) the ITS end state is HOT SHUTDOWN (MODE 4) with LCO 3.0.4.a allowances applicable.

L02 Unit 1 Only (Category 7 – Relaxation of Surveillance Frequency) CTS 4.6.1.1.c.4 requires a drawdown of the shield building annulus by each Shield Building Ventilation System (SBVS) train to within limits in accordance with the Surveillance Frequency Control Program. The Frequency in accordance with the Surveillance Frequency Control Program for PSL Unit 1 is “at least once per 18 months.” ITS SR 3.6.7.3 requires a drawdown of the shield building to within limits using one SBVS train." The specified Surveillance Frequency in accordance with the Surveillance Frequency Control Program is proposed to be changed to "36 months on a Staggered Test Basis for each SBVS train” consistent with the ISTS 3.6.11.4 (ITS 3.6.7.3) Frequency as modified by the CTS 1.32 definition of “Staggered Test Basis." This change continues to require each SBVS train to be tested but changes the CTS by allowing the drawdown test for each SBVS train to be performed less frequently. R1

The purpose of CTS 4.6.6.1.c.4 is to verify the integrity of the shield building boundary by ensuring the shield building annulus can be rapidly drawn to a negative pressure of at least -2.0 inches water gauge. Therefore, this is a test of shield building integrity and does not need to be performed every 18 months using each SBVS train. Staggering use of the SBVS train every 18 months (i.e., 36 months total) will ensure both trains are capable of producing the proper negative pressure in the shield building annulus. This change is acceptable because performing the drawdown test using one train of SBVS every 18 months will adequately verify shield building integrity. OPERABILITY of SBVS will be maintained through the application of the requirements of ITS 3.6.9, Shield Building Ventilation System (SBVS). This change is designated as less restrictive because the shield building annulus drawdown Surveillance will be performed less frequently with each SBVS train under the ITS than under the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.7, SHIELD BUILDING

1. The heading and title for ISTS 3.6.11 include the parenthetical expression (Dual). This identifying information is not included in the St. Lucie Plant (PSL) ITS. This information is provided in the NUREG to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. Therefore, necessary editorial changes were made. In addition, PSL design does not include the Hydrogen Mixing System (ISTS 3.6.9) and the Iodine Cleanup System (ISTS 3.6.10); the PSL Unit 2 design does not include the Spray Additive System (ISTS 3.6.7). Therefore, ISTS 3.6.9 and ISTS 3.6.10 are not included in the PSL ITS. The Spray Additive System (ISTS 3.6.7) is renumbered as ITS 3.6.10, the Shield Building Exhaust Air Cleanup System (ISTS 3.6.8) is renumbered as ITS 3.6.9 and the Shield Building (ISTS 3.6.11) is renumbered as ITS 3.6.7.

2. Changes are made (additions, deletions, and/or changes) to the ITS which reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. ISTS SR 3.6.11.1 requires a verification of annulus negative pressure is > [5] inches water gauge every 12 hours or in accordance with the Surveillance Frequency Control Program. PSL does not require a routine verification of static shield building annulus pressure. However, the ITS continues to require periodic verification that the shield building can be maintained at a pressure equal to or more negative than -2.0 inches water gauge in the annulus by one Shield Building Ventilation System (SBVS) train within the required time after a start signal consistent with current technical specifications. The Frequency specified for the shield building drawdown test continues to be in accordance with the Surveillance Frequency Control Program (i.e., at least every 18 months). Operational experience has shown that the frequency of the shield building drawdown test is adequate to detect degradation of shield building integrity such that the proper vacuum cannot be met and maintained within the required time. The current surveillance testing associated with the shield building is considered adequate to assure, pursuant to the requirements of 10 CFR 50.36(c)(3), that the necessary quality of the shield building is maintained, that facility operation will be within safety limits, and that the shield building limiting condition for operation will be met. As a result, ISTS SR 3.6.11.1 is not included in the ITS consistent with the PSL current licensing basis.

4. ISTS SR 3.6.11.2 requires verification that "one" access door in each shield building access opening is closed. However, PSL design consists of one door for each shield building access opening. Therefore, the Surveillance is changed to verify "the" shield building access door in each access opening closed, thereby reflecting the plant-specific design. There is no allowance in ISTS 3.6.11 for when a shield building access door is open for normal transit entry and exit. Therefore, an exception to the requirement that the access opening doors be closed is made to allow for normal transit entry and exit. Shield building entry may be required to perform Technical Specification (TS) Surveillances, as well as other activities on equipment inside the shield building that are required by TS or activities on equipment that support TS-required equipment. Normal transient entry and exit is not intended to preclude performing other activities (i.e., non TS-required activities) if the shield building is entered to perform an allowed activity. The basis of this exception is the assumption that the number of entries into the shield building is small while the unit is operating in MODES 1, 2, 3, and 4 and that the transit time during which a door is open will be

short. This allowance is acceptable due to the low probability of an event that could pressurize the shield building during the short time that the access door is expected to be open in MODES 1, 2, 3, and 4. This change from the ISTS is consistent with the current licensing basis as defined in CTS 1.28, definition of SHIELD BUILDING INTEGRITY, which provides this exception to the requirement for the door in each access opening to be closed.

5. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.~~11~~ Shield Building ~~(Dual)~~

BASES

BACKGROUND

The shield building is a concrete structure that surrounds the steel containment vessel. Between the containment vessel and the shield building inner wall is an annular space that collects any containment leakage that may occur following a loss of coolant accident (LOCA). This space also allows for periodic inspection of the outer surface of the steel containment vessel.

Following a LOCA, the Shield Building ~~Exhaust Air Cleanup~~ System (SB~~EAC~~S) establishes a negative pressure in the annulus between the shield building and the steel containment vessel. Filters in the system then control the release of radioactive contaminants to the environment. A description of the SB~~EAC~~S is provided in the Bases for Specification 3.6.~~8~~, "Shield Building ~~Exhaust Air Cleanup~~ System (SB~~EAC~~S)." Shield building OPERABILITY is required to ensure retention of primary containment leakage and proper operation of the SB~~EAC~~S.

APPLICABLE SAFETY ANALYSES

The design basis for shield building OPERABILITY is a large break LOCA. Maintaining shield building OPERABILITY ensures that the release of radioactive material from the primary containment atmosphere is restricted to those leakage paths and associated leakage rates assumed in the accident analysis.

The shield building satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Shield building OPERABILITY must be maintained to ensure proper operation of the SB~~EAC~~S and to limit radioactive leakage from the containment to those paths and leakage rates assumed in the accident analysis.

APPLICABILITY

Maintaining shield building OPERABILITY prevents leakage of radioactive material from the shield building. Radioactive material may enter the shield building from the primary containment following a LOCA. Therefore, shield building OPERABILITY is required in MODES 1, 2, 3, and 4 when a main steam line break, LOCA, or control element assembly ejection accident could release radioactive material to the primary containment atmosphere.

In MODES 5 and 6, the probability and consequences of these events are low due to the Reactor Coolant System temperature and pressure limitations in these MODES. Therefore, shield building OPERABILITY is not required in MODE 5 or 6.

2 **INSERT 1**

The isolation devices for the penetrations in the shield building boundary are a part of the shield building leak tight barrier. To maintain the shield building boundary leak tight, the sealing mechanism associated with each penetration (e.g., welds, bellows, or O-rings) are required to be OPERABLE.

BASES

ACTIONS

A.1

In the event shield building OPERABILITY is not maintained, shield building OPERABILITY must be restored within 24 hours.

Twenty-four hours is a reasonable Completion Time considering the limited leakage design of the containment and the low probability of a DBA occurring during this time period.

B.1 and B.2

~~---------- REVIEWER'S NOTE ----------~~
~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~
~~----------~~

4

If the shield building cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 1). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and

BASES

ACTIONS (continued)

establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

~~SR 3.6.11.1~~

~~Verifying that shield building annulus pressure is within limit ensures that operation remains within the limit assumed in the containment analysis. [The 12 hour Frequency of this SR was developed considering operating experience related to shield building annulus pressure variations and pressure instrument drift during the applicable MODES.~~
~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

SR 3.6.~~11~~.2

Each Maintaining shield building OPERABILITY requires verifying ~~one~~ the door in the access opening closed. ~~[An~~ access opening ~~may~~ contains one ~~inner and one outer~~ door~~, or in some cases, shield building access openings are shared such that a shield building barrier may have multiple inner or multiple outer doors. The intent is to not breach the shield building boundary at any time when the shield building boundary is required. This is achieved by maintaining the inner or outer portion of the barrier closed at all times.]~~ ~~However,~~ and all shield building access doors are normally kept closed, except when the access opening is being used for normal entry and exit for conveyance through the access opening. ~~or when maintenance is being performed on an access opening~~. ~~[The Frequency of 31 days is based on engineering judgment and is considered adequate in view of other indications of door status available to the operator.~~

~~OR~~

3 **INSERT 2**

Shield building entry may be required to perform Technical Specification (TS) Surveillances, as well as other activities on equipment inside the shield building that are required by TS or activities on equipment that support TS-required equipment. Normal transient entry and exit is not intended to preclude performing other activities (i.e., non-TS-required activities) if the shield building is entered to perform an allowed activity. This allowance is acceptable due to the low probability of an event that could pressurize the shield building during the short time that the access door is expected to be open.

SURVEILLANCE REQUIREMENTS (continued)

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

SR 3.6.~~11~~.3

~~This Surveillance would~~ give advance indication of gross deterioration of the concrete structural integrity of the shield building. The Frequency of this SR is the same as that of SR 3.6.1.1. The verification is done during shutdown and as part of Type A leakage tests associated with SR 3.6.1.1.

SR 3.6.~~11~~.4

The SB~~EAC~~S produces a negative pressure to prevent leakage from the building. SR 3.6.~~11~~.4 verifies that the shield building can be rapidly drawn down to ≥ [0.25] inch water. This test is used to ensure shield building boundary integrity. Establishment of this pressure is confirmed by SR 3.6.~~11~~.4, which demonstrates that the shield building can be drawn down to ≥ [0.25] inches of water ≤ 1 minute using one SB~~EAC~~S train. The time limit ensures that no significant quantity of radioactive material leaks from the shield building prior to developing the negative pressure. Since this SR is a shield building boundary integrity test, it does not need to be performed with each SB~~EAC~~S train. ~~[The SBEACS train used for this Surveillance is staggered to ensure that in addition to the requirements of LCO 3.6.11.4, either train will perform this test.]~~ The primary purpose of this SR is to ensure shield building integrity. The secondary purpose of this SR is to ensure that the SB~~EAC~~S being tested functions as designed. The inoperability of the SB~~EAC~~S train does not necessarily constitute a failure of this Surveillance relative to the shield building OPERABILITY. ~~[The 18 month Frequency is consistent with Regulatory Guide 1.52 (Ref. 2) guidance for functional testing of the ability of the SBEACS.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

B 3.6 CONTAINMENT SYSTEMS

B 3.6.~~11~~ Shield Building ~~(Dual)~~

BASES

BACKGROUND

The shield building is a concrete structure that surrounds the steel containment vessel. Between the containment vessel and the shield building inner wall is an annular space that collects any containment leakage that may occur following a loss of coolant accident (LOCA). This space also allows for periodic inspection of the outer surface of the steel containment vessel.

Following a LOCA, the Shield Building ~~Exhaust Air Cleanup~~ System (SB~~EAC~~S) establishes a negative pressure in the annulus between the shield building and the steel containment vessel. Filters in the system then control the release of radioactive contaminants to the environment. A description of the SB~~EAC~~S is provided in the Bases for Specification 3.6.~~8~~, "Shield Building ~~Exhaust Air Cleanup~~ System (SB~~EAC~~S)." Shield building OPERABILITY is required to ensure retention of primary containment leakage and proper operation of the SB~~EAC~~S.

APPLICABLE SAFETY ANALYSES

The design basis for shield building OPERABILITY is a large break LOCA. Maintaining shield building OPERABILITY ensures that the release of radioactive material from the primary containment atmosphere is restricted to those leakage paths and associated leakage rates assumed in the accident analysis.

The shield building satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Shield building OPERABILITY must be maintained to ensure proper operation of the SB~~EAC~~S and to limit radioactive leakage from the containment to those paths and leakage rates assumed in the accident analysis.

APPLICABILITY

Maintaining shield building OPERABILITY prevents leakage of radioactive material from the shield building. Radioactive material may enter the shield building from the primary containment following a LOCA. Therefore, shield building OPERABILITY is required in MODES 1, 2, 3, and 4 when a main steam line break, LOCA, or control element assembly ejection accident could release radioactive material to the primary containment atmosphere.

In MODES 5 and 6, the probability and consequences of these events are low due to the Reactor Coolant System temperature and pressure limitations in these MODES. Therefore, shield building OPERABILITY is not required in MODE 5 or 6.

2 **INSERT 1**

The isolation devices for the penetrations in the shield building boundary are a part of the shield building leak tight barrier. To maintain the shield building boundary leak tight, the sealing mechanism associated with each penetration (e.g., welds, bellows, or O-rings) are required to be OPERABLE.

BASES

ACTIONS

A.1

In the event shield building OPERABILITY is not maintained, shield building OPERABILITY must be restored within 24 hours.

Twenty-four hours is a reasonable Completion Time considering the limited leakage design of the containment and the low probability of a DBA occurring during this time period.

B.1 and B.2

~~---------- REVIEWER'S NOTE ----------~~
~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~
~~----------~~

4

If the shield building cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 1). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and

BASES

ACTIONS (continued)

establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

~~SR 3.6.11.1~~

~~Verifying that shield building annulus pressure is within limit ensures that operation remains within the limit assumed in the containment analysis. [The 12 hour Frequency of this SR was developed considering operating experience related to shield building annulus pressure variations and pressure instrument drift during the applicable MODES.~~
~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

3

SR 3.6.~~11~~.2

7.1

Each Maintaining shield building OPERABILITY requires verifying ~~one~~ the door in the access opening closed. ~~[An~~ access opening ~~may~~ contains one ~~inner and one outer~~ door~~, or in some cases, shield building access openings are shared such that a shield building barrier may have multiple inner or multiple outer doors. The intent is to not breach the shield building boundary at any time when the shield building boundary is required. This is achieved by maintaining the inner or outer portion of the barrier closed at all times.]~~ ~~However,~~ and all shield building access doors are normally kept closed, except when the access opening is being used for normal entry and exit ~~or when maintenance is being performed on an access opening~~. ~~[The Frequency of 31 days is based on engineering judgment and is considered adequate in view of other indications of door status available to the operator.~~

Insert 2

for conveyance through the access opening.

1 3 3 4 6 4

~~OR~~

3 **INSERT 2**

Shield building entry may be required to perform Technical Specification (TS) Surveillances, as well as other activities on equipment inside the shield building that are required by TS or activities on equipment that support TS-required equipment. Normal transient entry and exit is not intended to preclude performing other activities (i.e., non-TS-required activities) if the shield building is entered to perform an allowed activity. This allowance is acceptable due to the low probability of an event that could pressurize the shield building during the short time that the access door is expected to be open.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

SR 3.6.~~11~~.3

A visual inspection of the exposed accessible shield building interior and exterior surfaces and verification that no apparent changes in the appearance of concrete surfaces or other abnormal degradation will

~~This Surveillance would~~ give advance indication of gross deterioration of the concrete structural integrity of the shield building. The Frequency of this SR is the same as that of SR 3.6.1.1. The verification is done during shutdown and as part of Type A leakage tests associated with SR 3.6.1.1.

SR 3.6.~~11~~.4

The SB~~EAC~~S produces a negative pressure to prevent leakage from the building. SR 3.6.~~11~~.4 verifies that the shield building can be rapidly drawn down to ≥ [0.25] inch water. This test is used to ensure shield building boundary integrity. Establishment of this pressure is confirmed by SR 3.6.~~11~~.4, which demonstrates that the shield building can be drawn down to ≥ [0.25] inches of water ≤ 1 minute using one SB~~EAC~~S train. The time limit ensures that no significant quantity of radioactive material leaks from the shield building prior to developing the negative pressure. Since this SR is a shield building boundary integrity test, it does not need to be performed with each SB~~EAC~~S train. ~~[The SBEACS train used for this Surveillance is staggered to ensure that in addition to the requirements of LCO 3.6.11.4, either train will perform this test.]~~ The primary purpose of this SR is to ensure shield building integrity. The secondary purpose of this SR is to ensure that the SB~~EAC~~S being tested functions as designed. The inoperability of the SB~~EAC~~S train does not necessarily constitute a failure of this Surveillance relative to the shield building OPERABILITY. ~~[The 18 month Frequency is consistent with Regulatory Guide 1.52 (Ref. 2) guidance for functional testing of the ability of the SBEACS.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.7 BASES, SHIELD BUILDING

1. The heading and title for ISTS 3.6.11 include the parenthetical expression (Dual). This identifying information is not included in the St. Lucie Plant (PSL) ITS. This information is provided in the NUREG to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion, but serves no purpose in a plant-specific implementation. Therefore, necessary editorial changes were made. In addition, PSL design does not include the Hydrogen Mixing System (ISTS 3.6.9) and the Iodine Cleanup System (ISTS 3.6.10); the PSL Unit 2 design does not include the Spray Additive System (ISTS 3.6.7). Therefore, ISTS 3.6.9 and ISTS 3.6.10 are not included in the PSL ITS. The Spray Additive System (ISTS 3.6.7) is renumbered as ITS 3.6.10, the Shield Building Exhaust Air Cleanup System (ISTS 3.6.8) is renumbered as ITS 3.6.9 and the Shield Building (ISTS 3.6.11) is renumbered as ITS 3.6.7.

2. Changes are made (additions, deletions, and/or changes) to the ISTS Bases which reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. Changes have been made to be consistent with changes made to the Specification.

4. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is changed to reflect the current licensing basis.

5. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

6. There are no allowances in the LCO for a shield building access opening door to be open when maintenance is being performed on an access opening.

7. Changes are made to include details moved from the Current Technical Specifications to the Bases.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS

B 3.6 CONTAINMENT SYSTEMS

B 3.6.~~12~~ Vacuum Relief Valves ~~(Dual)~~
8
1

BASES

BACKGROUND

The vacuum relief valves protect the containment vessel against negative pressure (i.e., a lower pressure inside than outside). Excessive negative pressure inside containment can occur if there is an inadvertent actuation of ~~the Containment Cooling System or~~ the Containment Spray System. Multiple equipment failures or human errors are necessary to have inadvertent actuation. 2

The containment pressure vessel contains two 100% vacuum relief lines installed in parallel that protect the containment from excessive external loading. The vacuum relief lines are 24 inch penetrations that connect the shield building annulus to the containment. Each vacuum relief line is isolated by a pneumatically operated butterfly valve in series with a check valve located on the containment side of the penetration.

Each butterfly valve is actuated by a separate pressure controller that senses the differential pressure between the containment and the annulus. Each butterfly valve is provided with an air accumulator that allows the valve to open following a loss of instrument air.

The combined pressure drop at rated flow through either vacuum relief line will not exceed the containment pressure vessel design external pressure differential of ~~[0.65]~~ psig with any prevailing atmospheric pressure. 3

1.04

APPLICABLE SAFETY ANALYSES

Design of the vacuum relief lines involves calculating the effect of an inadvertent containment spray actuation that can reduce the atmospheric temperature (and hence pressure) inside containment (Ref. 1). Conservative assumptions are used for all the pertinent parameters in the calculation. For example, the minimum spray water temperature is assumed, as well as maximum initial containment temperature, maximum spray flow, all trains of spray operating, etc. The resulting containment pressure versus time is calculated, including the effect of the vacuum relief valves opening when their negative pressure setpoint is reached. It is also assumed that one vacuum relief line fails to open.

0.9996 psid
maximum annulus to
differential pressure
2

2 **INSERT 1**

in accordance with paragraph NE-3133.3 of Section III of the ASME Boiler and Pressure Vessel Code (Ref. 2).

BASES

APPLICABLE SAFETY ANALYSES (continued)

The vacuum relief valves must also perform the containment isolation function in a containment high pressure event. For this reason, the system is designed to take the full containment positive design pressure and the containment design basis accident (DBA) environmental conditions (temperature, pressure, humidity, radiation, chemical attack, etc.) associated with the containment DBA.

The vacuum relief valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO establishes the minimum equipment required to accomplish the vacuum relief function following the inadvertent actuation of the Containment Spray System. Two vacuum relief lines are required to be OPERABLE to ensure that at least one is available, assuming one or both valves in the other line fail to open.

APPLICABILITY

In MODES 1, 2, 3, and 4, the containment cooling features, such as the Containment Spray System, are required to be OPERABLE to mitigate the effects of a DBA. Excessive negative pressure inside containment could occur whenever these systems are required to be OPERABLE due to inadvertent actuation of these systems. Therefore, the vacuum relief lines are required to be OPERABLE in MODES 1, 2, 3, and 4 to mitigate the effects of inadvertent actuation of the Containment Spray System or Containment Cooling System.

In MODES 5 and 6, the probability and consequences of a DBA are reduced due to the pressure and temperature limitations of these MODES. The Containment Spray System and Containment Cooling System are not required to be OPERABLE in MODES 5 and 6. Therefore, maintaining OPERABLE vacuum relief lines is not required in MODE 5 or 6.

ACTIONS

A.1

With one of the required vacuum relief lines inoperable, the inoperable line must be restored to OPERABLE status within 72 hours. The specified time period is consistent with other LCOs for the loss of one train of a system required to mitigate the consequences of a LOCA or other DBA.

BASES

ACTIONS (continued)

B.1 and B.2

If the vacuum relief line cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.6.~~12~~.1

This SR references the INSERVICE TESTING PROGRAM, which establishes the requirement that inservice testing of the ASME Code Class 1, 2, and 3 pumps and valves shall be performed in accordance with the ASME Boiler and Pressure Vessel Code and applicable Addenda (Ref. ~~2~~). Therefore, SR Frequency is governed by the INSERVICE TESTING PROGRAM.

DEFINITIONS

RATED THERMAL POWER

1.25 RATED THERMAL POWER shall be a total reactor core heat transfer rate to the reactor coolant of 3020 MWt.

REACTOR TRIP SYSTEM RESPONSE TIME

1.26 The REACTOR TRIP SYSTEM RESPONSE TIME shall be the time interval from when the monitored parameter exceeds its trip setpoint at the channel sensor until electrical power to the CEA drive mechanism is interrupted. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC.

See ITS Chapter 1.0

REPORTABLE EVENT

1.27 A REPORTABLE EVENT shall be any of those conditions specified in Section 50.73 to 10 CFR Part 50.

~~SHIELD BUILDING INTEGRITY~~

1.28 SHIELD BUILDING INTEGRITY shall exist when:

a. Each door is closed except when the access opening is being used for normal transit entry and exit;

See ITS 3.6.7

LCO 3.6.9

b. The shield building ventilation system is in compliance with Specification 3.6.6.1, and

c. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.

See ITS 3.6.7

SHUTDOWN MARGIN

1.29 SHUTDOWN MARGIN shall be the instantaneous amount of reactivity by which the reactor is subcritical or would be subcritical from its present condition assuming all full-length control element assemblies (shutdown and regulating) are fully inserted except for the single assembly of highest reactivity worth which is assumed to be fully withdrawn.

SITE BOUNDARY

1.30 SITE BOUNDARY means that line beyond which the land or property is not owned, leased, or otherwise controlled by the licensee.

See ITS Chapter 1.0

SOURCE CHECK

1.31 A SOURCE CHECK shall be the qualitative assessment of channel response when the channel sensor is exposed to a radioactive source.

CONTAINMENT SYSTEMS

3/4.6.6 SECONDARY CONTAINMENT

SHIELD BUILDING VENTILATION SYSTEM (SBVS)

LIMITING CONDITION FOR OPERATION

SBVS trains

LCO 3.6.9 3.6.6.1 Two ~~independent~~ ~~Shield Building Ventilation Systems~~ shall be OPERABLE.

LA01

Applicability **APPLICABILITY:** ~~At all times in~~ MODES 1, 2, 3, and 4.
~~In addition,~~ during movement of recently irradiated fuel assemblies ~~or during crane operations with loads over recently irradiated fuel assemblies in the Spent Fuel Storage Pool in MODES 5 and 6~~.

L04

A02

ACTION:

~~a. With the SBVS inoperable solely due to loss of the SBVS capability to provide design basis filtered air evacuation from the Spent Fuel Pool area, only ACTION c is required. If the SBVS is inoperable for any other reason, concurrently implement ACTION b and ACTION c.~~

train

ACTION A
ACTION C
b. (1) With one SBVS inoperable in MODE 1, 2, 3, or 4, restore the inoperable ~~system~~ to OPERABLE status within 7 days; otherwise, be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

A02 | R1

ACTION B NOTE

NOTE
Action not applicable when second SBVS intentionally made inoperable.

ACTION B
(2) With both SBVSs inoperable, within 1 hour verify at least one train of containment spray is OPERABLE, and restore at least one SBVS to OPERABLE status within 24 hours; otherwise, be in at least HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours.

ACTION C

A02

ACTION A
c. (1) With one SBVS inoperable ~~in any MODE~~, restore the inoperable system to OPERABLE status within 7 days; otherwise, suspend movement of recently irradiated fuel assemblies within the Spent Fuel Storage Pool ~~and crane operations with loads over recently irradiated fuel in the Spent Fuel Storage Pool~~.

ACTION D

L04

during movement of recently irradiated fuel assemblies

DEFINITIONS

PRESSURE BOUNDARY LEAKAGE

1.22 PRESSURE BOUNDARY LEAKAGE shall be leakage (except primary-to-secondary leakage) through a non-isolable fault in a Reactor Coolant System component body, pipe wall or vessel wall.

PROCESS CONTROL PROGRAM (PCP)

1.23 The PROCESS CONTROL PROGRAM (PCP) shall contain the current formulas, sampling, analyses, test, and determinations to be made to ensure that processing and packaging of solid radioactive wastes based on demonstrated processing of actual or simulated wet solid wastes will be accomplished in such a way as to assure compliance with 10 CFR Parts 20, 61, and 71, State regulations, burial ground requirements, and other requirements governing the disposal of solid radioactive waste.

PURGE – PURGING

1.24 PURGE or PURGING is the controlled process of discharging air or gas from a confinement to maintain temperature, pressure, humidity, concentration or other operating condition, in such a manner that replacement air or gas is required to purify the confinement.

See ITS Chapter 1.0

RATED THERMAL POWER

1.25 RATED THERMAL POWER shall be a total reactor core heat transfer rate to the reactor coolant of 3020 MWt.

REACTOR TRIP SYSTEM RESPONSE TIME

1.26 The REACTOR TRIP SYSTEM RESPONSE TIME shall be the time interval from when the monitored parameter exceeds its trip setpoint at the channel sensor until electrical power to the CEA drive mechanism is interrupted. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC.

REPORTABLE EVENT

1.27 A REPORTABLE EVENT shall be any of those conditions specified in Section 50.73 to 10 CFR Part 50.

b. The shield building ventilation system is in compliance with Specification 3.6.6.1, and

c. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.

See ITS 3.6.7

DISCUSSION OF CHANGES
ITS 3.6.9, SHIELD BUILDING VENTILATION SYSTEM (SBVS)

ADMINISTRATIVE CHANGES

A01 In the conversion of the Plant (PSL) Unit 1 and 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 2 only** - CTS 3.6.6.1 Applicability requires the SBVS to be OPERABLE at all times in MODES, 1, 2, 3, and 4 and in addition, during movement of recently irradiated fuel assemblies or during crane operations with loads over recently irradiated fuel assemblies in the Spent Fuel Storage Pool in MODES 5 and 6. CTS 3.6.6.1 Action a clarifies that, “With the SBVS inoperable solely due to loss of the SBVS capability to provide design basis filtered air evacuation from the Spent Fuel Pool area, only ACTION-c is required. If the SBVS is inoperable for any other reason, concurrently implement ACTION-b and ACTION-c. ITS 3.6.9 Applicability requires the SBVS to be OPERABLE in MODES, 1, 2, 3, and 4, and during movement of recently irradiated fuel assemblies and does not include the information provided in CTS 3.6.6.1 Action a. This changes the CTS by eliminating certain wording (e.g., “at all times” and in MODES 5 and 6) because the information is unnecessary to comply with the Technical Specification requirements.

CTS 4.6.6.1.d.1 requires verifying that the SBVS starts on a Unit 2 containment isolation signal and on a fuel pool high radiation signal. CTS 4.6.6.1.d.4 requires, in effect, verifying each SBVS system (i.e., train) achieves the proper negative pressure in the fuel storage building following a high radiation actuation signal. ITS SRs 3.6.9.3, 3.6.9.4, and 3.6.9.5 incorporate these surveillance requirements and adds Notes to clarify when these SRs are required to be met based on their SBVS function (i.e., either in MODES 1, 2, 3, and 4 for the shield building ventilation mode or during activities involving recently irradiated fuel assemblies for the fuel pool area ventilation mode). This changes the CTS by adding clarification notes to ensure the appropriate SRs are applied.

The formatting of the ITS Applicability is in accordance with TSTF-GG-05-01, Writer’s Guide for Plant-Specific Improved Technical Specifications, dated June 2009 (ISTS Writer’s Guide) and it is understood that ITS 3.6.9 applies at all times in MODES 1, 2, 3, and 4. Additionally, due to the radioactive decay of irradiated fuel assemblies following plant operation, movement of recently irradiated fuel assemblies would only be possible within the first 72 hours following subcriticality during a reactor shutdown. Therefore, stating “in MODES 5 and 6” is unnecessary. Also, the ITS 3.6.9 format specifically clarifies the Conditions to ensure that when the SBVS is inoperable solely due to loss of the SBVS capability to provide design basis filtered air evacuation from the spent fuel pool area, the appropriate ACTIONS are applied. Therefore, the CTS action clarification is not required in the ITS.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.6.6.1 states that two "independent" shield building ventilation systems shall be OPERABLE. ITS 3.6.9 requires two shield building ventilation system trains to be OPERABLE but does not include the details of what constitutes OPERABILITY. This changes the CTS by moving the detail that the two systems must be "independent" to the Bases.

The removal of this detail, which is related to system design, from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement that two shield building ventilation system trains shall be OPERABLE. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change, because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.6.6.1.a requires each SBVS train to be operated for a specified time with the heaters on and specifies that flow through the HEPA filters and charcoal adsorbers be initiated from the control room. ITS SR 3.6.9.1 includes the surveillance to operate each SBVS train for a specified time with the heaters operating but does not include the requirement that flow through the HEPA filters and charcoal adsorbers be initiated from the control room. This changes the CTS by moving the procedural requirement that flow through the HEPA filters and charcoal adsorbers be initiated from the control room to the TS Bases.

The removal of these details, that are related to methods of surveillance test performance, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirements for operating each SBVS train for a specified time with the heaters operating. In addition, this change is acceptable because the removed

information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specifications Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to methods of surveillance test performance is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.6.6.1.c.2 and Unit 2 CTS 4.6.6.1.d.1 requires verification that the filtration system starts automatically on a Containment Isolation Signal (CIS). Unit 2 CTS 4.6.6.1.d.1 also requires verification that the system starts on a fuel pool high radiation signal. ITS SR 3.6.9.3 requires verification that each train actuates except for dampers and valves that are locked, sealed, or otherwise secured in the actuated position. This changes the CTS by excluding those valves that are locked, sealed, or otherwise secured in the actuated position from verification. | R1

The purpose of Unit 1 CTS 4.6.6.1.c.2 and Unit 2 CTS 4.6.6.1.d.1 is to provide assurance that if an event occurred requiring actuation of the shield building ventilation system, then those valves and dampers requiring automatic actuation would actuate to their correct position. Those automatic valves and dampers that are locked, sealed, or otherwise secured in position are not required to actuate on a containment isolation signal in order to perform their safety function because they are already in the required position. Testing such valves and dampers would not provide any additional assurance of OPERABILITY. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L02 *(Category 5 – Deletion of Surveillance Requirement)* Unit 1 CTS 4.6.6.1.c.3 and Unit 2 CTS 4.6.6.1.d.2 require verification that the filter cooling makeup air and cross-connection valves can be manually opened. This changes the CTS by deleting verification of the ability to manually open the filter cooling makeup air and cross-connection valves.

The purpose of Unit 1 CTS 4.6.6.1.c.3 and Unit 2 CTS 4.6.6.1.d.2 is to provide assurance that cooling air flow can be provided through the filters for the individual train or cross connected flow manually. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to provide confidence that the equipment can perform its assumed safety function. Manual operation of these valve is not required to perform their safety function and testing of the valves does not provide any additional assurance of OPERABILITY. Valves that are required to actuate will continue to be tested. This change is designated as less restrictive because less stringent

Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L03 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.6.6.1.c.2 and Unit 2 CTS 4.6.6.1.d.1 require verification that the filtration system starts automatically on a "Containment Isolation Signal (CIS)." In addition, Unit 2 CTS 4.6.6.1.d.1 requires verification that each train also starts automatically on a "fuel pool high radiation signal." ITS SR 3.6.9.3 and ITS SR 3.6.9.4 require verification that the system actuates on "an actual or simulated containment isolation signal." This changes the Unit 1 and Unit 2 CTS by explicitly allowing the use of either an actual or simulated signal for the tests.

The purpose of Unit 1 CTS 4.6.6.1.c.2 and Unit 2 CTS 4.6.6.1.d.1 is to ensure the SBVS filtration train actuates upon receipt of a CIS and for Unit 2 includes receipt of a fuel pool high radiation signal. This change is acceptable because it has been determined that the current Surveillance Requirement acceptance criteria are not the only method that can be used for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual" or "simulated" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L04 **Unit 2 only:** (*Category 2 – Relaxation of Applicability*) CTS 3.6.6.1 Applicability requires, in part, that two SBVS be operable during crane operations with loads over recently irradiated fuel assemblies in the spent fuel storage pool in MODES 5 and 6. ITS 3.6.9 does not include an equivalent applicability. In addition, since the Applicability now does not require the LCO to be met during crane operations with loads over recently irradiated fuel assemblies in the spent fuel storage pool, the portion of CTS 3.6.6.1 Actions c.(1) and c.(2) to suspend movement of crane operations, has also been deleted.

The purpose of CTS 3.6.6.1 Applicability is to ensure that the SBVS is OPERABLE to provide filtration to the shield building annulus area to minimize the consequences of accidents and transients, including a fuel handling accident (FHA) involving recently irradiated fuel (i.e., an irradiated fuel assembly that has occupied part of a critical reactor core within the previous 72 hours) in the containment. Since the SBVS also provides filtration of the spent fuel pool area in the fuel handling building, the CTS 3.6.6.1 Applicability also ensures that the SBVS can provide filtration to the fuel pool area to minimize the consequences of an FHA involving recently irradiated fuel in the spent fuel storage pool. According to UFSAR Section 15.7.4.1.2, an FHA is initiated by the dropping of an irradiated fuel assembly either in the containment or in the fuel building. The FHA analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. It is improbable to move irradiated fuel within 72 hours of a plant shutdown (i.e., keff < 0.99) because of the physical time required to perform a controlled plant shutdown, cooldown and depressurize the RCS, and disassemble the reactor vessel to

access irradiated fuel to begin fuel movement and PSL procedurally restricts movement of irradiated fuel until 72 hours after shutdown. However, the ITS requires two trains of the SBVS to be OPERABLE to ensure that, in the unlikely event an FHA in the containment or spent fuel storage pool occurs within 72 hours of a unit shutdown, ventilation and filtration are provided to minimize the consequences of this improbable event.

Crane travel related requirements were relocated from the CTS in Amendment 134, ("St. Lucie Units 1 and 2 – Issuance of Amendments Regarding the Relocation of Spent Fuel Pool Crane Technical Specification Requirements (TAC Nos. MB5667 and MB5668)," dated April 28, 2004 (ADAMS Accession No. ML 040440111)) to the Updated Final Safety Analysis Report where the operational detail is controlled under 10 CFR 50.59 criteria. As cited in the NRC Safety Evaluation associated with Amendment 134, NUREG-0612, "Control of Heavy Loads at Nuclear Power Plants," regulatory guidelines for control of heavy load lifts provide assurance of safe handling of heavy loads in areas where a load drop could impact stored spent fuel, fuel in the reactor core, or equipment that may be required to achieve safe shutdown or permit continued decay heat removal. Section 5.1.1 of NUREG-0612 provides guidelines for reducing the likelihood of dropping heavy loads and provides criteria for establishing safe load paths; procedures for load-handling operations; training of crane operators; design, testing, inspection, and maintenance of cranes and lifting devices; and analyses of the impact of heavy load drops. The guidelines in Sections 5.1.2 through 5.1.6 address alternatives to either further reduce the probability of a load-handling accident or mitigate the consequences of heavy load drops. These alternatives include using a single-failure-proof crane to improve reliability through increased factors of safety and through redundancy or duality in certain active components. Criteria for design of single-failure-proof cranes are included in NUREG-0554, "Single-Failure-Proof Cranes for Nuclear Power Plants."

This change is acceptable because the possibility of damage to a recently irradiated fuel assembly as a consequence of mishandling components other than a recently irradiated fuel assembly is minimized by thorough training, detailed procedures and equipment design. The PSL crane design precludes the handling of heavy objects, such as shipping casks, over the spent fuel pool storage racks. Administrative controls prevent the movement of heavy loads over the cask pit whenever the cask pit rack is installed in the cask area of the spent fuel storage pool. In addition, the cask handling crane design meets the regulatory guidance for single-failure-proof cranes in NUREG-0554, "Single-Failure-Proof Cranes for Nuclear Power Plants" and NUREG-0612. Administrative controls that control the movement of light loads or prevent movement of light loads over recently irradiated fuel assemblies are similar to those used for control of heavy loads, to the extent practicable, as advised in NUREG-0612. Consequently, the possibility of dropping a load other than a recently irradiated fuel assembly and damaging of recently irradiated fuel assemblies in the containment or spent fuel storage pool is remote. Therefore, the Applicability of CTS 3.6.6.1 requiring the SBVS to be operable during crane operations with loads over recently irradiated fuel assemblies in the spent fuel storage pool in MODES 5 and 6 and related actions to suspend crane operations is not necessary to be included in the technical specifications and is removed.

DISCUSSION OF CHANGES
ITS 3.6.9, SHIELD BUILDING VENTILATION SYSTEM (SBVS)

This change is designated as less restrictive because the LCO requirements are applicable in fewer conditions than in the CTS and the associated Required Actions are less stringent in the ITS than applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.9, SHIELD BUILDING VENTILATION SYSTEM (SBVS)

1. The ISTS 3.6.8 title "Shield Building Exhaust Air Cleanup System (SBEACS)" has been changed to "Shield Building Ventilation System (SBVS)" consistent with the St. Lucie Plant (PSL) site specific terminology. The heading for ISTS 3.6.8 includes the parenthetical expression (Dual). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Hydrogen Mixing System (ISTS 3.6.9) and the Iodine Cleanup System (ISTS 3.6.10)); the PSL Unit 2 design does not include the Spray Additive System (ISTS 3.6.7). Therefore, ISTS 3.6.9 and ISTS 3.6.10 are not included in the PSL ITS. The Spray Additive System (ISTS 3.6.7) is renumbered as ITS 3.6.10, the Shield Building Exhaust Air Cleanup System (ISTS 3.6.8) is renumbered as ITS 3.6.9, the Shield Building (ISTS 3.6.11) is renumbered as ITS 3.6.7 and Vacuum Relief Valves (ISTS 3.6.12) is renumbered as ITS 3.6.8.

2. Changes are made (additions, deletions, and/or changes) to the ITS which reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. ISTS SR 3.6.8.4 and ISTS 3.6.8.5 contain bracketed information and/or values that are generic to all Combustion Engineering vintage plants. ISTS SR 3.6.8.4 requires verification in accordance with the Surveillance Frequency Control Program that the filter bypass damper can be opened. ISTS 3.6.8.5 requires verification of SBVS train flow rate in accordance with the Surveillance Frequency Control Program. PSL does not have filter bypass dampers. Therefore, this SR is deleted. The flow rate of each SBVS train required by ISTS SR 3.6.8.5 is verified as required by the Ventilation Filter Test Program (VFTP). ISTS 3.6.8.2 (ITS SR 3.6.9.2) requires performance of filter testing in accordance with the VFTP. Therefore, this SR is duplicative and not adopted into the PSL ITS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.~~8~~ Shield Building ~~Exhaust Air Cleanup~~ System (~~SBEACS~~) ~~(Dual)~~

BASES

BACKGROUND

The ~~SBEACS~~ is required by 10 CFR 50, Appendix A, GDC 41, "Containment Atmosphere Cleanup" (Ref. 1), to ensure that radioactive material leaking from the primary containment of a dual containment into the shield building (secondary containment) following a Design Basis Accident are filtered and adsorbed prior to exhausting to the environment.

The containment has a secondary containment, the shield building, which is a concrete structure that surrounds the steel primary containment vessel. Between the containment vessel and the shield building inner wall is an annular space that collects any containment leakage that may occur following a loss of coolant accident (LOCA). This space also allows for periodic inspection of the outer surface of the steel containment vessel.

Following a LOCA, the ~~SBEACS~~ establishes a negative pressure in the annulus between the shield building and the steel containment vessel. Filters in the system then control the release of radioactive contaminants to the environment. Shield building OPERABILITY is required to ensure retention of primary containment leakage and proper operation of the ~~SBEACS~~.

The ~~SBEACS~~ consists of two separate and redundant trains. Each train includes ~~a heater~~, ~~cooling coils,~~ a prefilter, a moisture separator, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of radioiodines, and a fan. Ductwork, valves and/or dampers, and instrumentation also form part of the system. The moisture separator~~s~~ function to reduce the moisture content of the airstream. A second bank of HEPA filters follows the adsorber section to collect carbon fines and provide backup in case of failure of the main HEPA filter bank. Only the upstream HEPA filter and the charcoal adsorber section are credited in the analysis. The system initiates and maintains a negative air pressure in the shield building by means of filtered exhaust ventilation of the shield building following receipt of a ~~safety injection actuation~~ signal (~~SIAS~~). The system is described in Reference 2.

The prefilters remove any large particles in the air, and the moisture separator~~s~~ remove any entrained water droplets present, to prevent excessive loading of the HEPA filters and charcoal adsorbers. Heaters ~~may be~~ included to reduce the relative humidity of the airstream on

BASES

BACKGROUND (continued)

systems operating in high humidity. ~~[The cooling coils cool the air to keep the charcoal beds from becoming too hot due to absorption of fission products.]~~ 3

~~During normal operation, the Shield Building Cooling System is aligned to bypass the SBEACS HEPA filters and charcoal adsorbers. For SBEACS operation following a DBA, however, the bypass dampers automatically reposition to draw the air through the filters and adsorbers.~~ 2

SBVS

The ~~SBEACS~~ reduces the radioactive content in the shield building atmosphere following a DBA. Loss of the ~~SBEACS~~ could cause site boundary doses, in the event of a DBA, to exceed the values given in the licensing basis. 1

APPLICABLE SAFETY ANALYSES

SBVS

The ~~SBEACS~~ design basis is established by the consequences of the limiting DBA, which is a LOCA. The accident analysis (Ref. 3) assumes that only one train of the ~~SBEACS~~ is functional due to a single failure that disables the other train. The accident analysis accounts for the reduction in airborne radioactive material provided by the remaining one train of this filtration system. The amount of fission products available for release from containment is determined for a LOCA. 1

SBVS

The modeled ~~SBEACS~~ actuation in the safety analysis is based on a worst case response time associated with exceeding a~~n SIAS~~. The total response time from exceeding the signal setpoint to attaining the negative pressure of ~~[≥ 0.25]~~ inch water gauge in the shield building is ~~[1 minute]~~. This response time is composed of signal delay, diesel generator startup and sequencing time, system startup time, and time for the system to attain the required pressure after starting. 1 2 3

CIS

2.0

es

2 minutes

SBVS

The ~~SBEACS~~ satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

SBVS

In the event of a DBA, one ~~SBEACS~~ train is required to provide the minimum particulate iodine removal assumed in the safety analysis. Two trains of the ~~SBEACS~~ must be OPERABLE to ensure that at least one train will operate, assuming that the other train is disabled by a single active failure. 1 | R1

SBVS

independent 6

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could lead to fission product release to containment that leaks to the shield building. The large break LOCA, on which this system's design is based, is a full power event. Less severe LOCAs and leakage still require the system to be OPERABLE throughout these MODES. The probability and severity of a LOCA decrease as core power and Reactor Coolant System pressure decrease. With the reactor shut down, the probability of release of radioactivity resulting from such an accident is low.

In MODES 5 and 6, the probability and consequences of a DBA are low due to the pressure and temperature limitations in these MODES. Under these conditions, the Filtration System is not required to be OPERABLE.

ACTIONS

A.1

With one ~~SBEACS~~ train inoperable, the inoperable train must be restored to OPERABLE status within 7 days. The components in this degraded condition are capable of providing 100% of the iodine removal needs after a DBA. The 7 day Completion Time is based on consideration of such factors as the availability of the OPERABLE redundant ~~SBEACS~~ train and the low probability of a DBA occurring during this period.

B.1 and B.2

If two ~~SBEACS~~ trains are inoperable, at least one ~~SBEACS~~ train must be returned to OPERABLE status within 24 hours. The Condition is modified by a Note stating it is not applicable if the second ~~SBEACS~~ train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one train is inoperable for any reason and the second train is discovered to be inoperable, or if both trains are discovered to be inoperable at the same time. In addition, at least one train of containment spray must be verified to be OPERABLE within 1 hour. In the event of an accident, containment spray reduces the potential radioactive release from the containment, which reduces the consequences of the inoperable ~~SBEACS~~ trains. The Completion Time is based on Reference 4 which demonstrated that the 24 hour Completion Time is acceptable based on the infrequent use of the Required Actions and the small incremental effect on plant risk.

ACTIONS (continued)

C.1 and C.2

SBVS

If the ~~SBEACS~~ train cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.~~8~~ Shield Building ~~Exhaust Air Cleanup~~ System (~~SBEACS~~) ~~(Dual)~~

BASES

BACKGROUND

The ~~SBEACS~~ is required by 10 CFR 50, Appendix A, GDC 41, "Containment Atmosphere Cleanup" (Ref. 1), to ensure that radioactive material leaking from the primary containment of a dual containment into the shield building (secondary containment) following a Design Basis Accident are filtered and adsorbed prior to exhausting to the environment.

The containment has a secondary containment, the shield building, which is a concrete structure that surrounds the steel primary containment vessel. Between the containment vessel and the shield building inner wall is an annular space that collects any containment leakage that may occur following a loss of coolant accident (LOCA). This space also allows for periodic inspection of the outer surface of the steel containment vessel.

Following a LOCA, the ~~SBEACS~~ establishes a negative pressure in the annulus between the shield building and the steel containment vessel. Filters in the system then control the release of radioactive contaminants to the environment. Shield building OPERABILITY is required to ensure retention of primary containment leakage and proper operation of the ~~SBEACS~~.

The ~~SBEACS~~ consists of two separate and redundant trains. Each train includes ~~a heater~~, ~~cooling coils,~~ a prefilter, a moisture separator, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of radioiodines, and a fan. Ductwork, valves and/or dampers, and instrumentation also form part of the system. The moisture separator~~s~~ function to reduce the moisture content of the airstream. A second bank of HEPA filters follows the adsorber section to collect carbon fines and provide backup in case of failure of the main HEPA filter bank. Only the upstream HEPA filter and the charcoal adsorber section are credited in the analysis. The system initiates and maintains a negative air pressure in the shield building by means of filtered exhaust ventilation of the shield building following receipt of a ~~safety injection actuation~~ signal (~~SIAS~~). The system is described in Reference 2.

The prefilters remove any large particles in the air, and the moisture separator~~s~~ remove any entrained water droplets present, to prevent excessive loading of the HEPA filters and charcoal adsorbers. Heaters ~~may be~~ included to reduce the relative humidity of the airstream on

INSERT 1 2

A secondary function of the SBVS is to align and filter airborne radioactive particulate from the area of the fuel storage pool following a fuel handling accident.

INSERT 2 2

When aligned to evacuate the fuel handling building spent fuel pool area, the SBVS trains include two motor operated butterfly valves positioned to exhaust the fuel pool area.

INSERT 3 2

On a high fuel pool area radiation signal, the SBVS starts and aligns to exhaust the spent fuel pool area through the SBVS filtration units. In this alignment, the system achieves and maintains a negative air pressure in the fuel handling building of greater than 0.125 inch water gauge.

INSERT 13

This SR verifies proper operation of the SBVS and the ability of the fuel building to maintain negative pressure with respect to potentially uncontaminated adjacent areas. The system is designed to maintain a slight negative pressure in the fuel pool area after actuation of a fuel pool area high radiation signal to prevent unfiltered release of radioactivity.

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

A Note to the SR indicates that this test is only required to be met during movement of recently irradiated fuel assemblies because the fuel pool area ventilation mode of SBVS is only required during this operation.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.9 BASES, SHIELD BUILDING VENTILATION SYSTEM (SBVS)

1. The ISTS 3.6.8 title "Shield Building Exhaust Air Cleanup System (SBEACS)" has been changed to "Shield Building Ventilation System (SBVS)" consistent with the St. Lucie Plant (PSL) site specific terminology. The heading for ISTS 3.6.8 includes the parenthetical expression (Dual). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, the PSL design does not include the Hydrogen Mixing System (ISTS 3.6.9) and the Iodine Cleanup System (ISTS 3.6.10); the PSL Unit 2 design does not include the Spray Additive System (ISTS 3.6.7). Therefore, ISTS 3.6.9 and ISTS 3.6.10 are not included in the PSL ITS. The Spray Additive System (ISTS 3.6.7) is renumbered as ITS 3.6.10, the Shield Building Exhaust Air Cleanup System (ISTS 3.6.8) is renumbered as ITS 3.6.9, the Shield Building (ISTS 3.6.11) is renumbered as ITS 3.6.7 and Vacuum Relief Valves (ISTS 3.6.12) is renumbered as ITS 3.6.8.

2. Changes are made (additions, deletions, and/or changes) to the ISTS Bases which reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is changed to reflect the current licensing basis.

4. Changes are made to the ITS Bases consistent and in conformance with St. Lucie Unit 1 License Amendment 240 and Unit 2 License Amendment 191 (ADAMS Accession No. ML17219A556).

5. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

6. Changes have been made to be consistent with changes made to the Specification described in CTS DOCs LA01 and LA02. R1

DISCUSSION OF CHANGES
ITS 3.6.10, SPRAY ADDITIVE SYSTEM – UNIT 1 ONLY

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.6.2.2 Action states in part, “restore the spray additive system to OPERABLE status within the next 48 hours or be in COLD SHUTDOWN within the following 30 hours.” ITS 3.6.10 Required Action B.2 states that if the Required Action and associated Completion Time are not met, the plant must reduce pressurizer pressure to < 1750 psia within 12 hours.” This change replaces the requirement to, “restore the spray additive system to OPERABLE status within the next 48 hours or be in COLD SHUTDOWN within the following 30 hours,” with the requirement to reduce pressurizer pressure to < 1750 psia within 12 hours.

The purpose of the CTS 3.6.2.2 Action is to restore the system to OPERABLE status or place the unit in a condition in which the equipment is no longer required. Consistent with the Applicability of the Containment Spray System, which supports the Spray Additive System, the Applicability of CTS 3.6.2.2 only requires the Spray Additive System to be OPERABLE when pressurizer pressure is ≥ 1750 psia. The CTS 3.6.2.2 requirement to “restore the spray additive system to OPERABLE status within the next 48 hours or be in COLD SHUTDOWN within the following 30 hours,” is inconsistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2). CTS 3.0.2 states, in part, “If the LCO is met or is no longer applicable prior to expiration of the specified time interval(s), completion of the ACTIONS is not required, unless otherwise stated.” Once pressurizer pressure is < 1750 psia, LCO 3.6.2.2 (ITS LCO 3.6.10) is not applicable and, therefore, the remaining actions are no longer required. Therefore, the requirement to restore the spray additive system to OPERABLE status within the next 48 hours or be in COLD SHUTDOWN within the following 30 hours is no longer required to be completed.

This change is designated as administrative and has no technical impact because the requirement to “restore the spray additive system to OPERABLE status within the next 48 hours or be in COLD SHUTDOWN within the following 30 hours,” is an action that is never applicable since the CTS (and ITS) ACTIONS require the unit to be placed in a condition where the Spray Additive System is no longer required prior to the applicable action requirements becoming limiting.

MORE RESTRICTIVE CHANGES

None

DISCUSSION OF CHANGES
ITS 3.6.10, SPRAY ADDITIVE SYSTEM – UNIT 1 ONLY

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits*) CTS 3.6.2.2.b, in part, states, "the spray additive system shall be OPERABLE with:.....b. Two spray additive eductors each capable of adding NaOH solution from the chemical additive tank to a containment spray system pump flow." ITS 3.6.10 does not contain this level of detail. This changes the CTS by moving details concerning what constitutes an OPERABLE containment spray additive system to the Bases. |R1 |R1

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the information and is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.6.2.2.b.2 requires verification of the NaOH solution by chemical analysis. This changes the CTS by moving the procedural detail specifying the method of determining solution concentration to the Bases. |R1

The removal of these details for performing surveillance requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement to perform a verification of the spray additive tank NaOH solution concentration. Also, this change is acceptable because these types of procedural detail will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA03 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.6.2.2.d states in part "to a drain connection immediately downstream of the tank outlet valve, and a demineralized water flow rate of 18 $\pm$ 1.5 gpm from that same drain connection to each containment spray pump." This changes the CTS by moving the procedural detail to the Bases.

The removal of these details for performing surveillance requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement to perform a verification of minimum sodium hydroxide flow rate from the spray additive tank. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 8 – Deletion of Surveillance Requirement Shutdown Performance Requirements)* CTS 4.6.2.2.c requires verification during shutdown in accordance with the Surveillance Frequency Control Program that each automatic valve in the flow path actuates to its correct position on a CSAS signal. ITS SR 3.6.10.4 requires the same testing with no restriction as to when (i.e., during shutdown) the test can be performed. This changes the CTS by deleting the requirement to perform the Surveillance during shutdown.

The purpose of CTS 4.6.2.2.c is to ensure that each automatic valve in the Spray Additive System flow path actuates to its correct position on a CSAS. This change is acceptable because the Surveillance Requirement can be performed in other than shutdown conditions without jeopardizing safe plant operations. The control of unit conditions appropriate to perform the test is an issue for procedures and scheduling and has been determined by the NRC Staff to be unnecessary as a Technical Specification restriction. As indicated in Generic Letter 91-04, allowing this control is consistent with the vast majority of other Technical Specification Surveillances that do not dictate unit conditions for the Surveillance. This change is designated as less restrictive because the Surveillance may be performed at plant conditions other than shutdown.

L02 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* CTS 4.6.2.2.c requires verification that the spray additive system starts automatically on a Containment Spray Actuation Signal (CSAS). ITS SR 3.6.10.4 requires verification that each automatic valve in the flow path actuates to the correct position except for valves that are locked, sealed, or otherwise secured in the actuated position. This changes the CTS by excluding those valves that are locked, sealed, or otherwise secured in the actuated position from verification. | R1

The purpose of CTS 4.6.2.2.c is to provide assurance that if an event occurred requiring actuation of the spray additive system, then those valves and dampers requiring automatic actuation would actuate to their correct position. Those automatic valves and dampers that are locked, sealed, or otherwise secured in position are not required to actuate on a containment spray actuation signal in order to perform their safety function because they are already in the required position. Testing such valves and dampers would not provide any additional

assurance of OPERABILITY. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L03 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* CTS 4.6.2.2.c requires verification that the spray additive system starts automatically on a Containment Spray Actuation Signal (CSAS) test signal. ITS SR 3.6.10.4 |R1 requires verification that each automatic valve in the flow path actuates on an actual or simulated actuation signal. This changes the CTS by explicitly allowing the use of either an actual or simulated signal for the test.

The purpose of CTS 4.6.2.2.c is to ensure the spray additive system actuates upon receipt of a CSAS signal. This change is acceptable because it has been determined that the current Surveillance Requirement acceptance criteria are not the only method that can be used for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual" or "simulated" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.10, SPRAY ADDITIVE SYSTEM – UNIT 1 ONLY

1. The ISTS 3.6.7 title "Spray Additive System" includes the parenthetical expression (Dual). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Hydrogen Mixing System (ISTS 3.6.9) and the Iodine Cleanup System (ISTS 3.6.10); the PSL Unit 2 design does not include the Spray Additive System (ISTS 3.6.7). Therefore, ISTS 3.6.9 and ISTS 3.6.10 are not included in the PSL ITS. The Spray Additive System (ISTS 3.6.7) is renumbered as ITS 3.6.10, the Shield Building Exhaust Air Cleanup System (ISTS 3.6.8) is renumbered as ITS 3.6.9, the Shield Building (ISTS 3.6.11) is renumbered as ITS 3.6.7 and Vacuum Relief Valves (ISTS 3.6.12) is renumbered as ITS 3.6.8.

2. Changes are made (additions, deletions, and/or changes) to the ITS which reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. PSL Current Technical Specifications only require the Spray Additive and Containment Spray Systems to be OPERABLE in MODES 1, 2 and 3 when pressurizer pressure is ≥ 1750 psia. The Applicability of ISTS 3.6.7 (ITS 3.6.10) reflects this current licensing basis. In addition, the change made to Required Action B.2 reflects the new end state as described in Discussion of Change A02.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.~~7~~ Spray Additive System ~~(Atmospheric and Dual)~~

10

1

BASES

BACKGROUND

The Spray Additive System is a subsystem of the Containment Spray System that assists in reducing the iodine fission product inventory in the containment atmosphere in the event of an accident such as a loss of coolant accident (LOCA).

The addition of a spray additive to the boric acid spray solution increases the pH of the spray solution and maintains the containment sump pH above 8.~~0~~ during the recirculation phase of an accident. An elevated pH is desired since it enhances the iodine removal capacity of the sprays and aids in the retention of iodine in the water in the containment sump.

.5

2

operates in conjunction with the containment spray system and

(NaOH storage)

The Spray Additive System consists of a single spray additive tank and two redundant 100% capacity trains. Each train contains a ~~chemical addition pump, an injection valve,~~ isolation valve~~s~~, a flow ~~meter~~, and ~~a flow controller~~. Upon receipt of a containment spray actuation signal (CSAS), the ~~chemical addition pumps start and the injection valves open in each redundant train. The spray additive is then injected into the Containment Spray System at the suction of the containment spray pumps at metered amounts corresponding to the individual containment spray pump discharge flow rate. The rate at which the spray additive is added is reduced when a recirculation actuation signal is generated and the Containment Spray System enters the recirculation mode of operation.~~ The pH of the containment spray solution is maintained between ~~9.0 and 10.0~~ during the injection mode and ~~between 8.0 and 9.0 in~~ the recirculation mode. Upon reaching a Low-Low level in the spray ~~chemical addition~~ tank, the ~~spray chemical addition pumps stop and the injection and~~ isolation valves close (Ref. 1).

2

7.89 and 9.49

additive

caustic line

to isolate the tank

The Spray Additive System aids in reducing the iodine fission production inventory in the containment atmosphere.

APPLICABLE SAFETY ANALYSES

The Spray Additive System is essential to the effective removal of airborne iodine within containment following a Design Basis Accident (DBA).

Following the assumed release of radioactive materials into containment, the containment is assumed to leak at its design value following the accident.

Insert 1

tank isolation valves open and stored sodium hydroxide (NaOH) is drawn into the suction of the containment spray pumps through the use of eductors. Flow rate is measured by flow orifices and is determined by eductor size and containment spray pump suction pressure.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The DBA response time assumed for the Spray Additive System is the same as for the Containment Spray System and is discussed in the Bases for Specification 3.6.6, "Containment Spray and Cooling Systems."

The DBA analyses assume that one train of the Containment Spray System/Spray Additive System is inoperable and that the entire spray additive tank volume is added to the remaining Containment Spray System flow path.

During a LOCA, the iodine inventory released to the containment is considered to be released instantaneously and uniformly distributed in the containment free volume. The containment volume is made up of sprayed and unsprayed regions. The sprayed region is enveloped by direct spray and mixed by the ~~dome air circulators and emergency~~ fan coolers. Mixing between the sprayed and unsprayed regions is facilitated by the ~~emergency~~ fan coolers and condensation of steam by the sprays.

containment

2

The Spray Additive System satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The Spray Additive System is necessary to reduce the release of radioactive material to the environment in the event of a DBA. To be considered OPERABLE, the volume and concentration of the spray additive solution must be sufficient to maintain the pH of the spray solution between ~~[9.0 and 10.0]~~ in the injection mode and ~~[8.0 and 9.0] in~~ the recirculation mode. This pH range maximizes the effectiveness of the iodine removal mechanism, without introducing conditions that may induce caustic stress corrosion cracking of mechanical components.

7.89 and 9.49

3 2

During a LOCA, one Spray Additive System train is capable of providing 100% of the required iodine removal capacity. To ensure at least one train is available in the event of the limiting single failure, both trains must be maintained in an OPERABLE status.

APPLICABILITY

In MODES 1, 2, ~~3,~~ and ~~4~~, a DBA could cause a release of radioactive material to containment requiring the operation of the Spray Additive System. The Spray Additive System assists in reducing the iodine fission product inventory prior to release to the environment.

MODE 3 ≥ 1750 psia

the Containment Spray System

In MODE 3 with pressurizer pressure <1750 psia and in MODES 4, 5,

~~In MODES 5~~ and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations in these MODES. Thus, the Spray Additive System is not required to be OPERABLE ~~in MODES 5~~ and 6.

Additionally, the Containment Spray System is not required to be OPERABLE when pressurizer pressure is <1750 psia.

in MODE 3 when pressurizer pressure is <1750 psia and in MODES 4, 5,

5

BASES

ACTIONS

A.1

With the Spray Additive System inoperable, the system must be restored to OPERABLE status within 72 hours. The pH adjustment of the containment spray flow for corrosion protection and iodine removal enhancement are reduced in this condition. The Containment Spray System would still be available and would remove some iodine from the containment atmosphere in the event of a DBA. The 72 hour Completion Time takes into account the redundant flow path capabilities and the low probability of the worst case DBA occurring during this period.

B.1 and B.2

reduce pressurizer pressure to <1750 psia

If the Spray Additive System cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and ~~to MODE 5~~ within ~~84~~ hours. The allowed Completion Time ~~of 6 hours is~~ reasonable, based on operating experience, to reach ~~MODE 3~~ from full power conditions in an orderly manner and without challenging plant systems. ~~The extended interval to reach MODE 5 allows additional time for restoration of the Spray Additive System and is reasonable when considering the reduced pressure and temperature conditions in MODE 3 for the release of radioactive material from the Reactor Coolant System.~~

SURVEILLANCE REQUIREMENTS

SR 3.6.~~7~~.1
10
1

Verifying the correct alignment of Spray Additive System manual, power operated, and automatic valves in the spray additive flow path provides assurance that the system is able to provide additive to the Containment Spray System in the event of a DBA. This SR does not apply to valves that are locked, sealed, or otherwise secured in position since these valves were verified to be in the correct position prior to locking, sealing, or securing. This SR does not require any testing or valve manipulation. Rather, it involves verification that those valves outside containment and capable of potentially being mispositioned are in the correct position.

~~[The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.~~

3

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~ 3

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~ 4 3

SR 3.6.~~7~~.2 10 1

volume between 4010 and 5000 gallons

a

sodium hydroxide (NaOH)

To provide effective iodine removal, the containment spray must be an alkaline solution. Since the refueling water tank contents are normally acidic, ~~the volume of the~~ spray additive tank ~~must~~ provide s a sufficient volume of spray additive to adjust pH for all water injected. This SR is performed to verify the availability of sufficient ~~hydrazine (N_2H_4)~~ solution in the Spray Additive System. ~~[The 184 day Frequency is based on the low probability of an undetected change in tank volume occurring during the SR interval (the tank is isolated during normal unit operations). Tank level is also indicated and alarmed in the control room, such that there is a high confidence that a substantial change in level would be detected.~~ 2 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.~~7~~.3

10

This SR provides verification of the ~~N_2H_4~~ (NaOH) concentration in the spray additive tank ~~and is sufficient~~ to ensure that the spray solution being injected into containment is at the correct pH level. The concentration of ~~N_2H_4~~ (NaOH) in the spray additive tank must be determined by chemical analysis. ≥ 28.5% and ≤ 30.5% by weight

1
2

~~[The 184 day Frequency is sufficient to ensure that the concentration level of N_2H_4 in the spray additive tank remains within the established limits. This is based on the low likelihood of an uncontrolled change in concentration (the tank is normally isolated) and the probability that any substantial variance in tank volume will be detected.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

3

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

4
3

~~[SR 3.6.7.4~~

~~The chemical addition pump must be verified to provide the flow rate assumed in the accident analysis to the Containment Spray System. The Spray Additive System is not operated during normal operations. This prevents periodically subjecting systems, structures, and components within containment to a caustic spray solution. Therefore, this test must be performed on recirculation with the discharge flow path from each spray chemical addition pump aligned back to the spray additive tank. The differential pressure obtained by the pump on recirculation is analogous to the full spray additive flow provided to the Containment Spray System on an actual CSAS. The Frequency of this SR is in accordance with the INSERVICE TESTING PROGRAM and is sufficient to identify component degradation that may affect flow rate.]~~

3

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.~~7~~.5
10.4
2

This SR verifies that each automatic valve in the Spray Additive System flow path actuates to its correct position on a CSAS. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls~~. [The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.6.10 BASES, SPRAY ADDITIVE SYSTEM – UNIT 1 ONLY

1. The ISTS 3.6.7 title "Spray Additive System" includes the parenthetical expression (Dual). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Hydrogen Mixing System (ISTS 3.6.9) and the Iodine Cleanup System (ISTS 3.6.10); the PSL Unit 2 design does not include the Spray Additive System (ISTS 3.6.7). Therefore, ISTS 3.6.9 and ISTS 3.6.10 are not included in the PSL ITS. The Spray Additive System (ISTS 3.6.7) is renumbered as ITS 3.6.10, the Shield Building Exhaust Air Cleanup System (ISTS 3.6.8) is renumbered as ITS 3.6.9, the Shield Building (ISTS 3.6.11) is renumbered as ITS 3.6.7 and Vacuum Relief Valves (ISTS 3.6.12) is renumbered as ITS 3.6.8.

2. Changes are made (additions, deletions, and/or changes) to the ISTS Bases which reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is changed to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. Concomitant Bases changes made to reflect changes to the ISTS Specification regarding change to Applicability and ACTIONS to specify the end state as MODE 3 with a pressurizer pressure of 1750 psia.

6. Text changed to reflect that the Frequency is performed periodically. This change is consistent with similar ISTS Bases changes as a result of incorporation of TSTF-425, "Relocate Surveillance Frequencies to Licensee Control - RITSTF Initiative 5b," into the ISTS.

JUSTIFICATION FOR DEVIATIONS
ISTS 3.6.7, SPRAY ADDITIVE SYSTEM

1. ISTS 3.6.7, “Spray Additive System” is not being adopted for PSL Unit 2. The PSL Unit 2 technical specification requirements for the Iodine Removal System were eliminated with “Issuance of Amendment No. 201 Regarding Technical Specification Changes to Eliminate the Requirements of the Iodine Removal System,” dated November 20, 2019 (ADAMS Accession No. ML19248C238). Therefore, ISTS 3.6.7 is not included in the PSL Unit 2 ITS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.7 Spray Additive System (Atmospheric and Dual)

BASES

BACKGROUND The Spray Additive System is a subsystem of the Containment Spray System that assists in reducing the iodine fission product inventory in the containment atmosphere in the event of an accident such as a loss of coolant accident (LOCA).

The addition of a spray additive to the boric acid spray solution increases the pH of the spray solution and maintains the containment sump pH above 8.0 during the recirculation phase of an accident. An elevated pH is desired since it enhances the iodine removal capacity of the sprays and aids in the retention of iodine in the water in the containment sump.

The Spray Additive System consists of a single spray additive tank and two redundant 100% capacity trains. Each train contains a chemical addition pump, an injection valve, isolation valves, a flow meter, and a flow controller. Upon receipt of a containment spray actuation signal (CSAS), the chemical addition pumps start and the injection valves open in each redundant train. The spray additive is then injected into the Containment Spray System at the suction of the containment spray pumps at metered amounts corresponding to the individual containment spray pump discharge flow rate. The rate at which the spray additive is added is reduced when a recirculation actuation signal is generated and the Containment Spray System enters the recirculation mode of operation. The pH of the containment spray solution is maintained between 9.0 and 10.0 during the injection mode and between 8.0 and 9.0 in the recirculation mode. Upon reaching a Low-Low level in the spray chemical addition tank, the spray chemical addition pumps stop and the injection and isolation valves close (Ref. 1).

The Spray Additive System aids in reducing the iodine fission production inventory in the containment atmosphere.

APPLICABLE SAFETY ANALYSES The Spray Additive System is essential to the effective removal of airborne iodine within containment following a Design Basis Accident (DBA).

Following the assumed release of radioactive materials into containment, the containment is assumed to leak at its design value following the accident.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The DBA response time assumed for the Spray Additive System is the same as for the Containment Spray System and is discussed in the Bases for Specification 3.6.6, "Containment Spray and Cooling Systems."

The DBA analyses assume that one train of the Containment Spray System/Spray Additive System is inoperable and that the entire spray additive tank volume is added to the remaining Containment Spray System flow path.

During a LOCA, the iodine inventory released to the containment is considered to be released instantaneously and uniformly distributed in the containment free volume. The containment volume is made up of sprayed and unsprayed regions. The sprayed region is enveloped by direct spray and mixed by the dome air circulators and emergency fan coolers. Mixing between the sprayed and unsprayed regions is facilitated by the emergency fan coolers and condensation of steam by the sprays.

The Spray Additive System satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO The Spray Additive System is necessary to reduce the release of radioactive material to the environment in the event of a DBA. To be considered OPERABLE, the volume and concentration of the spray additive solution must be sufficient to maintain the pH of the spray solution between [9.0 and 10.0] in the injection mode and [8.0 and 9.0] in the recirculation mode. This pH range maximizes the effectiveness of the iodine removal mechanism, without introducing conditions that may induce caustic stress corrosion cracking of mechanical components.

During a LOCA, one Spray Additive System train is capable of providing 100% of the required iodine removal capacity. To ensure at least one train is available in the event of the limiting single failure, both trains must be maintained in an OPERABLE status.

APPLICABILITY In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment requiring the operation of the Spray Additive System. The Spray Additive System assists in reducing the iodine fission product inventory prior to release to the environment.

In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations in these MODES. Thus, the Spray Additive System is not required to be OPERABLE in MODES 5 and 6.

BASES

ACTIONS A.1

With the Spray Additive System inoperable, the system must be restored to OPERABLE status within 72 hours. The pH adjustment of the containment spray flow for corrosion protection and iodine removal enhancement are reduced in this condition. The Containment Spray System would still be available and would remove some iodine from the containment atmosphere in the event of a DBA. The 72 hour Completion Time takes into account the redundant flow path capabilities and the low probability of the worst case DBA occurring during this period.

B.1 and B.2

If the Spray Additive System cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 84 hours. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging plant systems. The extended interval to reach MODE 5 allows additional time for restoration of the Spray Additive System and is reasonable when considering the reduced pressure and temperature conditions in MODE 3 for the release of radioactive material from the Reactor Coolant System.

SURVEILLANCE REQUIREMENTS SR 3.6.7.1

Verifying the correct alignment of Spray Additive System manual, power operated, and automatic valves in the spray additive flow path provides assurance that the system is able to provide additive to the Containment Spray System in the event of a DBA. This SR does not apply to valves that are locked, sealed, or otherwise secured in position since these valves were verified to be in the correct position prior to locking, sealing, or securing. This SR does not require any testing or valve manipulation. Rather, it involves verification that those valves outside containment and capable of potentially being mispositioned are in the correct position.

[The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.

BASES

SURVEILLANCE REQUIREMENTS (continued)

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

SR 3.6.7.2

To provide effective iodine removal, the containment spray must be an alkaline solution. Since the refueling water tank contents are normally acidic, the volume of the spray additive tank must provide a sufficient volume of spray additive to adjust pH for all water injected. This SR is performed to verify the availability of sufficient hydrazine (N_2H_4) solution in the Spray Additive System. [The 184 day Frequency is based on the low probability of an undetected change in tank volume occurring during the SR interval (the tank is isolated during normal unit operations). Tank level is also indicated and alarmed in the control room, such that there is a high confidence that a substantial change in level would be detected.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.7.3

This SR provides verification of the N_2H_4 concentration in the spray additive tank and is sufficient to ensure that the spray solution being injected into containment is at the correct pH level. The concentration of N_2H_4 in the spray additive tank must be determined by chemical analysis. [The 184 day Frequency is sufficient to ensure that the concentration level of N_2H_4 in the spray additive tank remains within the established limits. This is based on the low likelihood of an uncontrolled change in concentration (the tank is normally isolated) and the probability that any substantial variance in tank volume will be detected.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

[SR 3.6.7.4

The chemical addition pump must be verified to provide the flow rate assumed in the accident analysis to the Containment Spray System. The Spray Additive System is not operated during normal operations. This prevents periodically subjecting systems, structures, and components within containment to a caustic spray solution. Therefore, this test must be performed on recirculation with the discharge flow path from each spray chemical addition pump aligned back to the spray additive tank. The differential pressure obtained by the pump on recirculation is analogous to the full spray additive flow provided to the Containment Spray System on an actual CSAS. The Frequency of this SR is in accordance with the INSERVICE TESTING PROGRAM and is sufficient to identify component degradation that may affect flow rate.]

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.6.7.5

This SR verifies that each automatic valve in the Spray Additive System flow path actuates to its correct position on a CSAS. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. [The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

[SR 3.6.7.6

To ensure that the correct pH level is established in the borated water solution provided by the Containment Spray System, the flow rate in the Spray Additive System is verified once per 5 years. This SR provides assurance that the correct amount of N_2H_4 will be metered into the flow path upon Containment Spray System initiation. [Due to the passive nature of the spray additive flow controls, the 5 year Frequency is sufficient to identify component degradation that may affect flow rate.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

JUSTIFICATION FOR DEVIATIONS
ISTS 3.6.9, HYDROGEN MIXING SYSTEM (HMS) (ATMOSPHERIC AND DUAL)

1. ISTS 3.6.9, “Hydrogen Mixing System (HMS) (Atmospheric and Dual)” is not being adopted because St. Lucie Plant (PSL) design does not include the HMS. The hydrogen mixing function is performed by ITS 3.6.6, “Containment Spray and Cooling System.” Therefore, ISTS 3.6.9 is not included in the PSL Unit 1 and 2 ITS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.9 Hydrogen Mixing System (HMS) (Atmospheric and Dual)

BASES

BACKGROUND

The HMS reduces the potential for breach of containment due to a hydrogen oxygen reaction by providing a uniformly mixed post accident containment atmosphere, thereby minimizing the potential for local hydrogen burns due to a local pocket of hydrogen above the flammable concentration and giving the operator the capability of preventing the occurrence of a bulk hydrogen burn inside containment per 10 CFR 50.44, "Standards for Combustible Gas Control Systems in Light-Water-Cooled Reactors" (Ref. 1), and 10 CFR 50, GDC 41, "Containment Atmosphere Cleanup" (Ref. 2).

The post accident HMS is an Engineered Safety Feature and is designed to withstand a loss of coolant accident (LOCA) without loss of function. The system has two independent trains, each of which consists of two dome air circulation fans, motors, and controls. Each train is sized for [37,000] cfm. The two trains are initiated automatically on a containment cooling actuation signal (CCAS) or can be manually started from the control room. Each train is powered from a separate emergency power supply. Since each train can provide 100% of the mixing requirements, the system will provide its design function with a limiting single active failure.

The HMS accelerates the air mixing process between the upper dome space of the containment atmosphere during LOCA operations. It also prevents any hot spot air pockets during the containment cooling mode and avoids any hydrogen concentration in pocket areas.

Hydrogen mixing within the containment is accomplished by the Containment Spray System, the containment emergency fan coolers, and the containment internal structure design, which permits convective mixing and prevents entrapment. The HMS, operating in conjunction with the Containment Spray System and the emergency fan coolers, prevents localized accumulations of hydrogen from exceeding the flammability limit of 4.1 volume percent (v/o).

APPLICABLE SAFETY ANALYSES

The HMS mixes the containment atmosphere to provide a uniform hydrogen concentration.

Hydrogen may accumulate in containment following a LOCA as a result of:

BASES

APPLICABLE SAFETY ANALYSES (continued)

a. A metal-steam reaction between the zirconium fuel rod cladding and the reactor coolant,

b. Radiolytic decomposition of water in the Reactor Coolant System (RCS) and the containment sump,

c. Hydrogen in the RCS at the time of the LOCA (i.e., hydrogen dissolved in the reactor coolant and hydrogen gas in the pressurizer vapor space), or

d. Corrosion of metals exposed to Containment Spray System and Emergency Core Cooling Systems solutions.

To evaluate the potential for hydrogen accumulation in containment following a LOCA, the hydrogen generation as a function of time following the initiation of the accident is calculated. Conservative assumptions recommended by Reference 3 are used to maximize the amount of hydrogen calculated.

The HMS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Two HMS trains must be OPERABLE, with power to each from an independent, safety related power supply. Each train typically consists of two fans with their own motors and controls and is automatically initiated by a CCAS.

Operation with at least one HMS train provides the mixing necessary to ensure uniform hydrogen concentration throughout containment.

APPLICABILITY

In MODES 1 and 2, the two HMS trains ensure the capability to prevent localized hydrogen concentrations above the flammability limit of 4.1 v/o in containment, assuming a worst case single active failure.

In MODE 3 or 4, both the hydrogen production rate and the total hydrogen produced after a LOCA would be less than that calculated for the DBA LOCA. Also, because of the limited time in these MODES, the probability of an accident requiring the HMS is low. Therefore, the HMS is not required in MODE 3 or 4.

In MODES 5 and 6, the probability and consequences of a LOCA or main steam line break are low due to the pressure and temperature limitations of these MODES. Therefore, the HMS is not required in these MODES.

BASES

ACTIONS A.1

With one HMS train inoperable, the inoperable train must be restored to OPERABLE status within 30 days. The 30 day Completion Time is based on the availability of the other HMS train, the small probability of a LOCA or SLB occurring (that would generate an amount of hydrogen that exceeds the flammability limit), the amount of time available after a LOCA or SLB (should one occur) for operator action to prevent hydrogen accumulation from exceeding the flammability limit, and the availability of the Containment Spray System and Hydrogen Purge System.

B.1 and B.2

REVIEWER'S NOTE

This Condition is only allowed for units with an alternate hydrogen control system acceptable to the technical staff.

With two HMS inoperable, the ability to perform the hydrogen control function via alternate capabilities must be verified by administrative means within 1 hour. The alternate hydrogen control capabilities are provided by [the containment Hydrogen Purge System/Hydrogen Ignitor System/HMS/Containment Air Dilution System/Containment Inerting System]. The 1 hour Completion Time allows a reasonable period of time to verify that a loss of hydrogen control function does not exist.

REVIEWER'S NOTE

The following is to be used if a non-Technical Specification alternate hydrogen control function is used to justify this Condition. In addition, the alternate hydrogen control system capability must be verified every 12 hours thereafter to ensure its continued availability.

[Both] the [initial] verification [and all subsequent verifications] may be performed as an administrative check, by examining logs or other information to determine the availability of the alternate hydrogen control system. It does not mean to perform the Surveillances needed to demonstrate OPERABILITY of the alternate hydrogen control system. If the ability to perform the hydrogen control function is maintained, continued operation is permitted with two HMS trains inoperable for up to 7 days. Seven days is a reasonable time to allow two HMS trains to be inoperable because the hydrogen control function is maintained and because of the low probability of the occurrence of a LOCA that would generate hydrogen in the amounts capable of exceeding the flammability limit.

BASES

ACTIONS (continued)

C.1

If an inoperable HMS train cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.6.9.1

Operating each HMS train for ≥ 15 minutes ensures that the train is OPERABLE and that all associated controls are functioning properly. It also ensures that blockage, fan and/or motor failure, or excessive vibration can be detected for corrective action. [The 92 day Frequency is consistent with INSERVICE TESTING PROGRAM Surveillance Frequencies, operating experience, the known reliability of the fan motors and controls, and the two train redundancy available.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

SR 3.6.9.2

Verifying that each HMS train flow rate on slow speed is ≥ [37,000] cfm ensures that each train is capable of maintaining localized hydrogen concentrations below the flammability limit. [The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.

BASES

SURVEILLANCE REQUIREMENTS (continued)

JUSTIFICATION FOR DEVIATIONS
ISTS 3.6.10, IODINE CLEANUP SYSTEM (ICS) (ATMOSPERIC AND DUAL)

1. ISTS 3.6.10, “Iodine Cleanup System (ICS) (Atmospheric and Dual)” is not being adopted. The iodine removal function is performed by ITS 3.6.6, “Containment Spray and Cooling System” for PSL Unit 1. The PSL Unit 2 technical specification requirements for the Iodine Removal System were eliminated with “Issuance of Amendment No. 201 Regarding Technical Specification Changes to Eliminate the Requirements of the Iodine Removal System,” dated November 20, 2019 (ADAMS Accession No. ML19248C238). Therefore, ISTS 3.6.10 is not included in the PSL Unit 1 and 2 ITS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.10 Iodine Cleanup System (ICS) (Atmospheric and Dual)

BASES

BACKGROUND The ICS is provided per GDC 41, "Containment Atmosphere Cleanup," GDC 42, "Inspection of Containment Atmosphere Cleanup Systems," and GDC 43, "Testing of Containment Atmosphere Cleanup Systems" (Ref. 1), to reduce the concentration of fission products released to the containment atmosphere following a postulated accident. The ICS would function together with the Containment Spray and Cooling systems following a Design Basis Accident (DBA) to reduce the potential release of radioactive material, principally iodine, from the containment to the environment.

The ICS consists of two 100% capacity separate, independent, and redundant trains. Each train includes a heater, [cooling coils,] a prefilter, a moisture separator, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of radioiodines, and a fan. Ductwork, valves and/or dampers, and instrumentation also form part of the system. The moisture separators function to reduce the moisture content of the airstream. A second bank of HEPA filters follows the adsorber section to collect carbon fines and provide backup in case of failure of the main HEPA filter bank. Only the upstream HEPA filter and the charcoal adsorber section are credited in the analysis. The system initiates filtered recirculation of the containment atmosphere following receipt of a containment isolation actuation signal. The system design is described in Reference 2.

The primary purpose of the heaters is to ensure that the relative humidity of the airstream entering the charcoal adsorbers is maintained below 70%, which is consistent with the assigned iodine and iodide removal efficiencies as per Regulatory Guide 1.52 (Ref. 3).

The moisture separator is included for moisture (free water) removal from the gas stream. Heaters are used to heat the gas stream, which lowers the relative humidity. Both the moisture separator and heater are important to the effectiveness of the charcoal adsorbers.

Two ICS trains are provided to meet the requirement for separation, independence, and redundancy. Each ICS train is powered from a separate Engineered Safety Features bus and is provided with a separate power panel and control panel. [Service water is required to supply cooling water to the cooling coils.]

BASES

APPLICABLE SAFETY ANALYSES

The DBAs that result in a release of radioactive iodine within containment are a loss of coolant accident (LOCA), a main steam line break (MSLB), or a control element assembly (CEA) ejection accident. In the analysis for each of these accidents, it is assumed that adequate containment leak tightness is intact at event initiation to limit potential leakage to the environment. Additionally, it is assumed that the amount of radioactive iodine release is limited by reducing the iodine concentration in the containment atmosphere.

The ICS design basis is established by the consequences of the limiting DBA, which is a LOCA. The accident analysis (Ref. 4) assumes that only one train of the ICS is functional due to a single failure that disables the other train. The accident analysis accounts for the reduction in airborne radioactive iodine provided by the remaining one train of this filtration system.

The ICS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Two separate, independent, and redundant trains of the ICS are required to ensure that at least one is available, assuming a single failure coincident with a loss of offsite power.

APPLICABILITY

In MODES 1, 2, 3, and 4, iodine is a fission product that can be released from the fuel to the reactor coolant as a result of a DBA. The DBAs that can cause a failure of the fuel cladding are a LOCA, MSLB, and CEA ejection accident. Because these accidents are considered credible accidents in MODES 1, 2, 3, and 4, the ICS must be operable in these MODES to ensure the reduction in iodine concentration assumed in the accident analysis.

In MODES 5 and 6, the probability and consequences of a LOCA are low due to the pressure and temperature limitations of these MODES. The ICS is not required in these MODES to remove iodine from the containment atmosphere.

ACTIONS

A.1

With one ICS train inoperable, the inoperable train must be restored to OPERABLE status within 7 days. The components in this degraded condition are capable of providing 100% of the iodine removal needs after a DBA. The 7 day Completion Time is based on consideration of such factors as:

a. The availability of the OPERABLE redundant ICS train,

BASES

ACTIONS (continued)

b. The fact that, even with no ICS train in operation, almost the same amount of iodine would be removed from the containment atmosphere through absorption by the Containment Spray System, and

c. The fact that the Completion Time is adequate to make most repairs.

B.1 and B.2

If two ICS trains are inoperable, at least one ICS train must be returned to OPERABLE status within 24 hours. The Condition is modified by a Note stating it is not applicable if the second ICS train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one train is inoperable for any reason and the second train is discovered to be inoperable, or if both trains are discovered to be inoperable at the same time. In addition, at least one train of containment spray must be verified to be OPERABLE within 1 hour. In the event of an accident, containment spray reduces the potential radioactive release from the containment, which reduces the consequences of the inoperable ICS trains. The Completion Time is based on Reference 5 which demonstrated that the 24 hour Completion Time is acceptable based on the infrequent use of the Required Actions and the small incremental effect on plant risk.

C.1 and C.2

If the ICS train(s) cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.6.10.1

Operating each ICS train for ≥ 15 minutes ensures that all trains are OPERABLE and that all associated controls are functioning properly. It also ensures that blockage, fan or motor failure, or excessive vibration can be detected for corrective action. [The 31 day Frequency was developed considering the known reliability of fan motors and controls, the two train redundancy available, and the iodine removal capability of the Containment Spray System independent of the ICS.

BASES

SURVEILLANCE REQUIREMENTS (continued)

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

SR 3.6.10.2

This SR verifies that the required ICS filter testing is performed in accordance with the Ventilation Filter Testing Program (VFTP). The VFTP includes testing HEPA filter performance, charcoal adsorber efficiency, minimum system flow rate, and the physical properties of the activated charcoal (general use and following specific operations). Specific test frequencies and additional information are discussed in detail in the VFTP.

SR 3.6.10.3

The automatic startup test verifies that both trains of equipment start upon receipt of an actual or simulated test signal. The SR excludes automatic dampers and valves that are locked, sealed, or otherwise secured in the actuated position. The SR does not apply to dampers or valves that are locked, sealed, or otherwise secured in the actuated position since the affected dampers or valves were verified to be in the actuated position prior to being locked, sealed, or otherwise secured. Placing an automatic valve or damper in a locked, sealed, or otherwise secured position requires an assessment of the OPERABILITY of the system or any supported systems, including whether it is necessary for the valve or damper to be repositioned to the non-actuated position to support the accident analysis. Restoration of an automatic valve or damper to the non-actuated position requires verification that the SR has been met within its required Frequency. [The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the

SURVEILLANCE REQUIREMENTS (continued)

Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint. Furthermore, the Frequency was developed considering that the system equipment OPERABILITY is demonstrated on a 31 day Frequency by SR 3.6.10.1.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

[SR 3.6.10.4

The ICS filter bypass dampers are tested to verify OPERABILITY. The dampers are in the bypass position during normal operation and must reposition for accident operation to draw air through the filters. The SR excludes automatic dampers that are locked, sealed, or otherwise secured in the open position. The SR does not apply to dampers that are locked, sealed, or otherwise secured in the open position since the affected dampers were verified to be in the open position prior to being locked, sealed, or otherwise secured. Placing an automatic damper in a locked, sealed, or otherwise secured position requires an assessment of the OPERABILITY of the system or any supported systems, including whether it is necessary for the damper to be closed to support the accident analysis. Restoration of an automatic damper to the closed position requires verification that the SR has been met within its required Frequency. [The [18] month Frequency is considered to be acceptable based on the damper reliability and design, the mild environmental conditions in the vicinity of the dampers, and the fact that operating experience has shown that the dampers usually pass the Surveillance when performed at the [18] month Frequency.

OR

BASES

SURVEILLANCE REQUIREMENTS (continued)

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

----------REVIEWER'S NOTE----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

JUSTIFICATION FOR DEVIATIONS
ISTS 3.6.13, CONTAINMENT SUMP

1. ISTS 3.6.13, “Containment Sump” is not being adopted. The Containment Sump function is performed by ITS 3.5.2, “ECCS – Operating”, ITS 3.5.3, “ECCS – Shutdown” and ITS 3.6.6, “Containment Spray and Cooling System” for PSL Unit 1 and Unit 2. Therefore, ISTS 3.6.13 is not included in the PSL Unit 1 and 2 ITS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.6 CONTAINMENT SYSTEMS

B 3.6.13 Containment Sump

BASES

BACKGROUND ---------- REVIEWER'S NOTE ----------
Some plant designs have more than one containment sump. LCO 3.6.13 provides the option of specifying one or two containment sumps. The Bases specify when to discuss differences between one or more sump designs by providing bracketed information. However, for clarity, all references to the containment sump are not provided with plural bracketed alternatives. Licensees adopting this Bases section for plants with two or more containment sumps should make the appropriate changes to the Bases to reflect the plant design.

The containment sump provides a borated water source to support recirculation of coolant from the containment sump for residual heat removal, emergency core cooling, containment cooling, and [containment atmosphere cleanup] during accident conditions.

The containment sump supplies both trains of the Emergency Core Cooling System (ECCS) and the Containment Spray System (CSS) during any accident that requires recirculation of coolant from the containment sump. The recirculation mode is initiated when the pump suction is transferred to the containment sump on low Refueling Water Tank (RWT) level, which ensures the containment sump has enough water to supply the net positive suction head to the ECCS and CSS pumps. [The use of a single containment sump to supply both trains of the ECCS and CSS is acceptable since the containment sump is a passive component, and passive failures are not required to be assumed to occur coincident with Design Basis Events.][Describe the design of plants with two or more containment sumps.]

The containment sump contains strainers to limit the quantity of the debris materials from entering the sump suction piping. Debris accumulation on the strainers can lead to undesirable hydraulic effects including air ingestion through vortexing or deaeration, and reduced net positive suction head (NPSH) at pump suction piping.

BASES

BACKGROUND (continued)

While the majority of debris accumulates on the strainers, some fraction penetrates the strainers and is transported to downstream components in the ECCS, CSS, and the Reactor Coolant System (RCS). Debris that penetrates the strainer can result in wear to the downstream components, blockages, or reduced heat transfer across the fuel cladding. Excessive debris in the containment sump water source could result in insufficient recirculation of coolant during the accident, or insufficient heat removal from the core during the accident.

APPLICABLE SAFETY ANALYSIS

During all accidents that require recirculation, the containment sump provides a source of borated water to the ECCS and CSS pumps. As such, it supports residual heat removal, emergency core cooling, containment cooling, and [containment atmosphere cleanup] during an accident. It also provides a source of negative reactivity (Ref. 1). The design basis transients and applicable safety analyses concerning each of these systems are discussed in the Applicable Safety Analyses section of B 3.5.2, "ECCS - Operating," B 3.5.3, "ECCS - Shutdown," and B 3.6.6, "Containment Spray and Cooling Systems."

FSAR Section X.XX (Ref. 2) describes evaluations that confirm long-term core cooling is assured following any accident that requires recirculation from the containment sump.

The containment sump satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

---------- REVIEWER'S NOTE ----------
The containment sump description should include all design features credited in the containment debris analysis.

[The][Two] containment sump is required to ensure a source of borated water to support ECCS and CSS OPERABILITY. A containment sump consists of the containment drainage flow paths, [design features upstream of the containment sump that are credited in the containment debris analysis,] the containment sump strainers, the pump suction trash racks, and the inlet to the ECCS and CSS piping. An OPERABLE containment sump has no structural damage or abnormal corrosion that could prevent recirculation of coolant and will not be restricted by containment accident generated and transported debris.

BASES

LCO (continued)

Containment accident generated and transported debris consists of the following:

a. Accident generated debris sources - Insulation, coatings, and other materials which are damaged by the high-energy line break (HELB) and transported to the containment sump. This includes materials within the HELB zone of influence and other materials (e.g., unqualified coatings) that fail due to the post-accident containment environment following the accident;

b. Latent debris sources – Pre-existing dirt, dust, paint chips, fines or shards of insulation, and other materials inside containment that do not have to be damaged by the HELB to be transported to the containment sump; and

c. Chemical product debris sources – Aluminum, zinc, carbon steel, copper, and non-metallic materials such as paints, thermal insulation, and concrete that are susceptible to chemical reactions within the post-accident containment environment leading to corrosion products that are generated within the containment sump pool or are generated within containment and transported to the containment sump.

Containment debris limits are defined in FSAR Section X.XX (Ref. 2).

APPLICABILITY In MODES 1, 2, 3, and 4, containment sump OPERABILITY requirements are dictated by the ECCS and CSS OPERABILITY requirements. Since both the ECCS and the CSS must be OPERABLE in MODES 1, 2, 3, and 4, the containment sump must also be OPERABLE to support their operation.

In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Thus, the containment sump is not required to be OPERABLE in MODES 5 or 6.

ACTIONS A.1, A.2, and A.3

Condition A is applicable when there is a condition which results in containment accident generated and transported debris exceeding the analyzed limits. Containment debris limits are defined in FSAR Section X.XX (Ref. 2).

BASES

ACTIONS (continued)

Immediate action must be initiated to mitigate the condition. Examples of mitigating actions are:

- Removing the debris source from containment or preventing the debris from being transported to the containment sump;
- Evaluating the debris source against the assumptions in the analysis;
- Deferring maintenance that would affect availability of the affected systems and other LOCA mitigating equipment;
- Deferring maintenance that would affect availability of primary defense-in-depth systems, such as containment coolers;
- Briefing operators on LOCA debris management actions; or
- Applying an alternative method to establish new limits.

While in this condition, the RCS water inventory balance, SR 3.4.13.1, must be performed at an increased Frequency of once per 24 hours. An unexpected increase in RCS leakage could be indicative of an increased potential for an RCS pipe break, which could result in debris being generated and transported to the containment sump. The more frequent monitoring allows operators to act in a timely fashion to minimize the potential for an RCS pipe break while the containment sump is inoperable.

[For the purposes of applying LCO 3.0.6 and the Safety Function Determination Program while in Condition A, the [two] containment sumps are considered a single support system for all ECCS and CSS trains because containment accident generated and transported debris issues that would render one sump inoperable would render all of the sumps inoperable.]

The inoperable containment sump must be restored to OPERABLE status in 90 days. A 90-day Completion Time is reasonable for emergent conditions that involve debris in excess of the analyzed limits that could be generated and transported to the containment sump under accident conditions. The likelihood of an initiating event in the 90-day Completion Time is very small and there is margin the associated analyses. The mitigating actions of Required Action A.1 provide additional assurance that the effects of debris in excess of the analyzed limits will be mitigated during the Completion Time.

BASES

ACTIONS (continued)

B.1

---------- Reviewer's Note ----------
The Required Action B.1 Completion Time should be the same as the LCO 3.6.6 Completion Time for a single inoperable CSS train.

When the containment sump is inoperable for reasons other than Condition A, such as blockage, structural damage, or abnormal corrosion that could prevent recirculation of coolant, it must be restored to OPERABLE status within [72 hours]. The [72 hour] Completion Time takes into account the reasonable time for repairs, and low probability of an accident that requires the containment sump occurring during this period. [Alternately, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]

Required Action B.1 is modified by two Notes. The first Note indicates that the applicable Conditions and Required Actions of LCO 3.5.2, "ECCS - Operating," and LCO 3.5.3, "ECCS - Shutdown," should be entered if an inoperable containment sump results in an inoperable ECCS train. The second Note indicates that the applicable Conditions and Required Actions of LCO 3.6.6, "Containment Spray and Cooling Systems," should be entered if an inoperable containment sump results in an inoperable CSS train. This is an exception to LCO 3.0.6 and ensures the proper actions are taken for these components.

C.1 and C.2

If the containment sump cannot be restored to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.6.13.1

Periodic inspections are performed to verify the containment sump does not show current or potential debris blockage, structural damage, or abnormal corrosion to ensure the operability and structural integrity of the containment sump (Ref. 1).

[The 18 month Frequency is based on the need to perform this Surveillance during a refueling outage, because of the need to enter containment. This Frequency is sufficient to detect any indication of structural damage, abnormal corrosion, or debris blockage of the containment sump.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

DISCUSSION OF CHANGES
ITS 3.7.1, MAIN STEAM SAFETY VALVES (MSSVs)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.7.1.1 states that “All main steam line code safety valves shall be OPERABLE with lift settings as specified in Table 4.7-1.” CTS Table 4.7-1 lists lift setting pressures for eight safety valves in each of the two loops. Unit 2 CTS 3.7.1.1 states that “All main steam line code safety valves shall be OPERABLE with lift settings as shown in Table 3.7-2.” CTS Table 3.7-2 lists lift setting pressures for eight safety valves in each of the two loops. ITS LCO 3.7.1 requires the MSSVs specified in Tables 3.7.1-1 and 3.7.1-2 to be OPERABLE. This changes the CTS by combining the current LCO requirement and portions of Unit 1 CTS Table 4.7-1 and Unit 2 CTS Table 3.7-2 into a single ITS LCO requirement for each respective unit.

This change is acceptable because the number of MSSVs required OPERABLE under the various conditions has not changed. This change results in a format change only to comply with the manner in which the ISTS presents the MSSV requirements. This change is designated as an administrative change since it does not result is any technical changes to the CTS.

A03 CTS 3.7.1.1 ACTION provides compensatory actions for one or more inoperable main steam line code safety valves. CTS 3.7.1.1 ACTION requires that within 4 hours the inoperable valve be restored to OPERABLE status or the Power Level-High trip setpoint be reduced per the requirements of CTS Table 3.7-1. CTS 3.7.1.1 ACTION requires a unit shutdown if the requirements of the ACTION are not met. ITS 3.7.1 ACTIONS Note states "Separate Condition entry is allowed for each MSSV." This changes the CTS by explicitly specifying separate condition entry for each inoperable MSSV.

The purpose of the CTS ACTION is to allow separate condition entry for each inoperable MSSV. Each time it is discovered that an MSSV is inoperable, entry is required and the specified Completion Time is allowed to complete the compensatory actions. The ITS 3.7.1 ACTIONS Note allows a separate Completion Time clock for each MSSV that is inoperable. This change is acceptable, because it only provides clarification of the Completion Time when one valve is inoperable and, subsequently, a second valve becomes inoperable. This change is designated as administrative, because it does not result in a technical change to the Specifications.

A04 CTS 3.7.1.1 ACTION states that the Power Level-High trip setpoint must be reduced per CTS Table 3.7-1 when one or more MSSVs are found to be inoperable. CTS Table 3.7-1 provides the maximum allowable Power Level-High trip setpoint corresponding to the maximum number of inoperable MSSVs on any

operating steam generator. ITS 3.7.1 ACTION A requires both a reduction in THERMAL POWER and a reduction in the Power Level-High trip setpoint consistent with the requirements of ITS Table 3.7.1-1. The Table has been revised to provide the associated maximum allowable power for the number of OPERABLE MSSVs. This changes the CTS by adding an additional explicit statement to reduce THERMAL POWER consistent with ITS Table 3.7.1-1 and by stating the maximum allowable power as a function of OPERABLE, instead of inoperable, MSSVs.

The purpose of CTS 3.7.1.1 ACTION is to reduce the Power Level-High trip setpoint to within the limits of the safety analyses. Current plant operation dictates that THERMAL POWER is reduced before reducing the setpoints to prevent a reactor trip. Explicitly stating this practice in TS and stating the maximum power level in terms of OPERABLE instead of inoperable MSSVs does not change how the plant is operated. This change is considered administrative because it does not result in technical changes to the CTS.

A05 CTS 3.7.1.1 ACTION states that with one or more MSSVs inoperable, either restore the inoperable valves to OPERABLE status or reduce the Power Level-High trip setpoint. ITS 3.7.1 ACTION A does not include the restoration requirement, only the alternate compensatory measure. This changes the CTS by eliminating the explicit statement to restore the MSSV(s) to OPERABLE status.

This change is acceptable, because it does not result in a technical change to the Technical Specifications. Restoration of compliance with the LCO is always an option in an ACTION, so eliminating the restoration ACTION from the CTS has no effect. In both the CTS and the ITS, if the inoperable MSSV(s) are not restored, actions are taken that result in reducing reactor power to within the relief capability of the OPERABLE MSSVs within 4 hours. This change is designated as administrative, because it does not result in a technical change to the CTS.

A06 CTS 3.7.1.1 ACTION requires in part, “otherwise be in… MODE 5...” when the actions cannot be performed within the required time. ITS 3.7.1 Required Action B.2 requires, when the Required Action and associated Completion Time is not met; or, with one or more steam generators with less than five MSSVs OPERABLE, to be in MODE 4 within 12 hours. This changes the end states in CTS 3.7.1.1 ACTION from MODE 5 to MODE 4.

The purpose of CTS 3.7.1 ACTION is to place the plant in a condition in which the equipment is no longer required. CTS 3.7.1 ACTION provides appropriate actions to take for the MSSVs when the unit is in MODE 1, 2, or 3. The MSSVs are not required to be OPERABLE when in MODE 4. Therefore, in accordance with CTS 3.0.2 (ITS LCO 3.0.2), with the Required Action and Completion time for one or more required MSSVs inoperable or one or more steam generators with less than five MSSVs OPERABLE completion of the Required Action to MODE 5 is not required. These changes are designated as administrative changes and are acceptable because they maintain the current requirement to place the unit in a condition in which the MSSVs are no longer required consistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2). The 12-hour Completion Time is reasonable based on operating experience to reach the required unit conditions.

A07 Unit 1 CTS Table 4.7-1 and Unit 2 CTS Table 3.7-2 specifies a lift setting band of ≥ 955.3 psig and ≤ 1015.3 psig for Bank 1 Main Steam Safety Valves and ≥ 994.1 psig and ≤ 1046.1 psig for Bank 2 Main Steam Safety Valves (MSSVs). ITS Table 3.7.1-2 a lift setting of 985 psig with a ± 3% tolerance for Bank 1 MSSVs and a lift setting of 1025 psig with a + 2%/− 3% tolerance for Bank 2 MSSVs. This changes the CTS by correcting the nominal lift setpoint to the value assumed in the overpressure protection report and documented in the UFSAR; 985 psig for Bank 1 and 1040 psig for Bank 2.

These changes are designated as administrative changes and are acceptable because they state the specific nominal lift setpoint assumed in the analysis instead of providing a band with an upper and lower value based on a nominal setpoint value.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 (*Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS SR 4.7.1.1 states, in part, “as left lift settings shall be within ± 1% of 1000 psia for valves 8201 through 8208, and within ± 1% of 1040 psia for valves 8209 through 8216 specified in Table 4.7-1.” ITS 3.7.1 does not contain the detail “of 1000 psia for valves 8201 through 8208, and within ± 1% of 1040 psia for valves 8209 through 8216 specified in Table 4.7-1” for Unit 1 or “of 1000 psia for valves 8201 through 8208, and within ± 1% of 1040 psia for valves 8209 through 8216 specified in Table 3.7-2” for Unit 2. This changes the CTS by moving details on setting the lift pressure in terms of psia to the ITS Bases.

The removal of these details for performing Surveillance Requirements from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the lift settings and the definition of OPERABLE states that the components must be capable of performing their safety function. In addition, ITS SR 3.7.1.1 continues to require lift settings to be within + 1% following testing. It is understood that the MSSVs must be adjusted to lift at the settings given under the conditions that the safety analysis assumes the MSSVs will operate. This change is acceptable, because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less

restrictive removal of detail change, because details for meeting Technical Specification requirements are being removed from the Technical Specifications to the ITS Bases.

LESS RESTRICTIVE CHANGES

L01 (*Category 3 – Relaxation of Completion Time)* CTS 3.7.1.1 ACTION specifies the compensatory actions when one or more main steam line code safety valves are inoperable. The action allows operation to continue provided that within 4 hours, either the inoperable main steam line code safety valves are restored to OPERABLE status or the Power Level-High trip setpoint is reduced per Table 3.7-1. ITS 3.7.1 Required Action A.2 requires the reduction of the Power Level-High trip setpoint to less than or equal to the Maximum Allowable Power Level-High trip setpoint (Percent of RATED THERMAL POWER) specified in Table 3.7-1 within 36 hours. This changes the CTS by extending the time allowed to reduce the Power Level-High trip setpoint. The discussion of the change that deletes the restoration option is discussed in DOC A05.

The purpose of CTS 3.7.1.1 ACTION is to limit the time the unit can operate with inoperable main steam line code safety valves without reducing the Power Level-High trip setpoints. This change is acceptable, because the Completion Time is consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs, and the low probability of a DBA occurring during the allowed Completion Time. This change extends the time allowed to reduce the Power Level-High trip setpoints when the MSSVs are inoperable. The time extension is from 4 hours to 36 hours. However, the time to reduce THERMAL POWER to within the same limits is maintained in ITS 3.7.1 Required Action A.1, as described in DOC A04. This change is acceptable since the Completion Time of 36 hours is based on a reasonable time to correct the MSSV inoperability, the time required to perform the power reduction, operating experience in resetting the channels of a protective function, and on the low probability of the occurrence of a transient that could result in steam generator overpressure during this period. In addition, the actual reactor power level continues to be required to be reduced within the same limits within 4 hours. Thus, operation of the unit at RATED THERMAL POWER with an inoperable MSSV is still only allowed for 4 hours, consistent with the current allowance. This change is designated as less restrictive, because additional time is allowed to reduce the applicable reactor trip setpoints than was allowed in the CTS.

L02 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.7.1.1 requires verification each main steam line code safety valve is OPERABLE in accordance with the INSERVICE TESTING PROGRAM. ITS SR 3.7.1.1 requires the same testing to verify OPERABILITY, however, a Note has been included that only requires the lift setpoint verification to be performed within its Frequency in MODES 1 and 2. This changes the CTS by adding a Note that allows the unit to enter MODE 3 without having performed the MSSV lift setpoint verification.

DISCUSSION OF CHANGES
ITS 3.7.1, MAIN STEAM SAFETY VALVES (MSSVs)

The purpose of CTS 4.7.1.1 is to perform the MSSV lift setpoint verification in accordance with the INSERVICE TESTING PROGRAM. The SR is modified by a Note that states the Surveillance is only required to be performed in MODES 1 and 2. The Note allows entry into and operation in MODE 3 prior to performing the SR. By allowing entry into MODE 3 prior to performing the SR, testing will be performed at hot conditions. This change is acceptable because the Technical Specifications continue to require the MSSVs to be OPERABLE in MODE 3. In addition, the Surveillance continues to provide an acceptable level of equipment reliability. This change is designated as less restrictive because Surveillances will be performed in fewer operating conditions than in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.1, MAIN STEAM SAFETY VALVES (MSSVs)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. ISTS LCO 3.7.1 refers to Tables 3.7.1-1 and 3.7.1-2 for MSSV OPERABILITY. Table 3.7.1-1 does not provide information related to MSSV OPERABILITY but rather provides the allowable power level for the THERMAL POWER and trip setpoint reductions as referenced in Required Actions A.1 and A.2. In addition, SR 3.7.1.1 references Table 3.7.1-2 for the MSSV lift settings. Therefore, reference to the tables in the LCO is unnecessary and is changed in the ITS as a presentation preference. ITS LCO 3.7.1 states that eight MSSVs per steam generator are required to be OPERABLE. This presentation preference is also consistent with the presentation used in LCO 3.7.1 of the Westinghouse Engineering ISTS (NUREG-1431, Revision 5).

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.1 Main Steam Safety Valves (MSSVs)

BASES

BACKGROUND

The primary purpose of the MSSVs is to provide overpressure protection for the secondary system. The MSSVs also provide protection against overpressurizing the reactor coolant pressure boundary (RCPB) by providing ~~a heat sink~~ for the removal of energy from the Reactor Coolant System (RCS) if the preferred heat sink, provided by the Condenser and Circulating Water System, is not available. 1

Eight MSSVs are located on each main steam header, outside containment, upstream of the main steam isolation valves, as described in the FSAR, Section ~~[~~5.2~~]~~ (Ref. 1). The MSSV ~~rated capacity passes the full steam flow at 102% RTP (100% + 2% for instrument error) with the valves full open~~. This meets the requirements of the ASME Code, Section III (Ref. 2). The MSSV design includes staggered setpoints, according to Table 3.7.1-~~1~~, in the accompanying LCO, so that only the number of valves needed will actuate. Staggered setpoints reduce the potential for valve chattering because of insufficient steam pressure to fully open all valves following a turbine reactor trip. 1

must have sufficient capacity to limit the secondary system pressure to ≤ 110% of design pressure

U

s

2

APPLICABLE SAFETY ANALYSES

The design basis for the MSSVs comes from Reference 2. The MSSV's purpose is to limit secondary system pressure to ≤ 110% of design pressure when passing ~~100~~% of design steam flow. This design basis is sufficient to cope with any anticipated operational occurrence (AOO) or accident considered in the Design Basis Accident (DBA) and transient analysis. 1

100.3

The events that challenge the MSSV relieving capacity, and thus RCS pressure, are those characterized as decreased heat removal events, and are presented in the FSAR, Section ~~[~~15.2~~]~~ (Ref. 3). Of these, the ~~full power loss of condenser vacuum (LOCV) event is the limiting AOO. An LOCV isolates the turbine and condenser, and terminates normal feedwater flow to the steam generators. Before delivery of auxiliary feedwater to the steam generators,~~ RCS pressure reaches ≤ ~~2630 psig~~. This peak pressure is < 110% of the design pressure of 2500 ~~psig~~, but high enough to actuate the pressurizer safety valves. The maximum relieving rate ~~during the LOCV event is 2.5 E6 lb/hour, which is less than~~ the rated capacity of ~~two~~ MSSVs. 2 1

U

limiting and bounding event is a loss of external load (LOEL),

2744 psia

psia

is within

the

The LOEL event analysis demonstrates that the MSSVs maintain Main Steam System integrity by limiting the maximum steam pressure to less than 110% of the steam generator design pressure. The peak main steam system pressure (steam generator dome) and peak secondary side pressure for the limiting case are less than 110% of design. The peak main steam system pressure (steam generator dome) is 1092 psia.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The first bank of four MSSVs per steam generator are assumed to lift at 1000 psia (985 psig) with a maximum tolerance of + 3% and the second bank of four MSSVs per steam generator lift at 1040 psia (1025 psig) with a maximum tolerance of + 2%.

~~The limiting accident for peak RCS pressure is the full power feedwater line break (FWLB), inside containment, with the failure of the backflow check valve in the feedwater line from the affected steam generator. Water from the affected steam generator is assumed to be lost through the break with minimal additional heat transfer from the RCS. With heat removal limited to the unaffected steam generator, the reduced heat transfer causes an increase in RCS temperature, and the resulting RCS fluid expansion causes an increase in pressure. The RCS pressure increases to ≤ 2730 psig, with the pressurizer safety valves providing relief capacity. The maximum relieving rate of the MSSVs during the FWLB event is ≤ 2.5 E6 lb/hour, which is less than the rated capacity of two MSSVs.~~

~~Using conservative analysis assumptions, a small range of FWLB sizes less than a full double ended guillotine break produce an RCS pressure of 2765 psig for a period of 20 seconds; exceeding 110% (2750 psig) of design pressure. This is considered acceptable as RCS pressure is still well below 120% of design pressure where deformation may occur. The probability of this event is in the range of 4 E-6/year.~~

1

The MSSVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

. The LCO is met when eight MSSVs per steam generator are OPERABLE. Operation with less than the required number of MSSVs per steam generator OPERABLE

This LCO requires all MSSVs to be OPERABLE ~~in compliance with Reference 2, even though this is not a requirement of the DBA analysis. This is because operation with less than the full number of MSSVs~~ requires limitations on allowable THERMAL POWER (to meet Reference 2 requirements), and adjustment to the Reactor Protection ~~n~~ ve System trip setpoints. These limitations are according to those shown in Table 3.7.1-1, Required Action A.1, and Required Action A.2 in the ~~accompanying LCO~~ ACTIONS. An MSSV is considered inoperable if it fails to open upon demand.

The OPERABILITY of the MSSVs is defined as the ability to open within the setpoint tolerances, relieve steam generator overpressure, and reseat when pressure has been reduced. The OPERABILITY of the MSSVs is determined by periodic surveillance testing in accordance with the INSERVICE TESTING PROGRAM.

The lift settings, according to Table 3.7.1-2 ~~in the accompanying LCO,~~ correspond to ambient conditions of the valve at nominal operating temperature and pressure.

This LCO provides assurance that the MSSVs will perform their designed safety function to mitigate the consequences of accidents that could result in a challenge to the RCPB.

1

1

BASES

s 1, 2, and 3

five

APPLICABILITY

In MODE ~~1,~~ a minimum of ~~two~~ MSSVs per steam generator are required to be OPERABLE, according to Table 3.7.1-1 ~~in the accompanying LCO,~~ which is limiting and bounds all lower MODES. ~~In MODES 2 and 3, both the ASME Code and the accident analysis require only one MSSV per steam generator to provide overpressure protection.~~

1

In MODES 4 and 5, there are no credible transients requiring the MSSVs.

The steam generators are not normally used for heat removal in MODES 5 and 6, and thus cannot be overpressurized; there is no requirement for the MSSVs to be OPERABLE in these MODES.

ACTIONS

The ACTIONS Table is modified by a Note indicating that separate Condition entry is allowed for each MSSV.

A.1 and A.2

THERMAL POWER is limited to the relief capacity of the remaining MSSVs. This is accomplished by restricting THERMAL POWER so that the energy transfer to the steam generators is no greater than the available relief capacity in that steam generator.

Operation at or below the maximum power will ensure the design overpressure limits will not be exceeded.

An alternative to restoring the inoperable MSSV(s) to OPERABLE status is to reduce power so that the available MSSV relieving capacity meets Code requirements for the power level. Operation may continue provided ~~the allowable THERMAL POWER is equal to the product of: 1) the ratio of the number of MSSVs available per steam generator to the total number of MSSVs per steam generator, and 2) the ratio of the available relieving capacity to total steam flow, multiplied by 100%.~~

~~Allowable THERMAL POWER = (8 - N) x 109.2~~
~~8~~

Power Level-High trip setpoint

. The reduced reactor trip allowable values are based on a detailed analysis of the LOEL with a concurrent single failure event. (Ref. 3).

With one or more MSSVs inoperable, the ~~ceiling on the variable overpower trip~~ is reduced ~~to an amount over the allowable THERMAL POWER equal to the band given for this trip, according to Table 3.7.1-1 in the accompanying LCO.~~

1

~~SP = Allowable THERMAL POWER + 9.8~~

~~where:~~

~~SP = Reduced reactor trip setpoint in percent RTP. This is a ratio of the available relieving capacity over the total steam flow at rated power.~~

~~8 = Total number of MSSVs per steam generator.~~

~~N = Number of inoperable MSSVs on the steam generator with the greatest number of inoperable valves.~~

1

BASES

ACTIONS (continued)

~~109.2 = Ratio of MSSV relieving capacity at 110% steam generator design pressure to calculated steam flow rate at 100% RTP + 2% instrument uncertainty expressed as a percentage (see text above).~~

~~9.8 = Band between the maximum THERMAL POWER and the variable overpower trip setpoint ceiling (Table 3.7.1-1).~~

1

The operator should limit the maximum steady state power level to some value slightly below this setpoint to avoid an inadvertent overpower trip.

The 4 hour Completion Time for Required Action A.1 is a reasonable time period to reduce power level and is based on the low probability of an event occurring during this period that would require activation of the MSSVs. An additional 32 hours is allowed in Required Action A.2 to reduce the setpoints. The Completion Time of 36 hours for Required Action A.2 is based on a reasonable time to correct the MSSV inoperability, the time required to perform the power reduction, operating experience in resetting all channels of a protective function, and on the low probability of the occurrence of a transient that could result in steam generator overpressure during this period.

B.1 and B.2

If the MSSVs cannot be restored to OPERABLE status in the associated Completion Time, or if one or more steam generators have less than ~~two~~ five MSSVs OPERABLE, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

1

2

SURVEILLANCE REQUIREMENTS

SR 3.7.1.1

This SR verifies the OPERABILITY of the MSSVs by the verification of each MSSV lift setpoints in accordance with the INSERVICE TESTING PROGRAM. The ASME Code (Ref. 4), requires that safety and relief valve tests be performed in accordance with ANSI/ASME OM~~-1-1987~~ Code 2004/2006a (Ref. 5). According to Reference 5, the following tests are required for MSSVs:

1

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

a. Visual examination,

b. Seat tightness determination,

c. Setpoint pressure determination (lift setting), and

d. Compliance with owner's seat tightness criteria~~, and~~

~~e. Verification of the balancing device integrity on balanced valves~~.

The ANSI/ASME Standard requires that all valves be tested every 5 years, and a minimum of 20% of the valves be tested every 24 months. The ASME Code specifies the activities and frequencies necessary to satisfy the requirements. Table 3.7.1-2 allows a ± ~~[~~3~~]~~% setpoint tolerance for OPERABILITY; however, the valves are reset to ± 1% during the Surveillance to allow for drift.

for the lower pressure setting valves and +2%/−3% setpoint tolerance for the higher pressure setting valves

This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. This is to allow testing of the MSSVs at hot conditions. The MSSVs may be either bench tested or tested in situ at hot conditions using an assist device to simulate lift pressure. If the MSSVs are not tested at hot conditions, the lift setting pressure shall be corrected to ambient conditions of the valve at operating temperature and pressure.

B 3.7 PLANT SYSTEMS

B 3.7.1 Main Steam Safety Valves (MSSVs)

BASES

BACKGROUND

The primary purpose of the MSSVs is to provide overpressure protection for the secondary system. The MSSVs also provide protection against overpressurizing the reactor coolant pressure boundary (RCPB) by providing ~~a heat sink~~ for the removal of energy from the Reactor Coolant System (RCS) if the preferred heat sink, provided by the Condenser and Circulating Water System, is not available. 1

Eight MSSVs are located on each main steam header, outside containment, upstream of the main steam isolation valves, as described in the FSAR, Section ~~[~~5.2~~]~~ (Ref. 1). The MSSV ~~rated capacity passes the full steam flow at 102% RTP (100% + 2% for instrument error) with the valves full open~~. This meets the requirements of the ASME Code, Section III (Ref. 2). The MSSV design includes staggered setpoints, according to Table 3.7.1-~~1~~, in the accompanying LCO, so that only the number of valves needed will actuate. Staggered setpoints reduce the potential for valve chattering because of insufficient steam pressure to fully open all valves following a turbine reactor trip. 1

must have sufficient capacity to limit the secondary system pressure to ≤ 110% of design pressure

U

s

2

APPLICABLE SAFETY ANALYSES

The design basis for the MSSVs comes from Reference 2. The MSSV's purpose is to limit secondary system pressure to ≤ 110% of design pressure when passing ~~100~~% of design steam flow. This design basis is sufficient to cope with any anticipated operational occurrence (AOO) or accident considered in the Design Basis Accident (DBA) and transient analysis. 1

100.3

The events that challenge the MSSV relieving capacity, and thus RCS pressure, are those characterized as decreased heat removal events, and are presented in the FSAR, Section ~~[~~15.2~~]~~ (Ref. 3). Of these, the ~~full power loss of condenser vacuum (LOCV) event is the limiting AOO. An LOCV isolates the turbine and condenser, and terminates normal feedwater flow to the steam generators. Before delivery of auxiliary feedwater to the steam generators,~~ RCS pressure reaches ≤ ~~2630 psig~~. This peak pressure is < 110% of the design pressure of 2500 ~~psig~~, but high enough to actuate the pressurizer safety valves. The maximum relieving rate ~~during the LOCV event is 2.5 E6 lb/hour, which is less than~~ the rated capacity of ~~two~~ MSSVs. 2 1

limiting and bounding event is a Loss of Condenser Vacuum (LOCV),

U

2669 psia

psia

is within

the

The LOCV event analysis demonstrates that the MSSVs maintain Main Steam System integrity by limiting the maximum steam pressure to less than 110% of the steam generator design pressure. The peak main steam system pressure (steam generator dome) and peak secondary side pressure for the limiting case are less than 110% of design. The peak main steam system pressure (steam generator dome) is 1094.6 psia. | R1

BASES

APPLICABLE SAFETY ANALYSES (continued)

The first bank of four MSSVs per steam generator are assumed to lift at 1000 psia (985 psig) with a maximum tolerance of + 3% and the second bank of four MSSVs per steam generator lift at 1040 psia (1025 psig) with a maximum tolerance of + 2%.

~~The limiting accident for peak RCS pressure is the full power feedwater line break (FWLB), inside containment, with the failure of the backflow check valve in the feedwater line from the affected steam generator. Water from the affected steam generator is assumed to be lost through the break with minimal additional heat transfer from the RCS. With heat removal limited to the unaffected steam generator, the reduced heat transfer causes an increase in RCS temperature, and the resulting RCS fluid expansion causes an increase in pressure. The RCS pressure increases to ≤ 2730 psig, with the pressurizer safety valves providing relief capacity. The maximum relieving rate of the MSSVs during the FWLB event is ≤ 2.5 E6 lb/hour, which is less than the rated capacity of two MSSVs.~~

1

~~Using conservative analysis assumptions, a small range of FWLB sizes less than a full double ended guillotine break produce an RCS pressure of 2765 psig for a period of 20 seconds; exceeding 110% (2750 psig) of design pressure. This is considered acceptable as RCS pressure is still well below 120% of design pressure where deformation may occur. The probability of this event is in the range of 4 E-6/year.~~

The MSSVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

. The LCO is met when eight MSSVs per steam generator are OPERABLE. Operation with less than the required number of MSSVs per steam generator OPERABLE

This LCO requires all MSSVs to be OPERABLE ~~in compliance with Reference 2, even though this is not a requirement of the DBA analysis. This is because operation with less than the full number of MSSVs~~ requires limitations on allowable THERMAL POWER (to meet Reference 2 requirements), and adjustment to the Reactor Protection ~~n~~ ve System trip setpoints. These limitations are according to those shown in Table 3.7.1-1, Required Action A.1, and Required Action A.2 in the ~~accompanying LCO~~. An MSSV is considered inoperable if it fails to open upon demand. ACTIONS

1

The OPERABILITY of the MSSVs is defined as the ability to open within the setpoint tolerances, relieve steam generator overpressure, and reseat when pressure has been reduced. The OPERABILITY of the MSSVs is determined by periodic surveillance testing in accordance with the INSERVICE TESTING PROGRAM.

The lift settings, according to Table 3.7.1-2 ~~in the accompanying LCO,~~ correspond to ambient conditions of the valve at nominal operating temperature and pressure.

This LCO provides assurance that the MSSVs will perform their designed safety function to mitigate the consequences of accidents that could result in a challenge to the RCPB.

BASES

APPLICABILITY

In MODE ~~1,~~ a minimum of ~~two~~ MSSVs per steam generator are required to be OPERABLE, according to Table 3.7.1-1 in the accompanying LCO, which is limiting and bounds all lower MODES. ~~In MODES 2 and 3, both the ASME Code and the accident analysis require only one MSSV per steam generator to provide overpressure protection.~~

In MODES 4 and 5, there are no credible transients requiring the MSSVs.

The steam generators are not normally used for heat removal in MODES 5 and 6, and thus cannot be overpressurized; there is no requirement for the MSSVs to be OPERABLE in these MODES.

ACTIONS

The ACTIONS Table is modified by a Note indicating that separate Condition entry is allowed for each MSSV.

A.1 and A.2

THERMAL POWER is limited to the relief capacity of the remaining MSSVs. This is accomplished by restricting THERMAL POWER so that the energy transfer to the Steam Generators is no greater than the available relief capacity in that Steam Generator.

Operation at or below the maximum power will ensure the design overpressure limits will not be exceeded.

An alternative to restoring the inoperable MSSV(s) to OPERABLE status is to reduce power so that the available MSSV relieving capacity meets Code requirements for the power level. Operation may continue provided ~~the allowable THERMAL POWER is equal to the product of: 1) the ratio of the number of MSSVs available per steam generator to the total number of MSSVs per steam generator, and 2) the ratio of the available relieving capacity to total steam flow, multiplied by 100%.~~

~~$$\text{Allowable THERMAL POWER} = \frac{(8 - N)}{8} \times 109.2$$~~

. The reduced reactor trip allowable values are based on a detailed analysis of the LOCV event with a concurrent single failure event. (Ref. 3).

With one or more MSSVs inoperable, the ~~ceiling on the variable overpower trip~~ is reduced ~~to an amount over the allowable THERMAL POWER equal to the band given for this trip, according to Table 3.7.1-1 in the accompanying LCO.~~

~~SP = Allowable THERMAL POWER + 9.8~~

~~where:~~

~~SP = Reduced reactor trip setpoint in percent RTP. This is a ratio of the available relieving capacity over the total steam flow at rated power.~~

~~8 = Total number of MSSVs per steam generator.~~

~~N = Number of inoperable MSSVs on the steam generator with the greatest number of inoperable valves.~~

BASES

ACTIONS (continued)

~~109.2 = Ratio of MSSV relieving capacity at 110% steam generator design pressure to calculated steam flow rate at 100% RTP + 2% instrument uncertainty expressed as a percentage (see text above).~~

~~9.8 = Band between the maximum THERMAL POWER and the variable overpower trip setpoint ceiling (Table 3.7.1-1).~~

1

The operator should limit the maximum steady state power level to some value slightly below this setpoint to avoid an inadvertent overpower trip.

The 4 hour Completion Time for Required Action A.1 is a reasonable time period to reduce power level and is based on the low probability of an event occurring during this period that would require activation of the MSSVs. An additional 32 hours is allowed in Required Action A.2 to reduce the setpoints. The Completion Time of 36 hours for Required Action A.2 is based on a reasonable time to correct the MSSV inoperability, the time required to perform the power reduction, operating experience in resetting all channels of a protective function, and on the low probability of the occurrence of a transient that could result in steam generator overpressure during this period.

B.1 and B.2

If the MSSVs cannot be restored to OPERABLE status in the associated Completion Time, or if one or more steam generators have less than ~~two~~ five MSSVs OPERABLE, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

DISCUSSION OF CHANGES
ITS 3.7.2, MAIN STEAM ISOLATION VALVES (MSIVs)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.7.1.5 Action for MODES 2 and 3 and Unit 2 CTS 3.7.1.5 Action for MODES 2, 3 and 4 requires entry when one or both main steam isolation valves are inoperable. ITS 3.7.2 ACTION C includes a Condition Note that specifies separate Condition entry is allowed for each MSIV. This changes the CTS by explicitly specifying separate entry Condition for each inoperable MSIV.

The purpose of the Unit 1 CTS 3.7.1.5 Action for MODES 2 and 3 and Unit 2 CTS 3.7.1.5 Action for MODES 2, 3 and 4 is to ensure the appropriate compensatory actions are in place for when one or more MSIVs are not OPERABLE. This change is acceptable because the intent of the CTS Action is to allow separate entry for each inoperable MSIV. This change is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.7.1.5 Action for MODE 1 compensatory measure states, in part, “provided the inoperable valve is either restored to OPERABLE status or closed” and Unit 2 CTS 3.7.1.5 Action for MODE 1 compensatory measure states when one MSIV is inoperable "but open." ITS 3.7.2 ACTION A provides compensatory actions for when an MSIV is inoperable, regardless of whether the valve is open or closed. This changes Unit 1 CTS 3.7.1.5 by deleting the compensatory measure allowing closure of the inoperable valve to fully satisfy the Action and changes the Unit 2 CTS 3.7.1.5 condition for entry into the action from "inoperable but open" to "inoperable."

The purpose of the CTS 3.7.1.5 Action for MODE 1 is to ensure that appropriate compensatory actions are in place when an MSIV valve will not close within the time specified. This change is necessary because the proposed Condition requires entry regardless of whether the MSIV is open or closed. Operation in MODE 1 with a steam generator isolated would result in an asymmetrical steam generator reactor trip. In addition, two Reactor Coolant System (RCS) loops are required to be in operation in MODE 1 and if an MSIV is closed, the steam generator would not be performing its design function to provide a heat sink to the associated RCS loop. The closure of the MSIV could cause the associated main steam safety valves to open with an associated transient requiring operator action. Nevertheless, if an MSIV is found inoperable, entry into the Condition would still be necessary in MODE 1 because MODE 1 operation cannot continue with a closed MSIV. ITS 3.7.2 ACTION A requires restoring the MSIV to

OPERABLE status within 8 hours. This change is acceptable because the MSIVs are associated with a containment penetration with a closed system (i.e., steam generator tubes). The Completion Time is consistent with safe operation under the specified Condition, the capacity and capability of remaining features (i.e., a closed system), a reasonable time for repairs of required features, and the low probability of a DBA occurring during the allowed Completion Time. This change is designated as more restrictive since it requires entry into the Condition regardless of the status (open or closed) of the inoperable MSIV and does not allow closure of the MSIV as a remedial action in MODE 1. (See DOC L04 for discussion Completion Time change.)

M02 **Unit 1 only:** CTS 3.7.1.5 Action requires, when other actions cannot be performed, to be in HOT STANDBY (MODE 3) within 6 hours and in HOT SHUTDOWN (MODE 4) within the following 24 hours. When a shutdown of the unit is required due to one or more inoperable MSIVs, ITS 3.7.2 ACTION D requires the unit to be in MODE 3 within 6 hours and MODE 4 within 12 hours. This changes the CTS Action from MODE 4 within the following 24 hours (i.e., 30 hours total) to within 12 hours.

The purpose of the time to reach the lower MODES of operation is to reach from full power conditions in an orderly manner and without challenging plant systems. The proposed Completion Time to reach MODE 4 is consistent with the other CTS actions to reach Hot Shutdown (e.g., CTS 3.6.1.3, Action a.3) and consistent with the ISTS. This change is designated as more restrictive because it requires less time to reach Hot Shutdown conditions than in the CTS.

M03 The CTS does not require testing to verify that the MSIVs close on an actuation signal. ITS SR 3.7.2.2 requires verification that each MSIV actuates to the isolation position on an actual or simulated actuation signal with a Frequency in accordance with the Surveillance Frequency Control Program (SFCP). A Note is included that requires the Surveillance to only be performed in MODES 1 and 2. This changes the CTS by requiring verification that each MSIV actuates to the isolation position on an actual or simulated actuation signal.

The purpose of the ITS SR 3.7.2.2 is to verify the MSIV can close on an actual or simulated actuation signal. This change is acceptable because the test is periodically conducted to ensure that the MSIV will perform its safety function. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, SR 3.7.2.2 will be performed at a periodic Frequency in accordance with the SFCP with an initial Frequency of 18 months consistent with ISTS SR 3.7.2.2. This Frequency based on the refueling cycle. Industry operating experience has shown that these components usually pass the Surveillance when performed at an 18 month Frequency. The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) “Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program” (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the

St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066).

The Note to ITS SR 3.7.2.2 allows entry into and operation in MODE 3 prior to performing the SR. This allows a delay of testing until MODE 3, in order to establish conditions consistent with those under which the acceptance criterion was generated. As specified in ITS Section 1.4, once the unit reaches MODE 1 or 2, the requirement for the Surveillance to be performed within its specified Frequency applies and would require that the Surveillance had been performed.

This change is designated as more restrictive because it adds additional requirements to the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program)* Unit 1 CTS 4.7.1.5 requires verification that the closure time of each MSIV is ≤ 6.0 seconds. Unit 2 CTS 4.7.1.5 requires verification that the closure time of each MSIV is ≤ 6.75 seconds. ITS SR 3.7.2.1 requires verification that the closure time of each MSIV is within limits. This changes the CTS by moving the MSIV closure time limit to the UFSAR. | R1 | R1

The removal of MSIV closure times from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications in order to provide adequate protection of public health and safety. The ITS retains the requirement to verify that the isolation time of each MSIV is within limits. Also, this change is acceptable because these types of details will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because a detail for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* Unit 1 CTS 3.7.1.5 is applicable in MODES 1, 2, and 3. Unit 2 CTS 3.7.1.5 is applicable, in part, in MODES 1, 2, and 3. ITS LCO 3.7.2 is applicable in MODE 1, and in MODES 2 and 3 except when all MSIVs are closed. This changes the CTS by making the Specification not applicable in MODES 2 and 3 when all MSIVs are closed.

The purpose of the CTS 3.7.1.5 Applicability is to ensure the MSIVs can be isolated in the event of a high energy secondary system pipe rupture (e.g., main steam line break (MSLB)). The exception to MODE 2 and 3 is added to clarify that the MSIVs are not required to be OPERABLE when they are in a position

that supports the safety analyses. When the valves are in the closed position, they are in their assumed accident position. This change is consistent with the ISTS. This change is acceptable, because when the MSIVs are closed, the adverse effects of a high energy secondary system pipe rupture are precluded and the requirements continue to ensure that the structures, systems, and components are maintained in the MODES and other specified conditions assumed in the safety analyses. This change is designated as less restrictive because the ITS LCO requirements are applicable in fewer operating conditions than in the CTS.

L02 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.7.1.5 requires the full closure time of each main steam isolation valve verified to be within the specified isolation time when tested pursuant to the INSERVICE TESTING PROGRAM. ITS SR 3.7.2.1 requires a similar test. However, a Note modifies the SR, stating the SR is only required to be performed in MODES 1 and 2. This changes the CTS by requiring Surveillance Requirement performance only in MODES 1 and 2; allowing entry into MODE 3 without performing the Surveillance Requirement.

The purpose of CTS 4.7.1.5 is to demonstrate that the closure time of each MSIV is within the limits assumed in the containment and accident analyses. This test should normally be conducted in MODE 3 with the unit at operating temperature and pressure. Addition of the Note modifying the Surveillance Requirement allows a delay in testing until plant temperature and pressure conditions are established consistent with the conditions assumed for the acceptance criterion basis. As specified in ITS Section 1.4, once the unit reaches MODE 1 or 2, the requirement for the Surveillance to be performed within its specified Frequency applies and would require that the Surveillance had been performed. The CTS change is designated as less restrictive because the ITS Surveillance Requirement is required to be performed in fewer operating conditions than in the CTS.

L03 **Unit 2 only:** *(Category 2 – Relaxation of Applicability)* CTS 3.7.1.5 is applicable, in part, in MODE 4. ITS LCO 3.7.2 is applicable in MODE 1, and in MODES 2 and 3 except when all MSIVs are closed. As a result of the elimination of MODE 4 from the Applicability, ITS 3.7.2 ACTION D requires, in part, for the unit to be in MODE 4 within 12 hours. This changes the CTS by deleting the requirement for the Specification to be applicable in MODE 4. As a result, this also changes the action end state from Cold Shutdown (MODE 5) to MODE 4 with a Completion Time of 12 hours.

The purpose of the CTS 3.7.1.5 Applicability is to ensure the MSIVs can be isolated in the event of a high energy secondary system pipe rupture (e.g., main steam line break (MSLB)). In MODE 4, the steam generator and main steam line energy is low and, therefore, MSIV isolation is not required. This change is consistent with the ISTS. This change is acceptable, because the MSIV requirements continue to ensure that the structures, systems, and components are maintained in the MODES and other specified conditions assumed in the safety analyses. In addition, the deletion of the MODE 4 Applicability is acceptable due to the low steam generator and main steam line energy and the low probability of high energy secondary system pipe rupture occurring in MODE 4.

The change in the end state is acceptable because once the unit reaches MODE 4, the MSIVs are no longer required to be OPERABLE. Therefore, it is unnecessary to cool the unit to MODE 5 conditions. The proposed time to reach MODE 4 is consistent with other CTS Actions to reach MODE 4 (e.g., CTS 3.7.1.6 Actions a and b) and the ISTS. The proposed Completion Time is reasonable, based on operating experience, to reach MODE 4 from full power conditions in an orderly manner and without challenging plant systems. This change is designated as less restrictive because the ITS LCO requirements are applicable in fewer operating conditions than in the CTS and the Action end state is changed from Cold Shutdown (MODE 5) to MODE 4.

L04 *(Category 3 – Relaxation of Completion Time)* CTS 3.7.1.5 Action MODE 1 requires restoration of an inoperable MSIV to OPERABLE status or closure of the MSIV within 4 hours. ITS 3.7.2 ACTION A requires restoring the MSIV to OPERABLE status within 8 hours. (See DOC M01 for further discussion.) This increases the CTS action time to restore an inoperable MSIV from 4 hours to 8 hours consistent with the ISTS.

This change is acceptable because the MSIVs are associated with a containment penetration with a closed system (i.e., steam generator tubes). The Completion Time is consistent with safe operation under the specified Condition, the capacity and capability of remaining features (i.e., a closed system), a reasonable time for repairs of required features, and the low probability of a DBA occurring during the allowed Completion Time. The Completion Time of 8 hours is reasonable considering the relative stability of the closed system to act as a penetration isolation boundary. This change is designated as less restrictive because the time allowed for restoration of an MSIV to OPERABLE status has been increased.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.2, MAIN STEAM ISOLATION VALVES (MSIVs)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.2 Main Steam Isolation Valves (MSIVs)

BASES

BACKGROUND

The MSIVs isolate steam flow from the secondary side of the steam generators following a high energy line break (HELB). MSIV closure terminates flow from the unaffected (intact) steam generator.

One MSIV is located in each main steam line outside, but close to, containment. The MSIVs are downstream from the main steam safety valves (MSSVs), atmospheric dump valves, and auxiliary feedwater pump turbine steam supplies to prevent their being isolated from the steam generators by MSIV closure. Closing the MSIVs isolates each steam generator from the other, and isolates the turbine, Steam Bypass System, and other auxiliary steam supplies from the steam generators.

in either steam generator

(MSIS)

The MSIVs close on a main steam isolation signal generated by ~~either~~ low steam generator pressure ~~or high containment pressure~~. ~~The MSIVs fail closed on loss of control or actuation power.~~ The MSIS also actuates the main feedwater isolation valves (MFIVs) to close. The MSIVs may also be actuated manually.

During normal at power operation the MSIVs fail open on loss of power to the solenoid actuator due to residual hydraulic pressure. On a loss of instrument air pressure, the MSIV remains open for at least 8 hours on residual hydraulic pressure.

1

U

A description of the MSIVs is found in the FSAR, Section ~~[~~10.3~~]~~ (Ref. 1).

1

2

APPLICABLE SAFETY ANALYSES

The design basis of the MSIVs is established by the containment analysis for the large steam line break (SLB) inside containment, as discussed in the FSAR, Section ~~[~~6.2~~]~~ (Ref. 2). It is also influenced by the accident analysis of the SLB events presented in the FSAR, Section ~~[15.1.5]~~ (Ref. 3). The design precludes the blowdown of more than one steam generator, assuming a single active component failure ~~(e.g., the failure of one MSIV to close on demand)~~.

U

U

15.4.6

1

2

full

The limiting case for the containment analysis is the hot ~~zero~~ power SLB inside containment with a ~~loss of offsite power following turbine trip, and~~ failure of ~~the MSIV on the affected steam generator to close~~. ~~At zero power, the steam generator inventory and temperature are at their maximum, maximizing~~ the analyzed mass and energy release to the containment. ~~Due to reverse flow, failure of the MSIV to close contributes to the total release of the additional mass and energy in the steam headers, which are downstream of the other MSIV.~~ With the most reactive rod ~~cluster control assembly~~ assumed stuck in the fully

BASES

APPLICABLE SAFETY ANALYSES (continued)

withdrawn position, there is an increased possibility that the core will become critical and return to power. The core is ultimately shut down by the borated water injection delivered by the Emergency Core Cooling System. Other failures considered are the failure of an MFIV to close, and failure of a ~~emergency diesel generator to start~~.

main feedwater pump (MFP) to trip

The cases considered for in-containment MSLB analysis include various power levels ranging from 0 to 100.3% power. Cases for SLBs inside and outside containment were analyzed with offsite and control room dose within the regulatory acceptance criteria

~~The accident analysis compares several different SLB events against different acceptance criteria. The large SLB outside containment upstream of the MSIV is limiting for offsite dose, although a break in this short section of main steam header has a very low probability. The large SLB inside containment at hot zero power is the limiting case for a post trip return to power. The analysis includes scenarios with offsite power available and with a loss of offsite power following turbine trip.~~

The analysis assumes

~~With offsite power available,~~ the reactor coolant pumps continue to circulate coolant through the steam generators, maximizing the Reactor Coolant System (RCS) cooldown. With a loss of offsite power, the response of mitigating systems, such as the ~~high pressure safety injection (HPSI)~~ pumps, is delayed. Significant single failures considered include: failure of a ~~MSIV~~ to close, failure of a~~n emergency diesel generator~~, and failure of a ~~HPSI~~ pump.

containment spray

MFIV

containment spray

MFP to trip

to close

1

3

The MSIVs serve only a safety function and remain open during power operation. These valves operate under the following situations:

The location of this break is at the steam generator outlet nozzle, upstream of the MSIVs. This location results in the largest possible steam flow for a given break size. The blowdown is limited to one steam generator due to the reverse flow check valve, which prevents flow from the intact steam generator. A MSIS occurs on low steam generator pressure to initiate the closure of the MSIVs.

a. An HELB inside containment. ~~In order to maximize the mass and energy release into the containment, the analysis assumes that the MSIV in the affected steam generator remains open. For this accident scenario, steam is discharged into containment from both steam generators until closure of the MSIV in the intact steam generator occurs. After MSIV closure, steam is discharged into containment only from the affected steam generator, and from the residual steam in the main steam header downstream of the closed MSIV in the intact loop~~.

b. A break outside of containment and upstream from the MSIVs. This scenario is not a containment pressurization concern. The uncontrolled blowdown of more than one steam generator must be prevented to limit the potential for uncontrolled RCS cooldown and positive reactivity addition. Closure of the MSIVs isolates the break, and limits the blowdown to a single steam generator.

BASES

APPLICABLE SAFETY ANALYSES (continued)

c. A break downstream of the MSIVs. This type of break will be isolated by the closure of the MSIVs. Events such as increased steam flow through the turbine or the steam bypass valves will also terminate on closure of the MSIVs.

d. A steam generator tube rupture. For this scenario, closure of the MSIV~~[~~s~~]~~ isolates the affected steam generator from the intact steam generator. In addition to minimizing radiological releases, this enables the operator to maintain the pressure of the steam generator with the ruptured tube below the MSSV setpoints, a necessary step toward isolating the flow through the rupture. (2)

e. The MSIVs are also utilized during other events such as a feedwater line break. These events are less limiting so far as MSIV OPERABILITY is concerned.

The MSIVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires that the MSIV in each of the ~~[~~two~~]~~ steam lines be OPERABLE. The MSIVs are considered OPERABLE when the isolation times are within limits, and they close on an isolation actuation signal. (2)

This LCO provides assurance that the MSIVs will perform their design safety function to mitigate the consequences of accidents that could result in offsite exposures comparable to the ~~10 CFR 100~~ (Ref. 4) limits ~~or the NRC staff approved licensing basis~~. (1) 10 CFR 50.67

APPLICABILITY

The MSIVs must be OPERABLE in MODE 1 and in MODES 2 and 3 except when all MSIVs are closed ~~and [deactivated]~~. In these MODES there is significant mass and energy in the RCS and steam generators. When the MSIVs are closed, they are already performing their safety function. (1) (2)

~~In MODE 4, the steam generator energy is low; therefore, the MSIVs are not required to be OPERABLE.~~

4, is low

In MODES 5 and 6, the steam generator~~s do not contain much~~ energy ~~because their temperature is below the boiling point of water~~; therefore, the MSIVs are not required for isolation of potential high energy secondary system pipe breaks in these MODES. (1)

BASES

ACTIONS

A.1

With one MSIV inoperable in MODE 1, time is allowed to restore the component to OPERABLE status. Some repairs can be made to the MSIV with the unit hot. The ~~[~~8~~]~~ hour Completion Time is reasonable, considering the probability of an accident occurring during the time period that would require closure of the MSIVs. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 2

The ~~[~~8~~]~~ hour Completion Time is greater than that normally allowed for containment isolation valves because the MSIVs are valves that isolate a closed system penetrating containment. These valves differ from other containment isolation valves in that the closed system provides an additional means for containment isolation. 2

B.1

If the MSIV cannot be restored to OPERABLE status within ~~[~~8~~]~~ hours, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in MODE 2 within 6 hours and Condition C would be entered. The Completion Time is reasonable, based on operating experience, to reach MODE 2, and close the MSIVs in an orderly manner and without challenging unit systems. 2

C.1~~, C.2.1,~~ and C.2~~.2~~ 4

Condition C is modified by a Note indicating that separate Condition entry is allowed for each MSIV.

Since the MSIVs are required to be OPERABLE in MODES 2 and 3, the inoperable MSIVs may either be restored to OPERABLE status or closed. When closed, the MSIVs are already in the position required by the assumptions in the safety analysis.

The ~~[~~8~~]~~ hour Completion Time is consistent with that allowed in Condition A. 2

Inoperable MSIVs that cannot be restored to OPERABLE status within the specified Completion Time, but are closed, must be verified on a periodic basis to be closed. This is necessary to ensure that the assumptions in the safety analysis remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, MSIV status indications available in the control room, and other administrative controls, to ensure these valves are in the closed position.

BASES

ACTIONS (continued)

D.1 and D.2

If the MSIVs cannot be restored to OPERABLE status, or closed, within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from MODE 2 conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.2.1

This SR verifies that the closure time of each MSIV is within the limit given in Reference ~~5~~ and is within that assumed in the accident and containment analyses. This SR also verifies the valve closure time is in accordance with the INSERVICE TESTING PROGRAM. This SR is normally performed upon returning the unit to operation following a refueling outage. The MSIVs should not be tested at power since even a part stroke exercise increases the risk of a valve closure with the unit generating power. As the MSIVs are not tested at power, they are exempt from the ASME Code (Ref. ~~6~~), requirements during operation in MODES 1 and 2.

The Frequency for this SR is in accordance with the INSERVICE TESTING PROGRAM.

This test is conducted in MODE 3, with the unit at operating temperature and pressure. This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. This allows a delay of testing until MODE 3, in order to establish conditions consistent with those under which the acceptance criterion was generated.

This test is conducted in MODE 3, with the unit at operating temperature and pressure. This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. This allows a delay of testing until MODE 3, in order to establish conditions consistent with those under which the acceptance criterion was generated.

SR 3.7.2.2

This SR verifies that each MSIV can close on an actual or simulated actuation signal. This Surveillance is normally performed upon returning the plant to operation following a refueling outage. ~~[The Frequency of MSIV testing is every [18] months. The [18] month Frequency for testing is based on the refueling cycle. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, this Frequency is acceptable from a reliability standpoint.~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

B 3.7 PLANT SYSTEMS

B 3.7.2 Main Steam Isolation Valves (MSIVs)

BASES

BACKGROUND

The MSIVs isolate steam flow from the secondary side of the steam generators following a high energy line break (HELB). MSIV closure terminates flow from the unaffected (intact) steam generator.

One MSIV is located in each main steam line outside, but close to, containment. The MSIVs are downstream from the main steam safety valves (MSSVs), atmospheric dump valves, and auxiliary feedwater pump turbine steam supplies to prevent their being isolated from the steam generators by MSIV closure. Closing the MSIVs isolates each steam generator from the other, and isolates the turbine, Steam Bypass System, and other auxiliary steam supplies from the steam generators.

The MSIVs close on a main steam isolation signal (MSIS) generated by either low steam generator pressure or high containment pressure. The MSIVs fail ~~closed~~ on loss of control ~~or actuation~~ power. The MSIS also actuates the main feedwater isolation valves (MFIVs) to close. The MSIVs may also be actuated manually.

MSIVs fail closed on a loss of Instrument Air.

A description of the MSIVs is found in the FSAR, Section ~~[~~10.3~~]~~ (Ref. 1).

APPLICABLE SAFETY ANALYSES

The design basis of the MSIVs is established by the containment analysis for the large steam line break (SLB) inside containment, as discussed in the FSAR, Section ~~[~~6.2~~]~~ (Ref. 2). It is also influenced by the accident analysis of the SLB events presented in the FSAR, Section ~~[15.1.5]~~ 15.1.6 (Ref. 3). The design precludes the blowdown of more than one steam generator, assuming a single active component failure (e.g., the failure of one MSIV to close on demand).

. The failure of one train of the containment heat removal system with offsite power available is the most limiting active failure.

The limiting case for the containment analysis is the hot zero power SLB inside containment ~~with a loss of offsite power following turbine trip, and failure of the MSIV on the affected steam generator to close.~~ At zero power, the steam generator inventory and temperature are at their maximum, maximizing the analyzed mass and energy release to the containment. ~~Due to reverse flow, failure of the MSIV to close contributes to the total release of the additional mass and energy in the steam headers, which are downstream of the other MSIV.~~ With the most reactive rod cluster control assembly assumed stuck in the fully

MSIVs are assumed in the analysis to function as designed. Initial conditions assume all rods are in the fully withdrawn position with the

BASES

APPLICABLE SAFETY ANALYSES (continued)

withdrawn position, there is an increased possibility that the core will become critical and return to power. The core is ultimately shut down by the borated water injection delivered by the Emergency Core Cooling System. Other failures considered are the failure of an MFIV to close, and failure of a emergency diesel generator to start.

or safety injection tank actuation

1

The cases considered for in-containment MSLB analysis include various power levels ranging from 0 to 100.3% power. Cases for SLBs inside and outside containment were analyzed with offsite and control room dose within the regulatory acceptance criteria.

~~The accident analysis compares several different SLB events against different acceptance criteria. The large SLB outside containment upstream of the MSIV is limiting for offsite dose, although a break in this short section of main steam header has a very low probability. The large SLB inside containment at hot zero power is the limiting case for a post trip return to power. The analysis includes scenarios with offsite power available and with a loss of offsite power following turbine trip.~~

The analysis assumes

~~With offsite power available,~~ the reactor coolant pumps continue to circulate coolant through the steam generators, maximizing the Reactor Coolant System (RCS) cooldown. With a loss of offsite power, the response of mitigating systems, such as the ~~high pressure safety injection (HPSI)~~ pumps, is delayed. 3

The MSIVs serve only a safety function and remain open during power operation. These valves operate under the following situations:

a. An HELB inside containment. ~~In order to maximize the mass and energy release into the containment, the analysis assumes that the MSIV in the affected steam generator remains open. For this accident scenario, steam is discharged into containment from both steam generators until closure of the MSIV in the intact steam generator occurs. After MSIV closure, steam is discharged into containment only from the affected steam generator, and from the residual steam in the main steam header downstream of the closed MSIV in the intact loop~~.

The location of this break is upstream of the MSIVs. The location results in the largest possible steam flow for a given break size. Blowdown of the other steam generator by backflow is prevented by closure of the steam isolation valve in the broken steam line. Blowdown of the intact steam generator is prevented by the steam isolation valve in the unbroken steam line. A MSIS occurs on low steam generator pressure to initiate the closure of the MSIVs.

b. A break outside of containment and upstream from the MSIVs. This scenario is not a containment pressurization concern. The uncontrolled blowdown of more than one steam generator must be prevented to limit the potential for uncontrolled RCS cooldown and positive reactivity addition. Closure of the MSIVs isolates the break, and limits the blowdown to a single steam generator.

BASES

APPLICABLE SAFETY ANALYSES (continued)

c. A break downstream of the MSIVs. This type of break will be isolated by the closure of the MSIVs. Events such as increased steam flow through the turbine or the steam bypass valves will also terminate on closure of the MSIVs.

d. A steam generator tube rupture. For this scenario, closure of the MSIV~~[~~s~~]~~ isolates the affected steam generator from the intact steam generator. In addition to minimizing radiological releases, this enables the operator to maintain the pressure of the steam generator with the ruptured tube below the MSSV setpoints, a necessary step toward isolating the flow through the rupture. (2)

e. The MSIVs are also utilized during other events such as a feedwater line break. These events are less limiting so far as MSIV OPERABILITY is concerned.

The MSIVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires that the MSIV in each of the ~~[~~two~~]~~ steam lines be OPERABLE. The MSIVs are considered OPERABLE when the isolation times are within limits, and they close on an isolation actuation signal. (2)

This LCO provides assurance that the MSIVs will perform their design safety function to mitigate the consequences of accidents that could result in offsite exposures comparable to the ~~10 CFR 100~~ (Ref. 4) limits ~~or the NRC staff approved licensing basis~~. (1)

10 CFR 50.67

APPLICABILITY

The MSIVs must be OPERABLE in MODE 1 and in MODES 2 and 3 except when all MSIVs are closed ~~and [deactivated]~~. In these MODES there is significant mass and energy in the RCS and steam generators. When the MSIVs are closed, they are already performing their safety function. (1) (2)

~~In MODE 4, the steam generator energy is low; therefore, the MSIVs are not required to be OPERABLE.~~

4,

is low

BASES

ACTIONS

A.1

With one MSIV inoperable in MODE 1, time is allowed to restore the component to OPERABLE status. Some repairs can be made to the MSIV with the unit hot. The ~~[~~8~~]~~ hour Completion Time is reasonable, considering the probability of an accident occurring during the time period that would require closure of the MSIVs. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 2

The ~~[~~8~~]~~ hour Completion Time is greater than that normally allowed for containment isolation valves because the MSIVs are valves that isolate a closed system penetrating containment. These valves differ from other containment isolation valves in that the closed system provides an additional means for containment isolation. 2

B.1

If the MSIV cannot be restored to OPERABLE status within ~~[~~8~~]~~ hours, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in MODE 2 within 6 hours and Condition C would be entered. The Completion Time is reasonable, based on operating experience, to reach MODE 2, and close the MSIVs in an orderly manner and without challenging unit systems. 2

C.1~~, C.2.1,~~ and C.2~~.2~~ 4

Condition C is modified by a Note indicating that separate Condition entry is allowed for each MSIV.

Since the MSIVs are required to be OPERABLE in MODES 2 and 3, the inoperable MSIVs may either be restored to OPERABLE status or closed. When closed, the MSIVs are already in the position required by the assumptions in the safety analysis.

The ~~[~~8~~]~~ hour Completion Time is consistent with that allowed in Condition A. 2

Inoperable MSIVs that cannot be restored to OPERABLE status within the specified Completion Time, but are closed, must be verified on a periodic basis to be closed. This is necessary to ensure that the assumptions in the safety analysis remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, MSIV status indications available in the control room, and other administrative controls, to ensure these valves are in the closed position.

BASES

ACTIONS (continued)

D.1 and D.2

If the MSIVs cannot be restored to OPERABLE status, or closed, within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from MODE 2 conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.2.1

This SR verifies that the closure time of each MSIV is within the limit given in Reference ~~5~~ and is within that assumed in the accident and containment analyses. This SR also verifies the valve closure time is in accordance with the INSERVICE TESTING PROGRAM. This SR is normally performed upon returning the unit to operation following a refueling outage. The MSIVs should not be tested at power since even a part stroke exercise increases the risk of a valve closure with the unit generating power. As the MSIVs are not tested at power, they are exempt from the ASME Code (Ref. ~~6~~), requirements during operation in MODES 1 and 2.

The Frequency for this SR is in accordance with the INSERVICE TESTING PROGRAM.

This test is conducted in MODE 3, with the unit at operating temperature and pressure. This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. This allows a delay of testing until MODE 3, in order to establish conditions consistent with those under which the acceptance criterion was generated.

This test is conducted in MODE 3, with the unit at operating temperature and pressure. This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. This allows a delay of testing until MODE 3, in order to establish conditions consistent with those under which the acceptance criterion was generated.

SR 3.7.2.2

This SR verifies that each MSIV can close on an actual or simulated actuation signal. This Surveillance is normally performed upon returning the plant to operation following a refueling outage. ~~[The Frequency of MSIV testing is every [18] months. The [18] month Frequency for testing is based on the refueling cycle. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, this Frequency is acceptable from a reliability standpoint.~~

ITS 3.7.2 BASES, MAIN STEAM ISOLATION VALVES (MSIVs)

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS Bases contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. Editorial/grammatical changes made for enhanced clarity.

4. Changes are made to be consistent with the Specification.

5. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.7.2, MAIN STEAM ISOLATION VALVES (MSIVs)

There are no specific No Significant Hazards Considerations for this Specification.

PLANT SYSTEMS

MAIN FEEDWATER ISOLATION VALVES (MFIVs)

LIMITING CONDITION FOR OPERATION

LCO 3.7.3 3.7.1.6 Four ~~main feedwater isolation valves (~~MFIVs~~)~~ shall be OPERABLE.

ACTIONS Note Applicability **APPLICABILITY:*** MODES 1, 2 and 3, except when ~~the~~ MFIV is closed and deactivated.

ACTION:

Action A a. ~~With o~~ne ~~MFIV~~ inoperable ~~in one or more main feedwater lines, OPERATION may continue provided each inoperable valve is restored to OPERABLE status,~~ close~~d,~~ or isolate~~d~~ within 72 hours. Otherwise, be in HOT STANDBY within ~~the next~~ 6 hours and in HOT SHUTDOWN within ~~the following 6~~ hours.

O; or more MFIVs; inoperable MFIV; 12; A02

Action B b. ~~With t~~wo ~~MFIVs inoperable~~ in the same flowpath, ~~restore at least one of the inoperable MFIVs to OPERABLE status or close one of the inoperable valves~~ within ~~4~~ hours. Otherwise, be in HOT STANDBY within ~~the next~~ 6 hours and in HOT SHUTDOWN ~~within the following 6~~ hours.

T; valves; inoperable; isolate affected flow path; 8; 12; A02; L01

Action C

SURVEILLANCE REQUIREMENTS

SR 3.7.3.1 4.7.1.6.a ~~Each MFIV shall be demonstrated OPERABLE by v~~erify~~ing full closure within 5.15 seconds when tested pursuant to~~ the INSERVICE TESTING PROGRAM. ~~The provisions of Specification 4.0.4 are not applicable for entry into MODE 3.~~

V; the isolation time of each MFIV is within limits; in accordance with; LA01; M02

Required Actions A.2 and B.2 4.7.1.6.b ~~For each~~ inoperable MFIV~~, verify that it~~ is closed or isolated once per 7 days.

Verify; M03

Add proposed SR 3.7.3.2

ACTIONS Note * ~~Each MFIV shall be treated independently.~~

Separate Condition entry is allowed for each valve.

DISCUSSION OF CHANGES
ITS 3.7.3, MAIN FEEDWATER ISOLATION VALVES (MFIVs)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 2 only:** CTS 3.7.1.6 Action a requires the restoration of each inoperable valve to OPERABLE status or close or isolate the inoperable MFIV within 72 hours. CTS 3.7.1.6 Action b requires that at least one of the inoperable MFIVs be restored to OPERABLE status or close one of the inoperable valves within 4 hours. ITS 3.7.3 does not state a requirement to restore an inoperable valve to OPERABLE status but includes other compensatory Required Actions to take within 72 hours or 4 hours, as applicable. This changes the CTS by not explicitly stating the requirement to restore an inoperable valve to OPERABLE status.

This change is acceptable because the technical requirements have not changed. Restoration of compliance with the LCO is always an available Required Action and it is the convention in the ITS to not state such "restore" options explicitly unless it is the only action or is required for clarity. This change is designated as administrative because it does not result in any technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only**: CTS does not have a requirement for Main Feedwater Isolation Valves (MFIVs) to be OPERABLE, Required Actions or Surveillance Requirements.

ITS LCO 3.7.3 requires MFIVs to be OPERABLE in MODES 1, 2 and 3, except when a MFIV is closed and deactivated. In addition, ITS 3.7.3 provides the necessary Required Actions and Surveillance Requirement that support MFIV OPERABILITY. SR 3.7.3.1 will be performed at a Frequency in accordance with the INSERVICE TESTING PROGRAM. SR 3.7.3.2 will be performed at a frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months consistent with the ISTS. In addition, PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per CTS 6.8.4.o. Industry operating experience has shown that these components usually pass the Surveillance when performed at the 18 month Frequency. This changes the CTS by incorporating the requirements of ITS 3.7.3.

The safety related function of MFIVs is to provide isolation of the feedwater system from the steam generators and AFW system during normal and emergency conditions. This change is acceptable because the safety analyses

assume the MFIVs function as designed. This change is designated as more restrictive because it adds new requirements to the CTS.

M02 **Unit 2 only:** CTS 4.7.1.6.a states that the provisions of Specification 4.0.4 are not applicable for entry into MODE 3, and thereby provides an allowance for entering the next higher MODE of Applicability when the Surveillance is not met. ITS 3.7.3 does not provide a Surveillance Note that states that the provisions of LCO 4.0.4 are not applicable. LCO 4.0.4 states that entry into a MODE or other specified condition in the Applicability of a Limiting Condition for Operation (LCO) shall only be made when the LCO's Surveillances have been met within their specified Frequency, except as provided by Surveillance Requirement 4.0.3. LCO 4.0.3 provides the provisions for a missed surveillance and does not apply to a surveillance known to not be met within its specified Frequency prior to entering the Mode of Applicability.

The purpose of CTS 4.7.1.6.a is to provide an allowance for entering the MODE of applicability when any Surveillance is not met. This changes CTS by allowing entry into the MODE of Applicability by only deferring the performance of the Surveillance Requirements instead of deferring compliance with the LCO. This change is designated as more restrictive because the CTS 4.0.4 MODE change allowance is deleted and entry into the applicable MODES shall only be made when the LCO's surveillances have been met within their specified Frequency.

M03 **Unit 2 only:** Unit 2 CTS does not require testing to verify that MFIVs close on an actuation signal. ITS SR 3.7.3.2 requires verification that each MFIV actuates to the isolation position on an actual or simulated actuation signal. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.q. Therefore, SR 3.7.3.2 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months consistent with the ISTS SR 3.7.3.2 and considers operating practice to regularly assess potential degradation and verify operation within the safety analysis. This changes the CTS by requiring verification that each MFIV actuates to the isolation position on an actual or simulated actuation signal.

The purpose of the ITS SR 3.7.3.2 is to verify each MFIV can close on an actual or simulated actuation signal. This change is acceptable because the test is conducted to ensure that the MFIV will perform its safety function. The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) "Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program" (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066). This change is designated as more restrictive because it adds additional requirements to the CTS.

DISCUSSION OF CHANGES
ITS 3.7.3, MAIN FEEDWATER ISOLATION VALVES (MFIVs)

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 **Unit 2 only:** *(Type 3 - Removing Procedural Detail for Meeting TS Requirements or Reporting Requirements)* CTS 4.7.1.6.a requires verification that the closure time of each MFIV is within 5.15 seconds. ITS SR 3.7.3.1 requires verification that the closure time of each MFIV is within limits. This changes the CTS by moving the MFIV closure time limit to the UFSAR. | R1

The removal of MFIV closure time from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement to verify that the closure time of each MFIV is within limits. This change is acceptable because these types of procedural details will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because a procedural detail for meeting Technical Specification requirements are being removed from the Technical Specifications. This change is designated as less restrictive, because the ITS LCO requirements are applicable in fewer operating conditions than in the CTS.

LESS RESTRICTIVE CHANGES

L01 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* CTS 3.7.1.6 Action b states that with two MFIVs inoperable in the same flow path restore at least one of the inoperable MFIVs to OPERABLE status or close one of the inoperable valves within 4 hours. ITS 3.7.3 ACTION B when two valves in the same flow path inoperable requires isolating the affected flow path within 8 hours. This changes the CTS 3.7.1.6 time to isolate an affected flow path from 4 hours to 8 hours. | R1

The purpose of the CTS 3.7.1.6 Action is to return the system to the condition where at least one valve in each flow path is performing the required safety function. The CTS action time of 4 hours is consistent with the time required to close an inoperable containment isolation valve. This change is consistent with the ISTS and acceptable because the MFIVs are associated with a containment penetration with a closed system (i.e., steam generator tubes). The relaxed Completion Time is consistent with safe operation under the specified Condition, the capacity and capability of remaining features (i.e., a closed system), a reasonable time for repairs of required features, and the low probability of a DBA occurring during the allowed Completion Time. In the case of two inoperable MFIVs, 8 hours is a reasonable time period considering the relative stability of the closed system to act as a penetration isolation boundary. This change is designated as less restrictive because additional time is allowed to isolate the affected flow path than was allowed in the CTS. | R1

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.3, MAIN FEEDWATER ISOLATION VALVES (MFIVs)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. **Unit 1 Only:** ISTS ACTION B is bracketed and deleted based on the Unit 1 design that includes only one MFIV in each feedwater line to its respective steam generator. ISTS ACTION C is renumbered in conformance.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.3 Main Feedwater Isolation Valves (MFIVs) ~~[and [MFIV] Bypass Valves]~~ 1

BASES

BACKGROUND

The MFIVs isolate main feedwater (MFW) flow to the secondary side of the steam generators following a high energy line break (HELB). Closure of the MFIVs ~~and the bypass valves~~ terminates flow to both steam generators, terminating the event for feedwater line breaks (FWLBs) occurring upstream of the MFIVs. The consequences of events occurring in the main steam lines or in the MFW lines downstream of the MFIVs will be mitigated by their closure. Closure of the MFIVs ~~and bypass valves~~ effectively terminates the addition of feedwater to an affected steam generator, limiting the mass and energy release for steam line breaks (SLBs) or FWLBs inside containment, and reducing the cooldown effects for SLBs. 1

The MFIVs ~~and bypass valves~~ isolate the nonsafety related portions from the safety related portion of the system. In the event of a secondary side pipe rupture inside containment, the valves limit the quantity of high energy fluid that enters containment through the break, and provide a pressure boundary for the controlled addition of auxiliary feedwater (AFW) to the intact loop. 1

One MFIV is located on each ~~A~~FW line, outside, but close to, containment. The MFIVs are located upstream of the AFW injection point so that AFW may be supplied to a steam generator following MFIV closure. The piping volume from the valve to the steam generator must be accounted for in calculating mass and energy releases, and refilled prior to AFW reaching the steam generator following either an SLB or FWLB. M 1

The MFIVs ~~and its bypass valves~~ close on receipt of a main steam isolation signal (MSIS) generated by ~~either~~ low steam generator pressure ~~or high containment pressure~~. The MSIS also actuates the main steam isolation valves (MSIVs) to close. The MFIVs ~~and bypass valves~~ may also be actuated manually. In addition to the MFIVs ~~and the bypass valves~~, a check valve inside containment is available to isolate the feedwater line penetrating containment, and to ensure that the consequences of events do not exceed the capacity of the containment heat removal systems. 1

and safety injection actuation signal (SIAS) on low-low pressurizer pressure or high containment pressure

~~A description of the~~ MFIV~~s~~ is ~~found~~ in the FSAR, Section ~~[~~10.4.~~7]~~ (Ref. 1). design U 6 discussed 1 2

BASES

APPLICABLE SAFETY ANALYSES

The design basis of the MFIVs is established by the analysis for the large SLB. It is also influenced by the accident analysis for the large FWLB. Closure of the MFIVs ~~and their bypass valves~~ may also be relied on to terminate a steam line break for core response analysis ~~and an excess feedwater flow event~~ upon receipt of a MSIS on ~~high~~ low steam generator ~~level~~ pressure. 1

Failure of an MFIV ~~and the bypass valve~~ to close following an SLB, FWLB, or excess feedwater flow event can result in additional mass and energy to the steam generators contributing to cooldown. This failure also results in additional mass and energy releases following an SLB or FWLB event. 1

The MFIVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO ensures that the MFIVs ~~and the bypass valves~~ will isolate MFW flow to the steam generators. Following an FWLB or SLB, these valves will also isolate the nonsafety related portions from the safety related portions of the system. This LCO requires that ~~[two]~~ one MFIV~~s [and [MFIV] bypass valves]~~ in each feedwater line be OPERABLE. The MFIVs ~~and the bypass valves~~ are considered OPERABLE when the isolation times are within limits, and ~~are~~ will close~~d~~ on an ~~isolation actuation signal~~ MSIS and SIAS. 1 2 1

Failure to meet the LCO requirements can result in additional mass and energy being released to containment following an SLB or FWLB inside containment. ~~If an MSIS on high steam generator level is relied on to terminate an excess feedwater flow event, failure to meet the LCO may result in the introduction of water into the main steam lines.~~ 2

APPLICABILITY

The MFIVs ~~and the bypass valves~~ must be OPERABLE whenever there is significant mass and energy in the Reactor Coolant System and steam generators. This ensures that, in the event of an HELB, a single failure cannot result in the blowdown of more than one steam generator. 1

In MODES 1, 2, and 3, the MFIV~~[or [MFIV] bypass valves]~~ s are required to be OPERABLE, except when they are closed and deactivated ~~or isolated by a closed manual valve~~, in order to limit the amount of available fluid that could be added to containment in the case of a secondary system pipe break inside containment. When the valves are closed and deactivated ~~or isolated by a closed manual valve~~, they are already performing their safety function. 2 1

In MODES 4, 5, and 6, steam generator energy is low. Therefore, the MFIVs ~~and the bypass valves~~ are normally closed since MFW is not required. 2

BASES

ACTIONS

The ACTIONS Table is modified by a Note indicating that separate Condition entry is allowed for each value.

A.1 and A.2

With one or more MFIV~~s~~ ~~or the bypass valve~~ inoperable, action must be taken to close or isolate the inoperable valves within ~~[~~8 ~~or 72]~~ hours. When these valves are closed or isolated, they are performing their required safety function (e.g., to isolate the line). (1) (2)

~~For units with only one MFIV per feedwater line:~~ The ~~[~~8~~]~~ hour Completion Time is reasonable to close the MFIV ~~or its bypass valve, which includes performing a controlled unit shutdown to MODE 2~~. (2)

~~The [72] hour Completion Time takes into account the redundancy afforded by the remaining OPERABLE valves, and the low probability of an event occurring during this time period that would require isolation of the MFW flow paths.~~ (1)

~~B.1~~

~~If more than one MFIV or [MFIV] bypass valve in the same flow path cannot be restored to OPERABLE status, then there may be no redundant system to operate automatically and perform the required safety function. Although the containment can be isolated with the failure of two valves in parallel in the same flow path, the double failure can be an indication of a common mode failure in the valves of this flow path, and as such is treated the same as a loss of the isolation capability of this flow path. Under these conditions, valves in each flow path must be restored to OPERABLE status, closed, or the flow path isolated within 8 hours. This action returns the system to the condition where at least one valve in each flow path is performing the required safety function. The 8 hour Completion Time is reasonable to close the MFIV or its bypass valve, or otherwise isolate the affected flow path.~~

~~Inoperable MFIVs and [MFIV] bypass valves that cannot be restored to OPERABLE status within the Completion Time, but are closed or isolated, must be verified on a periodic basis that they are closed or isolated. This is necessary to ensure that the assumptions in the safety analysis remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, in view of valve status indications available in the control room, and other administrative controls to ensure that these valves are closed or isolated~~. (1)

BASES

ACTIONS (continued)

B

~~C~~.1 and ~~[C~~.2~~]~~ (3) (2)

If the MFIVs ~~and their bypass valves~~ cannot be restored to OPERABLE status, closed, or isolated in the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours ~~[~~, and in MODE 4 within ~~[~~12~~]~~ hours~~]~~. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. (1) (2)

SURVEILLANCE REQUIREMENTS

SR 3.7.3.1

This SR verifies that the closure time of each MFIV ~~[and [MFIV] bypass valve]~~ is within the limit given in Reference 2 and is within that assumed in the accident and containment analyses. This SR also verifies that the valve closure time is in accordance with the INSERVICE TESTING PROGRAM. This SR is normally performed upon returning the unit to operation following a refueling outage. The MFIVs should not be tested at power since even a part stroke exercise increases the risk of a valve closure with the unit generating power. As these valves are not tested at power, they are exempt from the ASME Code (Ref. 3) requirements during operation in MODES 1 and 2. (2)

The Frequency is in accordance with the INSERVICE TESTING PROGRAM.

SR 3.7.3.2

This SR verifies that each MFIV ~~[and [MFIV] bypass valve]~~ can close on an actual or simulated actuation signal. This Surveillance is normally performed upon returning the plant to operation following a refueling outage. (2)

~~[The Frequency for this SR is every [18] months. The [18] month Frequency for testing is based on the refueling cycle. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, this Frequency is acceptable from a reliability standpoint.~~ (2)

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~ (2)

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ (4)

B 3.7 PLANT SYSTEMS

B 3.7.3 Main Feedwater Isolation Valves (MFIVs) ~~[and [MFIV] Bypass Valves]~~

BASES

BACKGROUND

The MFIVs isolate main feedwater (MFW) flow to the secondary side of the steam generators following a high energy line break (HELB). Closure of the MFIVs ~~and the bypass valves~~ terminates flow to both steam generators, terminating the event for feedwater line breaks (FWLBs) occurring upstream of the MFIVs. The consequences of events occurring in the main steam lines or in the MFW lines downstream of the MFIVs will be mitigated by their closure. Closure of the MFIVs ~~and bypass valves~~ effectively terminates the addition of feedwater to an affected steam generator, limiting the mass and energy release for steam line breaks (SLBs) or FWLBs inside containment, and reducing the cooldown effects for SLBs.

The MFIVs ~~and bypass valves~~ isolate the nonsafety related portions from the safety related portion of the system. In the event of a secondary side pipe rupture inside containment, the valves limit the quantity of high energy fluid that enters containment through the break, and provide a pressure boundary for the controlled addition of auxiliary feedwater (AFW) to the intact loop.

Two s are M

~~One~~ MFIV ~~is~~ located on each ~~A~~FW line, outside, but close to, containment. The MFIVs are located upstream of the AFW injection point so that AFW may be supplied to a steam generator following MFIV closure. The piping volume from the valve to the steam generator must be accounted for in calculating mass and energy releases, and refilled prior to AFW reaching the steam generator following either an SLB or FWLB.

The MFIVs ~~and its bypass valves~~ close on receipt of a main steam isolation signal (MSIS) generated by ~~either~~ low steam generator pressure or high containment pressure. The MSIS also actuates the main steam isolation valves (MSIVs) to close. The MFIVs ~~and bypass valves~~ may also be actuated manually. In addition to the MFIVs ~~and the bypass valves~~, a check valve inside containment is available to isolate the feedwater line penetrating containment, and to ensure that the consequences of events do not exceed the capacity of the containment heat removal systems.

and Auxiliary Feedwater Actuation Signal (AFAS) on low steam generator level

A description of the MFIVs is found in the FSAR, Section ~~[~~10.4.7~~]~~ (Ref. 1).

U

BASES

APPLICABLE SAFETY ANALYSES

The design basis of the MFIVs is established by the analysis for the large SLB. It is also influenced by the accident analysis for the large FWLB. Closure of the MFIVs ~~and their bypass valves~~ may also be relied on to terminate a steam line break for core response analysis and an excess feedwater flow event upon receipt of a MSIS on ~~high~~ low steam generator ~~level~~ pressure or high containment pressure. 1

Failure of an MFIV ~~and the bypass valve~~ to close following an SLB, FWLB, or excess feedwater flow event can result in additional mass and energy to the steam generators contributing to cooldown. This failure also results in additional mass and energy releases following an SLB or FWLB event. 1

The MFIVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO ensures that the MFIVs ~~and the bypass valves~~ will isolate MFW flow to the steam generators. Following an FWLB or SLB, these valves will also isolate the nonsafety related portions from the safety related portions of the system. This LCO requires that ~~[~~two~~]~~ MFIVs ~~[and [MFIV] bypass valves]~~ in each feedwater line be OPERABLE. The MFIVs ~~and the bypass valves~~ are considered OPERABLE when the isolation times are within limits, and ~~are~~ will close~~d~~ on an ~~isolation actuation signal~~ MSIS and AFAS. 1 2 | R1 1

Failure to meet the LCO requirements can result in additional mass and energy being released to containment following an SLB or FWLB inside containment. ~~If an MSIS on high steam generator level is relied on to terminate an excess feedwater flow event, failure to meet the LCO may result in the introduction of water into the main steam lines.~~ 2

APPLICABILITY

The MFIVs ~~and the bypass valves~~ must be OPERABLE whenever there is significant mass and energy in the Reactor Coolant System and steam generators. This ensures that, in the event of an HELB, a single failure cannot result in the blowdown of more than one steam generator. 1

In MODES 1, 2, and 3, the MFIV~~~~s ~~[or [MFIV] bypass valves]~~ are required to be OPERABLE, except when they are closed and deactivated ~~or isolated by a closed manual valve~~, in order to limit the amount of available fluid that could be added to containment in the case of a secondary system pipe break inside containment. When the valves are closed and deactivated ~~or isolated by a closed manual valve~~, they are already performing their safety function. 2 1

In MODES 4, 5, and 6, steam generator energy is low. Therefore, the MFIVs ~~and the bypass valves~~ are normally closed since MFW is not required. 2

BASES

ACTIONS

The ACTIONS Table is modified by a Note indicating that separate Condition entry is allowed for each value.

A.1 and A.2

With one or more MFIV~~s~~ ~~or the bypass valve~~ inoperable, action must be taken to close or isolate the inoperable valves within ~~[8 or~~ 72~~]~~ hours. When these valves are closed or isolated, they are performing their required safety function (e.g., to isolate the line). 1 2

~~For units with only one MFIV per feedwater line: The [8] hour Completion Time is reasonable to close the MFIV or its bypass valve, which includes performing a controlled unit shutdown to MODE 2.~~ 1

The ~~[~~72~~]~~ hour Completion Time takes into account the redundancy afforded by the remaining OPERABLE valves, and the low probability of an event occurring during this time period that would require isolation of the MFW flow paths. 2

B.1

If more than one MFIV ~~or [MFIV] bypass valve~~ in the same flow path cannot be restored to OPERABLE status, then there may be no redundant system to operate automatically and perform the required safety function. Although the containment can be isolated with the failure of two valves in parallel in the same flow path, the double failure can be an indication of a common mode failure in the valves of this flow path, and as such is treated the same as a loss of the isolation capability of this flow path. Under these conditions, valves in each flow path must be restored to OPERABLE status, closed, or the flow path isolated within 8 hours. This action returns the system to the condition where at least one valve in each flow path is performing the required safety function. The 8 hour Completion Time is reasonable to close the MFIV or its bypass valve, or otherwise isolate the affected flow path. 2 1

Inoperable MFIVs ~~and [MFIV] bypass valves~~ that cannot be restored to OPERABLE status within the Completion Time, but are closed or isolated, must be verified on a periodic basis that they are closed or isolated. This is necessary to ensure that the assumptions in the safety analysis remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, in view of valve status indications available in the control room, and other administrative controls to ensure that these valves are closed or isolated. 1 2

BASES

ACTIONS (continued)

C.1 and ~~[~~C.2~~]~~ (2)

If the MFIVs ~~and their bypass valves~~ cannot be restored to OPERABLE status, closed, or isolated in the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours ~~[~~, and in MODE 4 within ~~[~~12~~]~~ hours~~]~~. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. (1) (2)

SURVEILLANCE REQUIREMENTS

SR 3.7.3.1

This SR verifies that the closure time of each MFIV ~~[and [MFIV] bypass valve]~~ is within the limit given in Reference 2 and is within that assumed in the accident and containment analyses. This SR also verifies that the valve closure time is in accordance with the INSERVICE TESTING PROGRAM. This SR is normally performed upon returning the unit to operation following a refueling outage. The MFIVs should not be tested at power since even a part stroke exercise increases the risk of a valve closure with the unit generating power. As these valves are not tested at power, they are exempt from the ASME Code (Ref. 3) requirements during operation in MODES 1 and 2. (2)

The Frequency is in accordance with the INSERVICE TESTING PROGRAM.

SR 3.7.3.2

This SR verifies that each MFIV ~~[and [MFIV] bypass valve]~~ can close on an actual or simulated actuation signal. This Surveillance is normally performed upon returning the plant to operation following a refueling outage. (2)

~~[The Frequency for this SR is every [18] months. The [18] month Frequency for testing is based on the refueling cycle. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, this Frequency is acceptable from a reliability standpoint.~~ (2)

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

DISCUSSION OF CHANGES
ITS 3.7.4, ATMOSPHERIC DUMP VALVES (ADVs)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only**: CTS does not have a Specification for Atmospheric Dump Valves (ADVs). ITS LCO 3.7.4 requires ADV lines to be OPERABLE in MODES 1, 2, 3, and MODE 4 when the steam generator is being relied upon for heat removal. In addition, ITS 3.7.4 provides the necessary Required Actions to provide appropriate remedial actions when the LCO is not met and Surveillance Requirement that support ADV line OPERABILITY. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per CTS 6.8.4.o. Therefore, SR 3.7.4.1 and SR 3.7.4.2 will be performed at a frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months consistent with the ISTS. This changes the CTS by incorporating requirements for ADVs in ITS 3.7.4.

The safety related function of ADVs is to provide the capability to cool the unit to Shutdown Cooling (SDC) System entry conditions. The ADVs are assumed to be used by the operator to cool down the unit to SDC entry conditions for accidents accompanied by a loss of offsite power. This change is necessary because the safety analyses assume the ADVs function, coincident with a loss of offsite power, in the main steam line break upstream of the main steam isolation valves, a feedwater line break, and a steam generator tube rupture event. This change is designated as more restrictive because it adds new requirements to the CTS.

M02 **Unit 2 only:** CTS 3.7.1.7 is applicable in MODE 1. ITS 3.7.4 Applicability states MODES 1, 2, and 3, and MODE 4 when steam generator is being relied upon for heat removal. This changes the CTS to require OPERABILITY of the ADV lines, which include ADVs and associated block valves, in additional MODES of operation. The purpose of CTS 3.7.1.7 is to ensure the capability to cool the unit to SDC System entry conditions. These changes are acceptable because they ensure the necessary decay heat removal capacity is available when a steam generator is relied upon for heat removal to support the safety analysis and licensing basis.

These changes are designated as more restrictive because they add additional Applicability requirements that are not required by the CTS.

M03 **Unit 2 only:** CTS 3.7.1.7 Action a states, in part, to be in at least HOT STANDBY (MODE 3) within the next 6 hours. ITS 3.7.4 ACTION C requires the unit to be in

MODE 3 within 6 hours and in MODE 4 without reliance upon steam generator for heat removal within 24 hours. This changes the CTS by adding an additional requirement to be in MODE 4 without reliance upon steam generator for heat removal within 24 hours.

The purpose of the shutdown Actions is to place the unit outside of the Applicability of the Specification. ITS 3.7.4 ACTION C accomplishes this purpose by adding the additional requirement. (See DOC M02 for discussion of changes to the Applicability.) This change is acceptable because the requirement to be in MODE 4 without reliance upon steam generator for heat removal places the unit outside of the Applicability and the time required to be in MODE 4 is reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. This change is designated as more restrictive because additional Required Actions are now required that were not required in CTS.

M04 **Unit 2 only:** CTS 3.7.1.7 action a allows 72 hours to restore the required atmospheric dump and associated block valve to OPERABLE status with less than one ADV and associated block valve per steam generator OPERABLE. ITS 3.7.4 ACTION B requires the restoration of at least one ADV line to OPERABLE status within 24 hours whenever two ADV lines are inoperable. This changes CTS by adding an additional Required Action and Completion time when two ADV lines are inoperable.

The purpose of ITS 3.7.4 ACTION B is to restore one of the ADV lines to OPERABLE status when both ADV lines are inoperable (e.g., one or more ADVs or one or more block valves in both ADV lines are inoperable). Because the block valve can be closed to isolate an ADV line, repair may be possible with the unit at power and the 24 hour Completion Time is reasonable based on the availability of the steam bypass system and MSSVs, and the low probability of an event occurring during the period requiring the ADV lines. This change is designated as more restrictive because additional requirements are being added to the ITS than are required by the CTS.

M05 **Unit 2 only:** CTS LCO 3.7.1.7 requires the atmospheric dump and associated block valves shall be OPERABLE. The CTS does not include any Surveillance to verify the ADVs and associated block valves are capable of performing their safety function (i.e., manually open to cooldown the unit during accidents with a loss of offsite power and close to preclude an uncontrolled steam release). ITS SR 3.7.4.1 requires verification of one complete cycle of each ADV and SR 3.7.4.2 requires verification of one complete cycle of each ADV block valve. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.q. Therefore, ITS SRs 3.7.4.1 and 3.7.4.2 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months consistent with the ISTS and considers industry operating experience that has shown that components of this type usually pass the SR when performed at an 18 month Frequency. This changes the CTS by adding SRs to verify one complete cycle of each ADV and associated block valve. | R1

The purpose of ITS 3.7.4 is to ensure a safety grade method for cooling the unit to shutdown cooling entry conditions is available should the preferred method, via the steam bypass system to the condenser, not be available. This change is necessary because the ADV line is required to be OPERABLE to ensure the unit can be cooled to shutdown cooling entry conditions in the event of one of the steam generators becomes unavailable coincident with a loss of offsite power. SR 3.7.4.1 is being added to verify the function of the ADV, which is to be opened and throttled through its full range. Cycling the ADV closed and open demonstrates its capability to perform this function. SR 3.7.4.2 is being added to verify the function of the ADV block valve, which is to isolate a failed open ADV. Cycling the block valve closed and open demonstrates its capability to perform this function. The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) "Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program" (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066). This change is designated as more restrictive because additional requirements are being added to the ITS than are required by the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 **Unit 2 only:** *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* CTS 3.7.1.7 requires, in part, the atmospheric dump and associated block valves to be OPERABLE. CTS 3.7.1.7 Action a requires, with less than one atmospheric dump and associated block valve per steam generator OPERABLE, the required atmospheric dump and associated block valve be restored to OPERABLE status within 72 hours. ITS LCO 3.7.4 requires two ADV lines to be OPERABLE. ITS 3.7.4 ACTION A requires, with one ADV line inoperable, restoration of the inoperable ADV line to OPERABLE status within 72 hours. ITS 3.7.4 does not include the detail of what constitutes an OPERABLE ADV line. This changes the CTS by moving the details of what constitutes an OPERABLE ADV line to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement that the ADVs and associated block valves (i.e., ADV line) be OPERABLE and provides sufficient remedial actions to restore these components to OPERABLE status. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail

change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 **Unit 2 only:** *(Category 1 – Relaxation of LCO Requirements)* CTS 3.7.1.7 requires that the atmospheric dump and associated block valves shall be OPERABLE with: a) all atmospheric dump valves in manual control above 15% of RATED THERMAL POWER; and b) no more than one atmospheric dump valve per steam generator in automatic control below 15% of RATED THERMAL POWER. CTS 3.7.1.7 Action b and CTS 4.7.1.7 also provide requirements in support of CTS LCO 3.7.1.7.a and b. ITS 3.7.4 requires that two ADV lines shall be OPERABLE. Refer to DOC LA01 for additional description of changes. This changes the CTS by deleting procedural operating detail from the Technical Specifications, including CTS 3.7.1.7 Action b and CTS 4.7.1.7.

The purpose of CTS 3.7.1.7 is to ensure that sufficient ADV capacity is available for an operator to conduct a unit cooldown following an event with a loss of offsite power. This change is acceptable because the LCO and Surveillance requirements continue to ensure that the ADV capability is maintained consistent with the safety analysis and licensing basis. To support a unit cooldown during an accident concurrent with a loss of offsite power, the operator manually opens the ADV and, if necessary, the associated block valve. This can be accomplished whether the ADV controller is in automatic or manual. Additionally, if the ADV spuriously opens while THERMAL POWER is above 15% RTP, an OPERABLE block valve can be closed to isolate the uncontrolled steam release. The deleted procedural detail is a prudent operational consideration and more appropriately addressed and controlled in plant operating procedures. This change is designated as less restrictive because less stringent LCO requirements, Actions, and Surveillance Requirements are being applied in ITS than were applied in the CTS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.4 Atmospheric Dump Valves (ADVs)

BASES

BACKGROUND

The ADVs provide a ~~safety grade~~ method for cooling the unit to Shutdown Cooling (SDC) System entry conditions, should the preferred heat sink via the Steam Bypass System to the condenser not be available, as discussed in the FSAR, Section ~~[~~10.3~~]~~ (Ref. 1). This is done in conjunction with the Auxiliary Feedwater System providing cooling water from the condensate storage tank (CST). The ADVs may also be required to meet the design cooldown rate during a normal cooldown when steam pressure drops too low for maintenance of a vacuum in the condenser to permit use of the Steam Bypass System.

U

1

1 2

Two

~~Four~~ ADV lines are provided. Each ADV line consists of one ADV and an associated block valve. Two ADV lines per steam generator are required to meet ~~single failure~~ assumptions following an event ~~rendering one steam generator unavailable~~ for Reactor Coolant System (RCS) heat removal.

, one

in the safety analysis

,

1

The ADVs are provided with upstream block valves to permit their being tested at power, and to provide an alternate means of isolation. The ADVs are equipped with pneumatic controllers to permit control of the cooldown rate.

The ADVs have a non-safety automatic pressure control capability. However, the only function of the ADVs required by the safety analyses is the ability to cool down the plant following a design basis event.

~~The ADVs are usually provided with a pressurized gas supply of bottled nitrogen that, on a loss of pressure in the normal instrument air supply, automatically supplies nitrogen to operate the ADVs. The nitrogen supply is sized to provide sufficient pressurized gas to operate the ADVs for the time required for RCS cooldown to the SDC System entry conditions~~.

air operated valves designed to fail closed on loss of instrument air. The valves are operated from the control room.

A description of the ADVs is found in Reference 1. The ADVs are ~~OPERABLE with only a DC power source available~~. In addition, hand wheels are provided for local manual operation.

1

APPLICABLE SAFETY ANALYSES

The design basis of the ADVs is established by the capability to cool the unit to SDC System entry conditions. A cooldown rate of 75°F per hour is obtainable by ~~one or~~ both steam generators. This design is adequate to cool the unit to SDC System entry conditions ~~with only one ADV and one steam generator,~~ utilizing the cooling water supply available in the CST.

1

BASES

APPLICABLE SAFETY ANALYSES (continued)

U

In the accident analysis presented in the FSAR, the ADVs are assumed to be used by the operator to cool down the unit to SDC System entry conditions for accidents accompanied by a loss of offsite power. Prior to the operator action, the main steam safety valves (MSSVs) are used to maintain steam generator pressure and temperature at the MSSV setpoint. ~~This is typically 30 minutes following the initiation of an event. (This may be less for a steam generator tube rupture (SGTR) event.)~~ The limiting events are those that render one steam generator unavailable for RCS heat removal, with a coincident loss of offsite power; this results from a turbine trip and the single failure of one ADV on the unaffected steam generator. Typical initiating events falling into this category are a main steam line break (MSLB) upstream of the main steam isolation valves, a feedwater line break (MFLB), and ~~an SGTR~~ a steam generator tube rupture (SGTR) event ~~(although the ADVs on the affected steam generator may still be available following a SGTR event)~~. 1

The ADVs are not designed to meet redundancy requirements (each steam generator is provided with a single ADV). The short term consequences of design basis events that result in the loss of ADV capability (e.g., SGTR) are not bounded. Manual (local) operation is provided to address long term consequences.

~~The design must accommodate the single failure of one ADV to open on demand; thus, each steam generator must have at least two ADVs.~~ The ADVs are equipped with block valves in the event an ADV spuriously opens, or fails to close during use.

The ADVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii), each with an OPERABLE ADV and an OPERABLE block valve. This ensures

LCO

two ADVs are

~~[~~Two~~]~~ ADV lines are required to be OPERABLE ~~on each steam generator to ensure~~ that at least ~~one ADV is~~ OPERABLE to conduct a unit cooldown following an event ~~in which one steam generator becomes unavailable, accompanied by a single active failure of one ADV line on the unaffected steam generator~~. The block valves must be OPERABLE to isolate a failed open ADV. A closed block valve does not render it or its ADV line inoperable if operator action time to open the block valve is supported in the accident analysis. 2 1

Failure to meet the LCO can result in the inability to cool the unit to SDC System entry conditions following an event in which the condenser is unavailable for use with the Steam Bypass System.

An ADV is considered OPERABLE when it is capable of providing a controlled relief of the main steam flow, and is capable of fully opening and closing on demand.

BASES

APPLICABILITY

In MODES 1, 2, and 3, ~~[~~and in MODE 4, when steam generator is being relied upon for heat removal,~~]~~ the ADVs are required to be OPERABLE.

MSLB, MFLB or — are — s

In MODES 5 and 6, an SGTR ~~is~~ not ~~a~~ credible event.

ACTIONS

A.1

~~With one required ADV line inoperable, action must be taken to restore the OPERABLE status within 7 days [or in accordance with the Risk Informed Completion Time Program]. The 7 day Completion Time takes into account the redundant capability afforded by the remaining OPERABLE ADV lines, and a nonsafety grade backup in the Steam Bypass System and MSSVs.~~

1

~~B.1~~

3

one

With ~~[two]~~ or more ~~[required]~~ ADV lines inoperable, action must be taken to restore ~~[one] of~~ the ADV lines to OPERABLE status. As the block valve can be closed to isolate an ADV, some repairs may be possible with the unit at power. The 24 hour Completion Time is reasonable to repair inoperable ADV lines, based on the availability of the Steam Bypass System and MSSVs, and the low probability of an event occurring during this period that requires the ADV lines.

2

B

~~C~~.1 and ~~C~~.2

3

If the ADV lines cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4, without reliance upon the steam generator for heat removal, within ~~[~~24~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

2

SURVEILLANCE REQUIREMENTS

SR 3.7.4.1

To perform a controlled cooldown of the RCS, the ADVs must be able to be opened and throttled through their full range. This SR ensures the ADVs are tested through a full control cycle at least once per fuel cycle. Performance of inservice testing or use of an ADV during a unit cooldown may satisfy this requirement. ~~[Operating experience has shown that these components usually pass the SR when performed at the [18] month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.~~

2

In the accident analysis presented in the FSAR, the ADVs are assumed to be used by the operator to cool down the unit to SDC System entry conditions for accidents accompanied by a loss of offsite power. Prior to the operator action, the main steam safety valves (MSSVs) are used to maintain steam generator pressure and temperature at the MSSV setpoint. ~~This is typically 30 minutes following the initiation of an event. (This may be less for a steam generator tube rupture (SGTR) event.)~~ The limiting event~~s are those that render one steam generator unavailable for RCS heat removal~~, with a coincident loss of offsite power~~; this results from a turbine trip and the single failure of one ADV on the unaffected steam generator~~. Typical initiating events ~~falling into this category~~ are a main steam line break upstream of the main steam isolation valves, a feedwater line break, and ~~an~~ SGTR event ~~(although the ADVs on the affected steam generator may still be available following a SGTR event)~~.

is the loss of one DC emergency train

This event results in a loss of two ADVs, one in each ADV line. The remaining ADV in each line is sufficient to support the capability to cool the unit to SDC entry conditions

a steam generator tube rupture (

)

that results in the failure of two ADVs, one in each ADV line,

or failure of one ADV line to support single generator cooldown

1

The design must accommodate the single failure ~~of one ADV~~ to open on demand; thus, each steam generator must have at least two ADVs. The ADVs are equipped with block valves in the event an ADV spuriously opens, or fails to close during use.

The ADVs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

, each with two OPERABLE ADVs and two OPERABLE block valves in each line. This ensures

LCO

two ADVs are

~~[~~Two~~]~~ ADV lines are required to be OPERABLE ~~on each steam generator to ensure~~ that at least ~~one~~ ADV ~~is~~ OPERABLE to conduct a unit cooldown following an event ~~in which one steam generator becomes unavailable~~, accompanied by a single ~~active~~ failure ~~of one ADV line on the unaffected steam generator~~. The block valves must be OPERABLE to isolate a failed open ADV. A closed block valve does not render it or its ADV line inoperable if operator action time to open the block valve is supported in the accident analysis.

2

1

Failure to meet the LCO can result in the inability to cool the unit to SDC System entry conditions following an event in which the condenser is unavailable for use with the Steam Bypass System.

An ADV is considered OPERABLE when it is capable of providing a controlled relief of the main steam flow, and is capable of fully opening and closing on demand.

BASES

APPLICABILITY

In MODES 1, 2, and 3, ~~[~~and in MODE 4, when steam generator is being relied upon for heat removal,~~]~~ the ADVs are required to be OPERABLE. 2

main steam line break, main feedwater line break or

are

s

In MODES 5 and 6, an SGTR ~~is~~ not ~~a~~ credible event. 1

ACTIONS

A.1

(e.g., one or more ADVs or one or more block valves inoperable)

With one ~~required~~ ADV line inoperable, action must be taken to restore the OPERABLE status within ~~7 days [or in accordance with the Risk Informed Completion Time Program]~~. The ~~7 day~~ Completion Time takes into account the redundant capability afforded by the remaining OPERABLE ADV line~~s~~, and a nonsafety grade backup in the Steam Bypass System and MSSVs. 2 1

72 hours

line to

72 hour

B.1

(e.g., two ADVs or two block valves inoperable on each steam generator)

With ~~[~~two~~]~~ ~~or more [required]~~ ADV lines inoperable, action must be taken to restore ~~[~~one~~]~~ of the ADV lines to OPERABLE status. As the block valve can be closed to isolate an ADV, some repairs may be possible with the unit at power. The 24 hour Completion Time is reasonable to repair inoperable ADV lines, based on the availability of the Steam Bypass System and MSSVs, and the low probability of an event occurring during this period that requires the ADV lines. 2 1

C.1 and C.2

If the ADV lines cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4, without reliance upon the steam generator for heat removal, within ~~[~~24~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. 2

SURVEILLANCE REQUIREMENTS

SR 3.7.4.1

To perform a controlled cooldown of the RCS, the ADVs must be able to be opened and throttled through their full range. This SR ensures the ADVs are tested through a full control cycle at least once per fuel cycle. Performance of inservice testing or use of an ADV during a unit cooldown may satisfy this requirement. ~~[Operating experience has shown that these components usually pass the SR when performed at the [18] month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~ 4

~~[~~ SR 3.7.4.2

The function of the ADV block valve is to isolate a failed open ADV. Cycling the block valve closed and open demonstrates its capability to perform this function. Performance of inservice testing or use of the block valve during unit cooldown may satisfy this requirement. ~~[Operating experience has shown that these components usually pass the SR when performed at the [18] month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.~~ 2

~~OR~~

L03

DISCUSSION OF CHANGES
ITS 3.7.5, AUXILIARY FEEDWATER (AFW) SYSTEM

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS LCO 3.7.1.2 is applicable in MODES 1, 2, and 3. ITS LCO 3.7.5 is applicable in MODES 1, 2, and 3, and MODE 4 when the steam generator is relied upon for heat removal. To support this change in the Applicability, the following additional requirements are added to the CTS:

- A Note is added to the LCO that requires only one AFW train, which includes a motor driven pump, to be OPERABLE in MODE 4;
- A new ACTION F is added which requires immediate action to restore a required inoperable AFW train to OPERABLE status when the steam generator (SG) is relied upon for heat removal in MODE 4; and
- CTS 4.7.1.2.a, b, and c, which are applicable in MODES 1, 2, and 3, are now applicable in MODE 4 when the SG is relied upon for heat removal (ITS SR 3.7.5.1 and SR 3.7.5.2) for the required AFW train.

These changes are acceptable because they ensure the necessary support systems are available when a steam generator is being relied upon for heat removal in MODE 4. The CTS does not have specific requirements for an AFW train to be OPERABLE in MODE 4 when a steam generator is relied upon for heat removal. One AFW train, supplied by a motor driven pump, will provide sufficient water to the SG to remove decay heat in MODE 4. If the required AFW train is inoperable, ITS 3.7.5 ACTION F requires the initiation of action to restore the AFW train to OPERABLE status immediately. ITS SR 3.7.5.1 and SR 3.7.5.2 ensure the required AFW train is OPERABLE. This is acceptable because without the SG it may not be possible to cool down the unit and exit the MODE of Applicability. A modifying Note (Note 2) is added to ITS SR 3.7.5.3 (CTS 4.7.1.2.b.1) and ITS SR 3.7.5.4 (CTS 4.7.1.2.b.2) that state the SRs are not required to be met while in MODE 4 when the steam generator is relied upon for heat removal. This is acceptable because in MODE 4 the heat removal requirements are less providing more time for operator action to manually start a required AFW pump or the required AFW train is already aligned and operating. These changes are designated as more restrictive because they place additional requirements on unit operations in MODE 4 that are not required by the CTS.

M02 **Unit 1 only:** CTS 3.7.1.2 does not provide a surveillance requirement to verify proper alignment of the required AFW flowpaths prior to entering MODE 2 when the unit has been in MODE 5, MODE 6, or defueled for a cumulative period greater than 30 days. ITS SR 3.7.5.5 requires verification of the proper

alignment of the required AFW flow paths by verifying flow from the condensate storage tank to each steam generator prior to entering MODE 2 whenever the unit has been in MODE 5, MODE 6, or defueled for a cumulative period of greater than 30 days. This changes CTS 3.7.1.2 by adding a specific surveillance requirement (ITS SR 3.7.5.5) to verify alignment of the required AFW flow paths from the condensate storage tank to each steam generator prior to entering MODE 2 when the unit has been in MODE 5, MODE 6, or defueled for a cumulative period of greater than 30 days.

The purpose of ITS 3.7.5.5 is to verify that the AFW system is properly aligned by verifying the flow path to each steam generator prior to entering MODE 2 operation after 30 days in any combination of MODE 5 or 6, or defueled. This change is acceptable because it verifies the flow path from the CST to the steam generators is properly aligned by requiring verification that the minimum flow capacity is satisfied. This change is designated as more restrictive because ITS 3.7.5.5 contains surveillance requirements not previously specified in CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS LCO 3.7.1.2 requires three “independent” steam generator AFW “pumps and associated flow paths” to be OPERABLE. This includes two motor driven AFW pumps powered from separate emergency buses, and the steam turbine driven AFW pump capable of being powered from an OPERABLE steam supply system. ITS LCO 3.7.5 states “Three AFW trains shall be OPERABLE.” The ITS does not include design details or define the components and associated flow paths that comprise an OPERABLE AFW train. CTS 3.7.1.2 Actions a, b, c, d and e cover the inoperabilities associated with the auxiliary feedwater pump(s). ITS 3.7.5 ACTIONS A, B, C, D, and E cover the inoperabilities of the train(s) which includes both the pump and the associated flow path. This changes the CTS by moving the description of the AFW System to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included to provide adequate protection of public health and safety. The ITS retains all necessary requirements in the LCO to ensure OPERABILITY for the AFW trains. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* CTS 3.7.1.2 Action a requires with one auxiliary feedwater pump steam supply inoperable to be restored to an OPERABLE status within 7 days or in accordance with the Risk Informed Completion Time Program. CTS 3.7.1.2 Action b requires an inoperable AFW pump to be restored to an OPERABLE status within 72 hours for any condition of inoperability. ITS 3.7.5 ACTION A permits 7 days to restore the affected equipment to OPERABLE status when the turbine driven AFW pump is inoperable due to an inoperable steam supply valve or if the turbine driven AFW pump is inoperable in MODE 3 following refueling. In addition, the Condition is modified by a Note that restricts the Condition to "only applicable if MODE 2 has not been entered following refueling." This changes the CTS by adding the Condition of the turbine driven AFW pump inoperable in MODE 3 following refueling with restoration of the affected equipment to OPERABLE status required within 7 days or in accordance with the Risk Informed Completion Time and restricts the applicability of the condition to only if MODE 2 has not been entered.

The purpose of CTS 3.7.1.2 Action a is to provide a limit on the length of time the unit may remain in the MODES of Applicability with the turbine driven AFW pump inoperable. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions to minimize risk associated with continued operation while providing time to repair the inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the repair period. An inoperable turbine driven AFW pump in MODE 3 following a refueling is acceptable because the remaining motor driven AFW pumps remain capable of supplying additional redundant trains of AFW and the decay heat in the Reactor Coolant System is low. The probability of an event occurring during the extended outage time that would require the inoperable turbine driven AFW pump to function is low. The ACTION provides adequate assurance that the AFW System will continue to meet the assumptions stated in the safety analyses for the AFW system to mitigate postulated accidents. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.7.1.2 Action b states that with one AFW pump inoperable in MODE 1, 2, or 3, restore the inoperable AFW train to OPERABLE status within 72 hours or in accordance with the Risk Informed Completion Time Program; or, be in HOT STANDBY within 6 hours and HOT SHUTDOWN within the following 6 hours. CTS 3.7.1.2.a allows 7 days for restoration of an inoperable AFW pump steam supply which also results in inoperability of the AFW pump for which CTS 3.7.1.2.b requires restoration to OPERABLE status within 72 hours. ITS 3.7.5 ACTION B requires the restoration of one inoperable AFW train in MODES 1, 2, or 3 in 72 hours when the AFW train is inoperable for reasons other than Condition A. ITS LCO 3.7.5 ACTION A

states that with the turbine driven AFW train inoperable because of one inoperable steam supply or, if MODE 2 has not been entered following refueling, turbine driven AFW pump inoperable in MODE 3 following refueling, to restore affected equipment to OPERABLE status within 7 days. This changes the CTS by allowing a longer Completion Time (reasons other than Condition A) if the inoperable AFW train is the turbine driven AFW train or if the plant condition is following the refueling prior to entering MODE 2. (See DOC L01 for additional discussion)

The purpose of CTS 3.7.1.2, AFW system, is to provide redundant, independent, and diverse means of supplying feedwater to the SGs for cooling the RCS under emergency conditions. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features, the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the repair period. An inoperable turbine driven AFW pump in MODE 3 following a refueling is acceptable because the remaining motor driven AFW trains remain capable of supplying additional redundant trains of AFW and the decay heat in the Reactor Coolant System is low. The probability of an event occurring during the extended outage time that would require the turbine driven AFW pump to function is low. The ACTION provides adequate assurance that the AFW System will continue to meet the assumptions stated in the safety analyses for the AFW system to mitigate postulated accidents. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)*
CTS 4.7.1.2.b.1 requires that each automatic valve in the flow path actuates to its correct position upon receipt of actuation signal and CTS 4.7.1.2.b.2 requires that each auxiliary feedwater pump starts automatically as designed. In addition, Unit 1 CTS ITS 4.7.1.2.c and Unit 2 CTS 4.7.1.2.d require verification of AFW pump developed head. SR 3.7.5.3, SR 3.7.5.4, and SR 3.7.5.2 respectively, require similar Surveillances. However, they are modified by a Note that states the SR is not required to be performed for the turbine driven AFW pump until 24 hours after entering MODE 3. This changes the CTS by removing the specific text “and prior to entering MODE 2” from the surveillance requirement and providing an allowance to delay the performance of required testing without requiring the associated AFW train to be declared inoperable. R1

The purpose of CTS 4.7.1.2.b.1, CTS 4.7.1.2.b.2, CTS 4.7.1.2.c (Unit 1), and CTS 4.7.1.2.d (Unit 2) is to ensure the AFW train is OPERABLE in MODES 1, 2, and 3. The allowance provides for entry into MODE 3 before requiring the testing of the turbine driven AFW pump automatic valves or automatic pump start. This change is acceptable because the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. This change is necessary because the steam generator pressure may be insufficient in MODE 4 to properly test the R1

AFW train. One manner of performing this SR would be to combine the tests. The majority of SRs demonstrate equipment is, in fact, OPERABLE when the tests are performed. Inconsistent testing results may occur if testing of the AFW train is required before establishing sufficient conditions for the test. The allowance will permit the establishment of stable unit conditions and sufficient steam generator pressure to test the turbine driven AFW pump and valves and will allow an accurate and consistent method for the testing. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L04 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* CTS 4.7.1.2.b.1 requires the verification that each automatic valve in the flow path actuates to its correct position. ITS SR 3.7.5.3 requires verifying that each AFW automatic valve "not locked, sealed, or otherwise secured in position," actuates to the correct position. This changes the CTS by only requiring the testing of AFW valves that are not locked, sealed or otherwise secured in position.

The purpose of CTS 4.7.1.2.b.1 is to verify that the automatic valves in the AFW System flow paths align to the correct position. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. The testing of automatic valves that are aligned and secured into the required safety position is unnecessary. Valves secured in the safety position will satisfy the safety analyses assumptions for the mitigation of analyzed accidents. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L05 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* CTS 4.7.1.2.b.1 and CTS 4.7.1.2.b.2 require verification of actuation of automatic auxiliary feedwater components automatically upon receipt of an Auto Start actuation “test” signal. ITS SR 3.7.5.3 and SR 3.7.5.4 specify that the signal may be from either an "actual or simulated actuation” signal.

The purpose of CTS 4.7.1.2.b.1 and CTS 4.7.1.2.b.2 is to ensure that the auxiliary feedwater components operate correctly upon receipt of an actuation signal. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual," "simulated," or "test" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.5, AUXILIARY FEEDWATER (AFW) SYSTEM

1. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

2. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.5 Auxiliary Feedwater (AFW) System

BASES

BACKGROUND

The AFW System automatically supplies feedwater to the steam generators to remove decay heat from the Reactor Coolant System upon the loss of normal feedwater supply. The AFW pumps take suction ~~through separate and independent suction lines~~ from the condensate storage tank (CST) (LCO 3.7.6, "Condensate Storage Tank (CST)") and pump to the steam generator secondary side via separate and independent connections to the main feedwater (MFW) piping outside containment. The steam generators function as a heat sink for core decay heat. The heat load is dissipated by releasing steam to the atmosphere from the steam generators via the main steam safety valves (MSSVs) (LCO 3.7.1, "Main Steam Safety Valves (MSSVs)") or atmospheric dump valves (ADVs) (LCO 3.7.4, "Atmospheric Dump Valves (ADVs)"). If the main condenser is available, steam may be released via the steam bypass valves and recirculated to the CST.

1

1

A normally closed line also allows Unit 1 AFW pumps to take suction from the Unit 2 CST if the Unit 1 CST is not available.

greater than full flow capacity

full capacity

A train consisting of a pump and its associated flow path.

The AFW System consists of [two] motor driven AFW pumps and one steam turbine driven pump configured into three trains. Each motor driven pump provides 100% of AFW flow capacity; the turbine driven pump provides 100% of the required capacity to the steam generators as assumed in the accident analysis. The pumps are equipped with independent recirculation lines to prevent pump operation against a closed system.

2

1

the required

normally

Each motor driven AFW pump is powered from an independent Class 1E power supply, and feeds one steam generator, although each pump has the capability to be realigned from the control room to feed the other steam generator.

1

A cross connection is provided to enable the routing of flow from the motor-driven pumps to either steam generator. However, the full-flow capacity of the motor-driven AFW pumps does not assure delivery of 100% of the flow credited in the feedwater line break and main steam line break analyses by means of the cross-connection (accident analyses does not explicitly credit AFW flow via the cross-connection).

One pump at full flow is sufficient to remove decay heat and cool the unit to Shutdown Cooling (SDC) System entry conditions.

and relies solely on DC power for operation

The steam turbine driven AFW pump receives steam from either main steam header upstream of the main steam isolation valve (MSIV). Each of the steam feed lines will supply 100% of the requirements of the turbine driven AFW pump. The turbine driven AFW pump supplies a common header capable of feeding both steam generators, with DC powered control valves actuated to the appropriate steam generator by the ~~Emergency~~ Feedwater Actuation System (~~E~~FAS).

1

Auxiliary

A

The AFW System supplies feedwater to the steam generators during normal unit startup, shutdown, and hot standby conditions.

1

BASES

BACKGROUND (continued)

The AFW System is designed to supply sufficient water to the steam generator(s) to remove decay heat with steam generator pressure at the setpoint of the MSSVs. Subsequently, the AFW System supplies sufficient water to cool the unit to SDC entry conditions, and steam is released through the ADVs.

The AFW System actuates automatically on low steam generator level by the ~~E~~FAS as described in LCO 3.3.~~4~~, "Engineered Safety Feature Actuation System (ESFAS) Instrumentation." The ~~E~~FAS logic is designed to feed either or both steam generators with low levels, but will isolate the AFW System from a steam generator having a significantly lower steam pressure than the other steam generator. The ~~E~~FAS automatically actuates the AFW turbine driven pump and associated DC operated valves and controls when required, to ensure an adequate feedwater supply to the steam generators. ~~D~~DC operated valves are provided for each AFW line to control the AFW flow to each steam generator.

The AFW System is discussed in the FSAR, Section ~~[~~10.~~4. 9]~~ (Ref. 1).

APPLICABLE SAFETY ANALYSES

The AFW System mitigates the consequences of any event with a loss of normal feedwater.

The design basis of the AFW System is to supply water to the steam generator to remove decay heat and other residual heat, by delivering at least the minimum required flow rate to the steam generators at pressures corresponding to the lowest MSSV set pressure ~~plus 3%~~.

The limiting Design Basis Accidents (DBAs) and transients for the AFW System are as follows:

a. Feedwater Line Break (FWLB) and

b. Loss of normal feedwater.

In addition, the minimum available AFW flow and system characteristics are serious considerations in the analysis of a small break loss of coolant accident.

The AFW System design is such that it can perform its function following a~~n FWLB between the MFW isolation valve and containment,~~ combined with a loss of offsite power following turbine trip, and a single active failure of the steam turbine driven AFW pump. ~~In such a case, the EFAS logic might not detect the affected steam generator if the backflow check valve to the affected MFW header worked properly~~. ~~One motor driven AFW pump would deliver to the broken MFW header at the pump runout~~

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~flow until the problem was detected, and flow was terminated by the operator. Sufficient flow would be delivered to the intact steam generator by the redundant AFW pump~~.

In such a case, the motor driven pumps deliver sufficient flow to the steam generators.

The AFW System satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires that ~~[~~three~~]~~ AFW trains be OPERABLE to ensure that the AFW System will perform the design safety function to mitigate the consequences of accidents that could result in overpressurization of the reactor coolant pressure boundary. Three independent AFW pumps, in two diverse trains, ensure availability of residual heat removal capability for all events accompanied by a loss of offsite power and a single failure. This is accomplished by powering two pumps from independent emergency buses. The third AFW pump is powered by a diverse means, a steam driven turbine supplied with steam from a source not isolated by the closure of the MSIVs.

The AFW System is considered to be OPERABLE when the components and flow paths required to provide AFW flow to the steam generators are OPERABLE. This requires that the two motor driven AFW pumps be OPERABLE in two diverse paths, each supplying AFW to a separate steam generator. The turbine driven AFW pump shall be OPERABLE with redundant steam supplies from each of the two main steam lines upstream of the MSIVs and capable of supplying AFW flow to either of the two steam generators. The piping, valves, instrumentation, and controls in the required flow paths shall also be OPERABLE.

The LCO is modified by a Note indicating that only one AFW train, which includes a motor driven pump, is required to be OPERABLE in MODE 4. This is because of reduced heat removal requirements, the short period of time in MODE 4 during which AFW is required, and the insufficient steam supply available in MODE 4 to power the turbine driven AFW pump.

APPLICABILITY

In MODES 1, 2, and 3, the AFW System is required to be OPERABLE and to function in the event that ~~the MFW~~ normal feedwater is lost. In addition, the AFW System is required to supply enough makeup water to replace steam generator secondary inventory, lost as the unit cools to MODE 4 conditions.

In MODE 4, the AFW System may be used for heat removal via the steam generator.

In MODES 5 and 6, the steam generators are not normally used for decay heat removal, and the AFW System is not required.

BASES

ACTIONS

A Note prohibits the application of LCO 3.0.4.b to an inoperable AFW train. There is an increased risk associated with entering a MODE or other specified condition in the Applicability with an AFW train inoperable and the provisions of LCO 3.0.4.b, which allow entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, should not be applied in this circumstance.

~~[~~ A.1

If the turbine driven AFW pump is inoperable due to one inoperable steam supply, or if a turbine driven pump is inoperable for any reason while in MODE 3 immediately following refueling, action must be taken to restore the inoperable equipment to an OPERABLE status within 7 days ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The 7 day Completion Time is reasonable based on the following reasons: 2

a. For the inoperability of the turbine driven AFW pump due to one inoperable steam supply, the 7 day Completion Time is reasonable since there is a redundant steam supply line for the turbine driven pump and the turbine driven train is still capable of performing its specified function for most postulated events.

b. For the inoperability of a turbine driven AFW pump while in MODE 3 immediately subsequent to a refueling outage, the 7 day Completion Time is reasonable due to the minimal decay heat levels in this situation.

c. For both the inoperability of the turbine driven pump due to one inoperable steam supply and an inoperable turbine driven AFW pump while in MODE 3 immediately following a refueling outage, the 7 day Completion Time is reasonable due to the availability of redundant OPERABLE motor driven AFW pumps; and due to the low probability of an event requiring the use of the turbine driven AFW pump.

Condition A is modified by a Note which limits the applicability of the Condition for an inoperable turbine driven AFW pump in MODE 3 to when the unit has not entered MODE 2 following a refueling. Condition A allows one AFW train to be inoperable for 7 days vice the 72 hour Completion Time in Condition B. This longer Completion Time is based on the reduced decay heat following refueling and prior to the reactor being critical.~~]~~ 2

BASES

ACTIONS (continued)

B.1

With one of the required AFW trains (pump or flow path) inoperable in MODE 1, 2, or 3 [for reasons other than Condition A], action must be taken to restore OPERABLE status within 72 hours [or in accordance with the Risk Informed Completion Time Program]. This Condition includes the loss of two steam supply lines to the turbine driven AFW pump. The 72 hour Completion Time is reasonable based on the redundant capabilities afforded by the AFW System, the time needed for repairs, and the low probability of a DBA event occurring during this period. Two AFW pumps and flow paths remain to supply feedwater to the steam generators. 2

C.1 and C.2

With one of the required motor driven AFW trains (pump or flow path) inoperable and the turbine driven AFW train inoperable due to one inoperable steam supply, action must be taken to restore the affected equipment to OPERABLE status within [24] [48] hours. Assuming no single active failures when in this condition, the accident (a FLB or MSLB) could result in the loss of the remaining steam supply to the turbine driven AFW pump due to the faulted steam generator (SG). In this condition, the AFW system may no longer be able to meet the required flow to the SGs assumed in the safety analysis[, [either due to the analysis requiring flow from two AFW pumps or due to the remaining AFW pump having to feed a faulted SG]]. 2 2

---REVIEWER'S NOTE---

Licensees should adopt the appropriate Completion Time based on their plant design. The 24 hour Completion Time is applicable to plants that can no longer meet the safety analysis requirement of 100% AFW flow to the SG(s) assuming no single active failure and a FLB or MSLB resulting in the loss of the remaining steam supply to the turbine driven AFW pump. The 48 hour Completion Time is applicable to plants that can still meet the safety analysis requirement of 100% AFW flow to the SG(s) assuming no single active failure and a FLB or MSLB resulting in the loss of the remaining steam supply to the turbine driven AFW pump.

3

[The 24 hour Completion Time is reasonable based on the remaining OPERABLE steam supply to the turbine driven AFW pump, the availability of the remaining OPERABLE motor driven AFW pump, and the low probability of an event occurring that would require the inoperable steam supply to be available for the turbine driven AFW pump.]] 2

BASES

ACTIONS (continued)

~~[The 48 hour Completion Time is reasonable based on the fact that the remaining motor driven AFW train is capable of providing 100 % of the AFW flow requirements, and the low probability of an event occurring that would challenge the AFW system.]~~ 2

D.1 and D.2

When Required Action A.1, ~~[~~ B.1, C.1, or C.2~~]~~ cannot be completed within the required Completion Time, ~~[~~or if two AFW trains are inoperable in MODE 1, 2, or 3 for reasons other than Condition C~~]~~, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within ~~[18]~~ hours. 2 12

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

In MODE 4, with ~~[~~two AFW trains inoperable ~~in MODE 1, 2, or 3]~~, operation is allowed to continue because only one motor driven AFW pump is required in accordance with the Note that modifies the LCO. Although it is not required, the unit may continue to cool down and start the SDC. 2 System

E.1

Required Action E.1 is modified by a Note indicating that all required MODE changes are suspended until one AFW train is restored to OPERABLE status.

With all ~~[~~three~~]~~ AFW trains inoperable in MODE 1, 2, or 3, the unit is in a seriously degraded condition with no safety related means for conducting a cooldown, and only limited means for conducting a cooldown with nonsafety grade equipment. In such a condition, the unit should not be perturbed by any action, including a power change, that might result in a trip. The seriousness of this condition requires that action be started immediately to restore one AFW train to OPERABLE status. LCO 3.0.3 is not applicable, as it could force the unit into a less safe condition. 2

BASES

ACTIONS (continued)

F.1

Required Action F.1 is modified by a Note indicating that all required MODE changes or power reductions are suspended until one AFW train is restored to OPERABLE status.

the required

With ~~one~~ AFW train inoperable, action must be taken to immediately restore the inoperable train to OPERABLE status or to immediately verify, by administrative means, the OPERABILITY of a second train. LCO 3.0.3 is not applicable, as it could force the unit into a less safe condition.

In MODE 4, either the reactor coolant pumps or the SDC loops can be used to provide forced circulation as discussed in LCO 3.4.6, "RCS Loops - MODE 4."

SURVEILLANCE REQUIREMENTS

SR 3.7.5.1

Verifying the correct alignment for manual, power operated, and automatic valves in the AFW water and steam supply flow paths provides assurance that the proper flow paths exist for AFW operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these valves are verified to be in the correct position prior to locking, sealing, or securing. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves. This Surveillance does not require any testing or valve manipulations; rather, it involves verification that those valves capable of potentially being mispositioned are in the correct position.

~~[The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

3

2

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.7.5.2

Verifying that each AFW pump's developed head at the flow test point is greater than or equal to the required developed head ensures that AFW pump performance has not degraded during the cycle. Flow and differential head are normal tests of pump performance required by the ASME Code (Ref. 2). Because it is undesirable to introduce cold AFW into the steam generators while they are operating, this testing is performed on recirculation flow. This test confirms one point on the pump design curve and is indicative of overall performance. Such inservice tests confirm component OPERABILITY, trend performance, and detect incipient failures by indicating abnormal performance. Performance of inservice testing, as discussed in the ASME Code (Ref. 2) and the INSERVICE TESTING PROGRAM, satisfies this requirement.

turbine driven AFW pump

This SR is modified by a Note indicating that the SR should be deferred until suitable test conditions are established. This deferral is required because there is an insufficient steam pressure to perform the test. 1

SR 3.7.5.2

This SR ensures that AFW can be delivered to the appropriate steam generator, in the event of any accident or transient that generates an EFAS signal, by demonstrating that each automatic valve in the flow path actuates to its correct position on an actual or simulated actuation signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. A 1

~~[The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. The 18 month Frequency is acceptable, based on the design reliability and operating experience of the equipment.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 3

~~]~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

turbine driven AFW pump

This SR is modified by a Note indicating that the SR should be deferred until suitable test conditions have been established. This deferral is required because there is an insufficient steam pressure to perform the test. 1

Also, this SR is modified by a Note that states the SR is not required to be met in MODE 4. In MODE 4, the required AFW train is already aligned and operating.

SR 3.7.5.4

A

This SR ensures that the AFW pumps will start in the event of any accident or transient that generates an ~~E~~FAS signal by demonstrating that each AFW pump starts automatically on an actual or simulated actuation signal~~. [The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. The 18 month Frequency is acceptable, based on the design reliability and operating experience of the equipment.~~ 2

~~OR~~

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~
~~Some plants may not routinely use the AFW for heat removal in MODE 4. The second justification is provided for plants that use a startup feedwater pump rather than AFW for startup and shutdown.~~

3

SR 3.7.5.5

This SR ensures that the AFW System is properly aligned by verifying the flow path to each steam generator prior to entering MODE 2 operation, after 30 days in any combination of MODE 5 or 6, or defueled. OPERABILITY of AFW flow paths must be verified before sufficient core heat is generated that would require the operation of the AFW System during a subsequent shutdown. The Frequency is reasonable, based on engineering judgment, and other administrative controls to ensure that flow paths remain OPERABLE. To further ensure AFW System alignment, the OPERABILITY of the flow paths is verified following extended outages to determine that no misalignment of valves has occurred. This SR ensures that the flow path from the CST to the steam generators is properly aligned by requiring a verification of minimum flow capacity of ~~750~~ gpm at ~~1270 psi~~. ~~(This SR is not required by those units that use AFW for normal startup and shutdown.)~~

B 3.7 PLANT SYSTEMS

B 3.7.5 Auxiliary Feedwater (AFW) System

BASES

BACKGROUND

The AFW System automatically supplies feedwater to the steam generators to remove decay heat from the Reactor Coolant System upon the loss of normal feedwater supply. The AFW pumps take suction ~~through separate and independent suction lines~~ from the condensate storage tank (CST) (LCO 3.7.6, "Condensate Storage Tank (CST)") and pump to the steam generator secondary side via separate and independent connections to the main feedwater (MFW) piping outside containment. The steam generators function as a heat sink for core decay heat. The heat load is dissipated by releasing steam to the atmosphere from the steam generators via the main steam safety valves (MSSVs) (LCO 3.7.1, "Main Steam Safety Valves (MSSVs)") or atmospheric dump valves (ADVs) (LCO 3.7.4, "Atmospheric Dump Valves (ADVs)"). If the main condenser is available, steam may be released via the steam bypass valves and recirculated to the CST.

1

1

greater than full flow capacity

full capacity

A train consisting of a pump and its associated flow path.

The AFW System consists of ~~[~~two~~]~~ motor driven AFW pumps and one steam turbine driven pump configured into three trains. Each motor driven pump provides 100% of AFW flow capacity; the turbine driven pump provides 100% of the required capacity to the steam generators as assumed in the accident analysis. The pumps are equipped with independent recirculation lines to prevent pump operation against a closed system.

the required

2

1

normally

Each motor driven AFW pump is powered from an independent Class 1E power supply, and feeds one steam generator, although each pump has the capability to be realigned ~~from the control room~~ to feed the other steam generator.

1

A cross connection is provided to enable the routing of flow from the motor-driven pumps to either steam generator. However, the full-flow capacity of the motor-driven AFW pumps does not assure delivery of 100% of the flow credited in the feedwater line break and main steam line break analyses by means of the cross-connection (accident analyses does not explicitly credit AFW flow via the cross-connection).

One pump at full flow is sufficient to remove decay heat and cool the unit to Shutdown Cooling (SDC) System entry conditions.

and relies solely on DC power for operation

The steam turbine driven AFW pump receives steam from either main steam header upstream of the main steam isolation valve (MSIV). Each of the steam feed lines will supply 100% of the requirements of the turbine driven AFW pump. The turbine driven AFW pump supplies a common header capable of feeding both steam generators, with DC powered control valves actuated to the appropriate steam generator by the ~~Emergency~~ Feedwater Actuation System (~~E~~FAS).

1

Auxiliary

A

The AFW System supplies feedwater to the steam generators during normal unit startup, shutdown, and hot standby conditions.

1

BASES

BACKGROUND (continued)

The AFW System is designed to supply sufficient water to the steam generator(s) to remove decay heat with steam generator pressure at the setpoint of the MSSVs. Subsequently, the AFW System supplies sufficient water to cool the unit to SDC entry conditions, and steam is released through the ADVs.

The AFW System actuates automatically on low steam generator level by the ~~E~~EFAS as described in LCO 3.3.~~4~~, "Engineered Safety Feature Actuation System (ESFAS) Instrumentation." The ~~E~~EFAS logic is designed to feed either or both steam generators with low levels, but will isolate the AFW System from a steam generator having a significantly lower steam pressure than the other steam generator. The ~~E~~EFAS automatically actuates the AFW turbine driven pump and associated DC operated valves and controls when required, to ensure an adequate feedwater supply to the steam generators. ~~DC~~ operated valves are provided for each AFW line to control the AFW flow to each steam generator.

The AFW System is discussed in the FSAR, Section ~~[~~10.4. 9~~]~~ (Ref. 1).

APPLICABLE SAFETY ANALYSES

The AFW System mitigates the consequences of any event with a loss of normal feedwater.

The design basis of the AFW System is to supply water to the steam generator to remove decay heat and other residual heat, by delivering at least the minimum required flow rate to the steam generators at pressures corresponding to the lowest MSSV set pressure ~~plus 3%~~.

The limiting Design Basis Accidents (DBAs) and transients for the AFW System are as follows:

a. Feedwater Line Break (FWLB) and

b. Loss of normal feedwater.

In addition, the minimum available AFW flow and system characteristics are serious considerations in the analysis of a small break loss of coolant accident.

The loss of main feedwater is the limiting event in terms of decay heat removal by the AFW system.

loss of main feedwater and FWLB events both with and without offsite power

The AFW System design is such that it can perform its function following an ~~FWLB between the MFW isolation valve and containment, combined with a loss of offsite power following turbine trip,~~ and a single active failure of the steam turbine driven AFW pump. ~~In such a case, the EFAS logic might not detect the affected steam generator if the backflow check valve to the affected MFW header worked properly~~. ~~One motor driven AFW pump would deliver to the broken MFW header at the pump runout~~

The FWLB event with a non-isolable break between the steam generator and feedwater line check valve results in the lowest capacity of AFW to the intact steam generator

BASES

APPLICABLE SAFETY ANALYSES (continued)

In such a case, a faulted steam generator is sensed by steam generator pressure differences and main feedwater pressure differences and the available motor driven pump delivers sufficient flow to the intact steam generator.

~~flow until the problem was detected, and flow was terminated by the operator. Sufficient flow would be delivered to the intact steam generator by the redundant AFW pump~~. 1

The AFW System satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires that ~~[~~three~~]~~ AFW trains be OPERABLE to ensure that the AFW System will perform the design safety function to mitigate the consequences of accidents that could result in overpressurization of the reactor coolant pressure boundary. Three independent AFW pumps, in two diverse trains, ensure availability of residual heat removal capability for all events accompanied by a loss of offsite power and a single failure. This is accomplished by powering two pumps from independent emergency buses. The third AFW pump is powered by a diverse means, a steam driven turbine supplied with steam from a source not isolated by the closure of the MSIVs. 2

The AFW System is considered to be OPERABLE when the components and flow paths required to provide AFW flow to the steam generators are OPERABLE. This requires that the two motor driven AFW pumps be OPERABLE in two diverse paths, each supplying AFW to a separate steam generator. The turbine driven AFW pump shall be OPERABLE with redundant steam supplies from each of the two main steam lines upstream of the MSIVs and capable of supplying AFW flow to either of the two steam generators. The piping, valves, instrumentation, and controls in the required flow paths shall also be OPERABLE.

The LCO is modified by a Note indicating that only one AFW train, which includes a motor driven pump, is required to be OPERABLE in MODE 4. This is because of reduced heat removal requirements, the short period of time in MODE 4 during which AFW is required, and the insufficient steam supply available in MODE 4 to power the turbine driven AFW pump.

APPLICABILITY

In MODES 1, 2, and 3, the AFW System is required to be OPERABLE and to function in the event that ~~the~~ ~~MFW~~ normal feedwater is lost. In addition, the AFW System is required to supply enough makeup water to replace steam generator secondary inventory, lost as the unit cools to MODE 4 conditions. 1

In MODE 4, the AFW System may be used for heat removal via the steam generator.

In MODES 5 and 6, the steam generators are not normally used for decay heat removal, and the AFW System is not required.

BASES

ACTIONS

A Note prohibits the application of LCO 3.0.4.b to an inoperable AFW train. There is an increased risk associated with entering a MODE or other specified condition in the Applicability with an AFW train inoperable and the provisions of LCO 3.0.4.b, which allow entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, should not be applied in this circumstance.

~~[~~ A.1

If the turbine driven AFW pump is inoperable due to one inoperable steam supply, or if a turbine driven pump is inoperable for any reason while in MODE 3 immediately following refueling, action must be taken to restore the inoperable equipment to an OPERABLE status within 7 days ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The 7 day Completion Time is reasonable based on the following reasons: 2

a. For the inoperability of the turbine driven AFW pump due to one inoperable steam supply, the 7 day Completion Time is reasonable since there is a redundant steam supply line for the turbine driven pump and the turbine driven train is still capable of performing its specified function for most postulated events.

b. For the inoperability of a turbine driven AFW pump while in MODE 3 immediately subsequent to a refueling outage, the 7 day Completion Time is reasonable due to the minimal decay heat levels in this situation.

c. For both the inoperability of the turbine driven pump due to one inoperable steam supply and an inoperable turbine driven AFW pump while in MODE 3 immediately following a refueling outage, the 7 day Completion Time is reasonable due to the availability of redundant OPERABLE motor driven AFW pumps; and due to the low probability of an event requiring the use of the turbine driven AFW pump.

Condition A is modified by a Note which limits the applicability of the Condition for an inoperable turbine driven AFW pump in MODE 3 to when the unit has not entered MODE 2 following a refueling. Condition A allows one AFW train to be inoperable for 7 days vice the 72 hour Completion Time in Condition B. This longer Completion Time is based on the reduced decay heat following refueling and prior to the reactor being critical.~~]~~ 2

BASES

ACTIONS (continued)

B.1

With one of the required AFW trains (pump or flow path) inoperable in MODE 1, 2, or 3 [for reasons other than Condition A], action must be taken to restore OPERABLE status within 72 hours [or in accordance with the Risk Informed Completion Time Program]. This Condition includes the loss of two steam supply lines to the turbine driven AFW pump. The 72 hour Completion Time is reasonable based on the redundant capabilities afforded by the AFW System, the time needed for repairs, and the low probability of a DBA event occurring during this period. Two AFW pumps and flow paths remain to supply feedwater to the steam generators. 2

C.1 and C.2

With one of the required motor driven AFW trains (pump or flow path) inoperable and the turbine driven AFW train inoperable due to one inoperable steam supply, action must be taken to restore the affected equipment to OPERABLE status within [24] [48] hours. Assuming no single active failures when in this condition, the accident (a FLB or MSLB) could result in the loss of the remaining steam supply to the turbine driven AFW pump due to the faulted steam generator (SG). In this condition, the AFW system may no longer be able to meet the required flow to the SGs assumed in the safety analysis, [either due to the analysis requiring flow from two AFW pumps or due to the remaining AFW pump having to feed a faulted SG]. 2 2

---------- REVIEWER'S NOTE ----------
Licensees should adopt the appropriate Completion Time based on their plant design. The 24 hour Completion Time is applicable to plants that can no longer meet the safety analysis requirement of 100% AFW flow to the SG(s) assuming no single active failure and a FLB or MSLB resulting in the loss of the remaining steam supply to the turbine driven AFW pump. The 48 hour Completion Time is applicable to plants that can still meet the safety analysis requirement of 100% AFW flow to the SG(s) assuming no single active failure and a FLB or MSLB resulting in the loss of the remaining steam supply to the turbine driven AFW pump.
---------- 3

[The 24 hour Completion Time is reasonable based on the remaining OPERABLE steam supply to the turbine driven AFW pump, the availability of the remaining OPERABLE motor driven AFW pump, and the low probability of an event occurring that would require the inoperable steam supply to be available for the turbine driven AFW pump.]] 2

BASES

ACTIONS (continued)

~~[The 48 hour Completion Time is reasonable based on the fact that the remaining motor driven AFW train is capable of providing 100 % of the AFW flow requirements, and the low probability of an event occurring that would challenge the AFW system.]~~ 2

D.1 and D.2

When Required Action A.1, ~~[~~ B.1, C.1, or C.2~~]~~ cannot be completed within the required Completion Time, ~~[~~or if two AFW trains are inoperable in MODE 1, 2, or 3 for reasons other than Condition C~~]~~, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within ~~[18]~~ hours. 2 12

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

In MODE 4, with ~~[~~two AFW trains inoperable ~~in MODE 1, 2, or 3]~~, operation is allowed to continue because only one motor driven AFW pump is required in accordance with the Note that modifies the LCO. Although it is not required, the unit may continue to cool down and start the SDC. 2 System

E.1

Required Action E.1 is modified by a Note indicating that all required MODE changes are suspended until one AFW train is restored to OPERABLE status.

With all ~~[~~three~~]~~ AFW trains inoperable in MODE 1, 2, or 3, the unit is in a seriously degraded condition with no safety related means for conducting a cooldown, and only limited means for conducting a cooldown with nonsafety grade equipment. In such a condition, the unit should not be perturbed by any action, including a power change, that might result in a trip. The seriousness of this condition requires that action be started immediately to restore one AFW train to OPERABLE status. LCO 3.0.3 is not applicable, as it could force the unit into a less safe condition. 2

BASES

ACTIONS (continued)

F.1

Required Action F.1 is modified by a Note indicating that all required MODE changes or power reductions are suspended until one AFW train is restored to OPERABLE status.

the required

With ~~one~~ AFW train inoperable, action must be taken to immediately restore the inoperable train to OPERABLE status or to immediately verify, by administrative means, the OPERABILITY of a second train. LCO 3.0.3 is not applicable, as it could force the unit into a less safe condition.

In MODE 4, either the reactor coolant pumps or the SDC loops can be used to provide forced circulation as discussed in LCO 3.4.6, "RCS Loops - MODE 4."

SURVEILLANCE REQUIREMENTS

SR 3.7.5.1

Verifying the correct alignment for manual, power operated, and automatic valves in the AFW water and steam supply flow paths provides assurance that the proper flow paths exist for AFW operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these valves are verified to be in the correct position prior to locking, sealing, or securing. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves. This Surveillance does not require any testing or valve manipulations; rather, it involves verification that those valves capable of potentially being mispositioned are in the correct position.

~~[The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

3

2

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.7.5.2

Verifying that each AFW pump's developed head at the flow test point is greater than or equal to the required developed head ensures that AFW pump performance has not degraded during the cycle. Flow and differential head are normal tests of pump performance required by the ASME Code (Ref. 2). Because it is undesirable to introduce cold AFW into the steam generators while they are operating, this testing is performed on recirculation flow. This test confirms one point on the pump design curve and is indicative of overall performance. Such inservice tests confirm component OPERABILITY, trend performance, and detect incipient failures by indicating abnormal performance. Performance of inservice testing, as discussed in the ASME Code (Ref. 2) and the INSERVICE TESTING PROGRAM, satisfies this requirement.

turbine driven AFW pump

This SR is modified by a Note indicating that the SR should be deferred until suitable test conditions are established. This deferral is required because there is an insufficient steam pressure to perform the test. 1

SR 3.7.5.3

This SR ensures that AFW can be delivered to the appropriate steam generator, in the event of any accident or transient that generates an ~~E~~EFAS signal, by demonstrating that each automatic valve in the flow path actuates to its correct position on an actual or simulated actuation signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. A 1

~~[The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. The 18 month Frequency is acceptable, based on the design reliability and operating experience of the equipment.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 3

~~]~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

turbine driven AFW pump

This SR is modified by a Note indicating that the SR should be deferred until suitable test conditions have been established. This deferral is required because there is an insufficient steam pressure to perform the test.

Also, this SR is modified by a Note that states the SR is not required to be met in MODE 4. In MODE 4, the required AFW train is already aligned and operating.

SR 3.7.5.4

A

This SR ensures that the AFW pumps will start in the event of any accident or transient that generates an ~~E~~FAS signal by demonstrating that each AFW pump starts automatically on an actual or simulated actuation signal~~. [The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. The 18 month Frequency is acceptable, based on the design reliability and operating experience of the equipment.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

turbine driven AFW pump

~~[~~This SR is modified by two Notes. Note 1 indicates that the SR be deferred until suitable test conditions are established. This deferral is ~~required~~ because there is insufficient steam pressure to perform the test. Note 2 states that the SR is not required to be met in MODE 4. ~~[~~In MODE 4, the required pump is already operating and the autostart function is not required~~.] [In MODE 4,~~ the heat removal requirements would be less providing more time for operator action to manually start the required AFW pump.~~]~~

acceptable

and if a pump is not already operating

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Some plants may not routinely use the AFW for heat removal in MODE 4. The second justification is provided for plants that use a startup feedwater pump rather than AFW for startup and shutdown.~~

3

SR 3.7.5.5

This SR ensures that the AFW System is properly aligned by verifying the flow path to each steam generator prior to entering MODE 2 operation, after 30 days in any combination of MODE 5 or 6, or defueled. OPERABILITY of AFW flow paths must be verified before sufficient core heat is generated that would require the operation of the AFW System during a subsequent shutdown. The Frequency is reasonable, based on engineering judgment, and other administrative controls to ensure that flow paths remain OPERABLE. To further ensure AFW System alignment, the OPERABILITY of the flow paths is verified following extended outages to determine that no misalignment of valves has occurred. This SR ensures that the flow path from the CST to the steam generators is properly aligned by requiring a verification of minimum flow capacity of 275 ~~750~~ gpm at 1000 psia ~~1270 psi~~. ~~(This SR is not required by those units that use AFW for normal startup and shutdown.)~~

A02

DISCUSSION OF CHANGES
ITS 3.7.6, CONDENSATE STORAGE TANK (CST)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 2 Only**: CTS 4.7.1.3 states, in part, that the CST shall be demonstrated OPERABLE when the tank is the supply source for the auxiliary feedwater pumps. ITS SR 3.7.6.1 states that the CST level must be verified to be within the specified limit. This changes the CTS by not stating that the Surveillance must be performed when the CST is the supply source for the auxiliary feedwater pumps.

The purpose of CTS 4.7.1.3 is to ensure the CST is OPERABLE when it is the supply source for the auxiliary feedwater pumps. Surveillance requirements are not required to be performed on inoperable equipment. ITS SR 3.0.1 states "Surveillances do not have to be performed on inoperable equipment or variables outside specified limits." If the CST is not capable of supplying the auxiliary feedwater pumps, the CST is inoperable because it can no longer provide its required support function. Furthermore, since inoperable equipment does not have to be tested, the removal of the phrase "when the tank is the supply source for the auxiliary feedwater pumps" is acceptable. This change is designated as administrative because it does not result in technical changes to the CTS and includes revising the action end state consistent with the Applicability change.

MORE RESTRICTIVE CHANGES

M01 CTS 3.7.1.3 requirements for CST OPERABILITY are applicable in MODES 1, 2, and 3. ITS 3.7.6 is applicable in MODES 1. 2, and 3, and MODE 4 when a steam generator (SG) is relied upon for heat removal. In addition, consistent with this change in Applicability, the requirement to be in “COLD SHUTDOWN within the following 30 hours” is changed to “MODE 4 without reliance on steam generator for heat removal within 12 hours” in ITS 3.7.6 Required Action B.2. This changes the CTS requirements by requiring the CST to be OPERABLE in MODE 4 when a steam generator is relied upon for heat removal and includes revising the action end state consistent with the Applicability change.

These changes are necessary because the CST may be needed in MODE 4 if shutdown cooling (SDC) has not been placed in service. If offsite power is lost when SDC is not yet in service, the SGs are supplied by the auxiliary feedwater pumps for heat removal. Therefore, the CST must be available in MODE 4 to support the Auxiliary Feedwater System. This change is designated as more restrictive because the CST is now required to be OPERABLE in MODE 4 when a SG is relied upon for heat removal.

DISCUSSION OF CHANGES
ITS 3.7.6, CONDENSATE STORAGE TANK (CST)

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* CTS 3.7.1.3 ACTION allows four hours to restore the CST to OPERABLE status or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. ITS 3.7.6 Required Action A.1 requires the verification of an OPERABLE backup water supply within 4 hours and once per 12 hours thereafter and Required Action A.2 requires the CST to be restored to OPERABLE status within 7 days. This changes the CTS by extending the Completion Time in the CTS 3.7.1.3 ACTION to restore the CST to OPERABLE status from 4 hours to 7 days provided the backup water supply is verified OPERABLE within 4 hours and every 12 hours thereafter.

The purpose of CTS 3.7.1.3 ACTION is to provide compensatory actions for when the CST is found to be inoperable. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to degraded conditions to minimize risk associated with continued operation while providing time to repair inoperable features and the low probability of an event requiring the use of the water from the CST occurring during this period. The backup supply to the Unit 1 CST is the Unit 2 CST and the backup supply to the Unit 2 CST is the primary water and city water storage tanks. The Completion Time to restore the CST to OPERABLE status considers that the backup supply may be performing this function in addition to its normal functions. Verification of a backup water supply with periodic re-verification provides adequate assurance that the CTS volume analysis assumptions are satisfied and continued operation is justified for the 7 day allowed restoration period. In addition, the opportunity to restore the equipment to OPERABLE status is always available. ITS LCO 3.0.2 states that upon discovery of a failure to meet an LCO, the Required Actions of the associated Conditions shall be met. If the LCO is met or is no longer applicable prior to expiration of the specified Completion Time(s), completion of the Required Action(s) is not required unless otherwise stated. Therefore, based on ITS LCO 3.0.2 restoration is always an option. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.6, CONDENSATE STORAGE TANK (CST)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed, and the proper plant information/value is inserted to reflect the current licensing basis.

3. Improved Standard Technical Specifications (ISTS) Required Action A.1 requires verification of the OPERABILITY of a backup water supply. As discussed in NEI 18-03, the industry's OPERABILITY guidance, "OPERABILITY" only applies to SSCs that a TS LCO requires to be OPERABLE. Therefore, the OPERABILITY has been changed to that availability of the backup water supply must be verified. R1

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.6 Condensate Storage Tank (CST)

BASES

BACKGROUND

The CST provides a ~~safety grade~~ qualified source of water to the steam generators for removing decay and sensible heat from the Reactor Coolant System (RCS). The CST provides a passive flow of water, by gravity, to the Auxiliary Feedwater (AFW) System (LCO 3.7.4, "Auxiliary Feedwater (AFW) System"). The steam produced is released to the atmosphere by the main steam safety valves (MSSVs) or the atmospheric dump valves (ADVs). The AFW pumps operate with a continuous recirculation to the CST.

When the main steam isolation valves are open, the preferred means of heat removal is to discharge steam to the condenser by the nonsafety grade path of the steam bypass valves. The condensed steam ~~is~~ may be returned to the CST via the condensate ~~by transfer pump~~ System. ~~This has the advantage of conserving condensate while minimizing releases to the environment.~~

Because the CST is a principal component in removing residual heat from the RCS, it is designed to withstand earthquakes and other natural phenomena. The CST is designed to Seismic Category I requirements to ensure availability of the feedwater supply. Feedwater is also available from ~~an alternate source~~ the Unit 2 CST and enclosed by a vertical concrete missile barrier.

A description of the CST is found in the U FSAR, Section ~~[~~9.2.~~6]~~ 8 (Ref. 1).

APPLICABLE SAFETY ANALYSES

The CST provides cooling water to remove decay heat and to cool down the unit following all events in the accident analysis, discussed in the U FSAR, Chapters ~~[~~6~~]~~ and ~~[~~15~~]~~ (Refs. 2 and 3, respectively). For anticipated operational occurrences and accidents which do not affect the OPERABILITY of the steam generators, the analysis assumption is ~~generally [30] minutes~~ 1 hour at MODE 3, steaming through the ~~MSSVs~~ ADVs followed by a cooldown to shutdown cooling (SDC) entry conditions at the ~~design~~ cooldown rate of 75°F/hr.

The limiting event for the condensate volume is the large feedwater line break with a coincident loss of offsite power. Single failures that also affect this event include the following:

a. The failure of the diesel generator powering the motor driven AFW pump to the unaffected steam generator (requiring additional steam to drive the remaining AFW pump turbine) and

BASES

APPLICABLE SAFETY ANALYSES (continued)

b. The failure of the steam driven AFW pump (requiring a longer time for cooldown using only one motor driven AFW pump).

These are not usually the limiting failures in terms of consequences for these events.

~~A nonlimiting event considered in CST inventory determinations is a break either in the main feedwater, or AFW line near where the two join. This break has the potential for dumping condensate until terminated by operator action, as the Emergency Feedwater Actuation System would not detect a difference in pressure between the steam generators for this break location. This loss of condensate inventory is partially compensated by the retaining of steam generator inventory.~~ 1

design requirements and

The CST satisfies Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

8 hours

100.3

To satisfy accident analysis assumptions, the CST must contain sufficient cooling water to remove decay heat for ~~[30 minutes]~~ following a reactor trip from ~~102~~% RTP, and ~~then~~ cool down the RCS to SDC entry conditions, assuming a coincident loss of offsite power and the most adverse single failure. In doing this it must retain sufficient water to ensure adequate net positive suction head for the AFW pumps during the cooldown, as well as to account for any losses from the steam driven AFW pump turbine, or before isolating AFW to a broken line. 2

The CTS volume minimum of 153,400 gallons includes an unusable volume of 12,055 gallons and an additional margin of 10,845 gallons. In addition, the Unit 2 CTS is required to maintain a dedicated backup volume of ≥ 130,500 gallons available for Unit 1 use if the Unit 1 CST is made inoperable due to a vertical missile.

volume

equivalent to

≥ 130,500

1

The CST ~~level~~ required is a usable volume of ~~≤ [350,000]~~ gallons, which is based on holding the unit in MODE 3 for ~~[4]~~ hour~~s~~, followed by a cooldown to SDC entry conditions at 75°F per hour. This ~~basis is established by the NRC Standard Review Plan Branch Technical Position, Reactor Systems Branch 5-1 (Ref. 4) and~~ exceeds the volume required by the accident analysis. 2 1

OPERABILITY of the CST is determined by maintaining the tank ~~level~~ at or above the minimum required ~~level~~. 1

APPLICABILITY

In MODES 1, 2, and 3, ~~[~~and in MODE 4, when steam generator is being relied upon for heat removal,~~]~~ the CST is required to be OPERABLE. 2

In MODES 5 and 6, the CST is not required because the AFW System is not required.

BASES

ACTIONS

A.1 and A.2

availability

If the CST is not OPERABLE, the ~~OPERABILITY~~ of the backup water supply must be verified by administrative means within 4 hours and once every 12 hours thereafter. 4 R1

Availability

~~OPERABILITY~~ of the backup ~~feedwater~~ supply must include verification of the ~~OPERABILITY of flow paths from the backup supply to the AFW pumps, and availability of the~~ required volume of water in the backup supply. The CST must be returned to OPERABLE status within 7 days, as the backup supply may be performing this function in addition to its normal functions. The 4 hour Completion Time is reasonable, based on operating experience, to verify the OPERABILITY of the backup water supply. Additionally, verifying the backup water supply every 12 hours is adequate to ensure the backup water supply continues to be available. The 7 day Completion Time is reasonable, based on a~~n OPERABLE~~ backup water supply being available, and the low probability of an event requiring the use of the water from the CST occurring during this period. 4 R1 1

(Unit 2 CST volume ≥ 130,500 gallons)

B.1 and B.2

If the CST cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4, without reliance on steam generator for heat removal, within ~~[24]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. 2

BASES

qualified

BACKGROUND

The CST provides a ~~safety grade~~ source of water to the steam generators for removing decay and sensible heat from the Reactor Coolant System (RCS). The CST provides a passive flow of water, by gravity, to the Auxiliary Feedwater (AFW) System (LCO 3.7.4, "Auxiliary Feedwater (AFW) System"). The steam produced is released to the atmosphere by the main steam safety valves (MSSVs) or the atmospheric dump valves (ADVs). The AFW pumps operate with a continuous recirculation to the CST. 1

When the main steam isolation valves are open, the preferred means of heat removal is to discharge steam to the condenser by the nonsafety grade path of the steam bypass valves. The condensed steam ~~is~~ may be returned to the CST via the condensate ~~transfer pump~~ System. ~~This has the advantage of conserving condensate while minimizing releases to the environment.~~ 1

Because the CST is a principal component in removing residual heat from the RCS, it is designed to withstand earthquakes and other natural phenomena. The CST is designed to Seismic Category I requirements and enclosed by a vertical concrete missile barrier to ensure availability of the feedwater supply. Feedwater is also available from ~~an~~ alternate sources; primary water and city water storage tanks provide an alternate source of makeup water to the CST. 1

A description of the CST is found in the U FSAR, Section ~~[~~9.2.6~~]~~ (Ref. 1). 2

APPLICABLE SAFETY ANALYSES

The CST provides cooling water to remove decay heat and to cool down the unit following all events in the accident analysis, discussed in the FSAR, Chapters ~~[~~6~~]~~ and ~~[~~15~~]~~ (Refs. 2 and 3, respectively). For U anticipated operational occurrences and accidents which do not affect the OPERABILITY of the steam generators, the analysis assumption is 4 hours ~~generally [30] minutes~~ at MODE 3, steaming through the ~~MSSVs~~ ADVs followed by a cooldown to shutdown cooling (SDC) entry conditions at the ~~design~~ cooldown rate of 75°F/hr and equates to 154,000 gallons. 2

The limiting event for the condensate volume is the loss of one DC emergency train ~~large feedwater line break~~ with a coincident loss of offsite power. Single failures that also affect this event include the following: 1

a. The failure of the diesel generator powering the motor driven AFW pump to the unaffected steam generator (requiring additional steam to drive the remaining AFW pump turbine) and

BASES

APPLICABLE SAFETY ANALYSES (continued)

b. The failure of the steam driven AFW pump (requiring a longer time for cooldown using only one motor driven AFW pump).

These are not usually the limiting failures in terms of consequences for these events.

~~A nonlimiting event considered in CST inventory determinations is a break either in the main feedwater, or AFW line near where the two join. This break has the potential for dumping condensate until terminated by operator action, as the Emergency Feedwater Actuation System would not detect a difference in pressure between the steam generators for this break location. This loss of condensate inventory is partially compensated by the retaining of steam generator inventory.~~ 1

DISCUSSION OF CHANGES
ITS 3.7.7, COMPONENT COOLING WATER (CCW) SYSTEM

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 4.7.3.1.a and Unit 2 4.7.3.a do not contain an explicit reference to isolating CCW flow to individual components. ITS SR 3.7.7.1 contains a Note which states, "Isolation of CCW flow to individual components does not render the CCW System inoperable." This changes CTS by adding an allowance that is not explicitly stated in the CTS. The purpose of the CCW System Technical Specification is to provide assurance that CCW is available to the appropriate plant components. This change is acceptable because by current use and application of the CTS, isolation of a component supplied with CCW does not necessarily result in the CCW System being considered inoperable, but the respective component may be declared inoperable for its system. This change clarifies this application. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 Unit 1 CTS 4.7.3.1.a and Unit 2 CTS 4.7.3.a require verification that each CCW valve (manual, power operated, or automatic) servicing safety related equipment that is not locked, sealed, or otherwise secured in position, is in its correct position. ITS SR 3.7.7.1 requires verification that each CCW manual, power operated, and automatic valve “in the flow path” servicing safety related equipment that is not locked, sealed, or otherwise secured in position, is in the correct position.

Unit 1 CTS 4.7.3.1.b and Unit 2 CTS 4.7.3.b require verification that each CCW automatic valve servicing safety related equipment actuates to its correct position on a safety injection actuation signal. ITS SR 3.7.7.2 requires verification that each CCW automatic valve “in the flow path” servicing safety related equipment that is not locked, sealed, or otherwise secured in position, actuates to the correct position on an actuation signal. This changes the CTS by adding the words "in the flow path" to Unit 1 CTS 4.7.3.1.a and Unit 2 CTS 4.7.3.a, and to Unit 1 CTS 4.7.3.1.b and Unit 2 CTS 4.7.3.b.

The purpose of Unit 1 CTS 4.7.3.1.a and Unit 2 CTS 4.7.3.a is to ensure all valves in the CCW System flow path are in the correct position. The purpose of Unit 1 CTS 4.7.3.1.b and Unit 2 CTS 4.7.3.b is to ensure all automatic valves in the CCW System flow path actuate to the correct position on an actual or simulated actuation signal. The addition of the words "in the flow path" does not change the intent of the Surveillance Requirements. Each manual, power operated, and automatic valve servicing safety related equipment that is not locked, sealed, or otherwise secured in position will continue to be verified to be in the correct position. Each CCW automatic valve in the flow path that is not

locked, sealed or otherwise secured in position, will still be checked to ensure it actuates to the correct position on an actual or simulated actuation signal. This change is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 4.7.3.1 and Unit 2 CTS 4.7.3 do not contain a requirement to verify each CCW System pump starts automatically on an actuation signal. ITS SR 3.7.7.3 states; "Verify each CCW pump starts automatically on an actual or simulated actuation signal," with a Frequency specified in accordance with the Surveillance Frequency Control Program. This changes the CTS by adding a Surveillance Requirement to test the CCW System pumps.

This change is necessary because in order for the CCW System to perform the safety function assumed in the accident analysis, the CCW pumps must start automatically. The CCW System is a normally operating system that cannot be fully actuated as part of the normal testing during normal operation. Therefore, the SR periodically verifies proper automatic operation of the pumps on an actual or simulated actuation signal. This Surveillance is similar to the testing requirements for other safety related pumps. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, SR 3.7.7.3 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months consistent with the ISTS SR 3.7.7.3 and is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. This change is designated as more restrictive because it adds a new SR.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.7.3.1 and Unit 2 CTS 3.7.3 state that two "independent" CCW loops shall be OPERABLE. ITS 3.7.7 requires two CCW loops to be OPERABLE but does not contain the detail that the loops must be independent. This changes the CTS by moving the detail that the CCW loops are independent to the Bases. The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for two CCW loops to be OPERABLE. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification

Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 4.7.3.1.b and Unit 2 CTS 4.7.3.b require verification of the automatic actuation of CCW components on a safety injection actuation signal (SIAS). ITS SR 3.7.7.2 does not state the specific type of signal, but only specifies an actual or simulated "actuation" signal. This changes CTS by moving the type of actuation signal (i.e., SIAS) to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement to verify that appropriate equipment actuates upon receipt of an actuation signal. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5 of the ITS. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Specification.

LESS RESTRICTIVE CHANGES

L01 *(Category 6- Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.7.3.1.b and Unit 2 CTS 4.7.3.b require verification of the automatic actuation of component cooling water components on a safety injection actuation signal (SIAS) "test" signal. ITS SR 3.7.7.2 specifies that the signal may be from either an "actual" or simulated (i.e., test) signal. This changes the CTS by explicitly allowing the use of either an actual or simulated signal for the test.

The purpose of Unit 1 CTS 4.7.3.1.b and Unit 2 CTS 4.7.3.b is to ensure the CCW components operate correctly upon receipt of an actuation signal. This change is acceptable because the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual," "simulated," or "test" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L02 *(Category 5 - Deletion of Surveillance Requirement)* Unit 1 CTS 4.7.3.1.b and Unit 2 CTS 4.7.3.b require verification that each CCW automatic valve in the flow path actuates to its correct position. ITS SR 3.7.7.2 requires verification that

each CCW automatic valve in the flow path "that is not locked, sealed, or otherwise secured in position" actuates to the correct position. This changes the CTS by excluding those valves that are locked, sealed, or otherwise secured in position from the verification.

The purpose of Unit 1 CTS 4.7.3.1.b and Unit 2 CTS 4.7.3.b is to provide assurance that if an event occurred requiring CCW valves to be in their correct position, then those requiring automatic actuation would actuate to their correct position. This change is acceptable because the deleted Surveillance is not necessary to verify that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested to in a manner and at a Frequency necessary to provide confidence that the equipment can perform its assumed safety function. Those automatic valves that are locked, sealed, or otherwise secured in position are not required to actuate on a safety injection actuation signal in order to perform their safety function because they are already in the required position. Testing such valves would not provide any additional assurance of OPERABILITY. Valves that are required to actuate will continue to be tested. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L03 **Unit 2 only:** *(Category 5 - Deletion of Surveillance Requirement)* CTS 3.7.3 note requires verification that when CCW pump 2C is being used to satisfy the requirements of this specification, the alignment of the discharge valves shall be verified to be consistent with the appropriate power supply at least once per 24 hours. ITS 3.7.7 does not require this specific verification. This changes the CTS by deleting the specific verification of valve and power supply alignment when the swing CCW pump is being used.

The purpose of the CTS 3.7.3 Note is to ensure that when the swing CCW pump (Pump 2C) is used to satisfy the requirements, the proper valve and power supply alignment is verified periodically. The PSL CCW System design includes three pumps: each pump provides flow to a redundant CCW loop. These two pumps are powered from the associated essential bus. The third swing pump can be powered from either essential bus and the discharge valves can be aligned to either CCW loop. When used to support CCW loop OPERABILITY, the swing pump power and valves must be aligned to the correct CCW loop. The Surveillances retained in ITS will continue to ensure the valves and breakers are properly aligned when the swing pump is being used. ITS SR 3.7.7.1 requires verification that the valves that are not locked sealed or otherwise secured in position (i.e., accident position) are in the correct position. This includes verifying the discharge valves of the swing pump are in their correct position to support CCW loop OPERABILITY. In addition, there is an alarm that annunciates in the control room in the event the discharge valves to the swing pump are not aligned to the same loop as the pump breaker is aligned. ITS SR 3.7.7.3 requires verification that the required pump automatically starts on an actual or simulated actuation signal. This test ensures the swing pump is powered from the correct essential bus by verifying the pump can automatically start on the selected CCW loop. The Frequency in accordance with the Surveillance Frequency Control Program (i.e., 31 days for the valve position verification and 18 months for the automatic pump start) has been determined a sufficient periodicity for verification

of required equipment. This change is acceptable because the deleted Surveillance Requirement is not necessary to ensure that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to give confidence that the equipment can perform its assumed safety function. This change is designated as less restrictive because a Surveillance which is required in the CTS will not be required in the ITS

L04 **Unit 2 only:** *(Category 3 – Relaxation of Completion Time)* CTS 3.7.3 note requires verification that upon receipt of annunciation for improper alignment of the pump 2C motor power in relation to any of its motor-operated discharge valves positions, restore proper system alignment within 2 hours. ITS SR 3.7.7 does not require this specific action. This changes the CTS by deleting the action to restore proper alignment of the swing CCW pump.

The purpose of the CTS 3.7.3 Note is to ensure that when the swing CCW pump (Pump 2C) is used to satisfy the requirements and the valve and power supply to the swing pump are not aligned, action is required to restore the alignment. The PSL CCW System design includes three pumps: two pumps each provide flow to a redundant CCW loop. These two pumps are powered from the associated essential bus. The third swing pump can be powered from either essential bus and the discharge valves can be aligned to either CCW loop. When used to support CCW loop OPERABILITY the swing pump power and valves must be aligned to the correct CCW loop. The ACTIONS retained in ITS will continue to ensure the appropriate remedial actions are taken when the swing pump is used to support CCW loop OPERABILITY. When a CCW loop is inoperable, ITS 3.7.7 ACTION A requires the CCW loop to be restored to OPERABLE status within 72 hours or in accordance with the Risk Informed Completion Time Program. This action would include restoring the swing pump valve and power alignment when the swing pump is used to support OPERABILITY of the CCW loop. When the swing pump is not used to support OPERABILITY of a CCW loop, the requirement to restore alignment is not a required remedial action to restore the LCO as defined in 10 CFR 50.36(c)(2)(i). Therefore, the note is unnecessary. The ITS 3.7.7 ACTION A (CTS 3.7.3 Action) Completion Time has been determined sufficient to restore the CCW loop to OPERABLE status. This change is acceptable because the Completion Time of ITS 3.7.7 ACTION A is consistent with safe operation under the specified Condition, the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of a DBA occurring during the allowed Completion Time. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.7, COMPONENT COOLING WATER (CCW) SYSTEM

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Since Condition B applies to all Conditions in the ACTIONS Table, the term "of Condition A" is not necessary. This is consistent with the Writer's Guide for the Improved Standard Technical Specifications, TSTF-GG-05-01, Section 4.1.6.i.5.ii.

4. The PSL design includes a spare CCW pump that can be substituted for one of the normal CCW pumps. Therefore SR 3.7.7.3 has been modified to only require the "required" CCW pumps to be tested. This is consistent with the use of the word required in the ITS, as discussed in the Writer's Guide for the Improved Standard Technical Specifications, TSTF-GG-05-01, Section 4.1.3.b.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.7 Component Cooling Water (CCW) System

The surge tank is divided internally into two separate compartments. Each compartment serves one of the CCW loops.

BASES

BACKGROUND

The CCW System provides a heat sink for the removal of process and operating heat from safety related components during a Design Basis Accident (DBA) or transient. During normal operation, the CCW System also provides this function for various nonessential components, as well as the spent fuel pool. The CCW System serves as a barrier to the release of radioactive byproducts between potentially radioactive systems and the ~~Service~~ Water System, and thus to the environment.

Intake Cooling

loop

The CCW System is arranged as two independent full capacity cooling loops, and has isolatable nonsafety related components. Each safety related ~~train~~ includes a full capacity pump, surge tank, heat exchanger, piping, valves, ~~and~~ instrumentation. Each safety related ~~train~~ is powered from a separate bus. An open surge tank in the system ~~provides pump trip protective functions~~ to ensure sufficient net positive suction head is available. The pump in each ~~train~~ is automatically started on receipt of a safety injection actuation signal, and all nonessential components are isolated.

, and a common

loop

is equipped with a low level alarm that annunciates in the control room

Three CCW pumps are provided. A pump can be removed from service without reducing the capability or redundancy of the CCW System. Two of the CCW pumps are powered from the associated essential bus. The third CCW pump can be powered from either essential bus.

loop

U

Additional information on the design and operation of the system, along with a list of the components served, is presented in the FSAR, Section ~~[~~9.2.2~~]~~, Reference 1. The principal safety related function of the CCW System is the removal of decay heat from the reactor via the Shutdown Cooling (SDC) System heat exchanger. This may utilize the ~~SCS~~ heat exchanger, during a normal or post accident cooldown and shutdown, or the Containment Spray System during the recirculation phase following a loss of coolant accident (LOCA).

SDC

loop

APPLICABLE SAFETY ANALYSES

The design basis of the CCW System is for one CCW ~~train~~ in conjunction with a 100% capacity Containment Cooling System (containment spray, containment coolers, or a combination) removing core decay heat 20 minutes after a design basis LOCA. This prevents the containment sump fluid from increasing in temperature during the recirculation phase following a LOCA, and provides a gradual reduction in the temperature of this fluid as it is supplied to the Reactor Coolant System (RCS) by the safety injection pumps.

The CCW System is designed to perform its function with a single failure of any active component, assuming a loss of offsite power.

325

The CCW System also functions to cool the unit from SDC entry conditions (T_{cold} < ~~[~~350~~]~~°F) to MODE 5 (T_{cold} < ~~[~~200~~]~~°F) during normal and post accident operations. The time required to cool from ~~[350]~~°F to

325

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~[~~200~~]~~°F is a function of the number of CCW and SDC ~~trains~~ operating. One CCW ~~train~~ is sufficient to remove decay heat during subsequent operations with T_{cold} < ~~[~~200~~]~~°F. This assumes that a maximum seawater temperature of ~~76~~°F occurs simultaneously with the maximum heat loads on the system.

The CCW System satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The CCW ~~trains~~ are independent of each other to the degree that each has separate controls and power supplies and the operation of one does not depend on the other. In the event of a DBA, one CCW ~~train~~ is required to provide the minimum heat removal capability assumed in the safety analysis for the systems to which it supplies cooling water. To ensure this requirement is met, two CCW ~~trains~~ must be OPERABLE. At least one CCW ~~train~~ will operate assuming the worst single active failure occurs coincident with the loss of offsite power.

A CCW ~~train~~ is considered OPERABLE when the following:

a. The associated pump and surge tank are OPERABLE and

b. The associated piping, valves, heat exchanger and instrumentation and controls required to perform the safety related function are OPERABLE.

The spare CCW pump can be substituted for a normal CCW pump, provided the spare CCW valves are aligned to the applicable loop and the power supply for the spare pump is aligned to the same essential bus as the pump it is replacing.

The isolation of CCW from other components or systems not required for safety may render ~~those~~ components or systems inoperable, but does not affect the OPERABILITY of the CCW System.

APPLICABILITY

In MODES 1, 2, 3, and 4, the CCW System is a normally operating system that must be prepared to perform its post accident safety functions, primarily RCS heat removal by cooling the SDC heat exchanger.

Although the LCO for the CCW System is not applicable in MODES 5 and 6, the capability of the CCW System to perform its necessary related support functions may be required for OPERABILITY of supported systems.

ACTIONS

A.1

Required Action A.1 is modified by a Note indicating the requirement of entry into the applicable Conditions and Required Actions of LCO 3.4.6, "RCS Loops - MODE 4," for SDC made inoperable by CCW. This is an exception to LCO 3.0.6 and ensures the proper actions are taken for these components.

BASES

ACTIONS (continued)

With one CCW ~~train~~ inoperable, action must be taken to restore OPERABLE status within 72 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. In this Condition, the remaining OPERABLE CCW ~~train~~ is adequate to perform the heat removal function. The 72 hour Completion Time is based on the redundant capabilities afforded by the OPERABLE ~~train~~, and the low probability of a DBA occurring during this period.

B.1 and B.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

If the CCW ~~train~~ cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which overall plant risk is minimized. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 2). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. If CCW flow is lost to the reactor coolant pump (RCP) seals, entering MODE 5 and lowering the RCS temperature should be considered in order to avoid possible damage to the RCP seal materials.

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable,

BASES

ACTIONS (continued)

because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.7.1

Verifying the correct alignment for manual, power operated, and automatic valves in the CCW flow path provides assurance that the proper flow paths exist for CCW operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these valves are verified to be in the correct position prior to locking, sealing, or securing. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves. This Surveillance does not require any testing or valve manipulation; rather, it involves verification that those valves capable of potentially being mispositioned are in their correct position.

This SR is modified by a Note indicating that the isolation of the CCW components or systems may render those components inoperable but does not affect the OPERABILITY of the CCW System.

~~[The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.7.7.2

This SR verifies proper automatic operation of the CCW valves on an actual or simulated actuation signal. The CCW System is a normally operating system that cannot be fully actuated as part of routine testing during normal operation. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. ~~[The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~----------]~~

SR 3.7.7.3

This SR verifies proper automatic operation of the CCW pumps on an actual or simulated actuation signal. The CCW System is a normally operating system that cannot be fully actuated as part of routine testing during normal operation. ~~[The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

The principal safety related function of the CCW System is the removal of decay heat from the reactor via the Shutdown Cooling (SDC) System heat exchanger. This may utilize the ~~SCS~~ heat exchanger, during a normal or post accident cooldown and shutdown, or the Containment Spray System during the recirculation phase following a loss of coolant accident (LOCA).

SDC

APPLICABLE SAFETY ANALYSES

loop

The design basis of the CCW System is for one CCW ~~train~~ in conjunction with a 100% capacity Containment Cooling System (containment spray, containment coolers, or a combination) removing core decay heat 20 minutes after a design basis LOCA. This prevents the containment sump fluid from increasing in temperature during the recirculation phase following a LOCA, and provides a gradual reduction in the temperature of this fluid as it is supplied to the Reactor Coolant System (RCS) by the safety injection pumps.

The CCW System is designed to perform its function with a single failure of any active component, assuming a loss of offsite power.

325

The CCW System also functions to cool the unit from SDC entry conditions (T_{cold} < ~~[~~350~~]~~°F) to MODE 5 (T_{cold} < ~~[~~200~~]~~°F) during normal and post accident operations. The time required to cool from ~~[350]~~°F to

325

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~[~~200~~]~~°F is a function of the number of CCW and SDC ~~trains~~ operating. One CCW ~~train~~ is sufficient to remove decay heat during subsequent operations with T_{cold} < ~~[~~200~~]~~°F. This assumes that a maximum seawater temperature of ~~76~~°F occurs simultaneously with the maximum heat loads on the system.

The CCW System satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The CCW ~~trains~~ are independent of each other to the degree that each has separate controls and power supplies and the operation of one does not depend on the other. In the event of a DBA, one CCW ~~train~~ is required to provide the minimum heat removal capability assumed in the safety analysis for the systems to which it supplies cooling water. To ensure this requirement is met, two CCW ~~trains~~ must be OPERABLE. At least one CCW ~~train~~ will operate assuming the worst single active failure occurs coincident with the loss of offsite power.

A CCW ~~train~~ is considered OPERABLE when the following:

a. The associated pump and surge tank are OPERABLE and

b. The associated piping, valves, heat exchanger and instrumentation and controls required to perform the safety related function are OPERABLE.

The spare CCW pump can be substituted for a normal CCW pump, provided the spare CCW valves are aligned to the applicable loop and the power supply for the spare pump is aligned to the same essential bus as the pump it is replacing.

The isolation of CCW from other components or systems not required for safety may render ~~those~~ components or systems inoperable, but does not affect the OPERABILITY of the CCW System.

APPLICABILITY

In MODES 1, 2, 3, and 4, the CCW System is a normally operating system that must be prepared to perform its post accident safety functions, primarily RCS heat removal by cooling the SDC heat exchanger.

Although the LCO for the CCW System is not applicable in MODES 5 and 6, the capability of the CCW System to perform its necessary related support functions may be required for OPERABILITY of supported systems.

ACTIONS

A.1

Required Action A.1 is modified by a Note indicating the requirement of entry into the applicable Conditions and Required Actions of LCO 3.4.6, "RCS Loops - MODE 4," for SDC made inoperable by CCW. This is an exception to LCO 3.0.6 and ensures the proper actions are taken for these components.

BASES

ACTIONS (continued)

With one CCW ~~train~~ inoperable, action must be taken to restore OPERABLE status within 72 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. In this Condition, the remaining OPERABLE CCW ~~train~~ is adequate to perform the heat removal function. The 72 hour Completion Time is based on the redundant capabilities afforded by the OPERABLE ~~train~~, and the low probability of a DBA occurring during this period.

B.1 and B.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

If the CCW ~~train~~ cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which overall plant risk is minimized. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 2). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. If CCW flow is lost to the reactor coolant pump (RCP) seals, entering MODE 5 and lowering the RCS temperature should be considered in order to avoid possible damage to the RCP seal materials.

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable,

BASES

ACTIONS (continued)

because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.7.1

Verifying the correct alignment for manual, power operated, and automatic valves in the CCW flow path provides assurance that the proper flow paths exist for CCW operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these valves are verified to be in the correct position prior to locking, sealing, or securing. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves. This Surveillance does not require any testing or valve manipulation; rather, it involves verification that those valves capable of potentially being mispositioned are in their correct position.

This SR is modified by a Note indicating that the isolation of the CCW components or systems may render those components inoperable but does not affect the OPERABILITY of the CCW System.

~~[The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.~~ 2

~~OR~~

~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.7.7.2

This SR verifies proper automatic operation of the CCW valves on an actual or simulated actuation signal. The CCW System is a normally operating system that cannot be fully actuated as part of routine testing during normal operation. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. ~~[The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

DISCUSSION OF CHANGES
ITS 3.7.8, INTAKE COOLING WATER (ICW) SYSTEM

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 4.7.4.1.a and Unit 2 4.7.4.a do not contain an explicit reference to isolating ICW flow to individual components. ITS SR 3.7.8.1 contains a Note which states, "Isolation of ICW flow to individual components does not render the ICW System inoperable." This changes CTS by adding an allowance that is not explicitly stated in the CTS. The purpose of the ICW System Technical Specification is to provide assurance that ICW is available to the appropriate plant components. This change is acceptable because by current use and application of the CTS, isolation of a component supplied with ICW does not necessarily result in the ICW System being considered inoperable, but the respective component may be declared inoperable for its system. This change clarifies this application. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 Unit 1 CTS 4.7.4.1.a and Unit 2 CTS 4.7.4.a require verification that each ICW valve (manual, power operated, or automatic) servicing safety related equipment that is not locked, sealed, or otherwise secured in position, is in its correct position. ITS SR 3.7.8.1 requires verification that each ICW manual, power operated, and automatic valve “in the flow path” servicing safety related equipment that is not locked, sealed, or otherwise secured in position, is in the correct position.

Unit 1 CTS 4.7.4.1.b and Unit 2 CTS 4.7.4.b require verification that each ICW automatic valve servicing safety related equipment actuates to it correct position on a safety injection actuation signal. ITS SR 3.7.8.2 requires verification that each ICW automatic valve “in the flow path” servicing safety related equipment that is not locked, sealed, or otherwise secured in position, actuates to its correct position on an actuation signal. This changes the CTS by adding the words "in the flow path" to Unit 1 CTS 4.7.4.1.a and Unit 2 CTS 4.7.4.a, and to Unit 1 CTS 4.7.4.1.b and Unit 2 CTS 4.7.4.b.

The purpose of Unit 1 CTS 4.7.4.1.a and Unit 2 CTS 4.7.4.a is to ensure all valves in the ICW System flow path are in the correct position. The purpose of Unit 1 CTS 4.7.4.1.b and Unit 2 CTS 4.7.4.b is to ensure all automatic valves in the ICW System flow path actuate to the correct position on an actual or simulated actuation signal. The addition of the words "in the flow path" does not change the intent of the Surveillance Requirements. Each ICW manual, power operated, and automatic valve servicing safety related equipment that is not locked, sealed, or otherwise secured in position will continue to be verified to be in the correct position. Each ICW automatic valve in the flow path that is not

locked, sealed or otherwise secured in position, will still be checked to ensure it actuates to the correct position on an actual or simulated actuation signal. This change is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 4.7.4.1 and Unit 2 CTS 4.7.4 do not contain a requirement to verify each ICW System pump starts automatically on an actuation signal. ITS SR 3.7.8.3 states; "Verify each ICW pump starts automatically on an actual or simulated actuation signal," with a Frequency specified in accordance with the Surveillance Frequency Control Program. This changes the CTS by adding a Surveillance Requirement to test the ICW System pumps.

This change is necessary because in order for the ICW System to perform the safety function assumed in the accident analysis, the ICW pumps must start automatically. The ICW System is a normally operating system that cannot be fully actuated as part of the normal testing during normal operation. Therefore, the SR periodically verifies proper automatic operation of the pumps on an actual or simulated actuation signal. This Surveillance is similar to the testing requirements for other safety related pumps. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, SR 3.7.8.3 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months consistent with the ISTS SR 3.7.8.3 and is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. This change is designated as more restrictive because it adds a new SR.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.7.4.1 and Unit 2 CTS 3.7.4 states that two "independent" ICW loops shall be OPERABLE. ITS 3.7.8 requires two ICW loops to be OPERABLE but does not contain the detail that the loops must be independent. This changes the CTS by moving the detail that the ICW loops are independent to the Bases. The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for two ICW loops to be OPERABLE. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of

changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 4.7.4.1.b and Unit 2 CTS 4.7.4.b require verification of the automatic actuation of ICW components on a safety injection actuation signal (SIAS). ITS SR 3.7.8.2 does not state the specific type of signal, but only specifies an actual or simulated "actuation" signal. This changes CTS by moving the type of actuation signal (i.e., SIAS) to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement to verify that appropriate equipment actuates upon receipt of an actuation signal. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5 of the ITS. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Specification.

LESS RESTRICTIVE CHANGES

L01 *(Category 6- Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.7.4.1.b and Unit 2 CTS 4.7.4.b require verification of the automatic actuation of intake cooling water components on a safety injection actuation signal (SIAS) "test" signal. ITS SR 3.7.8.2 specifies that the signal may be from either an "actual" or simulated (i.e., test) signal. This changes the CTS by explicitly allowing the use of either an actual or simulated signal for the test.

The purpose of Unit 1 CTS 4.7.4.1.b and Unit 2 CTS 4.7.4.b is to ensure the ICW components operate correctly upon receipt of an actuation signal. This change is acceptable because the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual," "simulated," or "test" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L02 *(Category 5 - Deletion of Surveillance Requirement)* Unit 1 CTS 4.7.4.1.b and Unit 2 CTS 4.7.4.b require verification that each ICW automatic valve in the flow path actuates to its correct position. ITS SR 3.7.8.2 requires verification that each ICW automatic valve in the flow path "that is not locked, sealed, or

otherwise secured in position" actuates to the correct position. This changes the CTS by excluding those valves that are locked, sealed, or otherwise secured in position from the verification.

The purpose of Unit 1 CTS 4.7.4.1.b and Unit 2 CTS 4.7.4.b is to provide assurance that if an event occurred requiring ICW valves to be in their correct position, then those requiring automatic actuation would actuate to their correct position. This change is acceptable because the deleted Surveillance is not necessary to verify that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested to in a manner and at a Frequency necessary to provide confidence that the equipment can perform its assumed safety function. Those automatic valves that are locked, sealed, or otherwise secured in position are not required to actuate on a safety injection actuation signal in order to perform their safety function because they are already in the required position. Testing such valves would not provide any additional assurance of OPERABILITY. Valves that are required to actuate will continue to be tested. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L03 **Unit 2 only:** *(Category 5 - Deletion of Surveillance Requirement)* CTS 3.7.4 note requires verification that when ICW pump 2C is being used to satisfy the requirements of this specification, the alignment of the discharge valves must be verified to be consistent with the appropriate power supply at least once per 24 hours. ITS 3.7.8 does not require this specific verification. This changes the CTS by deleting the specific verification of valve and power supply alignment when the swing ICW pump is being used.

The purpose of the CTS 3.7.4 Note is to ensure that when the swing ICW pump (Pump 2C) is used to satisfy the requirements, the proper valve and power supply alignment is verified periodically. The PSL ICW System design includes three pumps: each pump provides flow to a redundant ICW loop. These two pumps are powered from the associated essential bus. The third swing pump can be powered from either essential bus and the discharge valves can be aligned to either ICW loop. When used to support ICW loop OPERABILITY, the swing pump power and valves must be aligned to the correct ICW loop. The Surveillances retained in ITS will continue to ensure the valves and breakers are properly aligned when the swing pump is being used. ITS SR 3.7.8.1 requires verification that the valves that are not locked sealed or otherwise secured in position (i.e., accident position) are in the correct position. This includes verifying the discharge valves of the swing pump are in their correct position to support ICW loop OPERABILITY. ITS SR 3.7.8.3 requires verification that the required pump automatically starts on an actual or simulated actuation signal. This test ensures the swing pump is powered from the correct essential bus by verifying the pump can automatically start on the selected ICW loop. The Frequency in accordance with the Surveillance Frequency Control Program (i.e., 31 days for the valve position verification and 18 months for the automatic pump start) has been determined a sufficient periodicity for verification of required equipment. This change is acceptable because the deleted Surveillance Requirement is not necessary to ensure that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a

manner and at a Frequency necessary to give confidence that the equipment can perform its assumed safety function. This change is designated as less restrictive because a Surveillance which is required in the CTS will not be required in the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.8, INTAKE COOLING WATER (ICW) SYSTEM

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. PSL Unit 1 and Unit 2 diesel generators are designed with a self-contained cooling system and do not depend on any support plant cooling water system. Therefore, Note 1 to ISTS 3.7.8 is unnecessary and deleted. Concomitant changes made to reflect the Note deletion.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.8 ~~Service Water System (SWS)~~ Intake Cooling Water (ICW) System

BASES

BACKGROUND

The ~~SWS~~ provides a heat sink for the removal of process and operating heat from safety related components during a Design Basis Accident (DBA) or transient. During normal operation or a normal shutdown, the ~~SWS~~ also provides this function for various safety related and nonsafety related components. The safety related function is covered by this LCO.

The ~~SWS~~ consists of two ~~separate~~, 100% capacity safety related cooling water ~~trains~~. Each ~~train~~ consists of ~~two~~ 100% capacity pump~~s~~, one component cooling water (CCW) heat exchanger, piping, valves, instrumentation, and ~~two cyclone separators~~. The pumps and valves are remote manually aligned, except in the unlikely event of a loss of coolant accident (LOCA). The pumps aligned to the critical loops are automatically started upon receipt of a safety injection actuation signal and all essential valves are aligned to their post accident positions. ~~The SWS also provides emergency makeup to the spent fuel pool and CCW System [and is the backup water supply to the Auxiliary Feedwater System]~~.

Additional information about the design and operation of the ~~SWS~~, along with a list of the components served, is presented in the FSAR, Section ~~[~~9.2.1~~]~~ (Ref. 1). The principal safety related function of the ~~SWS~~ is the removal of decay heat from the reactor via the ~~[~~CCW System~~]~~.

APPLICABLE SAFETY ANALYSES

The design basis of the ~~SWS~~ is for one ~~SWS train~~, in conjunction with the CCW System and a 100% capacity containment cooling system (containment spray, containment coolers, or a combination), removing core decay heat 20 minutes following a design basis LOCA, as discussed in the FSAR, Section ~~[~~6.2~~]~~ (Ref. 2). This prevents the containment sump fluid from increasing in temperature during the recirculation phase following a LOCA and provides for a gradual reduction in the temperature of this fluid as it is supplied to the Reactor Coolant System by the safety injection pumps. The ~~SWS~~ is designed to perform its function with a single failure of any active component, assuming the loss of offsite power.

The ~~SWS~~, in conjunction with the CCW System, also cools the unit from shutdown cooling (SDC), as discussed in the FSAR, Section ~~[5.4.7]~~ (Ref. 3) entry conditions to MODE 5 during normal and post accident operations. The time required for this evolution is a function of the

ICW System
ICW System
Three ICW pumps are provided. A pump can be removed from service without reducing the capability or redundancy of the ICW System. Two of the ICW pumps are powered from the associated essential bus. The third ICW pump can be powered from either essential bus.

All nonessential components are isolated. ICW flows through a Debris Filter System (DFS) at the inlet of each CCW heat exchanger. The DFS backwash automatically through a debris discharge valve and reenter the ICW System downstream of the ICW discharge valves. Automatic backwashing is not a safety-related function. During a DBA, the debris discharge valve is signaled to close by the safety injection actuation signal to prevent flow diversion past the heat exchanger.

1
2
1

BASES

APPLICABLE SAFETY ANALYSES (continued)

number of CCW and SDC System trains that are operating. One ~~SWS train~~ is sufficient to remove decay heat during subsequent operations in MODES 5 and 6. This assumes that a maximum ~~SWS~~ temperature of 95°F occurring simultaneously with maximum heat loads on the system.

The ~~SWS~~ satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Two ~~SWS trains~~ are required to be OPERABLE to provide the required redundancy to ensure that the system functions to remove post accident heat loads, assuming the worst single active failure occurs coincident with the loss of offsite power.

An ~~SWS train~~ is considered OPERABLE when:

a. The associated pump is OPERABLE and

b. The associated piping, valves, heat exchanger, and instrumentation and controls required to perform the safety related function are OPERABLE.

The spare ICW pump can be substituted for a normal ICW pump, provided the spare ICW valves are aligned to the applicable loop and the power supply for the spare pump is aligned to the same essential bus as the pump it is replacing.

APPLICABILITY

In MODES 1, 2, 3, and 4, the ~~SWS~~ System is a normally operating system, which is required to support the OPERABILITY of the equipment serviced by the ~~SWS~~ and required to be OPERABLE in these MODES.

Although the LCO for the ~~SWS~~ is not applicable in MODES 5 and 6, the capability of the ~~SWS~~ to perform its necessary related support functions may be required for OPERABILITY of supported systems.

ACTIONS

A.1

With one ~~SSW train~~ inoperable, action must be taken to restore OPERABLE status within 72 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. In this Condition, the remaining OPERABLE ~~SWS train~~ is adequate to perform the heat removal function. However, the overall reliability is reduced because a single failure in the ~~SWS train~~ could result in loss of ~~SWS~~ function. Required Action A.1 is modified by ~~two~~ Note~~s~~. ~~The first Note indicates that the applicable Conditions of LCO 3.8.1, "AC Sources - Operating," should be entered if the inoperable SWS train results in an inoperable emergency diesel generator.~~ The ~~second~~ Note indicates that the applicable Conditions and Required Actions of LCO 3.4.6, "RCS Loops - MODE 4," should be entered if an inoperable ~~SWS train~~ results in an inoperable SDC. The 72 hour Completion Time is based on the redundant capabilities afforded by the OPERABLE ~~train~~, and the low probability of a DBA occurring during this time period.

BASES

ACTIONS (continued)

B.1 and B.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

2

ICW loop

If the ~~SWS train~~ cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which overall plant risk is minimized. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 4 within 12 hours.

1

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 4). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.7.8.1

Verifying the correct alignment for manual, power operated, and automatic valves in the ~~SWS~~ flow path ensures that the proper flow paths exist for ~~SWS~~ operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since they are verified to be in the correct position prior to locking, sealing, or securing. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves. This Surveillance does not require any testing or valve manipulation; rather, it involves verification that those valves capable of potentially being mispositioned are in the correct position. This SR is modified by a Note indicating that the isolation of the ~~SWS~~ components or systems may render those components inoperable but does not affect the OPERABILITY of the ~~SWS~~.

B 3.7 PLANT SYSTEMS

B 3.7.8 ~~Service Water System (SWS)~~ Intake Cooling Water (ICW)

BASES

BACKGROUND

The ~~SWS~~ provides a heat sink for the removal of process and operating heat from safety related components during a Design Basis Accident (DBA) or transient. During normal operation or a normal shutdown, the ~~SWS~~ also provides this function for various safety related and nonsafety related components. The safety related function is covered by this LCO.

The ~~SWS~~ consists of two ~~separate~~, 100% capacity safety related cooling water ~~trains~~. Each ~~train~~ consists of ~~two~~ 100% capacity pump~~s~~, one component cooling water (CCW) heat exchanger, piping, valves, instrumentation, and ~~two cyclone separators~~. The pumps and valves are remote manually aligned, except in the unlikely event of a loss of coolant accident (LOCA). The pumps aligned to the critical loops are automatically started upon receipt of a safety injection actuation signal and all essential valves are aligned to their post accident positions. ~~The SWS also provides emergency makeup to the spent fuel pool and CCW System [and is the backup water supply to the Auxiliary Feedwater System]~~.

Additional information about the design and operation of the ~~SWS~~, along with a list of the components served, is presented in the FSAR, Section ~~[~~9.2.1~~]~~ (Ref. 1). The principal safety related function of the ~~SWS~~ is the removal of decay heat from the reactor via the ~~[~~CCW System~~]~~.

APPLICABLE SAFETY ANALYSES

The design basis of the ~~SWS~~ is for one ~~SWS train~~, in conjunction with the CCW System and a 100% capacity containment cooling system (containment spray, containment coolers, or a combination), removing core decay heat 20 minutes following a design basis LOCA, as discussed in the FSAR, Section ~~[~~6.2~~]~~ (Ref. 2). This prevents the containment sump fluid from increasing in temperature during the recirculation phase following a LOCA and provides for a gradual reduction in the temperature of this fluid as it is supplied to the Reactor Coolant System by the safety injection pumps. The ~~SWS~~ is designed to perform its function with a single failure of any active component, assuming the loss of offsite power.

The ~~SWS~~, in conjunction with the CCW System, also cools the unit from shutdown cooling (SDC), as discussed in the FSAR, Section ~~[5.4.7]~~ (Ref. 3) entry conditions to MODE 5 during normal and post accident operations. The time required for this evolution is a function of the

Three ICW pumps are provided. A pump can be removed from service without reducing the capability or redundancy of the ICW System. Two of the ICW pumps are powered from the associated essential bus. The third ICW pump can be powered from either essential bus.

All nonessential components are isolated. ICW flows through a Debris Filter System (DFS) at the inlet of each CCW heat exchanger. The DFS backwash automatically through a debris discharge valve and reenter the ICW System downstream of the ICW discharge valves. Automatic backwashing is not a safety-related function. During a DBA, the debris discharge valve is signaled to close by the safety injection actuation signal to prevent flow diversion past the heat exchanger.

BASES

APPLICABLE SAFETY ANALYSES (continued)

number of CCW and SDC System trains that are operating. One ~~SWS train~~ is sufficient to remove decay heat during subsequent operations in MODES 5 and 6. This assumes that a maximum ~~SWS~~ temperature of 95°F occurring simultaneously with maximum heat loads on the system.

The ~~SWS~~ satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Two ~~SWS trains~~ are required to be OPERABLE to provide the required redundancy to ensure that the system functions to remove post accident heat loads, assuming the worst single active failure occurs coincident with the loss of offsite power.

An ~~SWS train~~ is considered OPERABLE when:

a. The associated pump is OPERABLE and

b. The associated piping, valves, heat exchanger, and instrumentation and controls required to perform the safety related function are OPERABLE.

The spare ICW pump can be substituted for a normal ICW pump, provided the spare ICW valves are aligned to the applicable loop and the power supply for the spare pump is aligned to the same essential bus as the pump it is replacing.

APPLICABILITY

In MODES 1, 2, 3, and 4, the ~~SWS~~ System is a normally operating system, which is required to support the OPERABILITY of the equipment serviced by the ~~SWS~~ and required to be OPERABLE in these MODES.

Although the LCO for the ~~SWS~~ is not applicable in MODES 5 and 6, the capability of the ~~SWS~~ to perform its necessary related support functions may be required for OPERABILITY of supported systems.

ACTIONS

A.1

With one ~~SSW train~~ inoperable, action must be taken to restore OPERABLE status within 72 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. In this Condition, the remaining OPERABLE ~~SWS train~~ is adequate to perform the heat removal function. However, the overall reliability is reduced because a single failure in the ~~SWS train~~ could result in loss of ~~SWS~~ function. Required Action A.1 is modified by ~~two~~ Note~~s~~. ~~The first Note indicates that the applicable Conditions of LCO 3.8.1, "AC Sources - Operating," should be entered if the inoperable SWS train results in an inoperable emergency diesel generator.~~ The ~~second~~ Note indicates that the applicable Conditions and Required Actions of LCO 3.4.6, "RCS Loops - MODE 4," should be entered if an inoperable ~~SWS train~~ results in an inoperable SDC. The 72 hour Completion Time is based on the redundant capabilities afforded by the OPERABLE ~~train~~, and the low probability of a DBA occurring during this time period.

BASES

ACTIONS (continued)

B.1 and B.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

2

ICW loop

If the ~~SWS train~~ cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which overall plant risk is minimized. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 4 within 12 hours.

1

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 4). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.8, BASES, INTAKE COOLING WATER (ICW) SYSTEM

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. PSL Unit 1 and Unit 2 diesel generators are designed with a self-contained cooling system and do not depend on any support plant cooling water system. Therefore, Note 1 to ISTS 3.7.8 is unnecessary and deleted. Concomitant changes made to reflect the Note deletion.

DISCUSSION OF CHANGES
ITS 3.7.9, ULTIMATE HEAT SINK (UHS)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.7.5.1 does not provide any actions when the UHS water level is not OPERABLE, and either action is not completed within its completion time. Therefore, CTS 3.0.3 would be entered requiring entry into HOT STANDBY (MODE 3) within 7 hours and COLD SHUTDOWN (MODE 5) within 37 hours. ITS 3.7.9 ACTION B, which applies when the UHS in inoperable (i.e., water level is not within limit) and a Required Action and associated Completion Time is not met, requires entry into COLD SHUTDOWN (MODE 5) within 36 hours. ITS 3.7.9, Required Action A.1 required entry into MODE 3 within 6 hours, therefore, this requirement is not repeated in ACTION B. This changes the CTS by providing one less hour to shut down the unit to MODE 5 when the UHS water level is inoperable, and a Required Action and associated Completion Time is not met.

The purpose of requiring a shutdown when Required Action A.1 or Required Action A.2 is not completed within its associated Completion Time, is to place the unit in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in MODE 5 within 36 hours. This change is acceptable because it provides an adequate period of time to be in a MODE in which the requirement does not apply, commensurate with the severity of the inoperability. The Completion Time of 36 hours is reasonable, based on operating experience, for reaching MODE 5, from full power in an orderly manner and without challenging unit systems. The action to be in MODE 3 within 6 hours is provided in ACTION A. This change has been designated as more restrictive because it reduces the Completion Times to be in MODE 5.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.7.5.1.a states that the ultimate heat sink (UHS) shall be OPERABLE with cooling water from the Atlantic Ocean providing a water level above –10.5 feet elevation, Mean Low Water, at the plant intake structure. ITS

3.7.9 states that the UHS shall be OPERABLE. This changes the CTS by removing design details of the UHS water source (i.e., Atlantic Ocean, and plant intake structure from which UHS water level is determined).

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement that the UHS be OPERABLE and requires verification of the UHS water level at the Frequency specified in the Surveillance Frequency Control Program. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 4 - Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAPM, IST Program, or ISI Program)* CTS 3.7.5.1.b requires two OPERABLE isolation valves in the barrier dam between Big Mud Creek and the intake structure. CTS 3.7.5.1 Action b provides actions with one isolation valve in the barrier dam inoperable. CTS 3.7.5.1 Action c provides actions with both isolation valves in the barrier dam inoperable. Additionally, CTS 4.7.5.1.2 demonstrates the isolation valves are OPERABLE by cycling each valve through at least one complete cycle of full travel. These LCO, Action and Surveillance requirements are not included in the ITS. This changes the CTS by moving the explicit ultimate heat sink barrier dam valve requirements from the Technical Specifications to the Technical Requirements Manual (TRM).

The removal of these details from the Technical Specification is acceptable because this type of information is not necessary to provide adequate protection of public health and safety. The purpose of the valves in the barrier dam between Big Mud Creek and the intake structure is to provide an alternate intake structure fill system to support safe shutdown in the event the primary method of filling the intake structure (i.e., Atlantic Ocean) becomes unavailable following a design basis seismic event. These valves are not credited in the mitigation of any design basis accident or transient specified in Chapter 15 of the UFSAR.

This change is acceptable because the LCO requirements continue to ensure that the primary source of water to the ultimate heat sink (UHS) is OPERABLE consistent with the safety analyses and licensing basis. The UHS requirements associated with the valves in the barrier dam between Big Mud Creek and the intake structure are not part of a primary success path in the mitigation of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier. Additionally, these requirements are not discussed in the PSL probabilistic risk assessment and do not constitute a structure, system, or component which operating experience or probabilistic risk assessment has shown to be significant to public health and safety. Therefore, these CTS requirements do not meet the applicable 10 CFR 50.36(c)(2)(ii) criteria for retention in the Technical Specifications.

Also, this change is acceptable because the removed information will be adequately controlled in the TRM. Changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because a requirement is being removed from the Technical Specifications. | R1

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* CTS 3.7.5.1 Applicability is "at all times." ITS LCO 3.7.9 Applicability is MODES 1, 2, 3, and 4. This changes the CTS by only requiring the UHS to be OPERABLE in MODES 1, 2, 3, and 4.

The purpose of the CTS 3.7.5.1 Applicability is to specify the MODES and other specified conditions in which the LCO must be met. This change is acceptable because the requirements continue to ensure the UHS is maintained OPERABLE in the MODES assumed in the safety analyses and licensing basis. In MODES 1, 2, 3, and 4, the UHS is a normally operating system that is required to support the OPERABILITY of the equipment serviced by the UHS and required to be OPERABLE in these MODES. Although the LCO for the UHS is not applicable in MODES 5 and 6, the capability of the UHS to perform its necessary related support functions may be required for OPERABILITY of supported systems. UHS support requirements for systems required in MODES 5 and 6 are not the same as for the systems required in MODES 1, 2, 3, and 4 and the heat load requirements in the shutdown MODES is less. Therefore, the definition of OPERABILITY will ensure the UHS requirements necessary to support systems required in MODES 5 and 6 will not be impacted. This change is designated as less restrictive because the LCO requirements are applicable in fewer operating conditions than in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.9, ULTIMATE HEAT SINK (UHS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS ACTIONS numbering.

4. The PSL UHS design does not include cooling towers, therefore, ISTS 3.7.9 ACTION A and ISTS SR 3.7.9.3 are deleted.

5. ISTS 3.7.9 ACTION D (ITS ACTION B) is added to be in MODE 5 within 36 hours with the Required Action and associated Completion Time (i.e., of ITS Condition A) not met. The ISTS Required Action D.1 to be in MODE 3 within 6 hours is not included in the ITS because ITS 3.7.9, Required Action A.1 requires the unit to be in MODE 3 within 6 hours if the UHS is inoperable. See CTS Discussion of Change M01 for the discussion regarding the addition of ITS 3.7.9 ACTION B.

6. The PSL Current Technical Specifications do not include UHS water temperature. The ICW System was designed to remove the post-accident heat load from the CCW system, based on seawater temperature determined from historical data and Atlantic Ocean temperature surveys. To assure the operability of the CCW system, the maximum design seawater (ICW) inlet temperature is 95°F. Historical data and Atlantic Ocean temperature studies show maximum Atlantic Ocean seawater temperature at 87°F and represents ambient conditions at the St Lucie Plant in the Environmental Report. Therefore, ISTS 3.7.9 ACTION C and ISTS SR 3.7.9.2 are not included in the ITS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.9 Ultimate Heat Sink (UHS)

BASES

BACKGROUND

The UHS provides a heat sink for process and operating heat from safety related components during a Design Basis Accident (DBA) or transient, as well as during normal operation. This is done utilizing the ~~Service Water~~ System.

Intake Cooling Water (ICW)

1

Insert 1

~~The UHS has been defined as that complex of water sources, including necessary retaining structures (e.g., a pond with its dam, or a river with its dam), and the canals or conduits connecting the sources with, but not including, the cooling water system intake structures as, discussed in the FSAR, Section [9.2.5] (Ref. 1). If cooling towers or portions thereof are required to accomplish the UHS safety functions, they should meet the same requirements as the sink.~~ The two principal functions of the UHS are the dissipation of residual heat after reactor shutdown, and dissipation of residual heat after an accident.

1

~~A variety of complexes is used to meet the requirements for a UHS. A lake or an ocean may qualify as a single source. If the complex includes a water source contained by a structure, it is likely that a second source will be required.~~

1

The basic performance requirements are that a 30 day supply of water be available, and that the design basis temperatures of safety related equipment not be exceeded. ~~Basins of cooling towers generally include less than a 30 day supply of water, typically 7 days or less. A 30 day supply would be dependent on another source(s) and a makeup system(s) for replenishing the source in the cooling tower basin. For smaller basin sources, which may be as small as a 1 day supply, the systems for replenishing the basin and the backup source(s) become of sufficient importance that the makeup system itself may be required to meet the same design criteria as an Engineered Safety Feature (e.g., single failure considerations, and multiple makeup water sources may be required).~~

1

~~It follows that the many variations in the UHS configurations will result in many unit to unit variations in OPERABILITY determinations and SRs. The ACTIONS and SRs are illustrative of a cooling tower UHS without a makeup requirement.~~

1

Additional information on the design and operation of the system along with a list of components served can be found in Reference 1.

1

INSERT 1

The UHS supplies water to the ICW System to perform its intended function, as discussed in the UFSAR, Section 9.2.7 (Ref. 1). There are two independent water sources and a discharge canal for the UHS. The primary water source is the Atlantic Ocean through the intake canal. This water source is used for all plant normal and accident conditions. The second source (backup supply) is Big Mud Creek which is fed by the Indian River (ultimately the Atlantic Ocean). The backup supply is utilized in the event the intake canal is rendered unable to supply sufficient water, as indicated by UHS intake level, due to a safe shutdown earthquake. Regardless of source, the cooling water is discharged into the discharge canal and flows through the discharge canal to the Atlantic Ocean. To ensure a supply of water for safe shutdown or accident conditions following a design basis seismic event, the backup supply water flow from Big Mud Creek is initiated from either unit's control room whenever the intake canal level falls below -10.5 feet. The minimum required intake canal level provides adequate margin above the minimum level for continued operation of the ICW pumps.

BASES

APPLICABLE SAFETY ANALYSES

The UHS is the sink for heat removed from the reactor core following all accidents and anticipated operational occurrences in which the unit is cooled down and placed on shutdown cooling. ~~For those units using it as the normal heat sink for condenser cooling via the Circulating Water System, unit operation at full power is its maximum heat load. Its maximum post accident heat load occurs 20 minutes after a design basis loss of coolant accident (LOCA). Near this time, the unit switches from injection to recirculation, and the containment cooling systems are required to remove the core decay heat.~~ 1

The operating limits are based on conservative heat transfer analyses for the worst case LOCA. Reference 1 provides the details of the assumptions used in the analysis. ~~The assumptions include: worst expected meteorological conditions, conservative uncertainties when calculating decay heat, and the worst case failure (e.g., single failure of a manmade structure).~~ 1 The UHS is designed in accordance with Regulatory Guide 1.27 (Ref. 2), which requires a 30 day supply of cooling water in the UHS.

The UHS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The UHS is required to be OPERABLE. The UHS is considered OPERABLE if it contains a sufficient volume of water ~~at or below the maximum temperature~~ that would allow the ~~SWS~~ ICW System to operate for at least 30 days following the design basis LOCA without the loss of net positive suction head (NPSH), and without exceeding the maximum design temperature of the equipment served by the ~~SWS~~ ICW System. To meet this condition, the UHS ~~temperature should not exceed [90]°F and the~~ level should not fall below ~~[562 ft mean sea~~ -10.5 feet mean low water ~~level]~~ during normal unit operation. 1 R1 1 R1 2

APPLICABILITY

In MODES 1, 2, 3, and 4, the UHS is a normally operating system that is required to support the OPERABILITY of the equipment serviced by the UHS and required to be OPERABLE in these MODES.

Although the LCO for the UHS is not applicable in MODES 5 and 6, the capability of the UHS to perform its necessary related support functions may be required for OPERABILITY of supported systems.

ACTIONS

~~[A.1~~

~~If one or more cooling towers have one fan inoperable (i.e., at least one fan per cooling tower is OPERABLE), action must be taken to restore the inoperable cooling tower fan(s) to OPERABLE status within 7 days [or in accordance with the Risk Informed Completion Time Program].~~ 4

BASES

ACTIONS (continued)

~~The 7 day Completion Time is reasonable, based on the low probability of an accident occurring during the 7 days that one cooling tower fan is inoperable, the number of available systems, and the time required to complete the action.]~~ 4

A A

~~B~~.1 and ~~B~~.2 1

Insert 2

~~----------REVIEWER'S NOTE----------~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

~~----------~~

~~If the cooling tower fan cannot be restored to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to MODE 3 within 6 hours and to MODE 4 within 12 hours.~~

~~Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 3). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.~~

~~Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and~~

1

INSERT 2

With the UHS inoperable, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to MODE 3 and the backup cooling water supply must be aligned to the intake canal. Risk in MODE 3 is minimized by providing makeup from a backup water source to the intake canal. This action ensures the backup supply is aligned to restore cooling water for the ICW pumps if the primary supply cannot be restored to within limit. Also, there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms in MODES 3 and 4 than in MODE 5. Voluntary entry into MODE 4 or 5 may be made as these MODES are also acceptable low-risk states. Required Action A.2 is provided to supply cooling water from the backup water supply within 18 hours. The Completion Time for Required Action A.2 allows the operator time to evaluate and repair any discovered inoperabilities while providing adequate time to align the backup supply to the intake canal. If the backup water supply cannot be established within the required Completion Time, Condition B must be entered.

BASES

ACTIONS (continued)

establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power in an orderly manner and without challenging plant systems.

[C.1

REVIEWER'S NOTE

The [ ]°F is the maximum allowed UHS temperature value and is based on temperature limitations of the equipment that is relied upon for accident mitigation and safe shutdown of the unit.

With water temperature of the UHS > [90]°F, the design basis assumption associated with initial UHS temperature are bounded provided the temperature of the UHS averaged over the previous 24 hour period is ≤ [90]°F. With the water temperature of the UHS > [90]°F, long term cooling capability of the ECCS loads and DGs may be affected. Therefore, to ensure long term cooling capability is provided to the ECCS loads when water temperature of the UHS is > [90]°F, Required Action C.1 is provided to more frequently monitor the water temperature of the UHS and verify the temperature is ≤ [90]°F when averaged over the previous 24 hour period. The once per hour Completion Time takes into consideration UHS temperature variations and the increased monitoring frequency needed to ensure design basis assumptions and equipment limitations are not exceeded in this condition. If the water temperature of the UHS exceeds [90]°F when averaged over the previous 24 hour period or the water temperature of the UHS exceeds [ ]°F, Condition D must be entered immediately.] 5

B

[D.1 and D.2 3

A are

If the Required Actions or Completion Times of Condition C is not met, or the UHS is inoperable [for reasons other than Condition A or C], the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.] 2 1

B 3.7 PLANT SYSTEMS

B 3.7.9 Ultimate Heat Sink (UHS)

BASES

BACKGROUND

The UHS provides a heat sink for process and operating heat from safety related components during a Design Basis Accident (DBA) or transient, as well as during normal operation. This is done utilizing the ~~Service Water~~ System.

Intake Cooling Water (ICW)

1

Insert 1

~~The UHS has been defined as that complex of water sources, including necessary retaining structures (e.g., a pond with its dam, or a river with its dam), and the canals or conduits connecting the sources with, but not including, the cooling water system intake structures as, discussed in the FSAR, Section [9.2.5] (Ref. 1). If cooling towers or portions thereof are required to accomplish the UHS safety functions, they should meet the same requirements as the sink.~~ The two principal functions of the UHS are the dissipation of residual heat after reactor shutdown, and dissipation of residual heat after an accident.

1

~~A variety of complexes is used to meet the requirements for a UHS. A lake or an ocean may qualify as a single source. If the complex includes a water source contained by a structure, it is likely that a second source will be required.~~

1

The basic performance requirements are that a 30 day supply of water be available, and that the design basis temperatures of safety related equipment not be exceeded. ~~Basins of cooling towers generally include less than a 30 day supply of water, typically 7 days or less. A 30 day supply would be dependent on another source(s) and a makeup system(s) for replenishing the source in the cooling tower basin. For smaller basin sources, which may be as small as a 1 day supply, the systems for replenishing the basin and the backup source(s) become of sufficient importance that the makeup system itself may be required to meet the same design criteria as an Engineered Safety Feature (e.g., single failure considerations, and multiple makeup water sources may be required).~~

1

~~It follows that the many variations in the UHS configurations will result in many unit to unit variations in OPERABILITY determinations and SRs. The ACTIONS and SRs are illustrative of a cooling tower UHS without a makeup requirement.~~

1

Additional information on the design and operation of the system along with a list of components served can be found in Reference 1.

1

1

INSERT 1

The UHS supplies water to the ICW System to perform its intended function, as discussed in the UFSAR, Section 9.2.5 (Ref. 1). There are two independent water sources and a discharge canal for the UHS. The primary water source is the Atlantic Ocean through the intake canal. This water source is used for all plant normal and accident conditions. The second source (backup supply) is Big Mud Creek which is fed by the Indian River (ultimately the Atlantic Ocean). The backup supply is utilized in the event the intake canal is rendered unable to supply sufficient water, as indicated by UHS intake level, due to a safe shutdown earthquake. Regardless of source, the cooling water is discharged into the discharge canal and flows through the discharge canal to the Atlantic Ocean. To ensure a supply of water for safe shutdown or accident conditions following a design basis seismic event, the backup supply water flow from Big Mud Creek is initiated from either unit's control room whenever the intake canal level falls below -10.5 feet. The minimum required intake canal level provides adequate margin above the minimum level for continued operation of the ICW pumps.

BASES

APPLICABLE SAFETY ANALYSES

The UHS is the sink for heat removed from the reactor core following all accidents and anticipated operational occurrences in which the unit is cooled down and placed on shutdown cooling. ~~For those units using it as the normal heat sink for condenser cooling via the Circulating Water System, unit operation at full power is its maximum heat load. Its maximum post accident heat load occurs 20 minutes after a design basis loss of coolant accident (LOCA). Near this time, the unit switches from injection to recirculation, and the containment cooling systems are required to remove the core decay heat.~~ 1

The operating limits are based on conservative heat transfer analyses for the worst case LOCA. Reference 1 provides the details of the assumptions used in the analysis. ~~The assumptions include: worst expected meteorological conditions, conservative uncertainties when calculating decay heat, and the worst case failure (e.g., single failure of a manmade structure).~~ 1 The UHS is designed in accordance with Regulatory Guide 1.27 (Ref. 2), which requires a 30 day supply of cooling water in the UHS.

The UHS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The UHS is required to be OPERABLE. The UHS is considered OPERABLE if it contains a sufficient volume of water ~~at or below the maximum temperature~~ that would allow the ~~SWS~~ ICW System to operate for at least 30 days following the design basis LOCA without the loss of net positive suction head (NPSH), and without exceeding the maximum design temperature of the equipment served by the ~~SWS~~ ICW System. To meet this condition, the UHS ~~temperature should not exceed [90]°F and the~~ level should not fall below ~~[562 ft mean sea~~ -10.5 feet mean low water level~~]~~ during normal unit operation. 1 R1 1 R1 2

APPLICABILITY

In MODES 1, 2, 3, and 4, the UHS is a normally operating system that is required to support the OPERABILITY of the equipment serviced by the UHS and required to be OPERABLE in these MODES.

Although the LCO for the UHS is not applicable in MODES 5 and 6, the capability of the UHS to perform its necessary related support functions may be required for OPERABILITY of supported systems.

ACTIONS

~~[A.1~~

~~If one or more cooling towers have one fan inoperable (i.e., at least one fan per cooling tower is OPERABLE), action must be taken to restore the inoperable cooling tower fan(s) to OPERABLE status within 7 days [or in accordance with the Risk Informed Completion Time Program].~~ 4

BASES

ACTIONS (continued)

~~The 7 day Completion Time is reasonable, based on the low probability of an accident occurring during the 7 days that one cooling tower fan is inoperable, the number of available systems, and the time required to complete the action.]~~ 4

A A

~~B~~.1 and ~~B~~.2 1

Insert 2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

~~If the cooling tower fan cannot be restored to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to MODE 3 within 6 hours and to MODE 4 within 12 hours.~~

~~Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 3). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.~~

~~Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and~~

1

INSERT 2

With the UHS inoperable, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to MODE 3 and the backup cooling water supply must be aligned to the intake canal. Risk in MODE 3 is minimized by providing makeup from a backup water source to the intake canal. This action ensures the backup supply is aligned to restore cooling water for the ICW pumps if the primary supply cannot be restored to within limit. Also, there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms in MODES 3 and 4 than in MODE 5. Voluntary entry into MODE 4 or 5 may be made as these MODES are also acceptable low-risk states. Required Action A.2 is provided to supply cooling water from the backup water supply within 18 hours. The Completion Time for Required Action A.2 allows the operator time to evaluate and repair any discovered inoperabilities while providing adequate time to align the backup supply to the intake canal. If the backup water supply cannot be established within the required Completion Time, Condition B must be entered.

BASES

ACTIONS (continued)

establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power in an orderly manner and without challenging plant systems.

[C.1

REVIEWER'S NOTE

The [ ]°F is the maximum allowed UHS temperature value and is based on temperature limitations of the equipment that is relied upon for accident mitigation and safe shutdown of the unit.

With water temperature of the UHS > [90]°F, the design basis assumption associated with initial UHS temperature are bounded provided the temperature of the UHS averaged over the previous 24 hour period is ≤ [90]°F. With the water temperature of the UHS > [90]°F, long term cooling capability of the ECCS loads and DGs may be affected. Therefore, to ensure long term cooling capability is provided to the ECCS loads when water temperature of the UHS is > [90]°F, Required Action C.1 is provided to more frequently monitor the water temperature of the UHS and verify the temperature is ≤ [90]°F when averaged over the previous 24 hour period. The once per hour Completion Time takes into consideration UHS temperature variations and the increased monitoring frequency needed to ensure design basis assumptions and equipment limitations are not exceeded in this condition. If the water temperature of the UHS exceeds [90]°F when averaged over the previous 24 hour period or the water temperature of the UHS exceeds [ ]°F, Condition D must be entered immediately.] 5

B

[D.1 and D.2 3

A are

If the Required Actions or Completion Times of Condition C is not met, or the UHS is inoperable [for reasons other than Condition A or C], the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.] 2 1

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.9, BASES, ULTIMATE HEAT SINK (UHS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS ACTIONS numbering.

4. The PSL UHS design does not include cooling towers, therefore, ISTS 3.7.9 Bases ACTION A.1 discussion and ISTS SR 3.7.9.3 discussion are not included in the ITS Bases.

5. ITS 3.7.9 does not include UHS water temperature, therefore, ISTS 3.7.9 Bases ACTION C and ISTS SR 3.7.9.2 are not included in the ITS Bases.

DISCUSSION OF CHANGES
ITS 3.7.10, CONTROL ROOM EMERGENCY VENTILATION SYSTEM (CREVS)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.7.7.1 and Unit 2 CTS 3.7.7 provide requirements for the Control Room Emergency Ventilation System (CREVS) and include requirements for control room air conditioning. ITS 3.7.10, “Control Room Emergency Ventilation System (CREVS),” provides requirements for the control room filtration function and ITS 3.7.11, “Control Room Air Conditioning System (CRACS),” provides requirements for the control room cooling function. This changes the CTS by separating the CREVS and CRACS requirements into separate Specifications based on function.

Although CREVS and CRACS are subsystems within the Control Room Ventilation System and utilize some of the same components and ductwork, these systems provide two separate and distinct safety functions. Therefore, the ITS presentation allows the filtration and cooling functions to be addressed separately. This presentation change is consistent with the ISTS and is designated as administrative because it does not result in technical changes to the CTS. Any technical changes associated with the current CREVS and CRACS requirements are provided in the Discussion of Changes (DOCs) associated with that Specification.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 Only**: CTS 3.7.7.1 Action c (MODES 1, 2, 3, and 4) provide remedial actions when the filter train is inoperable for reasons other than an inoperable control room envelop boundary, including a time to restore the filter train within 24 hours. ITS 3.7.10 ACTION C requires similar actions when two CREVS trains are inoperable (e.g., the common filter train inoperable) in MODE 1, 2, 3, or 4 for reasons other than Condition B (i.e., inoperable control room envelop boundary) and includes a Note that does not allow these actions when a second CREVS train is intentionally made inoperable. This changes the CTS related to an inoperable filter train to only allow the actions when the filter train is discovered inoperable and not allow these actions if the single filter train is removed from service intentionally.

The purpose of the CTS actions is to allow a short period of time to restore the CREVS to OPERABLE status during the condition with no OPERABLE control room filter trains. However, this allowance is intended to only be used if the loss of filter function was unintentional. Voluntary removal of the filter safety function is not allowed, as indicated in the Note to CTS 3.7.7.1 Action e. The PSL Unit 1

CREVS design includes two redundant trains of active equipment and a single filter unit that is common to both CREVS trains. Therefore, when the filter unit is inoperable, both CREVS trains are inoperable and the control room filter safety function cannot be performed. Therefore, the CTS 3.7.7.1 Action c and Action e are combined in ITS 3.7.10 ACTION C and include the Note that does not allow these actions when a second CREVS train is intentionally made inoperable. This change will preclude the common filter unit from intentionally being removed from service that would result in a voluntarily removal of a required safety function. This change is designated as more restrictive because it adds a restriction that CTS does not have.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.7.7.1 states that the control room ventilation system shall be OPERABLE with; two booster fans, two isolation valves in each outside air intake duct, two isolation valves in the toilet area exhaust duct, one filter train, at least two air conditioning units and two isolation valves in the kitchen area exhaust duct. Unit 2 CTS 3.7.7 states that two independent control room emergency air cleanup systems shall be OPERABLE with; a filter train and its associated fan per system, at least one air conditioning unit per system, two isolation valves in the kitchen area exhaust duct, two isolation valves in the toilet area exhaust duct, and two isolation valves in each (North and South) air intake duct. ITS LCO 3.7.10 states that two CREV trains shall be OPERABLE, but the details of what constitutes an OPERABLE CREV train are moved to the Bases. This changes the CTS by removing details of what constitutes an OPERABLE train to the Bases.

The removal of these details, which are related to system design, from CTS 3.7.7 is acceptable because the information is not necessary within the technical specification to provide adequate protection of public health and safety. This change is acceptable because ITS retains the requirement for two CREVS trains to be OPERABLE and retains the detail of what constitutes a CREVS train within the Bases. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 2 – Removing Descriptions of System Operation)* Unit 1 CTS 4.7.7.1.b.1 states, in part, “initiating flow through the HEPA filter and charcoal adsorber train and verifying that each booster fan.” Unit 2 CTS 4.7.7.b states, in part, “initiating, from the control room, flow through the HEPA filters and charcoal adsorbers.” ITS SR 3.7.10.1 states, “Operate each CREVS train for ≥ 15 continuous minutes.” This changes the CTS by moving the system operational detail to the UFSAR.

The removal of these details, which are related to system operation, from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change, because information relating to system operation is being removed from the Technical Specifications.

LA03 *(Type 2 – Removing Descriptions of System Operation)* Unit 1 CTS 4.7.7.1.d states, in part, "that on a containment isolation signal the system automatically isolates the control room and switches into a recirculation mode of operation with flow through the HEPA filters and charcoal adsorber banks." Unit 2 CTS 4.7.7.d.1 and CTS 4.7.7.d.2 state, in part, "that on a containment isolation test signal the system automatically isolates the control room and switches into a recirculation mode of operation with flow through the HEPA filters and charcoal adsorber banks." ITS SR 3.7.10.3 states, "Verify each CREVS train actuates on an actual or simulated actuation signal." This changes the CTS by moving the system operational detail to the UFSAR. (See DOCs L01 and L02 for additional discussion.)

The removal of these details, which are related to system operation, from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change, because information relating to system operation is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.7.7.1 Actions b (MODES 1, 2, 3, and 4) and b (MODES 5 and 6 or during movement of irradiated fuel assemblies) and Unit 2 CTS 3.7.7 Actions c (MODES 1, 2, 3, and 4) and c (MODES 5 and 6 or during movement of irradiated fuel assemblies) provide actions when an isolation valve in an air intake duct or an air exhaust duct is inoperable. ITS 3.7.10 ACTIONS do not include specific actions for an inoperable valve in an air intake duct or an air exhaust duct. This changes the CTS by removing specific action requirements associated with an inoperable isolation valve in a CREVS intake or exhaust duct.

The purpose of the CTS actions is to ensure the control room envelop boundary is maintained when redundant isolation capability is lost on a CREVS intake or exhaust duct. The CREVS design includes dual valves on the common intake and exhaust ducts to ensure these penetrations are isolated in the event of accident requiring control room isolation. The series valves on each air intake and air exhaust duct are powered and actuated from redundant trains. Therefore, when one isolation valve in an air duct is inoperable, appropriate

action for that level of degradation is to declare the CREV train associated with the inoperable isolation valve inoperable. Additionally, closing and deactivating either valve in the isolated position ensures the safety function is performed and restores the LCO. Unit 1 CTS 4.7.7.1.d and Unit 2 CTS 4.7.7.d.1 and 2 requires CREV components to actuate on a containment isolation signal, which includes automatic isolation valves. ITS SR 3.7.10.3 also requires similar testing with an exception for dampers and valves that are locked, sealed, or otherwise secured in the actuated position (See DOC L04 for the addition of this exception). Therefore, the exception in the SR effectively allows continued operation when one or more isolation valve in an air intake or exhaust duct are inoperable, provided the isolation valves are locked, sealed, or otherwise secured in the actuated (i.e., isolated) position. This change is acceptable because actions retained in the ITS continue to ensure redundant isolation capability is restored or the isolation function is performed. These remedial actions, including the exception provided in ITS SR 3.7.10.3, are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant isolation valve and the low probability of a DBA occurring during this condition. This change is designated as less restrictive because removal of the CTS actions allows restoration of the isolation capability to be controlled by other ITS 3.7.10 actions, which are less restrictive and allows more than one isolation valve per air duct to be inoperable provided the isolation function is performed.

L02 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.7.7.1 Actions c and e (MODES 1, 2, 3 and 4) require when the action requirements for a filter train inoperability for reasons other than an inoperable control room envelope boundary or for the inoperability of two booster fans, respectively, cannot be met the unit must be in at least HOT STANDBY (MODE 3) with 6 hours and COLD SHUTDOWN (MODE 5) within the following 30 hours. Unit 1 CREVS trains share a common filter train, therefore, CTS Actions c and e are effectively addressing the same condition and are combined in ITS as ACTION E. Unit 2 CTS 3.7.7 Action d (MODES 1, 2, 3 and 4) requires when two control room emergency air cleanup systems are inoperable for reasons other than an inoperable control room envelope boundary and the specified required actions and completion times cannot be met that the unit be in at least HOT STANDBY (MODE 3) with 6 hours and COLD SHUTDOWN (MODE 5) within the following 30 hours. ITS ACTION E requires for a similar condition, to be in MODE 3 within 6 hours and in MODE 4 within 12 hours with a Note stating that LCO 3.0.4.a is not applicable when entering MODE 4. This changes the CTS by changing the end state from “COLD SHUTDOWN within the following 30 hours” to “MODE 4 within 12 hours with LCO 3.0.4.a allowance not applicable.”

The purpose in the CTS action to shutdown the unit when the LCO cannot be restored within the required Completion Time is to place the unit in a MODE that minimizes overall plant risk. Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 as indicated in CE-NPSD-1186-A, Revision 00, “Technical Justification for the Risk-Informed Modification to Selected Required Action End States for CEOG Member PWRs,” dated October 2001 (ADAMS Accession No. 110410539). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. Voluntary entry into MODE 5 may continue to be made as it is also an acceptable

low-risk state. The change is consistent with similar changes made to CTS 3.7.7 in Amendments 234 and 184, “St. Lucie Plant, Unit Nos. 1 and 2 – Issuance of Amendments Regarding Changes in Selected Technical Specifications End States (CAC Nos. MF8106 and MF8107; Formerly CAC NOS. MF6683 AND MF6684),” dated August 30, 2016, (ADAMS Accession No. ML16210A374). This change is acceptable because the modification of the end state from MODE 5 to MODE 4 is consistent with CE-NPSD-1186-A and corrects an inconsistency in the CTS end states for Actions intended to place the unit in a condition outside of the LCO Applicability. Therefore, this change corrects that oversight. This change is designated as less restrictive because instead of requiring the plant to achieve MODE 5 (COLD SHUTDOWN), the ITS end state is MODE 4 (HOT SHUTDOWN) with LCO 3.0.4.a allowance not applicable.

L03 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.7.7.1.d requires verification that on a containment isolation signal the system automatically isolates the control room and switches into a recirculation mode of operation with flow through the HEPA filters and charcoal adsorber banks.” Unit 2 CTS 4.7.7.d.1 and d.2 state, in part, “that on a containment isolation test signal the system automatically isolates the control room and switches into a recirculation mode of operation with flow through the HEPA filters and charcoal adsorber banks.” ITS SR 3.7.10.3 specifies that the signal may be either an "actual" or a simulated actuation signal. This changes the Unit 1 and Unit 2 CTS by allowing the use of either an actual or a simulated signal for the test.

The purpose of CTS Surveillances is to ensure that each CREVS train actuates (switches to the recirculation mode) upon receipt of an actuation signal. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual," "simulated," or "test" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L04 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.7.7.1.d requires verification that on a containment isolation signal the system automatically isolates the control room and switches into a recirculation mode of operation with flow through the HEPA filters and charcoal adsorber banks.” Unit 2 CTS 4.7.7 d.1 and d.2 require verification that Unit 1 and Unit 2 containment isolation test signals will automatically switch into a recirculation mode of operation. ITS SR 3.7.10.3 requires verification that each CREVS train actuates and additional states, except for dampers and valves that are locked, sealed, or otherwise secured in the actuated position. This changes the CTS by not requiring dampers and valves locked, sealed or otherwise secured in position to be tested to verify that they automatically actuate to their actuated position.

The purpose of the CTS Surveillances is to provide assurance that the dampers and valves required to actuate in case of a design basis accident (DBA) isolate the control room and shift CREVS into the recirculation mode. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Dampers and valves already in the isolated position and secured are not required to be tested to automatically actuate because, in case of a DBA, they are already in their required position and secured to prevent changing from the required position. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.10, CONTROL ROOM EMERGENCY VENTILATION SYSTEM (CREVS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS 3.7.11 title "Control Room Emergency Air Cleanup System (CREACS)" has been changed to "Control Room Emergency Ventilation System (CREVS)" consistent with the St. Lucie Plant (PSL) site specific terminology. In addition, PSL design does not include the Essential Chilled Water System (ISTS 3.7.10). Therefore, ISTS 3.7.10 is not included in the PSL ITS. The Control Room Emergency Air Cleanup System (ISTS 3.7.11) is renumbered as ITS 3.7.10.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

B 3.7 PLANT SYSTEMS

10
Ventilation
CREVS
B 3.7.~~11~~ Control Room Emergency ~~Air Cleanup~~ System (~~CREACS~~)
2
1

BASES

BACKGROUND

CREVS
The ~~CREACS~~ provides a protected environment from which occupants can control the unit following an uncontrolled release of radioactivity~~, hazardous chemicals, or smoke~~.

CREVS
The ~~CREACS~~ consists of two ~~independent,~~ redundant trains that recirculate and filter the air in the control room envelope (CRE) and a CRE boundary that limits the inleakage of unfiltered air. Each ~~CREACS~~ train consists of a prefilter ~~and demister~~, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and a fan. Ductwork, valves or dampers, doors, barriers, and instrumentation also form part of the system~~, as well as demisters that remove water droplets from the air stream~~. ~~A second bank of HEPA filters follows the adsorber section to collect carbon fines, and provides back up in case of failure of the main HEPA filter bank.~~

CREVS
f
shares a common filter train that
Also included within a filter train are one booster fan, at least one air conditioning unit, two kitchen area exhaust duct isolation valves, two toilet area exhaust duct isolation valves and two air intake duct isolation valves in each (north and south) intake duct.

The CRE is the area within the confines of the CRE boundary that contains the spaces that control room occupants inhabit to control the unit during normal and accident conditions. This area encompasses the control room, ~~and may encompass other non-critical areas to which frequent personnel access or continuous occupancy is not necessary in the event of an accident~~. The CRE is protected during normal operation, natural events, and accident conditions. The CRE boundary is the combination of walls, floor, roof, ducting, doors, penetrations and equipment that physically form the CRE. The OPERABILITY of the CRE boundary must be maintained to ensure that the inleakage of unfiltered air into the CRE will not exceed the inleakage assumed in the licensing basis analysis of Design Basis Accident (DBA) consequences to CRE occupants. The CRE and its boundary are defined in the Control Room Envelope Habitability Program.

kitchen and food storage room, restrooms, administrative offices, computer room, and technical support center.

1

CREVS
(ITS 5.5.15)
s
The ~~CREACS~~ is an emergency system, part of which ~~may~~ also operate during normal unit operations in the standby mode of operation. Upon receipt of the actuating signal(s), normal air supply to the CRE is isolated, and the stream of ventilation air is recirculated through the filter trains of the system. The prefilters ~~and demisters~~ remove any large particles in the air~~, and any entrained water droplets present~~ to prevent excessive loading of the HEPA filters and charcoal adsorbers. ~~Both the demister and heater are important to the effectiveness of the charcoal adsorbers.~~

BASES

BACKGROUND (continued)

CREVS

Actuation of the ~~CREACS~~ places the system into ~~either of two separate states of the emergency mode of operation, depending on the initiation signal. Actuation of the system to the emergency radiation state of the emergency~~ mode of operation closes the unfiltered outside air intake and unfiltered exhaust dampers, and aligns the system for recirculation of the air within the CRE through the ~~redundant trains of~~ HEPA and charcoal ~~filters~~. The ~~emergency radiation state also initiates~~ pressurization and filtered ventilation of the air supply to the CRE.

the recirculation
which
starts control room emergency cleanup fans, standby control room air conditioning unit,
adsorber
filter
recirculation mode also facilitates
1

Outside air is filtered~~, [diluted with building air from the electrical equipment and cable spreading rooms,]~~ and then added to the air being recirculated from the CRE. Pressurization of the CRE minimizes infiltration of unfiltered air through the CRE boundary from all the surrounding areas adjacent to the CRE boundary. ~~The actions taken in the toxic gas isolation state are the same, except that the signal switches the CREACS to an isolation mode, minimizing outside air entering the CRE through the CRE boundary.~~

3

The air entering the CRE is continuously monitored by radiation ~~and toxic gas detectors~~. One detector output above the setpoint will cause actuation of the ~~emergency radiation state or toxic gas isolation state~~ as required. ~~The actions of the toxic gas isolation state are more restrictive, and will override the actions of the emergency radiation state.~~

monitors
recirculation mode

In recirculation mode, a makeup
450
is acceptable to
surrounding
CREVS
U
and 6.4 (Ref. 3)

~~A single CREACS train operating at a~~ flow rate of ≤ ~~[~~3000~~]~~ cfm ~~will~~ pressurize the CRE to ~~about [~~0.125~~]~~ inches water gauge relative to ~~external~~ areas adjacent to the CRE boundary~~, and provides an air exchange rate in excess of 25% per hour~~. The ~~CREACS~~ operation in maintaining the CRE habitable is discussed in the FSAR, Sections ~~[~~9.4~~]~~ (Ref. 1).

3
1
3

~~Redundant supply and recirculation trains provide the required filtration should an excessive pressure drop develop across the other filter train~~. Normally open isolation ~~dampers~~ are arranged in series pairs so that the failure of one ~~damper~~ to shut will not result in a breach of isolation. The ~~CREACS~~ is designed in accordance with Seismic Category I requirements.

valves
valve
CREVS

CREVS

The ~~CREACS~~ is designed to maintain a habitable environment in the CRE for 30 days of continuous occupancy after a DBA without exceeding a ~~[5 rem whole body dose or its equivalent to any part of the body]~~ [5 rem total effective dose equivalent (TEDE)~~]~~.

3

BASES

APPLICABLE SAFETY ANALYSES

CREVS

The ~~CREACS~~ components are arranged in redundant safety related ventilation trains. The location of components and ducting within the CRE ensures an adequate supply of filtered air to all areas requiring access.

which share a common filter train

CREVS

The ~~CREACS~~ provides airborne radiological protection for the CRE occupants, as demonstrated by the CRE occupant dose analyses for the most limiting design basis accident fission product release presented in the FSAR, Chapter ~~[~~15~~]~~ (Ref. 2).

1

U

3

CREVS

The ~~CREACS~~ provides protection from smoke and hazardous chemicals to the CRE occupants. The analysis of hazardous chemical releases demonstrates that the toxicity limits are not exceeded in the CRE following a hazardous chemical release (Ref. 3). The evaluation of a smoke challenge demonstrates that it will not result in the inability of the CRE occupants to control the reactor either from the control room or from the remote shutdown panels ~~(Ref. 4)~~.

CREVS

The worst case single active failure of a component of the ~~CREACS~~, assuming a loss of offsite power, does not impair the ability of the system to perform its design function.

1

CREVS

The ~~CREACS~~ satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

CREVS

Two ~~independent and~~ redundant trains of the ~~CREACS~~ are required to be OPERABLE to ensure that at least one is available, if a single active failure disables the other train. Total system failure, such as from a loss of both ventilation trains or from an inoperable CRE boundary, could result in exceeding a dose of ~~[5 rem whole body or its equivalent to any part of the body]~~ [5 rem TEDE~~]~~ ~~or~~ the CRE occupants in the event of a large radioactive release.

1

3

to

CREVS

Each ~~CREACS~~ train is considered OPERABLE when the individual components necessary to limit CRE occupant exposure are OPERABLE.

CREVS

A ~~CREACS~~ train is considered OPERABLE when the associated:

a. Fan is OPERABLE,

b. HEPA filters and charcoal adsorber are not excessively restricting flow, and are capable of performing their filtration functions, and

c. ~~Heater, demister,~~ ductwork, valves, and dampers are OPERABLE, and air circulation can be maintained.

1

BASES

LCO (continued)

CREVS
In order for the ~~CREACS~~ trains to be considered OPERABLE, the CRE boundary must be maintained such that the CRE occupant dose from a large radioactive release does not exceed the calculated dose in the licensing basis consequence analyses for DBAs, and that CRE occupants are protected from hazardous chemicals and smoke. 1

The LCO is modified by a Note allowing the CRE boundary to be opened intermittently under administrative controls. This Note only applies to openings in the CRE boundary that can be rapidly restored to the design condition, such as doors, hatches, floor plugs, and access panels. For entry and exit through doors, the administrative control of the opening is performed by the person(s) entering or exiting the area. For other openings, these controls should be proceduralized and consist of stationing a dedicated individual at the opening who is in continuous communication with the operators in the CRE. This individual will have a method to rapidly close the opening and to restore the CRE boundary to a condition equivalent to the design condition when a need for CRE isolation is indicated.

APPLICABILITY

In MODES 1, 2, 3, 4, ~~[~~5, and 6~~]~~, and during movement of ~~[recently]~~ irradiated fuel assemblies, the ~~CREACS~~ must be OPERABLE to ensure that the CRE will remain habitable during and following a DBA. 3
CREVS

~~In MODES [5 and 6], the CREACS is required to cope with the release from a rupture of an outside waste gas tank.~~ 1

CREVS
During movement of ~~[recently]~~ irradiated fuel assemblies, the ~~CREACS~~ must be OPERABLE to cope with the release from a fuel handling accident ~~[involving handling recently irradiated fuel]~~. ~~[Due to radioactive decay, the CREACS is only required to cope with fuel handling accidents involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days).]~~ 3 3

ACTIONS

A.1

CREVS
With one ~~CREACS~~ train inoperable, for reasons other than an inoperable CRE boundary, action must be taken to restore OPERABLE status within 7 days. In this Condition, the remaining OPERABLE ~~CREACS~~ train is adequate to perform the CRE occupant protection function. However, the overall reliability is reduced because a failure in the OPERABLE ~~CREACS~~ train could result in loss of ~~CREACS~~ function. The 7 day Completion Time is based on the low probability of a DBA occurring during this time period, and the ability of the remaining train to provide the required capability. 1
CREVS
CREVS

BASES

ACTIONS (continued)

B.1, B.2, and B.3

If the unfiltered inleakage of potentially contaminated air past the CRE boundary and into the CRE can result in CRE occupant radiological dose greater than the calculated dose of the licensing basis analyses of DBA consequences (allowed to be up to ~~[5 rem whole body or its equivalent to any part of the body]~~ [5 rem TEDE~~]~~), or inadequate protection of CRE occupants from hazardous chemicals or smoke, the CRE boundary is inoperable. Actions must be taken to restore an OPERABLE CRE boundary within 90 days. 3

During the period that the CRE boundary is considered inoperable, action must be initiated to implement mitigating actions to lessen the effect on CRE occupants from the potential hazards of a radiological or chemical event or a challenge from smoke. Actions must be taken within 24 hours to verify that in the event of a DBA, the mitigating actions will ensure that CRE occupant radiological exposures will not exceed the calculated dose of the licensing basis analyses of DBA consequences, and that CRE occupants are protected from hazardous chemicals and smoke. These mitigating actions (i.e., actions that are taken to offset the consequences of the inoperable CRE boundary) should be preplanned for implementation upon entry into the condition, regardless of whether entry is intentional or unintentional. The 24 hour Completion Time is reasonable based on the low probability of a DBA occurring during this time period, and the use of mitigating actions. The 90 day Completion Time is reasonable based on the determination that the mitigating actions will ensure protection of CRE occupants within analyzed limits while limiting the probability that CRE occupants will have to implement protective measures that may adversely affect their ability to control the reactor and maintain it in a safe shutdown condition in the event of a DBA. In addition, the 90 day Completion Time is a reasonable time to diagnose, plan and possibly repair, and test most problems with the CRE boundary.

C.1, C.2, and C.3

CREVS
If both ~~CREACS~~ trains are inoperable in MODE 1, 2, 3, or 4 for reasons other than an inoperable control room boundary (i.e., Condition B), at least one ~~CREACS~~ train must be returned to OPERABLE status within 24 hours. The Condition is modified by a Note stating it is not applicable if the second ~~CREACS~~ train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one train is inoperable for any reason and the second train is discovered to be

CREVS
CREVS
1

BASES

ACTIONS (continued)

CREVS inoperable, or if both trains are discovered to be inoperable at the same time. During the period that the ~~CREACS~~ trains are inoperable, action must be initiated to implement mitigating actions to lessen the effect on CREVS CRE occupants from potential hazards while both trains of ~~CREACS~~ are inoperable. In the event of a DBA, the mitigating actions will reduce the consequences of radiological exposures to the CRE occupants.

Specification 3.4.16, "RCS Specific Activity," allows limited operation with the reactor coolant system (RCS) activity significantly greater than the LCO limit. This presents a risk to the plant operator during an accident CREVS when all ~~CREACS~~ trains are inoperable. Therefore, it must be verified within 1 hour that LCO 3.4.16 is met. This Required Action does not require additional RCS sampling beyond that normally required by LCO 3.4.16. 1

CREVS At least one ~~CREACS~~ train must be returned to OPERABLE status within 24 hours. The Completion Time is based on Reference 3 which demonstrated that the 24 hour Completion Time is acceptable based on the infrequent use of the Required Actions and the small incremental effect on plant risk.

D.1 and D.2

~~[~~In MODE 5 or 6, or~~]~~ during movement of ~~[recently]~~ irradiated fuel assemblies, if Required Action A.1 cannot be completed within the CREVS required Completion Time, the OPERABLE ~~CREACS~~ train must be recirculation immediately placed in the ~~emergency~~ mode of operation. This action ensures that the remaining train is OPERABLE, that no failures preventing automatic actuation will occur, and that any active failure will be readily detected. 3 1

An alternative to Required Action D.1 is to immediately suspend activities that could result in a release of radioactivity that might require isolation of the CRE. This places the unit in a condition that minimizes the accident risk. This does not preclude the movement of fuel assemblies to a safe position.

~~Required Action D.1 is modified by a Note indicating to place the system in the toxic gas protection mode if the automatic transfer to the toxic gas protection mode is inoperable.~~ 1

BASES

ACTIONS (continued)

E.1

When ~~[~~in MODE 5 or 6, or~~]~~ during movement of ~~[recently]~~ irradiated fuel assemblies, with two ~~CREACS~~ trains inoperable or with one or more ~~CREACS~~ trains inoperable due to an inoperable CRE boundary, action must be taken immediately to suspend activities that could result in a release of radioactivity that might require isolation of the CRE. This places the unit in a condition that minimizes the accident risk. This does not preclude the movement of fuel to a safe position.

CREVS
3
1

F.1 and F.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

4

CREVS

If the inoperable ~~CREACS~~ or control room boundary cannot be restored to OPERABLE status within the associated Completion Time in MODE 1, 2, 3, or 4, the unit must be placed in a MODE that minimizes the accident risk. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~5~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

4

1

Required Action F.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable,

BASES

ACTIONS (continued)

because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.~~11~~.1 (10) 5

Standby systems should be checked periodically to ensure that they function properly. Since the environment and normal operating conditions on this system are not severe, testing each train once every month provides an adequate check on this system.

Operation ~~[with the heaters on]~~ for ≥ 15 continuous minutes demonstrates OPERABILITY of the system. Periodic operation ensures that ~~[heater failure,]~~ blockage, fan or motor failure, or excessive vibration can be detected for corrective action. ~~[The 31 day Frequency is based on the known reliability of the equipment, and the two train redundancy available.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

SURVEILLANCE REQUIREMENTS (continued)

10
2
SR 3.7.~~11~~.2

CREVS
1
This SR verifies that the required ~~CREACS~~ testing is performed in accordance with the ~~[~~Ventilation Filter Testing Program (VFTP)~~]~~. The ~~[~~VFTP~~]~~ includes testing HEPA filter performance, charcoal adsorber efficiency, minimum system flow rate, and the physical properties of the activated charcoal (general use and following specific operations). Specific test Frequencies and additional information are discussed in detail in the ~~[~~VFTP~~]~~.
3

(ITS 5.5.8)

10
2
SR 3.7.~~11~~.3

CREVS
1
This SR verifies that each ~~CREACS~~ train starts and operates on an actual or simulated actuation signal. The SR excludes automatic dampers and valves that are locked, sealed, or otherwise secured in the actuated position. The SR does not apply to dampers or valves that are locked, sealed, or otherwise secured in the actuated position since the affected dampers or valves were verified to be in the actuated position prior to being locked, sealed, or otherwise secured. Placing an automatic valve or damper in a locked, sealed, or otherwise secured position requires an assessment of the OPERABILITY of the system or any supported systems, including whether it is necessary for the valve or damper to be repositioned to the non-actuated position to support the accident analysis. Restoration of an automatic valve or damper to the non-actuated position requires verification that the SR has been met within its required Frequency. ~~[The Frequency of [18] months is based on industry operating experience and is consistent with the typical refueling cycle.~~
3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------~~~~]~~
4
3

BASES

SURVEILLANCE REQUIREMENTS (continued)

(10) SR 3.7.~~11~~.4 (2)

This SR verifies the OPERABILITY of the CRE boundary by testing for unfiltered air inleakage past the CRE boundary and into the CRE. The details of the testing are specified in the Control Room Envelope Habitability Program.

The CRE is considered habitable when the radiological dose to CRE occupants calculated in the licensing basis analyses of DBA consequences is no more than ~~[5 rem whole body or its equivalent to any part of the body]~~ [5 rem TEDE~~]~~ and the CRE occupants are protected from hazardous chemicals and smoke. This SR verifies that the unfiltered air inleakage into the CRE is no greater than the flow rate assumed in the licensing basis analyses of DBA consequences. When unfiltered air inleakage is greater than the assumed flow rate, Condition B must be entered. Required Action B.3 allows time to restore the CRE boundary to OPERABLE status provided mitigating actions can ensure that the CRE remains within the licensing basis habitability limits for the occupants following an accident. Compensatory measures are discussed in Regulatory Guide 1.196, Section C.2.7.3, (Ref. ~~6~~) which endorses, with exceptions, NEI 99-03, Section 8.4 and Appendix F (Ref. ~~7~~). These compensatory measures may also be used as mitigating actions as required by Required Action B.2. Temporary analytical methods may also be used as compensatory measures to restore OPERABILITY (Ref. ~~8~~). Options for restoring the CRE boundary to OPERABLE status include changing the licensing basis DBA consequence analysis, repairing the CRE boundary, or a combination of these actions. Depending upon the nature of the problem and the corrective action, a full scope inleakage test may not be necessary to establish that the CRE boundary has been restored to OPERABLE status.

B 3.7 PLANT SYSTEMS

10
B 3.7.~~11~~ Control Room Emergency ~~Air Cleanup~~ System (~~CREACS~~)
Ventilation
CREVS
2
1

BASES

BACKGROUND

The ~~CREACS~~ provides a protected environment from which occupants can control the unit following an uncontrolled release of radioactivity~~, hazardous chemicals, or smoke~~.

CREVS

CREVS

The ~~CREACS~~ consists of two ~~independent,~~ redundant trains that recirculate and filter the air in the control room envelope (CRE) and a CRE boundary that limits the inleakage of unfiltered air. Each ~~CREACS~~ train consists of a prefilter ~~and demister~~, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and a fan. Ductwork, valves or dampers, doors, barriers, and instrumentation also form part of the system~~, as well as demisters that remove water droplets from the air stream~~. A second bank of HEPA filters follows the adsorber section to collect carbon fines, and provides back-up in case of failure of the main HEPA filter bank.

Also included within a filter train are one air conditioning unit, two kitchen area exhaust duct isolation valves, two toilet area exhaust duct isolation valves and two air intake duct isolation valves in each (north and south) intake duct.

CREVS

f

The CRE is the area within the confines of the CRE boundary that contains the spaces that control room occupants inhabit to control the unit during normal and accident conditions. This area encompasses the control room, ~~and may encompass other non-critical areas to which frequent personnel access or continuous occupancy is not necessary in the event of an accident~~. The CRE is protected during normal operation, natural events, and accident conditions. The CRE boundary is the combination of walls, floor, roof, ducting, doors, penetrations and equipment that physically form the CRE. The OPERABILITY of the CRE boundary must be maintained to ensure that the inleakage of unfiltered air into the CRE will not exceed the inleakage assumed in the licensing basis analysis of Design Basis Accident (DBA) consequences to CRE occupants. The CRE and its boundary are defined in the Control Room Envelope Habitability Program.

air conditioning equipment room, emergency equipment cleanup system equipment room, emergency food and water storage areas, toilet, kitchen/dining/conference room and supervisor's office.

(ITS 5.5.15)

1

CREVS

s

The ~~CREACS~~ is an emergency system, part of which ~~may~~ also operate during normal unit operations in the standby mode of operation. Upon receipt of the actuating signal(s), normal air supply to the CRE is isolated, and the stream of ventilation air is recirculated through the filter trains of the system. The prefilters ~~and demisters~~ remove any large particles in the air~~, and any entrained water droplets present~~ to prevent excessive loading of the HEPA filters and charcoal adsorbers. ~~Both the demister and heater are important to the effectiveness of the charcoal adsorbers.~~

BASES

BACKGROUND (continued)

CREVS

Actuation of the ~~CREACS~~ places the system into ~~either of two separate states of the emergency mode of operation, depending on the initiation signal. Actuation of the system to the emergency radiation state of the emergency~~ mode of operation closes the unfiltered outside air intake and unfiltered exhaust dampers, and aligns the system for recirculation of the air within the CRE through the redundant trains of HEPA and charcoal ~~filters~~. The ~~emergency radiation state also initiates~~ pressurization and filtered ventilation of the air supply to the CRE.

the recirculation

which

starts control room emergency cleanup fans, standby control room air conditioning unit,

adsorbers

recirculation mode also facilitates

1

Outside air is filtered~~, [diluted with building air from the electrical equipment and cable spreading rooms,]~~ and then added to the air being recirculated from the CRE. Pressurization of the CRE minimizes infiltration of unfiltered air through the CRE boundary from all the surrounding areas adjacent to the CRE boundary. ~~The actions taken in the toxic gas isolation state are the same, except that the signal switches the CREACS to an isolation mode, minimizing outside air entering the CRE through the CRE boundary.~~

3

The air entering the CRE is continuously monitored by radiation ~~and toxic gas detectors~~. One detector output above the setpoint will cause actuation of the ~~emergency radiation state or toxic gas isolation state~~ as required. ~~The actions of the toxic gas isolation state are more restrictive, and will override the actions of the emergency radiation state.~~

monitors

recirculation mode

In recirculation mode, a makeup

450

is acceptable to

3

~~A single CREACS train operating at a~~ flow rate of ≤ ~~[~~3000~~]~~ cfm ~~will~~ pressurize the CRE to ~~about [~~0.125~~]~~ inches water gauge relative to ~~external~~ areas adjacent to the CRE boundary, and provides an air exchange rate in excess of 25% per hour. The ~~CREACS~~ operation in maintaining the CRE habitable is discussed in the FSAR, Sections ~~[~~9.4~~]~~ (Ref. 1).

surrounding

CREVS

U

and 6.4 (Ref. 3)

1

3

Redundant supply and recirculation trains provide the required filtration should an excessive pressure drop develop across the other filter train. Normally open isolation ~~dampers~~ are arranged in series pairs so that the failure of one ~~damper~~ to shut will not result in a breach of isolation. The ~~CREACS~~ is designed in accordance with Seismic Category I requirements.

valves

valve

CREVS

CREVS

The ~~CREACS~~ is designed to maintain a habitable environment in the CRE for 30 days of continuous occupancy after a DBA without exceeding a ~~[5 rem whole body dose or its equivalent to any part of the body]~~ [5 rem total effective dose equivalent (TEDE)~~]~~.

3

BASES

APPLICABLE SAFETY ANALYSES

CREVS The ~~CREACS~~ components are arranged in redundant safety related ventilation trains. The location of components and ducting within the CRE ensures an adequate supply of filtered air to all areas requiring access. 1

CREVS The ~~CREACS~~ provides airborne radiological protection for the CRE occupants, as demonstrated by the CRE occupant dose analyses for the most limiting design basis accident fission product release presented in the U FSAR, Chapter ~~[~~15~~]~~ (Ref. 2). 1 3

CREVS The ~~CREACS~~ provides protection from smoke and hazardous chemicals to the CRE occupants. The analysis of hazardous chemical releases demonstrates that the toxicity limits are not exceeded in the CRE following a hazardous chemical release (Ref. 3). The evaluation of a smoke challenge demonstrates that it will not result in the inability of the CRE occupants to control the reactor ~~either~~ from the control room ~~or from the remote shutdown panels (Ref. 4)~~.

CREVS The worst case single active failure of a component of the ~~CREACS~~, assuming a loss of offsite power, does not impair the ability of the system to perform its design function. 1

CREVS The ~~CREACS~~ satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

CREVS Two ~~independent and~~ redundant trains of the ~~CREACS~~ are required to be OPERABLE to ensure that at least one is available, if a single active failure disables the other train. Total system failure, such as from a loss of both ventilation trains or from an inoperable CRE boundary, could result in exceeding a dose of ~~[5 rem whole body or its equivalent to any part of the body]~~ [5 rem TEDE~~]~~ ~~or~~ the CRE occupants in the event of a large radioactive release. 1 3

to

CREVS Each ~~CREACS~~ train is considered OPERABLE when the individual components necessary to limit CRE occupant exposure are OPERABLE.

CREVS A ~~CREACS~~ train is considered OPERABLE when the associated:

a. Fan is OPERABLE,

b. HEPA filters and charcoal adsorber are not excessively restricting flow, and are capable of performing their filtration functions, and

c. ~~Heater, demister,~~ ductwork, valves, and dampers are OPERABLE, and air circulation can be maintained. 1

BASES

LCO (continued)

CREVS

In order for the ~~CREACS~~ trains to be considered OPERABLE, the CRE boundary must be maintained such that the CRE occupant dose from a large radioactive release does not exceed the calculated dose in the licensing basis consequence analyses for DBAs, and that CRE occupants are protected from hazardous chemicals and smoke. 1

The LCO is modified by a Note allowing the CRE boundary to be opened intermittently under administrative controls. This Note only applies to openings in the CRE boundary that can be rapidly restored to the design condition, such as doors, hatches, floor plugs, and access panels. For entry and exit through doors, the administrative control of the opening is performed by the person(s) entering or exiting the area. For other openings, these controls should be proceduralized and consist of stationing a dedicated individual at the opening who is in continuous communication with the operators in the CRE. This individual will have a method to rapidly close the opening and to restore the CRE boundary to a condition equivalent to the design condition when a need for CRE isolation is indicated.

APPLICABILITY

CREVS

In MODES 1, 2, 3, 4, ~~[~~5, and 6~~]~~, and during movement of ~~[recently]~~ irradiated fuel assemblies, the ~~CREACS~~ must be OPERABLE to ensure that the CRE will remain habitable during and following a DBA. 3

~~In MODES [5 and 6], the CREACS is required to cope with the release from a rupture of an outside waste gas tank.~~ 1

CREVS

During movement of ~~[recently]~~ irradiated fuel assemblies, the ~~CREACS~~ must be OPERABLE to cope with the release from a fuel handling accident ~~[involving handling recently irradiated fuel]~~. ~~[Due to radioactive decay, the CREACS is only required to cope with fuel handling accidents involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days).]~~ 3 3

ACTIONS

A.1

CREVS

With one ~~CREACS~~ train inoperable, for reasons other than an inoperable CRE boundary, action must be taken to restore OPERABLE status within 7 days. In this Condition, the remaining OPERABLE ~~CREACS~~ train is adequate to perform the CRE occupant protection function. However, the overall reliability is reduced because a failure in the OPERABLE ~~CREACS~~ train could result in loss of ~~CREACS~~ function. The 7 day Completion Time is based on the low probability of a DBA occurring during this time period, and the ability of the remaining train to provide the required capability. 1

CREVS

CREVS

BASES

ACTIONS (continued)

B.1, B.2, and B.3

If the unfiltered inleakage of potentially contaminated air past the CRE boundary and into the CRE can result in CRE occupant radiological dose greater than the calculated dose of the licensing basis analyses of DBA consequences (allowed to be up to ~~[5 rem whole body or its equivalent to any part of the body]~~ [5 rem TEDE~~]~~), or inadequate protection of CRE occupants from hazardous chemicals or smoke, the CRE boundary is inoperable. Actions must be taken to restore an OPERABLE CRE boundary within 90 days. 3

During the period that the CRE boundary is considered inoperable, action must be initiated to implement mitigating actions to lessen the effect on CRE occupants from the potential hazards of a radiological or chemical event or a challenge from smoke. Actions must be taken within 24 hours to verify that in the event of a DBA, the mitigating actions will ensure that CRE occupant radiological exposures will not exceed the calculated dose of the licensing basis analyses of DBA consequences, and that CRE occupants are protected from hazardous chemicals and smoke. These mitigating actions (i.e., actions that are taken to offset the consequences of the inoperable CRE boundary) should be preplanned for implementation upon entry into the condition, regardless of whether entry is intentional or unintentional. The 24 hour Completion Time is reasonable based on the low probability of a DBA occurring during this time period, and the use of mitigating actions. The 90 day Completion Time is reasonable based on the determination that the mitigating actions will ensure protection of CRE occupants within analyzed limits while limiting the probability that CRE occupants will have to implement protective measures that may adversely affect their ability to control the reactor and maintain it in a safe shutdown condition in the event of a DBA. In addition, the 90 day Completion Time is a reasonable time to diagnose, plan and possibly repair, and test most problems with the CRE boundary.

C.1, C.2, and C.3

CREVS

If both ~~CREACS~~ trains are inoperable in MODE 1, 2, 3, or 4 for reasons other than an inoperable control room boundary (i.e., Condition B), at least one ~~CREACS~~ train must be returned to OPERABLE status within 24 hours. The Condition is modified by a Note stating it is not applicable if the second ~~CREACS~~ train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one train is inoperable for any reason and the second train is discovered to be

CREVS

CREVS

1

BASES

ACTIONS (continued)

CREVS
inoperable, or if both trains are discovered to be inoperable at the same time. During the period that the ~~CREACS~~ trains are inoperable, action must be initiated to implement mitigating actions to lessen the effect on
CREVS
CRE occupants from potential hazards while both trains of ~~CREACS~~ are inoperable. In the event of a DBA, the mitigating actions will reduce the consequences of radiological exposures to the CRE occupants.

Specification 3.4.16, "RCS Specific Activity," allows limited operation with the reactor coolant system (RCS) activity significantly greater than the LCO limit. This presents a risk to the plant operator during an accident
CREVS
when all ~~CREACS~~ trains are inoperable. Therefore, it must be verified within 1 hour that LCO 3.4.16 is met. This Required Action does not require additional RCS sampling beyond that normally required by LCO 3.4.16.

CREVS
At least one ~~CREACS~~ train must be returned to OPERABLE status within 24 hours. The Completion Time is based on Reference 3 which demonstrated that the 24 hour Completion Time is acceptable based on the infrequent use of the Required Actions and the small incremental effect on plant risk.

1

D.1 and D.2

~~[~~In MODE 5 or 6, or~~]~~ during movement of ~~[recently]~~ irradiated fuel assemblies, if Required Action A.1 cannot be completed within the
CREVS
required Completion Time, the OPERABLE ~~CREACS~~ train must be
recirculation
immediately placed in the ~~emergency~~ mode of operation. This action ensures that the remaining train is OPERABLE, that no failures preventing automatic actuation will occur, and that any active failure will be readily detected.

3

1

An alternative to Required Action D.1 is to immediately suspend activities that could result in a release of radioactivity that might require isolation of the CRE. This places the unit in a condition that minimizes the accident risk. This does not preclude the movement of fuel assemblies to a safe position.

~~Required Action D.1 is modified by a Note indicating to place the system in the toxic gas protection mode if the automatic transfer to the toxic gas protection mode is inoperable.~~

1

BASES

ACTIONS (continued)

E.1

When ~~[~~in MODE 5 or 6, or~~]~~ during movement of ~~[recently]~~ irradiated fuel assemblies, with two ~~CREACS~~ trains inoperable or with one or more ~~CREACS~~ trains inoperable due to an inoperable CRE boundary, action must be taken immediately to suspend activities that could result in a release of radioactivity that might require isolation of the CRE. This places the unit in a condition that minimizes the accident risk. This does not preclude the movement of fuel to a safe position.

CREVS
3
1

F.1 and F.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

4

CREVS

If the inoperable ~~CREACS~~ or control room boundary cannot be restored to OPERABLE status within the associated Completion Time in MODE 1, 2, 3, or 4, the unit must be placed in a MODE that minimizes the accident risk. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~5~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

4

1

Required Action F.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable,

BASES

ACTIONS (continued)

because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.~~11~~.1 (10) (2)

Standby systems should be checked periodically to ensure that they function properly. Since the environment and normal operating conditions on this system are not severe, testing each train once every month provides an adequate check on this system.

Operation ~~[with the heaters on]~~ for ≥ 15 continuous minutes demonstrates OPERABILITY of the system. Periodic operation ensures that ~~[heater failure,]~~ blockage, fan or motor failure, or excessive vibration can be detected for corrective action. ~~[The 31 day Frequency is based on the known reliability of the equipment, and the two train redundancy available.~~ (3)

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ (4) (3)

SURVEILLANCE REQUIREMENTS (continued)

10
2

SR 3.7.~~11~~.2

CREVS
1

This SR verifies that the required ~~CREACS~~ testing is performed in accordance with the ~~[~~Ventilation Filter Testing Program (VFTP)~~]~~. The ~~[~~VFTP~~]~~ includes testing HEPA filter performance, charcoal adsorber efficiency, minimum system flow rate, and the physical properties of the activated charcoal (general use and following specific operations). Specific test Frequencies and additional information are discussed in detail in the ~~[~~VFTP~~]~~.
3

(ITS 5.5.8)

10
2

SR 3.7.~~11~~.3

CREVS
1

This SR verifies that each ~~CREACS~~ train starts and operates on an actual or simulated actuation signal. The SR excludes automatic dampers and valves that are locked, sealed, or otherwise secured in the actuated position. The SR does not apply to dampers or valves that are locked, sealed, or otherwise secured in the actuated position since the affected dampers or valves were verified to be in the actuated position prior to being locked, sealed, or otherwise secured. Placing an automatic valve or damper in a locked, sealed, or otherwise secured position requires an assessment of the OPERABILITY of the system or any supported systems, including whether it is necessary for the valve or damper to be repositioned to the non-actuated position to support the accident analysis. Restoration of an automatic valve or damper to the non-actuated position requires verification that the SR has been met within its required Frequency. ~~[The Frequency of [18] months is based on industry operating experience and is consistent with the typical refueling cycle.~~
3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------~~~~]~~
4
3

BASES

SURVEILLANCE REQUIREMENTS (continued)

(10) SR 3.7.~~11~~.4 (2)

This SR verifies the OPERABILITY of the CRE boundary by testing for unfiltered air inleakage past the CRE boundary and into the CRE. The details of the testing are specified in the Control Room Envelope Habitability Program.

The CRE is considered habitable when the radiological dose to CRE occupants calculated in the licensing basis analyses of DBA consequences is no more than ~~[5 rem whole body or its equivalent to any part of the body]~~ [5 rem TEDE~~]~~ and the CRE occupants are protected from hazardous chemicals and smoke. This SR verifies that the unfiltered air inleakage into the CRE is no greater than the flow rate assumed in the licensing basis analyses of DBA consequences. When unfiltered air inleakage is greater than the assumed flow rate, Condition B must be entered. Required Action B.3 allows time to restore the CRE boundary to OPERABLE status provided mitigating actions can ensure that the CRE remains within the licensing basis habitability limits for the occupants following an accident. Compensatory measures are discussed in Regulatory Guide 1.196, Section C.2.7.3, (Ref. ~~6~~) which endorses, with exceptions, NEI 99-03, Section 8.4 and Appendix F (Ref. ~~7~~). These compensatory measures may also be used as mitigating actions as required by Required Action B.2. Temporary analytical methods may also be used as compensatory measures to restore OPERABILITY (Ref. ~~8~~). Options for restoring the CRE boundary to OPERABLE status include changing the licensing basis DBA consequence analysis, repairing the CRE boundary, or a combination of these actions. Depending upon the nature of the problem and the corrective action, a full scope inleakage test may not be necessary to establish that the CRE boundary has been restored to OPERABLE status.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.10 BASES, CONTROL ROOM EMERGENCY VENTILATION SYSTEM (CREVS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS 3.7.11 title "Control Room Emergency Air Cleanup System (CREACS)" has been changed to "Control Room Emergency Ventilation System (CREVS)" consistent with the St. Lucie Plant (PSL) site specific terminology. In addition, PSL design does not include the Essential Chilled Water System (ISTS 3.7.10). Therefore, ISTS 3.7.10 is not included in the PSL ITS. The Control Room Emergency Air Cleanup System (ISTS 3.7.11) is renumbered as ITS 3.7.10.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

Specific No Significant Hazards Considerations (NSHCs)

M02

b. In accordance with the Surveillance Frequency Control Program by:

1. Initiating flow through the HEPA filter and charcoal adsorber train and verifying that each booster fan operates for at least 15 minutes.

2. Starting (unless already operating) each air conditioning unit and verifying that it operates for at least 8 hours.

c. By performing required control room emergency ventilation system filter testing in accordance with the Ventilation Filter Testing Program.

See ITS 3.7.10

PLANT SYSTEMS

AIR CONDITIONING

(CRACS)

3/4.7.7 CONTROL ROOM ~~EMERGENCY AIR CLEANUP~~ SYSTEM ~~(CREACS)~~

LIMITING CONDITION FOR OPERATION

LCO 3.7.11

3.7.7 Two ~~independent control room emergency air cleanup systems~~ shall be OPERABLE ~~with~~:

CRACS trains

a. A filter train and its associated fan per system, and

b. ~~At least one air conditioning unit per system, and~~

c. Two isolation valves in the kitchen area exhaust duct, and

d. Two isolation valves in the toilet area exhaust duct, and

e. Two isolation valves in each (North and South) air intake duct.

See ITS 3.7.10

NOTE

The control room envelope boundary may be opened intermittently under administrative control.

Applicability

APPLICABILITY: MODES 1, 2, 3, 4, 5 and 6 or during movement of irradiated fuel assemblies.

ACTION:

Add proposed ACTIONS

M03

MODES 1, 2, 3, and 4:

a. With one control room emergency air cleanup system inoperable for reasons other than an inoperable Control Room Envelope boundary, restore the inoperable system to OPERABLE status within 7 days or be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

See ITS 3.7.10

b. With one or more control room emergency air cleanup systems inoperable due to an inoperable Control Room Envelope boundary:

1. Immediately initiate actions to implement mitigating actions, and
2. Within 24 hours, verify mitigating actions to ensure Control Room Envelope occupant exposures to radiological, chemical, and smoke hazards will not exceed limits, and
3. Restore Control Room Envelope boundary to OPERABLE status within 90 days.

With the above requirements not met, be in at least HOT STANDBY within the next 6 hours and HOT SHUTDOWN within the following 6 hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

c. With an isolation valve in an air intake duct or air exhaust duct inoperable, operation may continue provided the other isolation valve in the same air intake or air exhaust duct is maintained closed; otherwise be in at least HOT STANDBY in the next 6 hours and in HOT SHUTDOWN within the following 6 hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

NOTE

Action not applicable when second CREACS train intentionally made inoperable.

d. With two control room emergency air cleanup systems inoperable for reasons other than an inoperable Control Room Envelope boundary:

1. Immediately initiate actions to implement mitigating actions, and
2. Within 1 hour, verify LCO 3.4.8, "Specific Activity," is met, and
3. Within 24 hours restore at least one CREACS train to OPERABLE status.

With the above requirements not met, be in at least HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours.

PLANT SYSTEMS

SURVEILLANCE REQUIREMENTS

4.7.7 ~~Each control room emergency air cleanup system~~ CRACS shall be demonstrated OPERABLE:

the CRACS has the capability to remove the assumed heat load

SR 3.7.11.1

a. In accordance with the Surveillance Frequency Control Program ~~by~~ verify~~ing that the control room air temperature is ≤ 120°F~~.

M02

b. In accordance with the Surveillance Frequency Control Program by (1) initiating, from the control room, flow through the HEPA filters and charcoal adsorbers and verifying that the system operates for at least 15 minutes and ~~(2) starting, unless already operating each air conditioning unit and verifying that it operates for at least 8 hours~~.

M02

c. By performing required control room emergency air cleanup system filter testing in accordance with the Ventilation Filter Testing Program.

See ITS 3.7.10

DISCUSSION OF CHANGES
ITS 3.7.11, CONTROL ROOM AIR CONDITIONING SYSTEM (CRACS)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 1 only:** CTS 3.7.7.1 Action f (MODES 1, 2, 3 and 4) states that with air conditioning units inoperable "for reasons other than an inoperable Control Room Envelope boundary." This excludes any AC unit inoperability due to an inoperable control room envelope boundary. ITS 3.7.11 ACTIONS do not include an exclusion associated with the control room envelope boundary when two required (i.e., three) CRACS trains are inoperable. This changes the CTS by removing the exception associated with the control room envelope boundary when two required CRACS trains are inoperable.

The purpose of the CTS ACTIONS is to clarify that when the control room envelop boundary is breached, the condition related to inoperable AC units does not apply. However, the control room envelop boundary is applicable to the control room filtration function and not the control room cooling function. This change is acceptable because ITS retains the requirements associated with the control room envelope boundary within the Control Room Emergency Ventilation System (CREVS) Technical Specification (ITS 3.7.10) and the Control Room Envelope (CRE) Habitability Program in ITS Section 5.5. This change is designated as administrative and is acceptable because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS 3.7.7.1 does not provide a specific ACTION for the Condition of two required AC units inoperable when in MODES 5 and 6 or during movement of irradiated fuel assemblies. ITS 3.7.11 ACTION E requires the suspension of irradiated fuel assemblies immediately. This changes CTS by adding actions for two inoperable required CRACS trains in MODES 5 and 6 and during movement of irradiated fuel assemblies.

The purpose of ITS 3.7.7.1 ACTION E is to place the unit in a condition that minimizes accident risk. Suspending movement of irradiated fuel assemblies accomplishes this purpose by precluding an event (i.e., fuel handling accident) that could result in a release of radioactivity requiring isolation of the control room. This change is designated as more restrictive because it adds an additional ACTION that CTS did not have.

M02 Unit 1 CTS 4.7.7.1 and Unit 2 CTS 4.7.7.a require verification that the control room air temperature is ≤ 120°F in accordance with the Surveillance Frequency

Control Program. This check is performed as a parameter check during operator rounds. Unit 2 CTS 4.7.7.b requires, in part, starting each air conditioning unit, unless already operating, and verifying that it operates for at least 8 hours. CTS does not provide a specific surveillance that verifies the design capability of the control room AC units. ITS SR 3.7.11.1 requires a verification that the CRACS has the capability to remove the assumed heat load with a Frequency in accordance with the Surveillance Frequency Control Program. This changes the CTS by removing the parameter check of control room air temperature performed as part of operational and procedural processes and adding a specific surveillance to require verifying the capability of the CRACS to remove the design heat load. This also changes Unit 2 CTS by removing an operational consideration to balance AC unit runtime.

The purpose of the CRACS Surveillance is to ensure the equipment in the control room does not exceed the required equipment qualification requirements. Verifying a temperature of < 120°F does not consider heat load profile during the duration of a design basis accident. Operating each Unit 2 AC unit for 8 hours also does not necessarily confirm the capability of the AC unit under accident conditions. The proposed Surveillance verifies the heat removal capability of the CRACS is sufficient to meet design requirements and consists of a combination of testing and calculations. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, SR 3.7.11.1 will be performed at a periodic Frequency in accordance with the SFCP with an initial Frequency of 18 months consistent with ISTS SR 3.7.12.1. This Frequency is appropriate since significant degradation of the CRACS is slow and is not expected over this time period. This change is designated as more restrictive because it adds a Surveillance Requirement that is more comprehensive than the simplistic temperature verification provide in CTS.

M03 **Unit 2 only:** CTS 3.7.7 does not contain specific requirements for the Control Room Air Conditioning System (CRACS). Currently CRACS requirements are encompassed within the Control Room Emergency Air Cleanup System (CREACS)) Operability, Applicability and Actions requirements. ITS 3.7.11 provides a specific Technical Specification that addresses the Control Room Air Conditioning System (CRACS) separately with specific ACTIONS that address the inoperability of the air conditioning units. This changes CTS by incorporating new Technical Specification requirements for the CRACS based on ISTS 3.7.12 (ITS 3.7.11).

The purpose of the CRACS is to maintain the temperature of the control room during normal operations and accident conditions to support control room equipment and maintain temperatures within the respective equipment qualification temperature limits. This change is acceptable because the safety analyses assume the OPERABILITY of the control room equipment. This change is designated as more restrictive because it adds new requirements to CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 **Unit 1 only:** *(Category 3 – Relaxation of Completion Time)* CTS 3.7.7.1 Action d (MODES 1, 2, 3 and 4) and Action d (MODES 5 and 6 or during movement of irradiated fuel assemblies) states "with only one air conditioning unit OPERABLE, restore at least two air conditioning units to OPERABLE status within 7 days." ITS 3.7.11 ACTION A allows 30 days to restore a required inoperable CRACS train to OPERABLE status. This changes the CTS by increasing the time allowed to restore the inoperable components from 7 days to 30 days.

The purpose of CTS 3.7.7.1 is to provide a degree of assurance that the CRACS can provide cooling when required. This change is acceptable because the Completion Time is consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the allowed Completion Time. The CRACS train is still required to be restored to OPERABLE status and can perform its function without one air conditioning train. This change is designated as less restrictive because additional time is allowed in the ITS to restore inoperable equipment to within the LCO limits than was allowed in the CTS.

L02 **Unit 1 only:** *(Category 4 – Relaxation of Required Action)* CTS 3.7.7.1 Action f (MODES 1, 2, 3 and 4) requires, when three air conditioning units are inoperable for reasons other than an inoperable control room envelope boundary, to restore at least one air conditioning unit within 24 hours or be in at least HOT STANDBY (MODE 3) with 6 hours and COLD SHUTDOWN (MODE 5) within the following 30 hours. ITS ACTION C requires, for a similar condition, to be in MODE 3 within 6 hours and in MODE 4 within 12 hours with a Note stating that LCO 3.0.4.a is not applicable when entering MODE 4. This changes the CTS by changing the end state of CTS 3.7.7.1 Action f from "COLD SHUTDOWN within the following 30 hours" to "MODE 4 within 12 hours."

The purpose in the CTS action to shutdown the unit when the LCO cannot be restored within the required Completion Time is to place the unit in a MODE that minimizes overall plant risk. Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 as indicated in CE-NPSD-1186-A, Revision 00, "Technical Justification for the Risk-Informed Modification to Selected Required Action End States for CEOG Member PWRs," dated October 2001 (ADAMS Accession No. 110410539). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. Voluntary entry into MODE 5 may continue to be made as it is also an acceptable low-risk state. The change is consistent with similar changes made to CTS 3.7.7.1 in Amendment 234, "St. Lucie Plant, Unit Nos. 1 and 2 – Issuance of

Amendments Regarding Changes in Selected Technical Specifications End States (CAC Nos. MF8106 and MF8107; Formerly CAC NOS. MF6683 AND MF6684)," dated August 30, 2016, (ADAMS Accession No. ML16210A374). This change is acceptable because the modification of the end state from MODE 5 to MODE 4 is consistent with CE-NPSD-1186-A and corrects an inconsistency in the CTS end states for Actions intended to place the unit in a condition outside of the LCO Applicability. Therefore, this change corrects that oversight. This change is designated as less restrictive because instead of requiring the plant to achieve MODE 5 (COLD SHUTDOWN), the ITS end state is MODE 4 (HOT SHUTDOWN) with LCO 3.0.4.a allowance not applicable.

L03 **Unit 1 only:** *(Category 4 – Relaxation of Required Action)* CTS 3.7.7.1 Action d (MODES 5 and 6 or during movement of irradiated fuel assemblies) requires immediate suspension of irradiated fuel assembly movement when a required inoperable air conditioning (AC) unit cannot be restored within the required Completion Time. ITS 3.7.11 includes an optional action, Required Action D.1, to place an OPERABLE AC unit in operation. This changes the CTS by adding an optional action in MODES 5 and 6 and during movement of irradiated fuel assemblies to immediately suspend irradiated fuel assemblies.

The purpose of CTS 3.7.7.1 action in MODES 5, 6, or during movement of irradiated fuel assemblies is to place the plant in a condition where the consequences of a fuel handling accident are precluded or mitigated when the LCO cannot be restored within the allowed Completion Time. The proposed action to place the remaining OPERABLE CRACS train in service ensures the train is OPERABLE and any active failure will be readily detected. This change is acceptable because the optional action is consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant train and single active failure to start is precluded by placing the OPERABLE train in service. In addition, the option to immediately suspend irradiated fuel assemblies is retained in the ITS. Therefore, the remedial actions continue to ensure the consequences of a fuel handling accident are precluded or mitigated when the LCO cannot be restored within the required Completion Time. This change is designated as less restrictive because it adds an optional Required Action and Completion Time that CTS does not include.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.11, CONTROL ROOM AIR CONDITIONING SYSTEM (CRACS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS 3.7.12 title "Control Room Emergency Air Temperature Control System (CREATCS)" has been changed to "Control Room Air Conditioning System (CRACS)" consistent with the St. Lucie Plant (PSL) site specific terminology. In addition, PSL design does not include the Essential Chilled Water System (ISTS 3.7.10). Therefore, ISTS 3.7.10 is not included in the PSL ITS. The Control Room Emergency Air Temperature Control System (ISTS 3.6.12) is renumbered as ITS 3.7.11.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

APPLICABLE SAFETY ANALYSES

CRACS
ambient

The design basis of the ~~CREATCS~~ is to maintain temperature of the control room ~~environment throughout 30 days of continuous occupancy.~~

Insert 3

CRACS

The ~~CREATCS~~ components are arranged in redundant ~~safety related~~ trains. During emergency operation, the ~~CREATCS~~ maintains the temperature ~~between [70]°F and [85]~~°F. A single active failure of a component of the ~~CREATCS~~, assuming a loss of offsite power, does not impair the ability of the system to perform its design function. Redundant detectors and controls are provided for control room temperature control. The ~~CREATCS~~ is designed in accordance with Seismic Category I requirements. The ~~CREATCS~~ is capable of removing sensible and latent heat loads from the control room, considering equipment heat loads and personnel occupancy requirements, to ensure equipment OPERABILITY.

≤ 125

The ~~CREATCS~~ satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

3
1

LCO

Two independent and redundant trains of the ~~CREATCS~~ are required to be OPERABLE to ensure that at least one is available, assuming a single failure disables the other train. Total system failure could result in the equipment operating temperature exceeding limits in the event of an accident.

Insert 4

CRACS

The ~~CREATCS~~ is considered OPERABLE when the individual components that are necessary to maintain the control room temperature are OPERABLE in both trains. These components include the cooling coils and associated temperature control instrumentation. In addition, the ~~CREATCS~~ must be OPERABLE to the extent that air circulation can be maintained.

1

Insert 1 (1)

is a subsystem of the Control Room Ventilation System and

Insert 2 (1)

during normal operations and accident conditions

Insert 3 (1)

for equipment qualification. Since equipment within the control room is qualified for higher temperature, loss of all air conditioning units is acceptable. At 125°F, continued habitability for periods of 2 hours is permissible. Through judicious allocation of plant operating personnel it is possible to maintain continuous occupancy of the control room.

Insert 4

(1)

Electrical independence requires that the two trains be powered from separate emergency buses.

BASES

APPLICABILITY

CRACS

In MODES 1, 2, 3, 4, ~~[~~5, and 6,~~]~~ and during movement of ~~[recently]~~ irradiated fuel assemblies ~~[(i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~, the ~~CREATCS~~ must be OPERABLE to ensure that the control room temperature will not exceed equipment OPERABILITY requirements following isolation of the control room. 3 1

~~In MODES 5 and 6, CREATCS may not be required for those facilities which do not require automatic control room isolation.~~ 1

ACTIONS

A.1

required

With one ~~CREATCS~~ train inoperable, action must be taken to restore OPERABLE status within 30 days. In this Condition, the remaining OPERABLE ~~CREATCS~~ train is adequate to maintain the control room temperature within limits. The 30 day Completion Time is reasonable, based on the low probability of an event occurring requiring control room isolation, consideration that the remaining train can provide the required capabilities, and the alternate safety or nonsafety related cooling means that are available. 1

CRACS

B.1

CRACS

required

If two ~~CREATCS~~ trains are inoperable, at least one ~~CREATCS~~ train must be returned to OPERABLE status within 24 hours. The Condition is modified by a Note stating it is not applicable if the second ~~CREATCS~~ train is intentionally ~~declared~~ inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one train is inoperable for any reason and the second train is discovered to be inoperable, or if both trains are discovered to be inoperable at the same time. The Completion Time is based on Reference ~~2~~ 3 which demonstrated that the 24 hour Completion Time is acceptable based on the infrequent use of the Required Action and the small incremental effect on plant risk. 1

CRACS

made

C.1 and C.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~ 4

BASES

ACTIONS (continued)

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~ 4

required CRACS
In MODE 1, 2, 3, or 4, when one or more ~~CREATCS~~ trains cannot be restored to OPERABLE status within the required Completion Time, the unit must be placed in a MODE that minimizes overall plant risk. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours. 1

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~2~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 3 1

Required Action C.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

~~[~~ D.1 and D.2

CRACS
In MODE 5 or 6, or during movement of ~~[recently]~~ irradiated fuel assemblies, when Required Action A.1 cannot be completed within the required Completion Time, ~~the~~ OPERABLE ~~CREATCS~~ train must be placed in operation immediately. This action ensures that the remaining train is OPERABLE~~, that no failures preventing automatic actuation will occur,~~ and that any active failure will be readily detected. 3

an

BASES

ACTIONS (continued)

An alternative to Required Action D.1 is to immediately suspend activities that could result in a release of radioactivity that might require isolation of the control room. This places the unit in a condition that minimizes the accident risk. This does not preclude the movement of fuel assemblies to a safe position.~~]~~ 3

~~[~~ E.1

In ~~[~~MODE 5 or 6, or~~]~~ during movement of ~~[recently]~~ irradiated fuel assemblies, with two ~~CREATCS~~ trains inoperable, action must be taken immediately to suspend activities that could result in a release of radioactivity that might require isolation of the control room. This places the unit in a condition that minimizes the accident risk. This does not preclude the movement of fuel to a safe position.~~]~~ 3

B 3.7 PLANT SYSTEMS

B 3.7.12 Control Room Emergency Air Temperature Control System (CREATCS)

BASES

BACKGROUND

The CREATCS provides temperature control for the control room following isolation of the control room.

The CREATCS consists of two independent, redundant trains that provide cooling and heating of recirculated control room air. Each train consists of heating coils, cooling coils, instrumentation, and controls to provide for control room temperature control.

The CREATCS is an emergency system, parts of which may also operate during normal unit operations. A single train will provide the required temperature control to maintain the control room between [70]°F and [85]°F. The CREATCS operation to maintain the control room temperature is discussed in the FSAR, Section [6.4] (Ref. 1).

APPLICABLE SAFETY ANALYSES

The design basis of the CREATCS is to maintain temperature of the control room environment throughout 30 days of continuous occupancy.

The CREATCS components are arranged in redundant safety related trains. During emergency operation, the CREATCS maintains the temperature between [70]°F and [85]°F. A single active failure of a component of the CREATCS, assuming a loss of offsite power, does not impair the ability of the system to perform its design function. Redundant detectors and controls are provided for control room temperature control. The CREATCS is designed in accordance with Seismic Category I requirements. The CREATCS is capable of removing sensible and latent heat loads from the control room, considering equipment heat loads and personnel occupancy requirements, to ensure equipment OPERABILITY.

The CREATCS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Two independent and redundant trains of the CREATCS are required to be OPERABLE to ensure that at least one is available, assuming a single failure disables the other train. Total system failure could result in the equipment operating temperature exceeding limits in the event of an accident.

The CREATCS is considered OPERABLE when the individual components that are necessary to maintain the control room temperature are OPERABLE in both trains. These components include the cooling coils and associated temperature control instrumentation. In addition, the CREATCS must be OPERABLE to the extent that air circulation can be maintained.

Insert 1 (1)

is a subsystem of the Control Room Ventilation System and

Insert 2 (1)

during normal operations and accident conditions

Insert 3 (1)

for equipment qualification. CRACS is designed to control the environment assuming the simultaneous operation of all equipment located in the control room envelope coinciding with the highest site design ambient conditions. Under these assumptions, the system is capable of maintaining the environmental conditions of 76°F to 84°F and less than 70 percent relative humidity during an accident condition.

Insert 4 (1)

Electrical independence requires that the two trains be powered from separate emergency buses.

BASES

APPLICABILITY

CRACS

In MODES 1, 2, 3, 4, ~~[~~5, and 6,~~]~~ and during movement of ~~[recently]~~ irradiated fuel assemblies ~~[(i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~, the ~~CREATCS~~ must be OPERABLE to ensure that the control room temperature will not exceed equipment OPERABILITY requirements following isolation of the control room. 3 1

~~In MODES 5 and 6, CREATCS may not be required for those facilities which do not require automatic control room isolation.~~ 1

ACTIONS

A.1

required

With one ~~CREATCS~~ train inoperable, action must be taken to restore OPERABLE status within 30 days. In this Condition, the remaining OPERABLE ~~CREATCS~~ train is adequate to maintain the control room temperature within limits. The 30 day Completion Time is reasonable, based on the low probability of an event occurring requiring control room isolation, consideration that the remaining train can provide the required capabilities, and the alternate safety or nonsafety related cooling means that are available. 1

CRACS

B.1

CRACS

required

If two ~~CREATCS~~ trains are inoperable, at least one ~~CREATCS~~ train must be returned to OPERABLE status within 24 hours. The Condition is modified by a Note stating it is not applicable if the second ~~CREATCS~~ train is intentionally ~~declared~~ inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one train is inoperable for any reason and the second train is discovered to be inoperable, or if both trains are discovered to be inoperable at the same time. The Completion Time is based on Reference ~~2~~ 3 which demonstrated that the 24 hour Completion Time is acceptable based on the infrequent use of the Required Action and the small incremental effect on plant risk. 1

CRACS

made

3

C.1 and C.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~ 4

BASES

ACTIONS (continued)

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~ 4

required CRACS
In MODE 1, 2, 3, or 4, when one or more ~~CREATCS~~ trains cannot be restored to OPERABLE status within the required Completion Time, the unit must be placed in a MODE that minimizes overall plant risk. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours. 1

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~2~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 3 1

Required Action C.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

~~[~~ D.1 and D.2

CRACS
In MODE 5 or 6, or during movement of ~~[recently]~~ irradiated fuel assemblies, when Required Action A.1 cannot be completed within the required Completion Time, ~~the~~ OPERABLE ~~CREATCS~~ train must be placed in operation immediately. This action ensures that the remaining train is OPERABLE~~, that no failures preventing automatic actuation will occur,~~ and that any active failure will be readily detected. 3

an

BASES

ACTIONS (continued)

An alternative to Required Action D.1 is to immediately suspend activities that could result in a release of radioactivity that might require isolation of the control room. This places the unit in a condition that minimizes the accident risk. This does not preclude the movement of fuel assemblies to a safe position.~~]~~ 3

~~[~~ E.1

In ~~[~~MODE 5 or 6, or~~]~~ during movement of ~~[recently]~~ irradiated fuel assemblies, with two ~~CREATCS~~ trains inoperable, action must be taken immediately to suspend activities that could result in a release of radioactivity that might require isolation of the control room. This places the unit in a condition that minimizes the accident risk. This does not preclude the movement of fuel to a safe position.~~]~~ 3

required
CRACS

SURVEILLANCE REQUIREMENTS

SR 3.7.~~12~~.1 11

This SR verifies that the heat removal capability of the system is sufficient to meet design requirements. This SR consists of a combination of testing and calculations. ~~[An [18] month Frequency is appropriate, since significant degradation of the CREATCS is slow and is not expected over this time period.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. 3

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.11 BASES, CONTROL ROOM AIR CONDITIONING SYSTEM (CRACS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS 3.7.12 title "Control Room Emergency Air Temperature Control System (CREATCS)" has been changed to "Control Room Air Conditioning System (CRACS)" consistent with the St. Lucie Plant (PSL) site specific terminology. In addition, PSL design does not include the Essential Chilled Water System (ISTS 3.7.10). Therefore, ISTS 3.7.10 is not included in the PSL ITS. The Control Room Emergency Air Temperature Control System (ISTS 3.6.12) is renumbered as ITS 3.7.11.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.7.11, CONTROL ROOM AIR CONDITIONING SYSTEM (CRACS)

DISCUSSION OF CHANGES
ITS 3.7.12, ECCS AREA VENTILATION SYSTEM

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 ITS SR 3.7.12.4 states "Verify one ECCS area ventilation train can maintain a negative pressure relative to adjacent areas during the post accident mode of operation at a flow rate of < 27,000 cfm." CTS does not require this Surveillance. This changes CTS by adding a requirement that equipment be able to provide a negative pressure relative to adjacent areas inside the ECCS pump room boundary. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, SR 3.7.12.4 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months on a staggered test basis consistent with the ISTS SR 3.7.12.4 Frequency.

The purpose of ITS SR 3.7.12.4 is to provide assurance that the ECCS pump room boundary can support the function of the ECCS Area Ventilation System of maintaining a negative pressure inside the ECCS pump room boundary while filtering air discharged from those areas to prevent unfiltered LEAKAGE. This change is necessary to ensure sufficient testing is conducted at a frequency to assure that the necessary quality of systems and components is maintained, and that the ECCS Area Ventilation System LCO will be met. This SR verifies the integrity of the ECCS pump room boundary.

The performance Frequency of ITS SR 3.7.12.4 is in accordance with the Surveillance Frequency Control Program (SFCP). PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). The initial periodic Frequency established in accordance with the SFCP will be 18 months on a staggered test basis. See FPL (PSL Unit 1 and Unit 2) “Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program” (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066), which approved the adoption of a SFCP at PSL. This change is designated as more restrictive because a Surveillance Requirement is added to the Technical Specifications.

DISCUSSION OF CHANGES
ITS 3.7.12, ECCS AREA VENTILATION SYSTEM

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.7.8.1 and Unit 2 CTS 3.7.8 state that two "independent" ECCS area ventilation systems shall be OPERABLE. ITS LCO 3.7.12 states that two ECCS area ventilation trains shall be OPERABLE. This changes the CTS by removing details that the trains are "independent" from the CTS to the Bases.

The removal of these details, which are related to the system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement that two ECCS area ventilation trains shall be OPERABLE. The design detail that the trains are independent do not need to appear in the Specification in order for the requirement to apply. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS 4.7.8.1.a and Unit 2 CTS 4.7.8.a state, in part, that each ECCS area ventilation train shall be demonstrated OPERABLE by “initiating, from the control room, and verifying that the system operates for at least 15 minutes.” ITS SR 3.7.12.1 states "Operate each ECCS area ventilation train for ≥ 15 continuous minutes." This changes the CTS by moving the requirement to actuate the train from the control room to the Bases.

The removal of these details for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement to operate the ECCS area ventilation trains for ≥ 15 continuous minutes. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 1 – Relaxation of LCO Requirements)* Unit 1 CTS 3.7.8.1 and Unit 2 CTS 3.7.8 requires two ECCS area ventilation trains to be OPERABLE. ITS LCO 3.7.12 includes the same ECCS area ventilation trains OPERABILITY requirement but is modified by a Note, which states "The ECCS pump room boundary may be opened intermittently under administrative control." This changes the CTS by allowing the ECCS pump room boundary to be opened under administrative control when the ECCS area ventilation trains are required to be OPERABLE.

The purpose of the Note to ITS LCO 3.7.12 is to allow the ECCS pump room negative pressure boundary to be opened under administrative control. This change is acceptable because the LCO requirements continue to ensure that the structures, systems, and components are maintained consistent with the safety analyses and licensing basis. The ITS allowance requires administrative controls to be in place in order to open the boundary. For entry and exit through doors the administrative control of the opening is performed by the person(s) entering or exiting the area. For other openings, these controls consist of stationing a dedicated individual at the opening who is in continuous communication with the control room. This individual will have a method to rapidly close the opening when a need for ECCS pump room negative pressure boundary isolation is indicated. These administrative controls minimize risk by providing compensatory actions that ensure the boundary can be rapidly restored to the design condition. The required administrative controls are described in the Bases. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than were applied in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.7.8.1 and Unit 2 CTS 3.7.8 Action contain compensatory actions to take when one ECCS area ventilation train is inoperable. The Unit 1 CTS 3.7.8.1 and Unit 2 CTS 3.7.8 Action does not contain compensatory actions to take when two ECCS area ventilation trains are inoperable. Therefore, CTS 3.0.3 would be entered for two ECCS area ventilation trains inoperable. CTS 3.0.3 requires action to be initiated within one hour to be in HOT STANDBY (ITS MODE 3) in the following 6 hours, to be in HOT SHUTDOWN (ITS MODE 4) in the following 6 hours, and to be in COLD SHUTDOWN (ITS MODE 5) in the subsequent 36 hours. ITS 3.7.12 ACTION B states, with two ECCS area ventilation trains inoperable due to an inoperable ECCS pump room boundary, to restore the ECCS pump room boundary to OPERABLE status within 24 hours. Additionally, ITS 3.7.12 ACTION C requires, when two ECCS area ventilation trains are unintentionally inoperable for reasons other than Condition B (i.e., an inoperable ECCS pump room boundary), one ECCS area ventilation train to be restored to OPERABLE status within 24 hours. This changes the CTS by not requiring entry into LCO 3.0.3 and allowing 24 hours to restore the ECCS pump room boundary to OPERABLE status and allowing 24 hours to restore at least one ECCS area ventilation train to OPERABLE status when two ECCS area ventilation trains are unintentionally inoperable for reasons other than Condition B.

ITS 3.7.12 ACTION B allows 24 hours to restore the pressure ECCS pump room boundary to OPERABLE status before requiring an orderly shutdown from operating conditions. This change is acceptable because this change would allow for routine repairs. Compensatory measures will be taken to protect plant personnel from potential hazards, and preplanned compensatory measures will be in place to address both the intentional and unintentional inoperability of the ECCS pump room boundary. Furthermore, the 24 hour Completion Time is based on the low probability of a DBA occurring during this time period and the compensatory measures that will be taken.

The addition of ITS 3.7.12 ACTION B is consistent with the Revision 5 of the ISTS as adopted by Technical Specifications Task Force (TSTF) traveler TSTF-287-A, Revision 5, "Ventilation System Envelope Allowed Outage Time" dated March 16, 2000. As stated in the Unit 1 and Unit 2 UFSAR, Section 9.4.3.1, the ECCS Area Ventilation System is sized to maintain a slightly negative pressure in the ECCS pump room area with respect to surrounding areas of the reactor auxiliary building. Access into the ECCS pump room area from other areas of the reactor auxiliary building is through gasketed self-closing or locked closed doors. Opening of locked doors is controlled under administrative controls.

ITS 3.7.12 ACTION C allows 24 hours to restore at least one ECCS area ventilation trains to OPERABLE status before requiring an orderly shutdown from operating conditions. This change is acceptable because overall safety is enhanced by avoiding an unnecessary plant shutdown and minimizing plant transients and associated transitions and realignment risks. The Condition is modified by a Note stating it is not applicable if the second ECCS area ventilation train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. ITS 3.7.12, Condition C is only applicable if one ECCS area ventilation train is inoperable for any reason and the second ECCS area ventilation train is discovered to be inoperable, or if both ECCS area ventilation trains are discovered to be inoperable at the same time.

The addition of ITS 3.7.12 ACTION C is consistent with Revision 5 of the ISTS as adopted by TSTF traveler TSTF-426-A, Revision 5, "Revise or Add Actions to Preclude Entry into LCO 3.0.3 - RITSTF Initiatives 6b & 6c" dated May 30, 2013. The TSTF was approved for licensee adoption as documented in Federal Register Notice *78 FR 32476* (NRC ADAMS Accession No. ML13036A381). The PSL Unit 1 and Unit 2 ECCS Area Ventilation System design does not rely upon the system to provide temperature control of the ECCS pump rooms, and therefore, does not affect OPERABILITY of the ECCS pumps. The reactor auxiliary building ventilation systems are designed to provide ventilation to permit proper functioning of equipment during normal operation.

Additionally, ITS 3.7.12 ACTION D continues to require the unit to be placed outside of the MODE of Applicability when two ECCS area ventilation trains are inoperable if any Required Action of Condition A, B, or C cannot be met with the associated Completion Time. LCO 3.0.3 continues to apply when two ECCS area ventilation trains are intentionally made inoperable for reasons other than an inoperable ECCS pump room boundary. This change is designated as less

restrictive because the less stringent requirements are being applied in the ITS than were applied in the CTS.

L03 *(Category 6 - Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.7.8.1.c.2 and Unit 2 CTS 4.7.8.c require verification of the automatic actuation of ECCS area ventilation trains on a safety injection actuation signal (Unit 1) and safety injection actuation “test” signal (Unit 2). ITS SR 3.7.12.3 specifies that the signal may be from either an "actual" or simulated (i.e., test) signal. This changes the CTS by explicitly allowing the use of either an actual or simulated signal for the test.

The purpose of the ECCS area ventilation train actuation test is to ensure the ECCS area ventilation trains operate correctly upon receipt of an actuation signal. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an "actual," "simulated," or "test" signal and, therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L04 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.7.8.1.c.2 and Unit 2 CTS 4.7.8.c require verification of the automatic actuation of ECCS area ventilation trains on a safety injection actuation signal (Unit 1) and safety injection actuation “test” signal (Unit 2). ITS SR 3.7.12.3 requires verification that each ECCS area ventilation train actuates on an actual or simulated actuation signal, except for dampers and valves that are locked, sealed, or otherwise secured in the actuated position. This changes the CTS by excluding those ECCS area ventilation automatic dampers and valves that are locked, sealed, or otherwise secured in position from the verification.

The purpose of the ECCS area ventilation train actuation test is to provide assurance that if an event occurred requiring the ECCS area ventilation dampers and valves to be in their correct position, those requiring automatic actuation would actuate to their correct position. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Those automatic dampers and valves that are locked, sealed, or otherwise secured in the actuated position are not required to actuate on a safety injection actuation signal in order to perform their safety function because they are already in the required position. Testing such valves would not provide any additional assurance of OPERABILITY. Valves and dampers that are required to actuate will continue to be tested. In addition, restoration of an automatic valve or damper to the non-actuated position requires verification that the SR has been met within its required Frequency. This change

is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.12, ECCS AREA VENTILATION SYSTEM

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS Specification number and title.

4. As stated in the Unit 1 and Unit 2 UFSAR, Section 9.4.3.1, the ECCS Area Ventilation System is sized to maintain a slightly negative pressure in the ECCS area with respect to surrounding areas of the reactor auxiliary building. Access into the ECCS pump room area from other areas of the reactor auxiliary building is through gasketed self-closing or locked closed doors. Opening of locked doors is controlled under administrative controls.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

Area Ventilation System
B 3.7.~~13~~ Emergency Core Cooling System (ECCS) ~~Pump Room Exhaust Air Cleanup System (PREACS)~~

BASES

Area Ventilation System
BACKGROUND The ECCS ~~PREACS~~ filters air from the area of the active ECCS components during the recirculation phase of a loss of coolant accident (LOCA). The ECCS ~~PREACS~~, in conjunction with other, normally operating systems, also provides environmental control of temperature and humidity in the ECCS pump room area and the lower reaches of the Auxiliary Building. R1

Area Ventilation System
Reactor

Area Ventilation System
The ECCS ~~PREACS~~ consists of two independent and redundant trains. Each train consists of ~~a heater,~~ a prefilter ~~or demister~~, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and a fan. Ductwork, valves or dampers, and instrumentation also form part of the system~~, as well as demisters functioning to reduce the relative humidity of the air stream. A second bank of HEPA filters follows the adsorber section to collect carbon fines and provide backup in case the main HEPA filter bank fails. The downstream HEPA filter is not credited in the accident analysis, but serves to collect charcoal fines and to back up the upstream HEPA filter, should it develop a leak~~. The system initiates filtered ventilation of the pump room and lower region of the Auxiliary Building following receipt of a safety injection actuation signal ~~or coolant injection actuation signal~~.

Reactor

Area Ventilation System
The ECCS ~~PREACS~~ is a standby system, parts of which may also operate during normal unit operations. The Reactor Auxiliary Building Main Ventilation System provides normal cooling. During emergency operations, the ECCS ~~PREACS~~ dampers are realigned and fans are started to initiate filtration. Upon receipt of ~~the actuating Engineered Safety Feature Actuation System~~ signal~~(s)~~, normal air discharges from the ECCS pump room, the pump room is isolated, and the stream of ventilation air discharges through the system filter trains. The prefilters ~~or demisters~~ remove any large particles in the air, and any entrained water droplets present, to prevent excessive loading of the HEPA filters and charcoal adsorbers.

Area Ventilation System
a safety injection actuation

Area Ventilation System
U
6.3.1
9.4.3
The ECCS ~~PREACS~~ is discussed in the FSAR, Sections ~~[6.5.1]~~, ~~[9.4.5]~~, and ~~[15.6.5]~~ (Refs. 1, 2, and 3, respectively), as it may be used for normal, as well as post accident, atmospheric cleanup functions. ~~The primary purpose of the heaters is to maintain the relative humidity at an acceptable level consistent with iodine removal efficiencies, as discussed in the Regulatory Guide 1.52 (Ref. 4).~~

15.4.1

BASES

Area Ventilation System

APPLICABLE SAFETY ANALYSES

The design basis of the ECCS ~~PREACS~~ is established by the large break LOCA. The system evaluation assumes a passive failure of the ECCS outside containment, such as safety injection pump seal failure, during the recirculation mode. In such a case, the system limits the radioactive release to within ~~10 CFR 100~~ limits (Ref. ~~5~~); ~~or the NRC staff approved licensing basis (e.g., a specified fraction of 10 CFR 100 limits)~~. The analysis of the effects and consequences of a large break LOCA is presented in Reference 3. The ECCS ~~PREACS~~ also actuates following a small break LOCA, requiring the unit to go into the recirculation mode of long term cooling and to clean up releases of smaller leaks, such as from valve stem packing.

10 CFR 50.67

4

Area Ventilation System

The two types of system failures that are considered in the accident analysis are complete loss of function and excessive LEAKAGE. Either type of failure may result in a lower efficiency of removal for any gaseous and particulate activity released to the ECCS pump rooms following a LOCA.

Area Ventilation System

The ECCS ~~PREACS~~ satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

area ventilation

LCO

Two independent and redundant ECCS ~~PREACS~~ trains are required to be OPERABLE to ensure that at least one is available, assuming a single failure disables the other train coincident with a loss of offsite power. Total system failure could result in the atmospheric release from the ECCS pump room exceeding the required limits in the event of a Design Basis Accident (DBA).

Area Ventilation System

ECCS ~~PREACS~~ is considered OPERABLE when the individual components necessary to maintain the ECCS Pump Room filtration are OPERABLE in both trains.

area ventilation

An ECCS ~~PREACS~~ train is considered OPERABLE when its associated:

a. Fan is OPERABLE,

b. HEPA filter and charcoal adsorber are not excessively restricting flow and are capable of performing their filtration functions, and

c. ~~Heater, demister,~~ ductwork, valves, and dampers are OPERABLE, and air circulation can be maintained.

BASES

LCO (continued)

The LCO is modified by a Note allowing the ECCS pump room boundary to be opened intermittently under administrative controls. For entry and exit through doors, the administrative control of the opening is performed by the person(s) entering or exiting the area. For other openings, these controls consist of stationing a dedicated individual at the opening who is in continuous communication with the control room. This individual will have a method to rapidly close the opening when a need for ECCS pump room isolation is indicated.

APPLICABILITY

Area Ventilation System

In MODES 1, 2, 3, and 4, the ECCS ~~PREACS~~ is required to be OPERABLE consistent with the OPERABILITY requirements of the ECCS. 1

Area Ventilation System

In MODES 5 and 6, the ECCS ~~PREACS~~ is not required to be OPERABLE, since the ECCS is not required to be OPERABLE. 1

ACTIONS

A.1

area ventilation

Area Ventilation System

With one ECCS ~~PREACS~~ train inoperable, action must be taken to restore OPERABLE status within 7 days. During this time, the remaining OPERABLE train is adequate to perform the ECCS ~~PREACS~~ function. 1 1

The 7 day Completion Time is appropriate because the risk contribution is less than that for the ECCS (72 hour Completion Time) and this system is not a direct support system for the ECCS. The 7 day Completion Time is reasonable, based on the low probability of a DBA occurring during this time period, and the consideration that the remaining train can provide the required capability.

B.1

~~REVIEWER'S NOTE~~

~~Adoption of Condition B is dependent on a commitment from the licensee to have guidance available describing compensatory measures to be taken in the event of an intentional and unintentional entry into Condition B.~~ 4

BASES

ACTIONS (continued)

area ventilation

If the ECCS pump room boundary is inoperable, the ECCS ~~PREACS~~ trains cannot perform their intended functions. Actions must be taken to restore an OPERABLE ECCS pump room boundary within 24 hours. During the period that the ECCS pump room boundary is inoperable, appropriate compensatory measures ~~[~~consistent with the intent, as applicable, of GDC 19~~, 60, 64 and 10 CFR Part 100]~~ should be utilized to protect plant personnel from potential hazards such as radioactive contamination, toxic chemicals, smoke, temperature and relative humidity, and physical security. Preplanned measures should be available to address these concerns for intentional and unintentional entry into the condition. The 24 hour Completion Time is reasonable based on the low probability of a DBA occurring during this time period, and the use of compensatory measures. The 24 hour Completion Time is a typically reasonable time to diagnose, plan and possibly repair, and test most problems with the ECCS pump room boundary.

area ventilation system

~~REVIEWER'S NOTE~~

~~Condition C is not applicable to plant designs that rely on the ECCS PREACS to provide temperature control of the ECCS pump rooms. Reference 6 did not evaluate the effect of two inoperable ECCS PREACS trains on the ECCS pump room cooling function.~~

C.1

area ventilation

With two ECCS ~~PREACS~~ trains inoperable for reasons other than an inoperable boundary, action must be taken to restore at least one ECCS ~~PREACS~~ train to OPERABLE status within 24 hours. The Condition is modified by a Note stating it is not applicable if the second ECCS ~~PREACS~~ train is intentionally declared inoperable. The Required Action is not intended for voluntary removal of redundant systems or components from service. The Required Action is only applicable if one train is inoperable for any reason and the second train is found to be inoperable, or if both trains are found to be inoperable at the same time. The Completion Time is based on Reference ~~6~~ which demonstrated that the 24 hour Completion Time is acceptable based on the low frequency of the potential challenge and the small incremental risk associated with continued operation.

area ventilation

BASES

ACTIONS (continued)

D.1 and D.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

2

area ventilation

1

If the ECCS ~~PREACS~~ train or ECCS pump room boundary cannot be restored to OPERABLE status within the associated Completion Time, the unit must be in a MODE in which overall plant risk is minimized. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours.

6

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~7~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

1

Required Action C.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

B 3.7 PLANT SYSTEMS

B 3.7.~~13~~ 12 Emergency Core Cooling System (ECCS) ~~Pump Room Exhaust Air Cleanup System (PREACS)~~

BASES

BACKGROUND

The ECCS ~~PREACS~~ filters air from the area of the active ECCS components during the recirculation phase of a loss of coolant accident (LOCA). The ECCS ~~PREACS~~, in conjunction with other, normally operating systems, also provides environmental control of temperature and humidity in the ECCS pump room area and the lower reaches of the Auxiliary Building. R1

The ECCS ~~PREACS~~ consists of two independent and redundant trains. Each train consists of ~~a heater,~~ a prefilter ~~or demister~~, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and a fan. Ductwork, valves or dampers, and instrumentation also form part of the system ~~, as well as demisters functioning to reduce the relative humidity of the air stream~~. ~~A~~ second bank ~~of HEPA filters follows the adsorber section to collect carbon fines and provide backup in case the main HEPA filter bank fails. The downstream HEPA filter is not credited in the accident analysis, but serves to collect charcoal fines and to back up the upstream HEPA filter, should it develop a leak~~. The system initiates filtered ventilation of the pump room and lower region of the Auxiliary Building following receipt of a safety injection actuation signal ~~or coolant injection actuation signal~~.

The ECCS ~~PREACS~~ is a standby system, parts of which may also operate during normal unit operations. The Reactor Auxiliary Building Main Ventilation System provides normal cooling. During emergency operations, the ECCS ~~PREACS~~ dampers are realigned and fans are started to initiate filtration. Upon receipt of ~~the actuating Engineered Safety Feature Actuation System~~ signal~~(s)~~, normal air discharges from the ECCS pump room, the pump room is isolated, and the stream of ventilation air discharges through the system filter trains. The prefilters ~~or demisters~~ remove any large particles in the air, and any entrained water droplets present, to prevent excessive loading of the HEPA filters and charcoal adsorbers.

The ECCS ~~PREACS~~ is discussed in the FSAR, Sections ~~[~~6.5.1~~]~~, ~~[~~9.4.5~~]~~, and ~~[~~15.6.5~~]~~ (Refs. 1, 2, and 3, respectively), as it may be used for normal, as well as post accident, atmospheric cleanup functions. ~~The primary purpose of the heaters is to maintain the relative humidity at an acceptable level consistent with iodine removal efficiencies, as discussed in the Regulatory Guide 1.52 (Ref. 4).~~

BASES

Area Ventilation System

APPLICABLE SAFETY ANALYSES

The design basis of the ECCS ~~PREACS~~ is established by the large break LOCA. The system evaluation assumes a passive failure of the ECCS outside containment, such as safety injection pump seal failure, during the recirculation mode. In such a case, the system limits the radioactive release to within ~~10 CFR 100~~ limits (Ref. ~~5~~); ~~or the NRC staff approved licensing basis (e.g., a specified fraction of 10 CFR 100 limits)~~. The analysis of the effects and consequences of a large break LOCA is presented in Reference 3. The ECCS ~~PREACS~~ also actuates following a small break LOCA, requiring the unit to go into the recirculation mode of long term cooling and to clean up releases of smaller leaks, such as from valve stem packing.

10 CFR 50.67

4

Area Ventilation System

1

The two types of system failures that are considered in the accident analysis are complete loss of function and excessive LEAKAGE. Either type of failure may result in a lower efficiency of removal for any gaseous and particulate activity released to the ECCS pump rooms following a LOCA.

Area Ventilation System

The ECCS ~~PREACS~~ satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

area ventilation

LCO

Two independent and redundant ECCS ~~PREACS~~ trains are required to be OPERABLE to ensure that at least one is available, assuming a single failure disables the other train coincident with a loss of offsite power. Total system failure could result in the atmospheric release from the ECCS pump room exceeding the required limits in the event of a Design Basis Accident (DBA).

Area Ventilation System

ECCS ~~PREACS~~ is considered OPERABLE when the individual components necessary to maintain the ECCS Pump Room filtration are OPERABLE in both trains.

area ventilation

An ECCS ~~PREACS~~ train is considered OPERABLE when its associated:

a. Fan is OPERABLE,

b. HEPA filter and charcoal adsorber are not excessively restricting flow and are capable of performing their filtration functions, and

c. ~~Heater, demister,~~ ductwork, valves, and dampers are OPERABLE, and air circulation can be maintained.

BASES

LCO (continued)

The LCO is modified by a Note allowing the ECCS pump room boundary to be opened intermittently under administrative controls. For entry and exit through doors, the administrative control of the opening is performed by the person(s) entering or exiting the area. For other openings, these controls consist of stationing a dedicated individual at the opening who is in continuous communication with the control room. This individual will have a method to rapidly close the opening when a need for ECCS pump room isolation is indicated.

APPLICABILITY

Area Ventilation System

In MODES 1, 2, 3, and 4, the ECCS ~~PREACS~~ is required to be OPERABLE consistent with the OPERABILITY requirements of the ECCS. 1

Area Ventilation System

In MODES 5 and 6, the ECCS ~~PREACS~~ is not required to be OPERABLE, since the ECCS is not required to be OPERABLE. 1

ACTIONS

A.1

area ventilation

Area Ventilation System

With one ECCS ~~PREACS~~ train inoperable, action must be taken to restore OPERABLE status within 7 days. During this time, the remaining OPERABLE train is adequate to perform the ECCS ~~PREACS~~ function. 1 1

The 7 day Completion Time is appropriate because the risk contribution is less than that for the ECCS (72 hour Completion Time) and this system is not a direct support system for the ECCS. The 7 day Completion Time is reasonable, based on the low probability of a DBA occurring during this time period, and the consideration that the remaining train can provide the required capability.

area ventilation

1

If the ECCS ~~PREACS~~ train or ECCS pump room boundary cannot be restored to OPERABLE status within the associated Completion Time, the unit must be in a MODE in which overall plant risk is minimized. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours.

6

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~7~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

1

Required Action C.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SR 3.7.~~13~~.4 12 3

This SR verifies the integrity of the ECCS pump room enclosure. The ability of the ECCS pump room to maintain a negative pressure, with respect to potentially uncontaminated adjacent areas, is periodically tested to verify proper function of the ECCS ~~PREACS~~. During the post accident mode of operation, the ECCS ~~PREACS~~ is designed to maintain a slight negative pressure in the ECCS pump room with respect to adjacent areas to prevent unfiltered LEAKAGE. The ECCS ~~PREACS~~ is designed to maintain this negative pressure at a flow rate of ≤ ~~[20,000]~~ 27,000 cfm from the ECCS pump room. ~~[The Frequency of [18] months is consistent with the guidance provided in the NUREG-0800, Section 6.5.1 (Ref. 8).~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.12, BASES, ECCS AREA VENTILATION SYSTEM

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS Specification number and title.

4. As stated in the Unit 1 and Unit 2 UFSAR, Section 9.4.3.1, the ECCS Area Ventilation System is sized to maintain a slightly negative pressure in the ECCS area with respect to surrounding areas of the reactor auxiliary building. Access into the ECCS pump room area from other areas of the reactor auxiliary building is through gasketed self-closing or locked closed doors. Opening of locked doors is controlled under administrative controls.

5. PSL Unit 1 and Unit 2 ECCS Area Ventilation System design does not rely upon the ECCS Area Ventilation System to provide temperature control of the ECCS pump rooms during normal operation. Under normal operation, the reactor auxiliary building main ventilation supply (HVS-4A/B) and exhaust system (HVE-10A/B) provides the necessary ventilation of the ECCS pump rooms. Under accident conditions when ECCS pumps are operating, the ventilation supply to the nonessential section of the reactor auxiliary building is directed to the pump rooms to provide the additional cooling air requirement. Dampers are positioned automatically on SIAS signal to provide the proper flow path for supply air to the ECCS pump areas. The ECCS Area Ventilation System fans (HVE-9A and 9B) are automatically energized and dampers in the exhaust ductwork are automatically positioned to allow the fans to draw all exhaust air from the ECCS pump areas through the HEPA and charcoal filter banks before exhausting the air to the outside atmosphere. Additionally, the ECCS Area Ventilation System establishes and maintains a slightly negative pressure relative to surrounding areas assuming leakage in the ECCS areas.

DISCUSSION OF CHANGES
ITS 3.7.13, SPENT FUEL STORAGE POOL WATER LEVEL

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* CTS 3.9.11 states that the requirements on spent fuel storage pool water level are applicable "Whenever irradiated fuel assemblies are in the spent fuel storage pool." CTS 4.9.11 requires the water level in the storage pool to be verified in accordance with the Surveillance Frequency Control Program when irradiated fuel assemblies are in the spent fuel storage pool. ITS 3.7.13 is applicable "During movement of irradiated fuel assemblies in the spent fuel storage pool." ITS SR 3.7.14.1 requires verification of the spent fuel pool water level in accordance with the Surveillance Frequency Control Program. This changes the CTS by restricting the Applicability of the spent fuel pool water level Specification and performance of the Surveillance to only when there is a potential for a fuel handling accident, that is, during the movement of irradiated fuel assemblies in the spent fuel storage pool. In addition, since the Applicability is now limited to when irradiated fuel is being moved, the portion of CTS Action a. to restore water level to within its limit within 4 hours, after movement of fuel has been suspended, has also been deleted.

The purpose of CTS 3.9.11 is to ensure that the minimum spent fuel storage pool water level assumption in the fuel handling accident analysis is met. This change is acceptable because the requirements continue to ensure that the structures, systems, and components are maintained in the specified conditions assumed in

the safety analyses and licensing basis. According to UFSAR Section 15.4.3 (Unit 1) 15.7.4.1.2 (Unit 2), a fuel handling accident is initiated by the dropping of an irradiated fuel assembly either in the containment or in the fuel building and assumes all the fuel rods in the assembly are damaged. The PSL fuel handling accident analysis (outside containment) assumes a minimum water level of 23 feet above the damaged fuel assembly for both the containment and fuel handling building release locations. A minimum water level of 23 feet ensures an effective iodine decontamination factor of 200 per the guidance provided in NRC Regulatory Issue Summary 2006-04. A fuel handling accident is assumed to occur when an irradiated fuel assembly is being moved and is precluded when irradiated fuel assemblies are not being moved. Imposing the minimum spent fuel storage pool water level requirement whenever irradiated fuel assemblies are in the spent fuel storage pool is unnecessary. Therefore, the ITS imposes the controls on minimum spent fuel storage pool water level during the movement of irradiated fuel assemblies in the spent fuel storage pool. This change is designated as less restrictive because the LCO requirements are applicable in fewer operating conditions than in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.9.11 Action a. states that when the spent fuel pool water level is not met, suspend all movement of fuel assemblies and crane operations with loads in the fuel storage areas. ITS 3.7.13 Required Action A.1 states that when spent fuel storage pool water level is not within limit, immediately suspend movement of irradiated fuel assemblies in the spent fuel storage pool. This changes the CTS by deleting the requirement to suspend crane operation over the spent fuel storage areas.

The purpose of the CTS 3.9.11 Action is to preclude a fuel handling accident from occurring when the initial conditions for that accident are not met. This change is acceptable because the Required Action places the plant in a condition where a fuel handling accident is precluded. The initiator to a fuel handling accident assumed in the accident analysis is the damaging of a single irradiated fuel assembly. Damaging a fuel assembly which has not been irradiated has no significant radiological effects and is not assumed in the fuel handling accident analysis. Therefore, stopping the handling of fuel assemblies which have not been irradiated when the spent fuel pool water level is less than the limit is not required.

Crane travel related requirements were relocated from the CTS in Unit 1 and Unit 2 PSL Amendments 190 and 134, respectively, (“St. Lucie Units 1 and 2 – Issuance of Amendments Regarding the Relocation of Spent Fuel Pool Crane Technical Specification Requirements (TAC NOS. MB5667 and MB5668),” dated April 28, 2004 (ADAMS Accession No. ML 040440111)) to the respective unit Updated Final Safety Analysis Report where the operational detail is controlled under 10 CFR 50.59 criteria. As cited in the NRC Safety Evaluation associated with Amendments 190 (Unit 1) and 134 (Unit 2), NUREG-0612, “Control of Heavy Loads at Nuclear Power Plants,” regulatory guidelines for control of heavy load lifts provide assurance of safe handling of heavy loads in areas where a load drop could impact stored spent fuel, fuel in the reactor core, or equipment that may be required to achieve safe shutdown or permit continued decay heat removal. Section 5.1.1 of NUREG 0612 provides guidelines for reducing the likelihood of dropping heavy loads and provides criteria for establishing safe load

paths; procedures for load-handling operations; training of crane operators; design, testing, inspection, and maintenance of cranes and lifting devices; and analyses of the impact of heavy load drops. The guidelines in Sections 5.1.2 through 5.1.6 address alternatives to either further reduce the probability of a load-handling accident or mitigate the consequences of heavy load drops. These alternatives include using a single-failure-proof crane to improve reliability through increased factors of safety and through redundancy or duality in certain active components. Criteria for design of single-failure-proof cranes are included in NUREG-0554, “Single-Failure-Proof Cranes for Nuclear Power Plants.”

This change is acceptable because the possibility of damage to an irradiated fuel assembly as a consequence of mishandling components other than an irradiated fuel assembly is minimized by thorough training, detailed procedures and equipment design. The PSL crane design precludes the handling of heavy objects, such as shipping casks, over the spent fuel pool storage racks. Administrative controls prevent the movement of heavy loads over the cask pit whenever the cask pit rack is installed in the cask area of the spent fuel storage pool. In addition, the cask handling crane design meets the regulatory guidance for single-failure-proof cranes in NUREG-0554, “Single-Failure-Proof Cranes for Nuclear Power Plants” and NUREG-0612. Administrative controls that control the movement of light loads or prevent movement of light loads over irradiated fuel assemblies are similar to those used for control of heavy loads, to the extent practicable, as advised in NUREG 0612. Consequently, the possibility of dropping a load other than an irradiated fuel assembly and damaging of irradiated fuel assemblies in the spent fuel storage pool is remote. Therefore, the CTS 3.9.11 action related to suspension of crane operation with loads in the fuel storage areas is not necessary to be included in the technical specifications and is removed.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.13, SPENT FUEL STORAGE POOL WATER LEVEL

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS Specification number and title. The numbering is changed from 3.7.16 to 3.7.13, and the title is changed to “Spent Fuel Pool Water Level.”

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.~~16~~ Spent 13 Fuel Storage Pool Water Level

Sufficient water is necessary to retain iodine fission product activity in the water in the event of an FHA (Refs. 1 and 2). Sufficient iodine activity would be retained to limit offsite doses from the accident to within the radiation dose criteria set forth in 10 CFR 50.67, as provided by the guidance of Reference 1.

BASES

BACKGROUND

The minimum water level in the fuel storage pool meets the assumptions of iodine decontamination factors following a fuel handling accident (FHA). The specified water level shields and minimizes the general area dose when the storage racks are filled to their maximum capacity. The water also provides shielding during the movement of spent fuel.

A general description of the fuel storage pool design is given in the FSAR, Section ~~[~~9.1.2~~]~~, Reference ~~1~~, and the Spent Fuel Pool Cooling and ~~Cleanup~~ Purification System is given in the FSAR, Section ~~[~~9.1.3~~]~~ (Ref. ~~2~~). The assumptions of the fuel handling accident are given in the FSAR, Section ~~[15.7.4]~~ 15.4.3 (Ref. ~~3~~ 2).

APPLICABLE SAFETY ANALYSES

~~The minimum water level in the fuel storage pool meets the assumptions of the fuel handling accident described in Regulatory Guide 1.25 (Ref. 4). The resultant 2 hour thyroid dose to a person at the exclusion area boundary is a small fraction of the 10 CFR 100 (Ref. 5) limits.~~

~~According to Reference 4, there is 23 ft of water between the top of the damaged fuel bundle and the fuel pool surface for a fuel handling accident. With a 23 ft water level, the assumptions of Reference 4 can be used directly. In practice, this LCO preserves this assumption for the bulk of the fuel in the storage racks. In the case of a single bundle, dropped and lying horizontally on top of the spent fuel racks, however, there may be < 23 ft of water above the top of the bundle and the surface, by the width of the bundle. To offset this small nonconservatism, the analysis assumes that all fuel rods fail, although analysis shows that only the first few rods fail from a hypothetical maximum drop.~~ INSERT 1

The fuel storage pool water level satisfies Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The specified water level preserves the assumptions of the ~~fuel handling accident~~ FHA analysis (Ref. ~~3~~ 2). As such, it is the minimum required for fuel storage and movement within the fuel storage pool.

APPLICABILITY

This LCO applies during movement of irradiated fuel assemblies in the fuel storage pool since the potential for a release of fission products exists.

1

INSERT 1

The FHA analysis is described in Reference 2. During movement of irradiated fuel assemblies, the water level in the spent fuel storage pool is an initial condition design parameter in the analysis of the FHA in the spent fuel storage pool postulated in Appendix B of Regulatory Guide (RG) 1.183 (Ref. 1). A minimum water level of 23 feet is maintained above the damaged fuel assembly for both the containment and fuel handling building (FHB) release locations. Fuel handling accidents consist of dropping a single irradiated fuel assembly either in the FHB or inside the containment and assumes all the fuel rods in the assembly are damaged. The offsite dose analysis does not credit filtration during an FHA inside containment with the maintenance hatch open or in the spent fuel storage pool. The control room dose analysis credits control room emergency ventilation filtration during an FHA inside or outside the containment.

In the event of an FHA, a minimum water level of 23 feet and a minimum decay time of 72 hours prior to fuel handling ensures an effective iodine decontamination factor of 200 per the guidance provided in NRC Regulatory Issue Summary 2006-04 (Ref. 5). The FHA assumes 100% of the noble gas is released from the damaged fuel assembly and escapes from the pool. All of the non-iodine particulates released from the damaged fuel assembly are assumed to be retained by the water. Iodine released from the damaged fuel assembly is assumed to be composed of 99.85% elemental and 0.15% organic. Activity released from the FHA is assumed to leak to the environment over a two-hour period and no credit is taken for dilution in the spent fuel pool level.

BASES

ACTIONS

A.1

Required Action A.1 is modified by a Note indicating that LCO 3.0.3 does not apply.

When the initial conditions for an accident cannot be met, steps should be taken to preclude the accident from occurring. When the fuel storage pool water level is lower than the required level, the movement of irradiated fuel assemblies in the fuel storage pool is immediately suspended. This ~~effectively~~ precludes ~~a spent fuel handling accident~~ an FHA from occurring. This does not preclude moving a fuel assembly to a safe position.

If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODES 1, 2, 3, and 4, the fuel movement is independent of reactor operations. Therefore, in either case, inability to suspend movement of irradiated fuel assemblies is not sufficient reason to require a reactor shutdown.

SURVEILLANCE REQUIREMENTS

SR 3.7.~~16~~13.1

This SR verifies sufficient fuel storage pool water is available in the event of ~~a fuel handling accident~~ an FHA. The water level in the fuel storage pool must be checked periodically. ~~[The 7 day Frequency is appropriate because the volume in the pool is normally stable. Water level changes are controlled by unit procedures and are acceptable, based on operating experience.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

~~During refueling operations, the level in the fuel storage pool is at equilibrium with that of the refueling canal, and the level in the refueling canal is checked daily in accordance with LCO 3.7.17, "Fuel Storage Pool Boron Concentration."~~

B 3.7 PLANT SYSTEMS

B 3.7.~~16~~ Spent 13 Fuel Storage Pool Water Level

Sufficient water is necessary to retain iodine fission product activity in the water in the event of an FHA (Refs. 1 and 2). Sufficient iodine activity would be retained to limit offsite doses from the accident to within the radiation dose criteria set forth in 10 CFR 50.67, as provided by the guidance of Reference 1.

BASES

BACKGROUND

The minimum water level in the fuel storage pool meets the assumptions of iodine decontamination factors following a fuel handling accident (FHA). The specified water level shields and minimizes the general area dose when the storage racks are filled to their maximum capacity. The water also provides shielding during the movement of spent fuel.

A general description of the fuel storage pool design is given in the FSAR, Section ~~[~~9.1.2~~]~~, Reference ~~1~~, and the Spent Fuel Pool Cooling and ~~Cleanup~~ Purification System is given in the FSAR, Section ~~[~~9.1.3~~]~~ (Ref. ~~2~~). The assumptions of the fuel handling accident are given in the FSAR, Section ~~[~~15.7.4~~]~~ (Ref. ~~3~~).

APPLICABLE SAFETY ANALYSES

~~The minimum water level in the fuel storage pool meets the assumptions of the fuel handling accident described in Regulatory Guide 1.25 (Ref. 4). The resultant 2 hour thyroid dose to a person at the exclusion area boundary is a small fraction of the 10 CFR 100 (Ref. 5) limits.~~

INSERT 1

~~According to Reference 4, there is 23 ft of water between the top of the damaged fuel bundle and the fuel pool surface for a fuel handling accident. With a 23 ft water level, the assumptions of Reference 4 can be used directly. In practice, this LCO preserves this assumption for the bulk of the fuel in the storage racks. In the case of a single bundle, dropped and lying horizontally on top of the spent fuel racks, however, there may be < 23 ft of water above the top of the bundle and the surface, by the width of the bundle. To offset this small nonconservatism, the analysis assumes that all fuel rods fail, although analysis shows that only the first few rods fail from a hypothetical maximum drop.~~

The fuel storage pool water level satisfies Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The specified water level preserves the assumptions of the ~~fuel handling accident~~ FHA analysis (Ref. ~~3~~). As such, it is the minimum required for fuel storage and movement within the fuel storage poo l.

APPLICABILITY

This LCO applies during movement of irradiated fuel assemblies in the fuel storage pool since the potential for a release of fission products exists.

1

INSERT 1

The FHA analysis is described in Reference 2. During movement of irradiated fuel assemblies, the water level in the spent fuel storage pool is an initial condition design parameter in the analysis of the FHA in the spent fuel storage pool postulated in Appendix B of Regulatory Guide (RG) 1.183 (Ref. 1). A minimum water level of 23 feet is maintained above the damaged fuel assembly for both the containment and fuel handling building (FHB) release locations. Fuel handling accidents consist of dropping a single irradiated fuel assembly either in the FHB or inside the containment and assumes all the fuel rods in the assembly are damaged. The offsite dose analysis does not credit filtration during an FHA inside containment with the maintenance hatch open or in the spent fuel storage pool. The control room dose analysis credits control room emergency ventilation filtration during an FHA inside or outside the containment.

In the event of an FHA, a minimum water level of 23 feet and a minimum decay time of 72 hours prior to fuel handling ensures an effective iodine decontamination factor of 200 per the guidance provided in NRC Regulatory Issue Summary 2006-04 (Ref. 5). The FHA assumes 100% of the noble gas is released from the damaged fuel assembly and escapes from the pool. All of the non-iodine particulates released from the damaged fuel assembly are assumed to be retained by the water. Iodine released from the damaged fuel assembly is assumed to be composed of 99.85% elemental and 0.15% organic. Activity released from the FHA is assumed to leak to the environment over a two-hour period and no credit is taken for dilution in the spent fuel pool level.

BASES

ACTIONS

A.1

Required Action A.1 is modified by a Note indicating that LCO 3.0.3 does not apply.

When the initial conditions for an accident cannot be met, steps should be taken to preclude the accident from occurring. When the fuel storage pool water level is lower than the required level, the movement of irradiated fuel assemblies in the fuel storage pool is immediately suspended. This ~~effectively~~ precludes ~~a spent fuel handling accident~~ an FHA from occurring. This does not preclude moving a fuel assembly to a safe position.

If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODES 1, 2, 3, and 4, the fuel movement is independent of reactor operations. Therefore, in either case, inability to suspend movement of irradiated fuel assemblies is not sufficient reason to require a reactor shutdown.

SURVEILLANCE REQUIREMENTS

SR 3.7.~~16~~13.1

This SR verifies sufficient fuel storage pool water is available in the event of ~~a fuel handling accident~~ an FHA. The water level in the fuel storage pool must be checked periodically. ~~[The 7 day Frequency is appropriate because the volume in the pool is normally stable. Water level changes are controlled by unit procedures and are acceptable, based on operating experience.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

~~During refueling operations, the level in the fuel storage pool is at equilibrium with that of the refueling canal, and the level in the refueling canal is checked daily in accordance with LCO 3.7.17, "Fuel Storage Pool Boron Concentration."~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.13, BASES, SPENT FUEL STORAGE POOL WATER LEVEL

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS Specification number and title. The numbering is changed from 3.7.16 to 3.7.13, and the title is changed to “Spent Fuel Pool Water Level.”

4. ISTS SR 3.7.16.1 Bases refers to the incorrect ISTS LCO regarding refueling water level. Also, this statement does not provide any additional supporting information related to the Surveillance associated with spent fuel storage pool water level. Therefore, the statement is not included in the Bases for ITS SR 3.7.13.1

DISCUSSION OF CHANGES
ITS 3.7.14, SPENT FUEL STORAGE POOL BORON CONCENTATIION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* CTS 3.9.11 is applicable whenever irradiated fuel assemblies are in the spent fuel storage pool. ITS 3.7.14 is applicable when fuel assemblies are stored in the fuel storage pool and a fuel storage pool verification has not been performed since the last movement of fuel assemblies in the fuel storage pool. In addition, ITS 3.7.14 Required Action A.2.2 provides an alternative action to allow exiting the specified condition in the Applicability when the LCO is not met. This changes the CTS by adding the Applicability statement “and a spent fuel storage pool verification has not been performed since the last movement of fuel assemblies in the fuel storage pool,” and adding an ACTION that allows exiting the Applicability if the LCO is not met.

The purpose of CTS 3.9.11 is to ensure adequate dissolved boron is in the spent fuel storage pool water to maintain the required subcriticality margin. This change is acceptable because the requirements continue to ensure that the process variable is maintained in the specified condition assumed in the safety analyses and licensing basis. Following performance of a fuel storage pool verification to ensure the fuel assemblies are in the prescribed spent fuel storage rack location, there is no potential for criticality based on the design of the storage racks. Performing a fuel storage pool verification provides assurance that no fuel assemblies have been inadvertently misplaced in the fuel storage pool. This change is consistent with the ISTS and is designated as less

restrictive because the LCO requirements are applicable in a less stringent operating condition than in the CTS and because less stringent Required Actions are being applied in the ITS than applied in the CTS.

assuming a minimum soluble boron concentration in the spent fuel storage pool of 500 ppm for normal conditions and 1500 ppm for accident conditions

separate and distinct regions, each with various prescribed patterns,

BASES

15 Pool

BACKGROUND

As described in LCO 3.7.~~18~~, "Spent Fuel ~~Assembly~~ Storage," fuel assemblies are stored in the spent fuel racks ~~[~~in ~~a "checkerboard" pattern]~~ in accordance with criteria based on ~~[~~initial enrichment and discharge burnup~~]~~. Although the water in the spent fuel pool is normally borated to ≥ ~~[1800]~~ ppm, the criteria that limit the storage of a fuel assembly to specific rack locations is conservatively developed ~~without taking credit for boron~~. 1

1900 storage 2 2 1

15

APPLICABLE SAFETY ANALYSES

Most accident conditions do not result in an increase in the activity of the spent fuel pool storage regions. However, accidents can be postulated that could increase the reactivity.

A fuel assembly could be inadvertently loaded into a spent fuel rack location not allowed by LCO 3.7.~~18~~ (e.g., an unirradiated fuel assembly ~~or an insufficiently depleted fuel assembly~~). ~~This accident is analyzed assuming the extreme case of completely loading the fuel pool racks with unirradiated assemblies of maximum enrichment.~~ Another type of postulated accident is associated with a fuel assembly that is dropped onto the fully loaded fuel pool storage rack. Either incident could have a positive reactivity effect, decreasing the margin to criticality. However, the negative reactivity effect of the soluble boron compensates for the increased reactivity caused by either one of the two postulated accident scenarios. 1

The concentration of dissolved boron in the fuel pool satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The fuel storage pool boron concentration is required to be ≥ 1900 ppm.

The specified concentration of dissolved boron in the fuel pool preserves the assumptions used in the analyses of the potential accident scenarios described above. This concentration of dissolved boron is the minimum required concentration for fuel assembly storage and movement within the fuel pool. 1

storage

APPLICABILITY

This LCO applies whenever fuel assemblies are stored in the spent fuel pool until a complete spent fuel pool verification has been performed following the last movement of fuel assemblies in the spent fuel pool. This LCO does not apply following the verification since the verification would confirm that there are no misloaded fuel assemblies. With no further fuel assembly movements in progress, there is no potential for a misloaded fuel assembly or a dropped fuel assembly. 1

BASES

ACTIONS A.1, A.2.1, and A.2.2

The Required Actions are modified by a Note indicating that LCO 3.0.3 does not apply.

When the concentration of boron in the spent fuel storage pool is less than required, immediate action must be taken to preclude an accident from happening or to mitigate the consequences of an accident in progress. This is most efficiently achieved by immediately suspending the movement of fuel assemblies. This does not preclude the movement of fuel assemblies to a safe position. In addition, action must be immediately initiated to restore boron concentration to within limit. Alternately, beginning a verification of the spent fuel storage pool fuel locations, to ensure proper locations of the fuel, can be performed.

If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operation. Therefore, inability to suspend movement of fuel assemblies is not sufficient reason to require a reactor shutdown.

SURVEILLANCE REQUIREMENTS SR 3.7.17.1

This SR verifies that the concentration of boron in the spent fuel pool is within the required limit. As long as this SR is met, the analyzed incidents are fully addressed. ~~[The 7 day Frequency is appropriate because no major replenishment of pool water is expected to take place over a short period of time.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

	20	-12.6469	15.4575	-0.5906

NOTES:

1. To qualify in a ”fuel type,” the burnup of a fuel assembly must exceed the minimum burnup “BU” calculated by inserting the “coefficients” for the associated “fuel type” and “cooling time” into the polynomial function:

   $BU = A + B*E + C*E^2$, where:

   BU = Minimum Burnup (GWD/MTU)

   E = Initial Maximum Planar Average Enrichment (weight percent uranium-235)

   A, B, C = Coefficients

2. Interpolation between values of cooling time is not permitted.

NOTES:

3 → ~~1~~. WH represents an empty cell. For the interface of Pattern "C" with Region 1, the empty cell must be on the rack periphery facing Region 1 racks. Diagrams are for illustration only.

4 → ~~2~~. For the interface of pattern "D" with Region 1, at least one cell on the rack periphery facing Region 1 rack must contain an insert (either Metamic of full-length full-strength CEA) in the 2x2 array. If the insert is Metamic, the insert must be oriented so that the corner of the L-shape is located closest to the Region 1 rack. Diagram is for illustration only.

5 → ~~3~~. For the interface of Pattern "E" with Region 1, the insert must be on the rack periphery facing the Region 1 rack. The insert may be either a Metamic of full-length full strength CEA. If the insert is Metamic, the insert must be oriented so that the corner of the L-shape is located closest to the Region 1 rack. Diagram is for illustration only.

1 → ~~4~~. Empty cells with any pattern are acceptable.

2 → ~~5~~. There are no interface requirements within Region 1. Any Pattern within Region 1 may be used for the interface. Pattern "B" was used only as an illustration.

DESIGN FEATURES

5.5 DELETED

5.6 FUEL STORAGE

CRITICALITY

5.6.1 a. The spent fuel storage racks are designed and shall be maintained with:

1. A k_{eff} equivalent to less than 1.0 when flooded with unborated water, including a conservative allowance for biases and uncertainties as described in Section 9.1 of the Updated Final Safety Analysis Report.

See ITS 4.0

2. A k_{eff} equivalent to less than or equal to 0.95 when flooded with water containing 500 ppm boron, including a conservative allowance for biases and uncertainties as described in Section 9.1 of the Updated Final Safety Analysis Report.

3. A nominal 8.965 inch center-to-center distance between fuel assemblies placed in the spent fuel pool storage racks and a nominal 8.80 inch center-to-center distance between fuel assemblies placed in the cask pit storage rack.

4. For storage of enriched fuel assemblies, requirements of Specification 5.6.1.a.1 and 5.6.1.a.2 shall be met by positioning fuel in the spent fuel pool storage racks consistent with the requirements of Specification 5.6.1.c.

5. Fissile material, not contained in a fuel assembly lattice, shall be stored in accordance with the requirements of Specifications 5.6.1.a.1 and 5.6.1.a.2.

6. The Metamic neutron absorber inserts shall have a ^{10}B areal density greater than or equal to 0.015 grams $^{10}B/cm^2$.

b. The cask pit storage rack shall contain neutron absorbing material (Boral) between stored fuel assemblies when installed in the spent fuel pool.

LCO 3.7.15

Add proposed LCO 3.7.15 and Applicability

A02

~~c. Loading of spent fuel pool storage racks shall be controlled as described below.~~

LCO 3.7.15.a

a → ~~1~~. The maximum initial planar average U-235 enrichment of any fuel assembly inserted in a spent fuel pool storage rack shall be less than or equal to 4.6 weight percent.

LCO 3.7.15.b

b → ~~2~~. Fuel placed in Region 1 of the spent fuel pool storage racks shall comply with the storage pattern definitions of Figure ~~5.6~~-1 and the minimum burnup requirements as defined in Table ~~5.6~~-1. (See Specification ~~5.6.1.c.7~~ for exceptions)

3.7.15 3.7.15 3.7.15.g

LCO 3.7.15.c

c → ~~3~~. Fuel placed in Region 2 of the spent fuel pool storage racks shall comply with the storage pattern definitions or allowed special arrangement definitions of Figure ~~5.6~~-2 and the minimum burnup requirements as defined in Table ~~5.6~~-1 (See Specification ~~5.6.1.c.7~~ for exceptions)

3.7.15 3.7.15.g

A01

~~DESIGN FEATURES~~ ~~(continued)~~

~~CRITICALITY~~ ~~(continued)~~

~~5.6.1 c. (continued)~~

LCO 3.7.15.d

d → ~~4~~. The 2x2 array of fuel assemblies that span the interface between Region 1 and Region 2 of the spent fuel pool storage racks shall comply with the storage pattern definitions of Figure ~~5.6~~-3 and the minimum burnup requirements as defined in Table 5.6-1. The allowed special arrangements in Region 2 as shown in Figure ~~5.6~~-2 shall not be placed adjacent to Region 1. (See Specification ~~5.6.1.c.7~~ for exceptions)

3.7.15.g 3.7.15 3.7.15

LCO 3.7.15.e

e → ~~5~~. Fuel placed in the cask pit storage rack shall comply with the storage pattern definitions of Figure ~~5.6~~-4 and the minimum burnup requirements as defined in Table ~~5.6~~-1. (See Specification ~~5.6.1.c.7~~ for exceptions)

3.7.15 3.7.15.g

LCO 3.7.15.f

f → ~~6~~. The same directional orientation for Metamic inserts is required for contiguous groups of 2x2 arrays where Metamic inserts are required.

LCO 3.7.15.g

g → ~~7~~. Fresh or spent fuel in any allowed configuration may be replaced with non-fuel hardware, and fresh fuel in any allowed configuration may be replaced with a fuel rod storage basket containing fuel rod(s). ~~Also,~~ storage of Metamic inserts or control rods, without any fissile material, is acceptable in locations designated as completely water-filled cells.

d. The new fuel storage racks are designed for dry storage of unirradiated fuel assemblies having a maximum planar average U-235 enrichment less than or equal to 4.6 weight percent, while maintaining a k_{eff} of less than or equal to 0.98 under the most reactive condition.

See ITS 4.0

DRAINAGE

5.6.2 The spent fuel storage pool is designed and shall be maintained to prevent inadvertent draining of the pool below elevation 56 feet.

CAPACITY

5.6.3 The spent fuel pool storage racks are designed and shall be maintained with a storage capacity limited to no more than 1491 fuel assemblies, and the cask pit storage rack is designed and shall be maintained with a storage capacity limited to no more than 225 fuel assemblies. The total Unit 2 spent fuel pool and cask pit storage capacity is limited to no more than 1716 fuel assemblies.

NOTES:

1. To qualify in a “fuel type”, the burnup of a fuel assembly must exceed the minimum burnup “BU” calculated by inserting the “coefficients” for the associated “fuel type” and “cooling time” into the following polynomial function:

   $BU = A + B*E + C*E^2$, where:

   BU = Minimum Burnup (GWD/MTU)

   E = Maximum Initial Planar Average Enrichment (weight percent U-235)

   A, B, C = Coefficients for each fuel type

2. Interpolation between values of cooling time is not permitted.

~~DEFINITIONS for Figure 5.6-2~~

Figure 3.7.15-2 (page 2 of 3)

Notes for Figure 3.7.15-2

3 → ~~1~~. Allowable pattern is fuel assemblies that meet the requirements of type 3 in three of the 2x2 array locations in combination with one completely water-filled cell. Minimum burnup for fuel assembly type 3 is defined in Table ~~5.6~~-1 as a function of maximum initial planar average enrichment. Diagram is for illustration only.

3.7.15

4 → ~~2~~. Allowable pattern is fuel assemblies that meet the requirements of type 4 in each of the 2x2 array locations with at least two Metamic inserts placed anywhere in the 2x2 array. Minimum burnup for fuel assembly type 4 is defined in Table ~~5.6~~-1 as a function of maximum initial planar average enrichment and cooling time. Diagram is for illustration only.

3.7.15

5 → ~~3~~. Allowable pattern is fuel assemblies that meet the requirements of type 5 in each of the 2x2 array locations with at least one Metamic insert placed anywhere in the 2x2 array. Minimum burnup for fuel assembly type 5 is defined in Table ~~5.6~~-1 as a function of maximum initial planar average enrichment and cooling time. Diagram is for illustration only.

3.7.15

6 → ~~4~~. Allowable pattern is fuel assemblies that meet the requirements of type 6 in each of the 2x2 array locations with at least two full-length, full strength 5 finger CEAs placed anywhere in the 2x2 array. Minimum burnup for fuel assembly type 6 is defined in Table ~~5.6~~-1 as a function of maximum initial planar average enrichment and cooling time. Diagram is for illustration only.

3.7.15

7 → ~~5~~. Allowable pattern is fuel assemblies that meet the requirements of type 7 in each of the 2x2 array locations with at least one full-length, full strength 5 finger CEA placed anywhere in the 2x2 array. Minimum burnup for fuel assembly type 7 is defined in Table ~~5.6~~-1 as a function of maximum initial planar average enrichment and cooling time. Diagram is for illustration only.

3.7.15

SR1. Allowable pattern is up to four fresh or burned fuel assemblies placed in a 3x3 array in combination with Pattern “D” placed outside the 3x3 array. Fresh or burned fuel shall be placed in the corners of the 3x3 array with completely water-filled cells placed face-adjacent on all sides. A fuel assembly that meets the requirements of type 3 shall be placed in the center of the 3x3 array. Minimum burnup for fuel assembly type 3 is defined in Table ~~5.6~~-1 as a function of maximum initial planar average enrichment. Diagram is for illustration only.

3.7.15

SR2. Allowable pattern is up to four fresh or burned fuel assemblies placed in a 3x3 array in combination with Pattern “E” placed outside the 3x3 array. Fresh or burned fuel shall be placed in the corners of the 3x3 array with completely water-filled cells placed face-adjacent on all sides. A fuel assembly that meets the requirements of type 4 with a Metamic insert shall be placed in the center of the 3x3 array. Minimum burnup for fuel assembly type 4 is defined in Table ~~5.6~~-1 as a function of maximum initial planar average enrichment and cooling time. Diagram is for illustration only.

Allowable Cask Pit Storage Rack Patterns

DISCUSSION OF CHANGES
ITS 3.7.15, SPENT FUEL POOL STORAGE

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 5.6.1.c provides the criteria for fuel storage in the spent fuel storage pool, based on enrichment and burnup, for Region 1, Region 2, or cask pit storage racks. Unit 1 ITS LCO 3.7.15 requires that the initial enrichment and burnup of each fuel assembly stored in Region 1 or Region 2 be in accordance with Table 3.7.15-1 and the configuration requirements specified in LCO 3.7.15.a, b, c, d, e and f. Unit 2 ITS LCO 3.7.15 requires that the initial enrichment and burnup of each fuel assembly stored in Region 1, Region 2, or cask pit storage rack be in accordance with Table 3.7.15-1 and the configuration requirements specified in LCO 3.7.15.a, b, c, d, e, f, and g. In addition, ITS 3.7.15 provides an explicit ACTION to initiate action to immediately move the noncomplying fuel assembly to an acceptable location if the requirements of the LCO are not met. This changes the CTS by moving the storage requirements for spent fuel stored in Region 1, Region 2, and cask pit storage racks to an explicit LCO and adds an explicit ACTION to be taken if the LCO is not met.

The purpose of CTS 5.6.1 is to provide the design criteria to preserve assumptions in the spent fuel storage pool criticality analysis. Spent fuel storage requirements are more appropriately provided in an LCO. Therefore, the spent fuel storage requirements specified in CTS 5.6.1.c, including associated table and figures are moved to a separate Technical Specifications; ITS 3.7.15, “Spent Fuel Storage.” Although the CTS does not provide an explicit Action associated with noncompliance with the storage requirements of CTS 5.6.1.c, this condition would result in the spent fuel storage pool being in an unanalyzed condition and immediate corrective action would be taken to restore compliance. This change is acceptable because the ITS preserves the assumptions of the spent fuel storage pool criticality analysis and provides an appropriate ACTION to restore compliance when fuel storage is not within the required configuration. This change is designated as an administrative change because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 The CTS does not provide a Surveillance Requirement for spent fuel storage. ITS SR 3.7.15.1 requires a verification by administrative means that the initial enrichment and burnup of the fuel assembly is in accordance with Table 3.7.15-1 and configuration requirements of LCO 3.7.15.a, b, c, d, e, f and g (Unit 2 only). This changes the CTS by incorporating the requirements of ITS SR 3.7.15.1.

DISCUSSION OF CHANGES
ITS 3.7.15, SPENT FUEL POOL STORAGE

The safety related function of the spent fuel storage pool is to assure by the spacing and geometrically safe configurations of new and spent fuel assemblies with initial planar average U-235 enrichment up to 4.6 wt% ensure a subcritical array of keff ≤ 0.95 is maintained, assuming credit for a portion of the soluble boron present in the fuel pool water. This change is acceptable because the proposed Surveillance Requirement provides assurance that fuel assembly storage will be controlled in accordance with the assumptions of the spent fuel storage pool criticality analysis. This change is designated as more restrictive because it adds a new Surveillance Requirement to the CTS.

	2.5	-11.8506	16.1475	-0.3969
	5	-16.5196	18.5309	-0.7837
	10	-13.6831	16.3475	-0.5844
	15	-12.5819	15.6175	-0.5656
	20	-12.6469	15.4575	-0.5906

Notes:

1. To qualify in a ”fuel type,” the burnup of a fuel assembly must exceed the minimum burnup “BU” calculated by inserting the “coefficients” for the associated “fuel type” and “cooling time” into the polynomial function:

   $BU = A + B*E + C*E^2$, where:

   BU = Minimum Burnup (GWD/MTU)

   E = Initial Maximum Planar Average Enrichment (weight percent uranium-235)

   A, B, C = Coefficients

2. Interpolation between values of cooling time is not permitted.

INSERT 5 (continued)

Notes to Figure 3.7.15-3

Notes:

1. Empty cells with any pattern are acceptable.

2. There are no interface requirements within Region 1. Any Pattern within Region 1 may be used for the interface. Pattern “B” was used only as an illustration.

3. WH represents an empty cell. For the interface of Pattern “C” with Region 1, the empty cell must be on the rack periphery facing Region 1 racks. Diagrams are for illustration only.

4. For the interface of pattern “D” with Region 1, at least one cell on the rack periphery facing Region 1 rack must contain an insert (either Metamic of full-length full-strength CEA) in the 2x2 array. If the insert is Metamic, the insert must be oriented so that the corner of the L-shape is located closest to the Region 1 rack. Diagram is for illustration only.

5. For the interface of Pattern “E” with Region 1, the insert must be on the rack periphery facing the Region 1 rack. The insert may be either a Metamic of full-length full strength CEA. If the insert is Metamic, the insert must be oriented so that the corner of the L-shape is located closest to the Region 1 rack. Diagram is for illustration only.

Notes for Figure 3.7.15-2 (page 1 of 3)

Notes:

1. The storage arrangements of fuel within a rack module may contain more than one pattern. Each cell is a part of up to four 2x2 arrays, and each cell must simultaneously meet the requirements of all those arrays of which it is a part.

2. Completely water-filled cells within any pattern are acceptable.

3. Allowable pattern is fuel assemblies that meet the requirements of type 3 in three of the 2x2 array locations in combination with one completely water-filled cell. Minimum burnup for fuel assembly type 3 is defined in Table 3.7.15-1 as a function of maximum initial planar average enrichment. Diagram is for illustration only.

4. Allowable pattern is fuel assemblies that meet the requirements of type 4 in each of the 2x2 array locations with at least two Metamic inserts placed anywhere in the 2x2 array. Minimum burnup for fuel assembly type 4 is defined in Table 3.7.15-1 as a function of maximum initial planar average enrichment and cooling time. Diagram is for illustration only.

5. Allowable pattern is fuel assemblies that meet the requirements of type 5 in each of the 2x2 array locations with at least one Metamic insert placed anywhere in the 2x2 array. Minimum burnup for fuel assembly type 5 is defined in Table 3.7.15-1 as a function of maximum initial planar average enrichment and cooling time. Diagram is for illustration only.

6. Allowable pattern is fuel assemblies that meet the requirements of type 6 in each of the 2x2 array locations with at least two full-length, full strength 5 finger CEAs placed anywhere in the 2x2 array. Minimum burnup for fuel assembly type 6 is defined in Table 3.7.15-1 as a function of maximum initial planar average enrichment and cooling time. Diagram is for illustration only.

7. Allowable pattern is fuel assemblies that meet the requirements of type 7 in each of the 2x2 array locations with at least one full-length, full strength 5 finger CEA placed anywhere in the 2x2 array. Minimum burnup for fuel assembly type 7 is defined in Table 3.7.15-1 as a function of maximum initial planar average enrichment and cooling time. Diagram is for illustration only.

SR1. Allowable pattern is up to four fresh or burned fuel assemblies placed in a 3x3 array in combination with Pattern “D” placed outside the 3x3 array. Fresh or burned fuel shall be placed in the corners of the 3x3 array with completely water-filled cells placed face-adjacent on all sides. A fuel assembly that meets the requirements of type 3 shall be placed in the center of the 3x3 array. Minimum burnup for fuel assembly type 3 is defined in Table 3.7.15-1 as a function of maximum initial planar average enrichment. Diagram is for illustration only.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.15, SPENT FUEL POOL STORAGE

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the Specification Number and Title.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.~~18~~ 15 Spent Fuel Pool Storage

BASES

BACKGROUND

~~The spent fuel storage facility is designed to store either new (nonirradiated) nuclear fuel assemblies, or burned (irradiated) fuel assemblies in a vertical configuration underwater. The storage pool is sized to store [735] fuel assemblies, which includes storage for [15] failed fuel containers. The spent fuel storage cells are installed in parallel rows with center to center spacing of [12 31/32] inches in one direction, and [13 3/16] inches in the other orthogonal direction. This spacing and "flux trap" construction, whereby the fuel assemblies are inserted into neutron absorbing stainless steel cans, is sufficient to maintain a k_{eff} of ≤ 0.95 for spent fuel of original enrichment of up to [3.3]%. However, as higher initial enrichment fuel assemblies are stored in the spent fuel pool, they must be stored in a checkerboard pattern taking into account fuel burnup to maintain a k_{eff} of 0.95 or less.~~

INSERT 1

APPLICABLE SAFETY ANALYSES

~~The spent fuel storage facility is designed for noncriticality by use of adequate spacing, and "flux trap" construction whereby the fuel assemblies are inserted into neutron absorbing stainless steel cans.~~

INSERT 2

The spent fuel pool storage satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The restrictions on the placement of fuel assemblies within the spent fuel pool, according to ~~[Figure 3.7.18-1],~~ in the ~~accompanying~~ LCO, ensures that the k_{eff} of the spent fuel pool will always remain < 0.95 ~~assuming the pool to be flooded with unborated water~~. The restrictions are consistent with the criticality safety analysis performed for the spent fuel pool ~~according to [Figure 3.7.18-1], in the accompanying LCO~~. ~~Fuel assemblies not meeting the criteria of [Figure 3.7.18-1] shall be stored in accordance with Specification 4.3.1.1.~~

criteria for Region 1, Region 2, and cask pit specified

APPLICABILITY

This LCO applies whenever any fuel assembly is stored in ~~[Region 2]~~ of the spent fuel pool.

Region 1, Region 2, or cask pit storage rack

ACTIONS

A.1

Required Action A.1 is modified by a Note indicating that LCO 3.0.3 does not apply.

Region 1, Region 2, or the cask pit storage rack

When the configuration of fuel assemblies stored in ~~[Region 2] the spent fuel pool~~ is not in accordance with ~~Figure [3.7.18-1]~~, immediate action must be taken to make the necessary fuel assembly movement(s) to bring the configuration into compliance ~~with Figure [3.7.18-1]~~.

criteria for Region 1, Region 2, and cask pit specified in the LCO

1

INSERT 1

The spent fuel storage pool is designed for the underwater storage of 1706 spent fuel assemblies plus 143 fuel assemblies in the cask pit storage rack, when installed. The total storage capability is 1849 assemblies with the cask pit rack installed.

The spent fuel storage pool high density spent fuel storage racks are divided into three separate and distinct regions. Region 1, with a maximum storage capacity of 342 fuel assemblies, is designed to accommodate new fuel with a maximum U-235 enrichment up to 4.95 weight percent (wt%) or spent fuel regardless of the discharge fuel burnup. Region 2, with a maximum storage capacity of 1364 fuel assemblies, is designed to accommodate high burnup fuel. The cask pit rack, with a maximum storage capacity of 143 fuel assemblies, is a Region 1 design capable of storing either new fuel or spent fuel regardless of the discharge fuel burnup. | R1

Criticality is precluded by the spacing and geometrically safe configurations of new and spent fuel assemblies with a maximum initial planar average U-235 enrichment up to 4.6 wt% to ensure a subcritical array of keff ≤ 0.95 is maintained, assuming 500 ppm of soluble boron is present in the fuel pool water.

1

INSERT 2

The misplacement of a fresh (unburned) fuel assembly with a minimum soluble poison of 500 ppm in the spent fuel storage pool could result in exceeding the regulatory limit of keff ≤ 0.95. This could possibly occur if a fresh fuel assembly of the highest permissible enrichment (4.6 wt%) were to be inadvertently misloaded into a Region 2 storage cell intended to be empty, or into a cell intended to hold a low reactivity fuel assembly. The reactivity consequences of these situations determined that the misloading of a fresh assembly into a cell intended to remain empty is the bounding condition. A boron concentration of 1500 ppm is required to ensure a keff ≤ 0.95 is maintained in the event of a misloaded fuel assembly.

BASES

ACTIONS (continued)

If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operation. Therefore, in either case, inability to move fuel assemblies is not sufficient reason to require a reactor shutdown.

SURVEILLANCE REQUIREMENTS

SR 3.7.~~18~~.1

15

3

This SR verifies by administrative means that the initial enrichment and burnup of the fuel assembly is in accordance with ~~Figure~~ [~~3.7.18-1~~] in the ~~accompanying~~ LCO. ~~For fuel assemblies in the unacceptable range of [Figure 3.7.18-1], performance of this SR will ensure compliance with Specification 4.3.1.1.~~

B 3.7 PLANT SYSTEMS

B 3.7.~~18~~ Spent Fuel Pool Storage
15

BASES

BACKGROUND

~~The spent fuel storage facility is designed to store either new (nonirradiated) nuclear fuel assemblies, or burned (irradiated) fuel assemblies in a vertical configuration underwater. The storage pool is sized to store [735] fuel assemblies, which includes storage for [15] failed fuel containers. The spent fuel storage cells are installed in parallel rows with center to center spacing of [12 31/32] inches in one direction, and [13 3/16] inches in the other orthogonal direction. This spacing and "flux trap" construction, whereby the fuel assemblies are inserted into neutron absorbing stainless steel cans, is sufficient to maintain a k_{eff} of ≤ 0.95 for spent fuel of original enrichment of up to [3.3]%. However, as higher initial enrichment fuel assemblies are stored in the spent fuel pool, they must be stored in a checkerboard pattern taking into account fuel burnup to maintain a k_{eff} of 0.95 or less.~~

INSERT 1

APPLICABLE SAFETY ANALYSES

~~The spent fuel storage facility is designed for noncriticality by use of adequate spacing, and "flux trap" construction whereby the fuel assemblies are inserted into neutron absorbing stainless steel cans.~~

INSERT 2

The spent fuel pool storage satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The restrictions on the placement of fuel assemblies within the spent fuel pool, according to ~~[Figure 3.7.18-1],~~ in the ~~accompanying~~ LCO, ensures that the k_{eff} of the spent fuel pool will always remain < 0.95 ~~assuming the pool to be flooded with unborated water~~. The restrictions are consistent with the criticality safety analysis performed for the spent fuel pool ~~according to [Figure 3.7.18-1], in the accompanying LCO~~. ~~Fuel assemblies not meeting the criteria of [Figure 3.7.18-1] shall be stored in accordance with Specification 4.3.1.1.~~

criteria for Region 1, Region 2, and cask pit specified

APPLICABILITY

This LCO applies whenever any fuel assembly is stored in ~~[Region 2]~~ of the spent fuel pool.

Region 1, Region 2, or cask pit storage rack

ACTIONS

A.1

Required Action A.1 is modified by a Note indicating that LCO 3.0.3 does not apply.

Region 1, Region 2, or the cask pit storage rack

When the configuration of fuel assemblies stored in ~~[Region 2] the spent fuel pool~~ is not in accordance with ~~Figure [3.7.18-1]~~, immediate action must be taken to make the necessary fuel assembly movement(s) to bring the configuration into compliance ~~with Figure [3.7.18-1]~~.

criteria for Region 1, Region 2, and cask pit specified in the LCO

1

INSERT 1

The spent fuel storage pool is designed for the underwater storage of 1491 spent fuel assemblies plus 225 fuel assemblies in the cask pit storage rack, when installed. The total storage capability is 1716 assemblies with the cask pit rack installed.

The spent fuel storage pool high density spent fuel storage racks are divided into three separate and distinct regions. Region 1, with a maximum storage capacity of 366 fuel assemblies, is designed to accommodate new fuel with a maximum U-235 enrichment up to 4.95 weight percent (wt%) or spent fuel regardless of the discharge fuel burnup. Region 2, with a maximum storage capacity of 1125 fuel assemblies, is designed to accommodate high burnup fuel. The cask pit rack, with a maximum storage capacity of 225 fuel assemblies, is a Region 2 design capable of storing spent fuel regardless of the discharge fuel burnup. | R1

Criticality is precluded by the spacing and geometrically safe configurations of new and spent fuel assemblies a maximum initial planar average U-235 enrichment up to 4.6 wt% to ensure a subcritical array of keff ≤ 0.95 is maintained, assuming 500 ppm of soluble boron is present in the fuel pool water.

1

INSERT 2

The misplacement of a fresh (unburned) fuel assembly with a minimum soluble poison of 500 ppm in the spent fuel storage pool could result in exceeding the regulatory limit of keff ≤ 0.95. This could possibly occur if a fresh fuel assembly of the highest permissible enrichment (4.6 wt%) were to be inadvertently misloaded into a Region 2 storage cell intended to be empty, or into a cell intended to hold a low reactivity fuel assembly. The reactivity consequences of these situations determined that the misloading of a fresh assembly into a cell intended to remain empty is the bounding condition. A boron concentration of 1500 ppm is required to ensure a keff ≤ 0.95 is maintained in the event of a misloaded fuel assembly.

BASES

ACTIONS (continued)

If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operation. Therefore, in either case, inability to move fuel assemblies is not sufficient reason to require a reactor shutdown.

DISCUSSION OF CHANGES
ITS 3.7.16, SECONDARY SPECIFIC ACTIVITY

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS Table 4.7-2 and Unit 2 CTS Table 4.7-1 Item 2 require an isotopic analysis to determine whether DOSE EQUIVALENT I-131 concentration is within limit. ITS SR 3.7.16.1 requires the verification that specific activity of the secondary coolant is within limit. This changes the CTS by moving the detail that an isotopic analysis must be performed to satisfy the requirements of the Surveillance to the Bases.

The removal of this detail for performing a Surveillance Requirement from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS SR 3.7.16.1 still retains the requirement to verify secondary coolant DOSE EQUIVALENT I-131 is within limit. Also, this change is acceptable because this type of procedural detail will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA02 (*Type 5 – Removal of SR Frequency to the Surveillance Frequency Control Program*) Unit 1 CTS Table 4.7-2 and Unit 2 CTS Table 4.7-1 Item 2.a require the DOSE EQUIVALENT I-131 sampling frequency to be once per 31 days whenever the gross activity determination indicates iodine concentration greater than 10% of the allowable limit. Unit 1 CTS Table 4.7-2 and Unit 2 CTS Table

4.7-1 Item 2.b allows the sampling frequency for the DOSE EQUIVALENT I-131 to be extended to once per 6 months whenever the gross activity determination indicates iodine concentrations below 10% of the allowable limits. ITS SR 3.7.16.1 requires the DOSE EQUIVALENT I-131 to be verified at a periodic Frequency in accordance with the Surveillance Frequency Control Program (SFCP). This changes the CTS by relocating a Surveillance Frequency to the SFCP.

The purpose of this Surveillance is to assure that the necessary parameter is maintained within limits. The Frequency is proposed to be specified in accordance with the Surveillance Frequency Control Program and is acceptable because the periodic Frequency is placed under licensee control pursuant to the methodology described in NEI 04-10, which is specified in ITS Section 5.5. The SFCP provides the necessary administrative controls to require that surveillances related to testing, calibration and inspection are conducted at a frequency to assure that the necessary quality of systems and components is maintained, that facility operation will be within safety limits, and that the limiting conditions for operation will be met. Florida Power & Light Company has determined that the control of the periodic Frequency in accordance with the SFCP is consistent with the intent of TSTF-425, Revision 3, and with the NRC's model SE dated July 6, 2009 (74 FR 32001). The current sampling Frequencies specified in Items 2a and 2b of Unit 1 CTS Table 4.7-2 and Unit 2 CTS Table 4.7-1 represent periodic frequencies of 31 days versus 61 days based on iodine concentration determined during verification of gross activity. However, the requirement to verify gross activity is being deleted from the CTS (Refer to Discussion of Change (DOC) L01). Therefore, the periodic Frequency relocated to the SFCP for ITS SR 3.7.16.1 is 31 days. The ITS SR 3.7.16.1 frequency in accordance with the SFCP is a periodic frequency and does not meet the scope exclusion criteria identified in Section 1.0, "Introduction," of the TSTF-425 model SE.

PSL Unit 1 and Unit 2 adopted a SFCP in Amendment Nos. 223 (Unit 1) and 173 (Unit 2) (ADAMS Accession No. ML15127A066) as contained in CTS 6.8.4.o (Unit 1) and 6.8.4.q (Unit 2) (ITS 5.5.16). This change is designated as a less restrictive removal of detail change because the Surveillance Frequency is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 5 – Deletion of Surveillance Requirement)* Unit 1 CTS Table 4.7-2 and Unit 2 CTS Table 4.7-1 Item 1 require that the gross activity determination in accordance with the Surveillance Frequency Control Program. ITS 3.7.16 does not require any sampling to be performed to determine the gross activity of the secondary coolant. This changes the CTS by deleting the requirement for gross activity determination.

The purpose of Unit 1 CTS Table 4.7-2 and Unit 2 CTS Table 4.7-1 Item 1 is to determine the gross activity in order to determine the sampling Frequency for secondary coolant DOSE EQUIVALENT I-131. Based on the gross activity, the sample Frequency for determining DOSE EQUIVALENT I-131 can be extended to once per 6 months from once per 31 days. This change is acceptable

because the deleted Surveillance Requirement is not necessary to verify that the values used to meet the LCO are consistent with the safety analysis. Thus, appropriate values continue to be tested in a manner and at a Frequency necessary to give confidence that the assumptions in the safety analyses are protected. ITS SR 3.7.16.1 continues to require that the DOSE EQUIVALENT I-131 be determined within an acceptable periodic Frequency in accordance with the Surveillance Frequency Control Program. Refer to DOC LA02 for relocation of the DOSE EQUIVALENT I-131 Frequency. The secondary coolant DOSE EQUIVALENT I-131 is used in the accident analyses. The gross activity of the secondary coolant is not used in any accident analysis and is not relevant to the LCO or associated ACTIONS. This change is designated as less restrictive because a Surveillance that is required in the CTS will not be required in the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.16, SECONDARY SPECIFIC ACTIVITY

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes have been made to reflect the change to the Specification number.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.~~19~~ 16 Secondary Specific Activity

BASES

BACKGROUND

Activity in the secondary coolant results from steam generator tube outleakage from the Reactor Coolant System (RCS). Under steady state conditions, the activity is primarily iodines with relatively short half lives, and thus is indication of current conditions. During transients, I-131 spikes have been observed as well as increased releases of some noble gases. Other fission product isotopes, as well as activated corrosion products in lesser amounts, may also be found in the secondary coolant.

A limit on secondary coolant specific activity during power operation minimizes releases to the environment because of normal operation, anticipated operational occurrences, and accidents.

This limit is lower than the activity value that might be expected from a 1 gpm tube leak (LCO 3.4.13, "RCS Operational LEAKAGE") of primary coolant at the limit of 1.0 µCi/gm (LCO 3.4.16, "RCS Specific Activity"). The steam line failure is assumed to result in the release of the noble gas and iodine activity contained in the steam generator inventory, the feedwater, and reactor coolant LEAKAGE. Most of the isotopes have short half-lives (i.e., < 20 hours).

With the specified activity level, the resultant 2 hour thyroid dose to a person at the exclusion area boundary (EAB) would be about ~~[.13]~~ 0.27 rem should the main steam safety valves (MSSVs) open for the 2 hours following a trip from full power.

Operating a unit at the allowable limits could result in a 2 hour EAB exposure of a small fraction of the 10 CFR ~~100~~ 50.67 (Ref. 1) limits.

APPLICABLE SAFETY ANALYSES

The accident analysis of the main steam line break (MSLB), as discussed in the FSAR, Chapter ~~[15]~~ U 15.4.6 (Ref. 2), assumes the initial secondary coolant specific activity to have a radioactive isotope concentration of ~~[~~0.10~~]~~ µCi/gm DOSE EQUIVALENT I-131. This assumption is used in the analysis for determining the radiological consequences of the postulated accident. The accident analysis, based on this and other assumptions, shows that the radiological consequences of an MSLB do not exceed a small fraction of the unit EAB limits (Ref. 1) for whole body and thyroid dose rates.

BASES

APPLICABLE SAFETY ANALYSES (continued)

With the loss of offsite power, the remaining steam generator is available for core decay heat dissipation by venting steam to the atmosphere through MSSVs and atmospheric dump valves (ADVs). The Auxiliary Feedwater System supplies the necessary makeup to the steam generator. Venting continues until the reactor coolant temperature and pressure have decreased sufficiently for the Shutdown Cooling System to complete the cooldown.

In the evaluation of the radiological consequences of this accident, the activity released from the steam generator connected to the failed steam line is assumed to be released directly to the environment. The unaffected steam generator is assumed to discharge steam and any entrained activity through MSSVs and ADVs during the event.

Secondary specific activity limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

As indicated in the Applicable Safety Analyses, the specific activity limit in the secondary coolant system of ≤ ~~[~~0.10~~]~~ µCi/gm DOSE EQUIVALENT I-131 to limit the radiological consequences of a Design Basis Accident (DBA) to a small fraction of the required limit (Ref. 1). 2

Monitoring the specific activity of the secondary coolant ensures that when secondary specific activity limits are exceeded, appropriate actions are taken in a timely manner to place the unit in an operational MODE that would minimize the radiological consequences of a DBA.

APPLICABILITY

In MODES 1, 2, 3, and 4, the limits on secondary specific activity apply due to the potential for secondary steam releases to the atmosphere.

In MODES 5 and 6, the steam generators are not being used for heat removal. Both the RCS and steam generators are depressurized, and primary to secondary LEAKAGE is minimal. Therefore, monitoring of secondary specific activity is not required.

BASES

ACTIONS

A.1 and A.2

DOSE EQUIVALENT I-131 exceeding the allowable value in the secondary coolant, is an indication of a problem in the RCS, and contributes to increased post accident doses. If secondary specific activity cannot be restored to within limits in the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.~~19~~ 16.1 3

This SR ensures that the secondary specific activity is within the limits of the accident analysis. A gamma isotope analysis of the secondary coolant, which determines DOSE EQUIVALENT I-131, confirms the validity of the safety analysis assumptions as to the source terms in post accident releases. It also serves to identify and trend any unusual isotopic concentrations that might indicate changes in reactor coolant activity or LEAKAGE. ~~[The [31] day Frequency is based on the detection of increasing trends of the level of DOSE EQUIVALENT I-131, and allows for appropriate action to be taken to maintain levels below the LCO limit.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

B 3.7 PLANT SYSTEMS

B 3.7.~~19~~ 16 Secondary Specific Activity

BASES

BACKGROUND

Activity in the secondary coolant results from steam generator tube outleakage from the Reactor Coolant System (RCS). Under steady state conditions, the activity is primarily iodines with relatively short half lives, and thus is indication of current conditions. During transients, I-131 spikes have been observed as well as increased releases of some noble gases. Other fission product isotopes, as well as activated corrosion products in lesser amounts, may also be found in the secondary coolant.

A limit on secondary coolant specific activity during power operation minimizes releases to the environment because of normal operation, anticipated operational occurrences, and accidents.

This limit is lower than the activity value that might be expected from a 1 gpm tube leak (LCO 3.4.13, "RCS Operational LEAKAGE") of primary coolant at the limit of 1.0 µCi/gm (LCO 3.4.16, "RCS Specific Activity"). The steam line failure is assumed to result in the release of the noble gas and iodine activity contained in the steam generator inventory, the feedwater, and reactor coolant LEAKAGE. Most of the isotopes have short half-lives (i.e., < 20 hours).

With the specified activity level, the resultant 2 hour thyroid dose 0.27 to a person at the exclusion area boundary (EAB) would be about ~~[.13]~~ rem should the main steam safety valves (MSSVs) open for the 2 hours following a trip from full power.

Operating a unit at the allowable limits could 50.67 result in a 2 hour EAB exposure of a small fraction of the 10 CFR ~~100~~ (Ref. 1) limits.

APPLICABLE SAFETY ANALYSES

The U accident analysis 15.1.6 of the main steam line break (MSLB), as discussed in the FSAR, Chapter ~~[15]~~ (Ref. 2), assumes the initial secondary coolant specific activity to have a radioactive isotope concentration of ~~[~~0.10~~]~~ µCi/gm DOSE EQUIVALENT I-131. This assumption is used in the analysis for determining the radiological consequences of the postulated accident. The accident analysis, based on this and other assumptions, shows that the radiological consequences of an MSLB do not exceed a small fraction of the unit EAB limits (Ref. 1) for whole body and thyroid dose rates.

BASES

APPLICABLE SAFETY ANALYSES (continued)

With the loss of offsite power, the remaining steam generator is available for core decay heat dissipation by venting steam to the atmosphere through MSSVs and atmospheric dump valves (ADVs). The Auxiliary Feedwater System supplies the necessary makeup to the steam generator. Venting continues until the reactor coolant temperature and pressure have decreased sufficiently for the Shutdown Cooling System to complete the cooldown.

In the evaluation of the radiological consequences of this accident, the activity released from the steam generator connected to the failed steam line is assumed to be released directly to the environment. The unaffected steam generator is assumed to discharge steam and any entrained activity through MSSVs and ADVs during the event.

Secondary specific activity limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

As indicated in the Applicable Safety Analyses, the specific activity limit in the secondary coolant system of ≤ ~~[~~0.10~~]~~ µCi/gm DOSE EQUIVALENT I-131 to limit the radiological consequences of a Design Basis Accident (DBA) to a small fraction of the required limit (Ref. 1). 2

Monitoring the specific activity of the secondary coolant ensures that when secondary specific activity limits are exceeded, appropriate actions are taken in a timely manner to place the unit in an operational MODE that would minimize the radiological consequences of a DBA.

DISCUSSION OF CHANGES
ITS 3.7.17, FUEL POOL AREA VENTILATION SYSTEM
UNIT 1 ONLY

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.9.12 provides requirements for the fuel pool ventilation system. ITS LCO 3.7.17 provides similar requirements and specifically requires one fuel pool area ventilation train to be OPERABLE. CTS 3.9.12 utilizes the terms system and train interchangeably. The Fuel Pool Area Ventilation System is a subsystem of the Fuel Handling Building Ventilation System and consists of two exhaust fans and a common filter system. Therefore, for the purpose of this LCO, each exhaust fan and associated dampers and valves, including the common filter system, is defined as a train. The ACTIONS and Surveillance Requirements are modified to reflect this presentation preference and includes the word “required” where appropriate in accordance with the ISTS Writer’s Guide. This change is a presentation preference and designated as an administrative change. This change is acceptable because it does not result in a technical change to the CTS.

A03 CTS 4.9.12.b.1 through b.4 specify the fuel pool ventilation filter system Surveillances to be performed within the frequency requirements specified in CTS 4.9.12.b. CTS 4.9.12.1.c.1, c.2, d, and e also specify fuel pool ventilation filter system Surveillances to be performed within the frequency requirements specified in CTS 4.9.12.c, d, and e, respectively. ITS SR 3.7.17.2 requires performing required fuel pool area ventilation train filter testing in accordance with the Ventilation Filter Testing Program (VFTP). CTS 4.9.12 does not include a VFTP, but the requirements that make up the VFTP are retained in ITS Section 5.5. This changes the CTS by requiring testing in accordance with the VFTP and moving the specific filter requirements to ITS Section 5.5. This presentation change is acceptable because filter testing requirements are being retained in the VFTP as part of ITS Section 5.5, and ITS SR 3.7.17.2 references the VFTP for performing these tests. This change is designated as administrative because it does not result in technical changes to the CTS.

RELOCATED SPECIFICATIONS

None

DISCUSSION OF CHANGES
ITS 3.7.17, FUEL POOL AREA VENTILATION SYSTEM
UNIT 1 ONLY

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 (*Category 2 – Relaxation of Applicability*) CTS 3.9.12 states that the requirements on Fuel Pool Ventilation System – Fuel Storage are applicable "Whenever recently irradiated fuel is in the spent fuel pool." ITS 3.7.17 is applicable "During movement of recently irradiated fuel assemblies in the spent fuel storage pool." This changes the CTS by restricting the Applicability of the Fuel Pool Area Ventilation System Specification to only when there is a potential for a fuel handling accident (FHA) involving recently irradiated fuel, that is, during the movement of recently irradiated fuel assemblies in the spent fuel storage pool. In addition, since the Applicability is now limited to when recently irradiated fuel is being moved, the portion of CTS Action a to restore at least one fuel pool ventilation system to OPERABLE status, after movement of fuel has been suspended, has also been deleted.

The purpose of CTS 3.9.12 is to ensure that the Fuel Pool Area Ventilation System can provide filtration to minimize the consequences of an FHA involving recently irradiated fuel (i.e., an irradiated fuel assembly that has occupied part of a critical reactor core within the previous 72 hours). This change is acceptable because the requirements continue to ensure that the structures, systems, and components are maintained in the specified conditions needed to minimize event consequences. The FHA analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. It is improbable to move irradiated fuel within 72 hours of a plant shutdown (i.e., keff < 0.99) because of the physical time required to perform a controlled plant shutdown, cooldown and depressurize the Reactor Coolant System (RCS), and disassemble the reactor vessel to access irradiated fuel to begin fuel movement. Additionally, filtration of the fuel handling building is not assumed for an FHA in the spent fuel storage pool. The ITS requires one train of the Fuel Pool Area Ventilation System to be OPERABLE to ensure that, in the unlikely event an FHA in the spent fuel storage pool occurs within 72 hours of a unit shutdown, fuel pool area ventilation and filtration are provided to minimize the consequences of this improbable event. This change is designated as less restrictive because the LCO requirements are applicable in fewer conditions than in the CTS.

L02 (*Category 4 – Relaxation of Required Action*) CTS 3.9.12 Action a states, in part, with no fuel pool ventilation system OPERABLE, suspend …crane operation with loads over the recently irradiated spent fuel. ITS 3.7.17 ACTIONS do not include

this action. This changes the CTS Actions by removing actions to suspend crane operation with loads over recently irradiated spent fuel.

The purpose of CTS 3.9.12 is to ensure that the Fuel Pool Area Ventilation System can provide filtration to minimize the consequences of an FHA involving recently irradiated fuel (i.e., an irradiated fuel assembly that has occupied part of a critical reactor core within the previous 72 hours). According to UFSAR Section 15.4.3 (Unit 1) 15.7.4.1.2 (Unit 2), an FHA is initiated by the dropping of an irradiated fuel assembly either in the containment or in the fuel building. The FHA analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. It is improbable to move irradiated fuel within 72 hours of a plant shutdown (i.e., keff < 0.99) because of the physical time required to perform a controlled plant shutdown, cooldown and depressurize the RCS, and disassemble the reactor vessel to access irradiated fuel to begin fuel movement and PSL procedurally restricts movement of irradiated fuel until 72 hours after shutdown. However, the ITS requires one train of the Fuel Pool Area Ventilation System to be OPERABLE to ensure that, in the unlikely event an FHA in the spent fuel storage pool occurs within 72 hours of a unit shutdown, fuel pool area ventilation and filtration are provided to minimize the consequences of this improbable event.

Crane travel related requirements were relocated from the CTS in PSL Unit 1 Amendment 190, ("St. Lucie Units 1 and 2 – Issuance of Amendments Regarding the Relocation of Spent Fuel Pool Crane Technical Specification Requirements (TAC NOS. MB5667 and MB5668)," dated April 28, 2004 (ADAMS Accession No. ML 040440111)) to the Updated Final Safety Analysis Report where the operational detail is controlled under 10 CFR 50.59 criteria. As cited in the NRC Safety Evaluation associated with Amendment 190, NUREG-0612, "Control of Heavy Loads at Nuclear Power Plants," regulatory guidelines for control of heavy load lifts provide assurance of safe handling of heavy loads in areas where a load drop could impact stored spent fuel, fuel in the reactor core, or equipment that may be required to achieve safe shutdown or permit continued decay heat removal. Section 5.1.1 of NUREG-0612 provides guidelines for reducing the likelihood of dropping heavy loads and provides criteria for establishing safe load paths; procedures for load-handling operations; training of crane operators; design, testing, inspection, and maintenance of cranes and lifting devices; and analyses of the impact of heavy load drops. The guidelines in Sections 5.1.2 through 5.1.6 address alternatives to either further reduce the probability of a load-handling accident or mitigate the consequences of heavy load drops. These alternatives include using a single-failure-proof crane to improve reliability through increased factors of safety and through redundancy or duality in certain active components. Criteria for design of single-failure-proof cranes are included in NUREG-0554, "Single-Failure-Proof Cranes for Nuclear Power Plants."

This change is acceptable because the possibility of damage to a recently irradiated fuel assembly as a consequence of mishandling components other than a recently irradiated fuel assembly is minimized by thorough training, detailed procedures and equipment design. The PSL crane design precludes the handling of heavy objects, such as shipping casks, over the spent fuel pool storage racks. Administrative controls prevent the movement of heavy loads

over the cask pit whenever the cask pit rack is installed in the cask area of the spent fuel storage pool. In addition, the cask handling crane design meets the regulatory guidance for single-failure-proof cranes in NUREG-0554, "Single-Failure-Proof Cranes for Nuclear Power Plants" and NUREG-0612. Administrative controls that control the movement of light loads or prevent movement of light loads over recently irradiated fuel assemblies are similar to those used for control of heavy loads, to the extent practicable, as advised in NUREG-0612. Consequently, the possibility of dropping a load other than a recently irradiated fuel assembly and damaging of recently irradiated fuel assemblies in the spent fuel storage pool is remote. Therefore, the CTS 3.9.12 action related to suspension of crane operation with loads over recently irradiated spent fuel is not necessary to be included in the technical specifications and is removed.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.17, FUEL POOL AREA VENTILATION SYSTEM
UNIT 1 ONLY

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The Fuel Building Ventilation System (ISTS 3.7.14) is renumbered as ITS 3.7.17 and renamed Fuel Pool Area Ventilation System. This results in renumbering the subsequent ISTS Specifications, as applicable, in the ITS. St. Lucie Plant (PSL) Unit 2 design does not utilize the Fuel Building Air Cleanup System (FBACS) for emergency filtration in the event of a fuel handling accident in the fuel handling building. Unit 2 utilizes the fuel pool area ventilation mode of the Shield Building Ventilation System for the emergency filtration function (ITS 3.6.9). Therefore, ISTS 3.7.14 is not included in the PSL Unit 2 ITS.

3. ISTS LCO 3.7.14 requires two FBACS trains to be OPERABLE and provides actions and Surveillances based on requiring both trains. ITS LCO 3.7.17 requires one fuel pool area ventilation train to be OPERABLE consistent with the CTS. The Fuel Pool Area Ventilation System is a subsystem of the Fuel Handling Building Ventilation System and consists of two exhaust fans and a common filter system. Since the Fuel Pool Area Ventilation System design utilizes a common filter and, as a result, does not support the single failure criterion, only one train is required to be OPERABLE. As a result, the ACTIONS applicable to one of two trains inoperable are not included in the ITS and the Surveillances are modified to require testing on the “required” fuel pool area ventilation train. Additionally, the ACTIONS applicable to MODES 1, 2, 3, and 4 are deleted since this Specification is not required in MODES 1, 2, 3, and 4 consistent with the CTS. Because the Specification is only required during movement of recently irradiated fuel assemblies in the spent fuel storage pool, ISTS 3.7.14, Condition E (ITS 3.7.17, Condition A) is modified to eliminate unnecessary reference to “during movement of [recently] irradiated fuel assemblies in the fuel building.” Because the Fuel Pool Area Ventilation System filters radioactivity in the spent fuel storage pool area and not the entire fuel handling building; and use of this Specification is unlikely (i.e., movement of recently irradiated fuel in the spent fuel storage pool is improbable), the Note to the LCO is not needed and not included in the ITS.

4. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

7 Pool Area Ventilation

B 3.7.1~~4~~ Fuel ~~Building Air Cleanup~~ System ~~(FBACS)~~

2

Fuel Pool Area Ventilation System

BASES

1

BACKGROUND

The ~~FBACS~~ filters airborne radioactive particulates from the area of the fuel pool following a fuel handling accident or loss of coolant accident. The ~~FBACS~~, in conjunction with other normally operating systems, also provides environmental control of temperature and humidity in the fuel pool area.

exhaust fans and a common filter system. The common filter system

Fuel Pool Area Ventilation System

The ~~FBACS~~ consists of two ~~independent, redundant trains. Each train~~ consists of a ~~heater, a~~ prefilter ~~or demister~~, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and ~~a fan~~. Ductwork, valves or dampers, and instrumentation also form part of the system~~, as well as demisters, functioning to reduce the relative humidity of the air stream. A second bank of HEPA filters follows the adsorber section to collect carbon fines and provide backup in case of failure of the main HEPA filter bank. The downstream HEPA filter is not credited in the analysis, but serves to collect charcoal fines, and to back up the upstream HEPA filter should it develop a leak.~~ The system initiates filtered ventilation of the fuel ~~handling building~~ following ~~receipt of a high radiation signal~~.

1

pool area

manual actuation from the control room

The ~~FBACS is a standby system~~, part of which may also be operated during normal unit operations. Upon ~~receipt of the actuating signal~~, ~~normal air discharges from the fuel handling building, the fuel handling building is isolated, and the stream of ventilation air discharges through the system filter trains~~. The prefilters ~~or demisters~~ remove any large particles in the air~~, and any entrained water droplets present,~~ to prevent excessive loading of the HEPA filters and charcoal adsorber~~s~~.

Fuel Pool Area Ventilation System is a subsystem of the Fuel Handling Building Ventilation System

Insert 1

U

6 and 12.2.2.5

Fuel Pool Area Ventilation System

The ~~FBACS~~ is discussed in the FSAR, Sections ~~[6.5.1], [~~9.4.~~5]~~, ~~and [15.7.4]~~ (Refs. 1, 2, and ~~3, respectively), because it may be used for normal, as well as post accident, atmospheric cleanup functions~~.

1

used

APPLICABLE SAFETY ANALYSES

The ~~FBACS~~ is ~~designed~~ to mitigate the consequences of a fuel handling accident ~~[~~involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous ~~[X] days~~)~~]~~ in which ~~[~~all~~]~~ rods in the fuel assembly are assumed to be damaged. The analysis of the ~~fuel handling accident~~ is given in Reference 3. ~~The~~

(FHA)

72 hours

3

1

FHA

Insert 1 (1)

manual initiation, the fuel pool area air is exhausted through air inlets around the periphery of the spent fuel storage pool, through the common system filter, and discharged by two 100% capacity exhaust fans to the atmosphere via the fuel handling building vent stack.

APPLICABLE SAFETY ANALYSES (continued)

Insert 2 → ~~Design Basis Accident analysis of the fuel handling accident assumes that only one train of the FBACS is functional, due to a single failure that disables the other train. The accident analysis accounts for the reduction in airborne radioactive material provided by the remaining one train of this filtration system. The amount of fission products available for release from the fuel handling building is determined for a fuel handling accident. These assumptions and the analysis follow the guidance provided in Regulatory Guide 1.25 (Ref. 4).~~

Fuel Pool Area Ventilation System

The ~~FBACS~~ satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

minimize

1

LCO

One train of the Fuel Pool Area Ventilation System is

~~Two independent and redundant trains of the FBACS are~~ required to be OPERABLE to ~~ensure that at least one is available, assuming a single failure that disables the other train coincident with a loss of offsite power. Total system failure could result in the~~ atmospheric release from the fuel building ~~exceeding the 10 CFR 100 limits (Ref. 5)~~ in the ~~event of a fuel handling accident~~.

required fuel pool area ventilation train

spent fuel pool area

The ~~FBACS~~ is considered OPERABLE when the individual components necessary to control exposure in the ~~fuel handling building~~ are OPERABLE ~~in both trains~~. ~~An FBACS~~ train is considered OPERABLE when ~~its associated~~:

A fuel pool area ventilation

unlikely event of an FHA occurring within 72 hours of a unit shutdown

1

The exhaust

a. Fan is OPERABLE,

b. HEPA filter and charcoal adsorber are not excessively restricting flow, and are capable of performing their filtration functions, and

c. ~~Heater, demister,~~ ductwork, valves, and dampers are OPERABLE, and air circulation can be maintained.

~~The LCO is modified by a Note allowing the fuel building boundary to be opened intermittently under administrative controls. For entry and exit through doors, the administrative control of the opening is performed by the person(s) entering and exiting the area. For other openings, these controls consist of stationing a dedicated individual at the opening who is in continuous communication with the control room. This individual will have a method to rapidly close the opening when a need for fuel building isolation is indicated.~~

2

Insert 2 (1)

The FHA analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. Additionally, filtration of the fuel handling building is not assumed for an FHA in the spent fuel storage pool. The Technical Requirements Manual includes a decay time requirement that no fuel movement will commence until 72 hours after shutdown. This ensures that the FHA assumptions, including no filtration of the fuel handling building, are preserved. In the event an FHA in the spent fuel storage pool occurs within 72 hours of a unit shutdown, the Fuel Pool Area Ventilation System will provide filtration to minimize the consequences of this improbable event.

BASES

APPLICABILITY

~~In MODES 1, 2, 3, and 4, the FBACS is required to be OPERABLE to provide fission product removal associated with ECCS leaks due to a LOCA (refer to LCO 3.7.13, "Emergency Core Cooling System (ECCS) Pump Room Exhaust Air Cleanup System (PREACS)") for units that use this system as part of their ECCS PREACS.~~ 2

spent fuel storage pool, one fuel pool area ventilation train

During movement of ~~[~~recently~]~~ irradiated fuel assemblies in the ~~fuel building, the FBACS~~ is required to be OPERABLE ~~to mitigate the consequences of a fuel handling accident [involving handling recently irradiated fuel~~. Due to radioactive decay, ~~FBACS~~ is only required to mitigate ~~fuel handling accidents involving~~ handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous ~~[X] days~~)~~]~~. 3 2

FHAs that involve

72 hours

the Fuel Pool Area Ventilation System

1 3

Insert 3

~~In MODES 5 and 6, the FBACS is not required to be OPERABLE, since the ECCS is not required to be OPERABLE~~. 1

ACTIONS

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4, the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operations. Entering LCO 3.0.3, while in MODE 1, 2, 3, or 4 would require the unit to be shutdown unnecessarily.

~~A.1~~

~~If one FBACS train is inoperable, action must be taken to restore OPERABLE status within 7 days. During this time period, the remaining OPERABLE train is adequate to perform the FBACS function. The 7 day Completion Time is reasonable, based on the risk from an event occurring requiring the inoperable FBACS train, and ability of the remaining FBACS train to provide the required protection.~~

~~B.1~~

~~REVIEWER'S NOTE~~
~~Adoption of Condition B is dependent on a commitment from the licensee to have guidance available describing compensatory measures to be taken in the event of an intentional and unintentional entry into Condition B.~~

2

1

Insert 3

When movement of irradiated fuel assemblies within the spent fuel storage pool is not being conducted, the potential for an FHA within the fuel pool area does not exist. Additionally, due to radioactive decay, an FHA that involves handling non-recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core longer than 72 hours) will result in doses that are well within the guideline values specified in 10 CFR 50.67 even without fuel pool area ventilation filtration capability. Therefore, under these conditions the Fuel Pool Area Ventilation System is not required to be OPERABLE.

BASES

ACTIONS (continued)

If the fuel building boundary is inoperable in MODE 1, 2, 3, or 4, the FBACS trains cannot perform their intended functions. Actions must be taken to restore an OPERABLE fuel building boundary within 24 hours. During the period that the fuel building boundary is inoperable, appropriate compensatory measures [consistent with the intent, as applicable, of GDC 19, 60, 61, 63, 64 and 10 CFR Part 100] should be utilized to protect plant personnel from potential hazards such as radioactive contamination, toxic chemicals, smoke, temperature and relative humidity, and physical security. Preplanned measures should be available to address these concerns for intentional and unintentional entry into the condition. The 24 hour Completion Time is reasonable based on the low probability of a DBA occurring during this time period, and the use of compensatory measures. The 24 hour Completion Time is a typically reasonable time to diagnose, plan and possibility repair, and test most problems with the fuel building boundary.

[C.1 and C.2

In MODE 1, 2, 3, or 4, when Required Action A.1 or B.1 cannot be completed within the Completion Time, or when both FBACS trains are inoperable for reasons other than an inoperable fuel building boundary (i.e., Condition B), the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in MODE 3 within 6 hours, and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.]

D.1 and D.2

When Required Action A.1 cannot be completed within the required Completion Time during movement of [recently] irradiated fuel assemblies in the fuel building, the OPERABLE FBACS train must be started immediately or fuel movement suspended. This action ensures that the remaining train is OPERABLE, that no undetected failures preventing system operation will occur, and that any active failure will be readily detected.

If the system is not placed in operation, this action requires suspension of [recently] irradiated fuel movement, which precludes a fuel handling accident. This does not preclude the movement of fuel to a safe position.

2

BASES

ACTIONS (continued)

A
one required fuel pool area ventilation train is
spent fuel storage pool

~~E~~.1

When ~~two trains of the FBACS are~~ inoperable during movement of ~~[~~recently~~]~~ irradiated fuel assemblies in the ~~fuel building~~, action must be taken to place the unit in a condition in which the LCO does not apply. This LCO involves immediately suspending movement of ~~[~~recently~~]~~ irradiated fuel assemblies in the ~~fuel building~~. This does not preclude the movement of fuel to a safe position.

JUSTIFICATION FOR DEVIATIONS
ITS 3.7.17 BASES, FUEL POOL AREA VENTILATION SYSTEM
UNIT 1 ONLY

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. Changes have been made to be consistent with changes made to the Specifications.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

Current Technical Specifications (CTS) Markup and Discussion of Changes (DOCs)

PLANT SYSTEMS

3/4.7.2 STEAM GENERATOR PRESSURE/TEMPERATURE LIMITATION

LIMITING CONDITION FOR OPERATION

3.7.2.1 The temperatures of both the primary and secondary coolants in the steam generators shall be > 70°F when the pressure of either coolant in the steam generator is > 200 psig.

APPLICABILITY: ALL MODES.

ACTION:

With the requirements of the above specification not satisfied:

a. Reduce the steam generator pressure of the applicable side to ≤ 200 psig within 30 minutes, and

b. Perform an analysis to determine the effect of the overpressurization on the structural integrity of the steam generator. Determine that the steam generator remains acceptable for continued operation prior to increasing its temperatures above 200°F.

SURVEILLANCE REQUIREMENTS

4.7.2.1 The pressure in each side of the steam generators shall be determined to be < 200 psig at least once per hour when the temperature of either the primary or secondary coolant in the steam generators is < 70°F.

R1

PLANT SYSTEMS

3/4.7.2 STEAM GENERATOR PRESSURE/TEMPERATURE LIMITATION

LIMITING CONDITION FOR OPERATION

3.7.2 The temperature of the secondary coolant in the steam generators shall be greater than 100°F when the pressure of the secondary coolant in the steam generator is greater than 200 psig.

APPLICABILITY: At all times.

ACTION:

With the requirements of the above specification not satisfied:

a. Reduce the steam generator pressure to less than or equal to 200 psig within 30 minutes, and

b. Perform an engineering evaluation to determine the effect of the overpressurization on the structural integrity of the steam generator. Determine that the steam generator remains acceptable for continued operation prior to increasing its temperatures above 200°F.

SURVEILLANCE REQUIREMENTS

4.7.2 The pressure of the secondary side of the steam generators shall be determined to be less than 200 psig at least once per hour when the temperature of the secondary coolant is less than 100°F.

RELOCATED SPECIFICATIONS

R01 Steam generator pressure/temperature limitation OPERABILITY requirements are intended to ensure that the pressure induced stresses in the steam generators do not exceed the maximum allowable fracture toughness stress limits. The limitations are based on a steam generator RTNDT and are sufficient to prevent brittle fracture.

The ITS does not include this Specification. This changes the CTS by relocating this Specification to the Technical Requirements Manual (TRM). This change is acceptable because the steam generator pressure/temperature limitation Specification does not meet the 10 CFR 50.36(c)(2)(ii) criteria for inclusion into the ITS.

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. Steam generator P/T limits are ASME Code parameter limits and are not instrumentation used for, or capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. Steam generator P/T limits ae ASME Code parameter limits and do not represent a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. Steam generator P/T limits are ASME Code parameter limits and not a structure, system, or component that is part of a primary success path in the mitigation of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. Steam generator P/T limits and are not structures, systems, or components which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

Since 10 CFR 50.36(c)(2)(ii) criteria have not been satisfied, the steam/generator pressure/temperature limitation may be relocated to a licensee controlled document outside the Technical Specifications. Requirements associated with the steam generator pressure/temperature limitation in support of safety related systems are addressed in ITS LCO 3.0.8. Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as relocation

R1

because the Specification does not meet the criteria in 10 CFR 50.36(c)(2)(ii) and has been relocated to the TRM.

Unit 2 CTS 3/4.7.6, Flood Protection

R1

Current Technical Specifications (CTS) Markup and Discussion of Changes (DOCs)

R1

PLANT SYSTEMS

3/4.7.6 FLOOD PROTECTION

LIMITING CONDITION FOR OPERATION

3.7.6.1 Flood protection shall be provided for the facility site via stoplogs which shall be installed on the southside of the RAB and the southernmost door on east wall whenever a hurricane warning for the plant is posted.

APPLICABILITY: At all times.

ACTION:

With a Hurricane Watch issue for the facility site, ensure the stoplogs are removed from storage and are prepared for installation. The stoplogs shall be installed anytime a Hurricane Warning is posted.

SURVEILLANCE REQUIREMENTS

4.7.6.1 Meteorological forecasts shall be obtained from the National Hurricane Center in Miami, Florida at least once per 6 hours during either a Hurricane Watch or a Hurricane Warning.

DISCUSSION OF CHANGES

UNIT 2 CTS 3/4.7.6, FLOOD PROTECTION

ADMINISTRATIVE CHANGES R1

None

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

R01 External flooding during hurricane conditions is not designated as a PSL DBA or transient event. In addition, external flooding due to a hurricane is not postulated to occur during any DBA or transient, thus water level (as it pertains to wave run up effects during a hurricane) is not credited in any safety analysis. The Flood Protection Technical Specification requirements ensure that facility protective actions will be taken in the event of flood conditions whenever a hurricane warning is issued. The installation of the stoplogs ensures adequate protection for wave run-up effects where no permanent adjacent structures exist and provides protection to safety-related equipment.

The ITS does not include this Specification. This changes the CTS by relocating this Specification to the Technical Requirements Manual (TRM). This change is acceptable because the Flood Protection Specification does not meet the 10 CFR 50.36(c)(2)(ii) criteria for inclusion into the ITS.

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. Flood protection requirements are not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary prior to a DBA.

2. Flood protection requirements are not process variables that are initial conditions of a DBA or transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. Flood protection requirements are not part of the primary success path that functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The specific requirements specified in the Flood Protection Specification related to a hurricane are found to be non-significant risk contributors to core damage frequency and offsite releases and do not represent structures, systems, or components which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

Since the screening criteria have not been satisfied, the Flood Protection Specification may be relocated to a licensee controlled document outside the Unit 2 Technical Specifications. A general requirement associated with hazard

R1

barriers (ITS LCO 3.0.9), which includes external flooding barriers, is added to ITS Section 3.0. A hazard barrier that cannot perform its related support function will be evaluated and managed under the Maintenance Rule plant configuration control requirement, 10 CFR 50.65(a)(4), and associated industry guidance, NUMARC 93-01, Revision 4A. Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as relocation because the Specification does not meet the criteria in 10 CFR 50.36(c)(2)(ii) and has been relocated to the TRM.

RELOCATED SPECIFICATIONS

LA01 (*Type 4 - Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAPM, IST Program, or ISI Program*) Unit 1 CTS 3.7.10 and Unit 2 CTS 3.7.9 provide requirements for all safety-related snubbers. This specification, with the exception of the Action to restore an inoperable snubber within 72 hours, is not included in the ITS. This changes the CTS by moving the explicit snubber requirements from the Technical Specifications to the Technical Requirements Manual (TRM).

The removal of these details from the Technical Specification is acceptable because this type of information is not necessary to provide adequate protection of public health and safety. The purpose of the snubber requirements is to ensure that the structural integrity of the Reactor Coolant System and other safety related systems is maintained during and following a seismic or other event initiating dynamic loads.

This change is acceptable because the LCO requirements continue to ensure that the structures, systems, and components are maintained consistent with the safety analyses and licensing basis. Specifically, ITS LCO 3.0.8 continues to require, in part, action to assess and manage risk during the period one or more required snubbers are unable to perform their associated support function(s). ITS LCO 3.0.8 also places limits on the delay period when one or more required snubbers are unable to perform their associated support function(s) based on the affect the degraded snubber has on the support system (e.g., affects one train or multiple trains). Refer to Section 3.0 Discussion of Changes related to the addition of ITS LCO 3.0.8. The requirement to perform snubber inspections is specified in 10 CFR 50.55a and the requirement to perform snubber inspections and testing is specified in ASME Section XI, as modified by approved relief requests. Therefore, both PSL commitments and NRC regulations or generic guidance contain the necessary programmatic requirements for the inspection and testing of safety related snubbers without repeating them in the ITS. ASME code requirements associated with snubber inspections and testing will continue to be controlled pursuant 10 CFR 50.55a Also, this change is acceptable because the removed information will be adequately controlled in the TRM. The TRM is incorporated by reference into the UFSAR, and any changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because a requirement is being removed from the Technical Specifications.

PLANT SYSTEMS

3/4.7.9 SEALED SOURCE CONTAMINATION

LIMITING CONDITION FOR OPERATION

3.7.9.1 Each sealed source containing radioactive material either in excess of 100 microcuries of beta and/or gamma emitting material or 5 microcuries of alpha emitting material shall be free of ≥ 0.005 microcuries of removable contamination.

APPLICABILITY: At all times.

ACTION:

a. Each sealed source with removable contamination in excess of the above limit shall be immediately withdrawn from use and:

1. Either decontaminated and repaired, or

2. Disposed of in accordance with Commission Regulations.

b. The provisions of Specification 3.0.3 are not applicable.

SURVEILLANCE REQUIREMENTS

4.7.9.1.1 Test Requirements – Each sealed source shall be tested for leakage and/or contamination by:

a. The licensee, or

b. Other persons specifically authorized by the Commission or an Agreement State.

The test method shall have a detection sensitivity of at least 0.005 microcuries per test sample.

4.7.9.1.2 Test Frequencies – Each category of sealed sources shall be tested at the frequencies described below.

a. Sources in use (excluding startup sources previously subjected to core flux) – In accordance with the Surveillance Frequency Control Program for all sealed sources containing radioactive material:

SURVEILLANCE REQUIREMENTS (Continued)

1. With a half-life greater than 30 days (excluding Hydrogen 3), and

2. In any form other than gas.

b. Stored sources not in use – Each sealed source shall be tested prior to use or transfer to another licensee unless tested within the previous six months. Sealed sources transferred without a certificate indicating the last test date shall be tested prior to being placed into use.

c. Startup sources – Each sealed startup source shall be tested within 31 days prior to being subjected to core flux and following repair or maintenance to the source.

4.7.9.1.3 Reports – A Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days if source leakage tests reveal the presence of ≥ 0.005 microcuries of removable contamination.

R01

PLANT SYSTEMS

3/4.7.10 SEALED SOURCE CONTAMINATION

LIMITING CONDITION FOR OPERATION

3.7.10 Each sealed source containing radioactive material either in excess of 100 microcuries of beta and/or gamma emitting material or 5 microcuries of alpha emitting material shall be free of greater than or equal to 0.005 microcuries of removable contamination.

APPLICABILITY: At all times.

ACTION:

a. With a sealed source having removable contamination in excess of the above limit, immediately withdraw the sealed source from use and either:

1. Decontaminate and repair the sealed source, or

2. Dispose of the sealed source in accordance with Commission Regulations.

b. The provisions of Specification 3.0.3 are not applicable.

SURVEILLANCE REQUIREMENTS

4.7.10.1 Test Requirements – Each sealed source shall be tested for leakage and/or contamination by:

a. The licensee, or

b. Other persons specifically authorized by the Commission or an Agreement State.

The test method shall be a detection sensitivity of at least 0.005 microcuries per test sample.

4.7.10.2 Test Frequencies – Each category of sealed sources (excluding startup sources and fission detectors previously subjected to core flux) shall be tested at the frequencies described below.

a. Sources in use – In accordance with the Surveillance Frequency Control Program for all sealed sources containing radioactive material:

1. With a half-life greater than 30 days (excluding Hydrogen 3), and

2. In any form other than gas.

R01

PLANT SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

b. Stored sources not in use – Each sealed source and fission detector shall be tested prior to use or transfer to another licensee unless tested within the previous 6 months. Sealed sources and fission detectors transferred without a certification indicating the last test date shall be tested prior to being placed into use.

c. Startup sources and fission detectors – Each sealed startup source and fission detector shall be tested within 31 days prior to being subjected to core flux or installed in the core and following repair or maintenance to the source or detector.

4.7.10.3 Reports – A report shall be prepared and submitted to the Commission on an annual basis if sealed source or fission detector leakage tests reveal the presence of greater than or equal to 0.005 microcuries of removable contamination.

DISCUSSION OF CHANGES
UNIT 1 CTS 3/4.7.9.1, SEALED SOURCE CONTAMINATION
UNIT 2 CTS 3/4.7.10, SEALED SOURCE CONTAMINATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

R01 The limitations on sealed source contamination are intended to ensure that the total body and individual organ irradiation doses do not exceed allowable limits in the event of ingestion or inhalation. This is done by imposing a maximum limitation of < 0.005 microcuries of removable contamination on each sealed source. This requirement and the associated surveillance requirements bear no relation to the conditions or limitations that are necessary to ensure safe reactor operation.

The ITS does not include this Specification. This changes the CTS by relocating this Specification to the Technical Requirements Manual (TRM). This change is acceptable because the Seal Source Contamination Specification does not meet the 10 CFR 50.36(c)(2)(ii) criteria for inclusion into the ITS.

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. The sealed source contamination limitation is not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. The sealed source contamination limitation is not a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. The sealed source contamination limitation is not part of a primary success path in the mitigation of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The sealed source contamination limitation is not discussed in the PSL PRA and is not a structure, system, or component which operating experience or

probabilistic risk assessment has shown to be significant to public health and safety.

Since 10 CFR 50.36(c)(2)(ii) criteria have not been satisfied, the Sealed Source Contamination Specification may be relocated to a licensee controlled document outside the Technical Specifications. Requirements associated with the sealed sources are governed by 10 CFR Part 70. Compliance with applicable portions of 10 CFR Part 70 is required by the operating licenses of PSL Units 1 and 2. Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as relocation because the Specification does not meet the criteria in 10 CFR 50.36(c)(2)(ii) and has been relocated to the TRM.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.7 PLANT SYSTEMS

B 3.7.10 Essential Chilled Water (ECW) System

1

BASES

BACKGROUND

The ECW System provides a heat sink for the removal of process and operating heat from selected safety related air handling systems during a Design Basis Accident (DBA) or transient.

The ECW System is a closed loop system consisting of two independent trains. Each 100% capacity train includes a heat exchanger, surge tank, pump, chemical addition tank, piping, valves, controls, and instrumentation. An independent 100% capacity chilled water refrigeration unit cools each train. The ECW System is actuated on a safety injection actuation signal (SIAS) and supplies chilled water to the heating, ventilation, and air conditioning (HVAC) units in Engineered Safety Feature (ESF) equipment areas (e.g., the main control room, electrical equipment room, and safety injection pump area).

The flow path for the ECW System includes the closed loop of piping to all serviced equipment, and branch lines up to the first normally closed isolation valve.

During normal operation, the normal HVAC System performs the cooling function of the ECW System. The normal HVAC System is a nonsafety grade system that automatically shuts down when the ECW System receives a start signal. Additional information about the design and operation of the system, along with a list of components served, can be found in the FSAR, Section [9.2.9] (Ref. 1).

APPLICABLE SAFETY ANALYSES

The design basis of the ECW System is to remove the post accident heat load from ESF spaces following a DBA coincident with a loss of offsite power. Each train provides chilled water to the HVAC units at the design temperature of 42°F and flow rate of 400 gpm.

The maximum heat load in the ESF pump room area occurs during the recirculation phase following a loss of coolant accident. During recirculation, hot fluid from the containment sump is supplied to the high pressure safety injection and containment spray pumps. This heat load to the area atmosphere must be removed by the ECW System to ensure that these pumps remain OPERABLE.

The ECW satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

[Two] ECW trains are required to be OPERABLE to provide the required redundancy to ensure that the system functions to remove post accident heat loads, assuming the worst single failure. 1

An ECW train is considered OPERABLE when:

a. The associated pump and surge tank are OPERABLE and

b. The associated piping, valves, heat exchanger, refrigeration unit, and instrumentation and controls required to perform the safety related function are OPERABLE.

The isolation of the ECW from other components or systems may render those components or systems inoperable, but does not affect the OPERABILITY of the ECW System.

APPLICABILITY

In MODES 1, 2, 3, and 4, the ECW System is required to be OPERABLE when a LOCA or other accident would require ESF operation.

In MODES 5 and 6, potential heat loads are smaller and the probability of accidents requiring the ECW System is low.

ACTIONS

A.1

If one ECW train is inoperable, action must be taken to restore OPERABLE status within 7 days [or in accordance with the Risk Informed Completion Time Program]. In this condition, one OPERABLE ECW train is adequate to perform the cooling function. The 7 day Completion Time is reasonable, based on the low probability of an event occurring during this time, the 100% capacity OPERABLE ECW train, and the redundant availability of the normal HVAC System.

B.1 and B.2

----------REVIEWER'S NOTE ----------
Adoption of a MODE 4 end state requires the licensee to make the following commitments:

1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].

2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion

BASES

ACTIONS (continued)

Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.

If the ECW train cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which overall plant risk is minimized. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 2). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.10.1

Verifying the correct alignment for manual, power operated, and automatic valves in the ECW flow path provides assurance that the proper flow paths exist for ECW operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since they are verified to be in the correct position prior to locking, sealing, or securing. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves. This Surveillance does not require any testing or valve manipulation; rather, it involves verification that those valves capable of potentially being mispositioned are in the correct position.

BASES

SURVEILLANCE REQUIREMENTS (continued)

1

This SR is modified by a Note indicating that the isolation of ECW flow to components or systems may render those components inoperable but does not affect the OPERABILITY of the ECW System.

[The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

----------REVIEWER'S NOTE----------

Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

----------]

SR 3.7.10.2

This SR verifies proper automatic operation of the ECW System components that the ECW pumps will start in the event of any accident or transient that generates an SIAS. This SR also ensures that each automatic valve in the flow paths actuates to its correct position on an actual or simulated SIAS. The SR excludes automatic valves that are locked, sealed, or otherwise secured in the actuated position. The SR does not apply to valves that are locked, sealed, or otherwise secured in the actuated position since the affected valves were verified to be in the actuated position prior to being locked, sealed, or otherwise secured. Placing an automatic valve in a locked, sealed, or otherwise secured position requires an assessment of the OPERABILITY of the system or any supported systems, including whether it is necessary for the valve to be repositioned to the non-actuated position to support the accident analysis. Restoration of an automatic valve to the non-actuated position requires verification that the SR has been met within its required Frequency. The ECW System cannot be fully actuated as part of the SIAS CHANNEL FUNCTIONAL TEST during normal operation. The actuation logic is tested as part of the SIAS functional test every 92 days, except for the subgroup relays that actuate the system that cannot be

BASES

SURVEILLANCE REQUIREMENTS (continued)

tested during normal unit operation. [The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. The [18] month Frequency is based on operating experience and design reliability of the equipment.
OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

----------REVIEWER'S NOTE----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

B 3.7 PLANT SYSTEMS

B 3.7.15 Penetration Room Exhaust Air Cleanup System (PREACS)

1

BASES

BACKGROUND

The PREACS filters air from the penetration area between containment and the Auxiliary Building.

The PREACS consists of two independent and redundant trains. Each train consists of a heater, a prefilter or demister, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and a fan. Ductwork, valves or dampers, and instrumentation also form part of the system, as well as demisters functioning to reduce the relative humidity of the air stream. A second bank of HEPA filters, which follows the adsorber section, collects carbon fines and provides backup in case of failure of the main HEPA filter bank. The downstream HEPA filter, although not credited in the accident analysis, collects charcoal fines and serves as a backup should the upstream HEPA filter develop a leak. The system initiates filtered ventilation following receipt of a safety injection actuation signal or containment isolation actuation signal.

The PREACS is a standby system, parts of which may also operate during normal unit operations. During emergency operations, the PREACS dampers are realigned, and fans are started to initiate filtration. Upon receipt of the actuating Engineered Safety Feature Actuation System signal(s), normal air discharges from the penetration room, the penetration room is isolated, and the stream of ventilation air discharges through the system filter trains. The prefilters or demisters remove any large particles in the air, as well as any entrained water droplets, to prevent excessive loading of the HEPA filters and charcoal adsorbers.

The PREACS is discussed in the FSAR, Sections [6.5.1], [9.4.5], and [15.6.5] (Refs. 1, 2, and 3, respectively), as it may be used for normal, as well as post accident, atmospheric cleanup functions. Heaters may be included for moisture removal on systems operating in high humidity conditions. The primary purpose of the heaters is to maintain the relative humidity at an acceptable level, consistent with iodine removal efficiencies, as discussed in the Regulatory Guide 1.52 (Ref. 4).

BASES

APPLICABLE SAFETY ANALYSES

The design basis of the PREACS is established by the large break loss of coolant accident (LOCA). The system evaluation assumes a passive failure outside containment, such as a valve packing leakage during a Design Basis Accident (DBA). In such a case, the system restricts the radioactive release to within 10 CFR 100 (Ref. 5) limits, or the NRC staff approved licensing basis (e.g., a specified fraction of 10 CFR 100 limits). The analysis of the effects and consequences of a large break LOCA are presented in Reference 3.

There are two types of system failures considered in the accident analysis: a complete loss of function and an excessive LEAKAGE. Either type of failure may result in less efficient removal for any gaseous or particulate material released to the penetration rooms following a LOCA.

The PREACS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Two independent and redundant trains of the PREACS are required to be OPERABLE to ensure that at least one train is available, assuming there is a single failure disabling the other train coincident with a loss of offsite power.

The PREACS is considered OPERABLE when the individual components necessary to control radioactive releases are OPERABLE in both trains. A PREACS train is considered OPERABLE when its associated:

a. Fan is OPERABLE,

b. HEPA filter and charcoal absorber are not excessively restricting flow, and are capable of performing the filtration functions, and

c. Heater, demister, ductwork, valves, and dampers are OPERABLE, and circulation can be maintained.

The LCO is modified by a Note allowing the penetration room boundary to be opened intermittently under administrative controls. For entry and exit through doors, the administrative control of the opening is performed by the person(s) entering or exiting the area. For other openings, these controls consist of stationing a dedicated individual at the opening who is in continuous communication with the control room. This individual will have a method to rapidly close the opening when a need for penetration room isolation is indicated.

APPLICABILITY

In MODES 1, 2, 3, and 4, the PREACS is required to be OPERABLE, consistent with the OPERABILITY requirements of the Emergency Core Cooling System (ECCS).

In MODES 5 and 6, the PREACS is not required to be OPERABLE, since the ECCS is not required to be OPERABLE.

BASES

ACTIONS

A.1

With one PREACS train inoperable, action must be taken to restore OPERABLE status within 7 days. During this time period, the remaining OPERABLE train is adequate to perform the PREACS function. The 7 day Completion Time is appropriate because the risk contribution of the PREACS is less than that for the ECCS (72 hour Completion Time), and because this system is not a direct support system for the ECCS. The 7 day Completion Time is reasonable based on the low probability of a DBA occurring during this time period, and the consideration that the remaining train can provide the required capability.

B.1

----------REVIEWER'S NOTE----------
Adoption of Condition B is dependent on a commitment from the licensee to have guidance available describing compensatory measures to be taken in the event of an intentional and unintentional entry into Condition B.

If the penetration room boundary is inoperable, the PREACS trains cannot perform their intended functions. Actions must be taken to restore an OPERABLE penetration room boundary within 24 hours. During the period that the penetration room boundary is inoperable, appropriate compensatory measures [consistent with the intent, as applicable, of GDC 19, 60, 64 and 10 CFR Part 100] should be utilized to protect plant personnel from potential hazards such as radioactive contamination, toxic chemicals, smoke, temperature and relative humidity, and physical security. Preplanned measures should be available to address these concerns for intentional and unintentional entry into the condition. The 24 hour Completion Time is reasonable based on the low probability of a DBA occurring during this time period, and the use of compensatory measures. The 24 hour Completion Time is reasonable based on the low probability of a DBA occurring during this time period, and the use of compensatory measures. The 24 hour Completion Time is a typically reasonable time to diagnose, plan and possibly repair, and test most problems with the penetration room boundary.

BASES

ACTIONS (continued)

1

C.1 and C.2

With two PREACS trains inoperable for reasons other than an inoperable boundary, action must be taken to restore at least one PREACS train to OPERABLE status within 24 hours. The Condition is modified by a Note stating it is not applicable if the second PREACS train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one train is inoperable for any reason and the second train is discovered to be inoperable, or if both trains are discovered to be inoperable at the same time. In addition, at least one train of containment spray must be verified to be OPERABLE within 1 hour. In the event of an accident, containment spray reduces the potential radioactive release from the containment which reduces the consequences of the inoperable PREACS trains. The Completion Time is based on Reference 6 which demonstrated that the 24 hour Completion Time is acceptable based on the infrequent use of the Required Actions and the small incremental effect on plant risk.

D.1 and D.2

----------REVIEWER'S NOTE ----------
Adoption of a MODE 4 end state requires the licensee to make the following commitments:

1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].

2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.

If the inoperable PREACS train or penetration room boundary cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which plant risk is minimized. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours.

BASES

ACTIONS (continued)

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 7). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action C.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE REQUIREMENTS

SR 3.7.15.1

Standby systems should be checked periodically to ensure that they function properly. As the environment and normal operating conditions on this system are not severe, testing each train once every month provides an adequate check on this system.

Operation [with the heaters on] for ≥ 15 continuous minutes demonstrates OPERABILITY of the system. Periodic operation ensures that [heater failure,] blockage, fan or motor failure, or excessive vibration can be detected for corrective action. [The 31 day Frequency is based on the known reliability of the equipment and the two train redundancy available.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

1

----------REVIEWER'S NOTE----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

SR 3.7.15.2

This SR verifies the performance of PREACS filter testing in accordance with the [Ventilation Filter Testing Program (VFTP)]. The [VFTP] includes testing the performance of the HEPA filter, charcoal adsorber efficiency, minimum system flow rate, and the physical properties of the activated charcoal (general use and following specific operations). Specific test frequencies and additional information are discussed in detail in the [VFTP].

[SR 3.7.15.3

This SR verifies that each PREACS train starts and operates on an actual or simulated actuation signal. The SR excludes automatic dampers and valves that are locked, sealed, or otherwise secured in the actuated position. The SR does not apply to dampers or valves that are locked, sealed, or otherwise secured in the actuated position since the affected dampers or valves were verified to be in the actuated position prior to being locked, sealed, or otherwise secured. Placing an automatic valve or damper in a locked, sealed, or otherwise secured position requires an assessment of the OPERABILITY of the system or any supported systems, including whether it is necessary for the valve or damper to be repositioned to the non-actuated position to support the accident analysis. Restoration of an automatic valve or damper to the non-actuated position requires verification that the SR has been met within its required Frequency. [The [18] month Frequency is consistent with that specified in Reference 4.]

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

1

----------REVIEWER'S NOTE----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]]

[SR 3.7.15.4

This SR verifies the integrity of the penetration room enclosure. The ability of the penetration room to maintain negative pressure, with respect to potentially uncontaminated adjacent areas, is periodically tested to verify proper function of the PREACS. During the post accident mode of operation, PREACS is designed to maintain a slightly negative pressure at a flow rate of ≤ [3000] cfm in the penetration room with respect to adjacent areas to prevent unfiltered LEAKAGE.

The minimum system flow rate maintains a slight negative pressure in the penetration room area and provides sufficient air velocity to transport particulate contaminants, assuming only one filter train is operating.

The number of filter elements is selected to limit the flow rate through any individual element to about [1000] cfm. This may vary based on filter housing geometry. The maximum limit ensures that flow through, and pressure drop across, each filter element is not excessive.

The number and depth of the adsorber elements ensures that, at the maximum flow rate, the residence time of the air stream in the charcoal bed achieves the desired adsorption rate. At least a [0.125] second residence time is necessary for an assumed [99]% efficiency.

The filters have a certain pressure drop at the design flow rate when clean. The magnitude of the pressure drop indicates acceptable performance, and is based on manufacturer's recommendations for the filter and adsorber elements at the design flow rate. An increase in pressure drop or decrease in flow indicates that the filter is being loaded or is indicative of other problems with the system.

[The Frequency of [18] months is consistent with the guidance provided in NUREG-0800, Section 6.5.1 (Ref. 8). This test is conducted with the tests for filter penetration; thus, an [18] month Frequency on a STAGGERED TEST BASIS consistent with other filtration SRs.

BASES

SURVEILLANCE REQUIREMENTS (continued)

1

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

----------REVIEWER'S NOTE----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]]

[SR 3.7.15.5

Operating the PREACS filter bypass damper is necessary to ensure that the system functions properly. The OPERABILITY of the PREACS filter bypass damper is verified if it can be opened. The SR excludes automatic dampers that are locked, sealed, or otherwise secured in the open position. The SR does not apply to dampers that are locked, sealed, or otherwise secured in the open position since the affected dampers were verified to be in the open position prior to being locked, sealed, or otherwise secured. Placing an automatic damper in a locked, sealed, or otherwise secured position requires an assessment of the OPERABILITY of the system or any supported systems, including whether it is necessary for the damper to be closed to support the accident analysis. Restoration of an automatic damper to the closed position requires verification that the SR has been met within its required Frequency. [An [18] month Frequency is consistent with that specified in Reference 4.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

----------REVIEWER'S NOTE----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

DISCUSSION OF CHANGES
ITS 3.8.1, AC SOURCES - OPERATING

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 1 only:** CTS 3.8.1.1 Actions b.4 and c.3 contain footnote * that applies a "one time extension for the inoperable 1B EDG" to allow 30 days to restore the diesel generator to OPERABLE status. The extension expired on August 14, 2019. Footnote * is deleted and not included in ITS. The change is designated as administrative and does not result in technical changes to the CTS.

A03 CTS 3.8.1.1 Actions c.6, d.3, and last sentence of Action e, each provide requirements to follow other CTS 3.8.1.1 Actions upon restoration of the inoperable equipment. The ITS provide these requirements in Section 1.3, Completion Times. This changes the CTS by removing the requirements on application of Completion Times from individual CTS Actions to the use and application chapter in ITS.

The purpose of the CTS requirement to follow other actions upon restoration of the inoperable equipment is to provide direction, when multiple components are inoperable, on the appropriate application of action completion times when one component remains inoperable following the restoration of other required equipment. These CTS requirements were added as a result of adopting portions of the ISTS without fully converting to the ISTS.

ITS includes Section 1.3, "Completion Times," which provides requirements on the proper use and application of Completion Times when components remain inoperable following restoration of other equipment. Therefore, it is unnecessary to duplicate the requirements in individual Specifications. This change is designated as administrative because the CTS requirements are consistent with the Completion Time requirements in ITS Section 1.3 and does not result in technical changes to the CTS.

A04 Unit 1 CTS 4.8.1.1.2.a.5 requires that the DG is synchronized, loaded to greater than or equal to 3500 kW in accordance with the manufacturer's recommendations and operates within a load band of 3300 to 3500 kW for at least an additional 60 minutes. Unit 2 CTS 4.8.1.1.2.a.5 requires that the DG is synchronized, loaded to greater than or equal to 3685 kW in accordance with the manufacturer's recommendations, and operates within a load band of 3450 to 3685 kW for at least an additional 60 minutes. ITS SR 3.8.1.3 is modified by Note 1 that states DG loadings may include gradual loadings as recommended by the manufacturer. This changes the CTS by allowing the DG loading to be gradual "as recommended by the manufacturer."

The purpose of CTS 4.8.1.1.2.a.5 is to ensure each DG can be loaded from standby conditions and operated at load for at least one hour. The change to CTS 4.8.1.1.2.a.5 includes the intent provided by the manufacturer to continue the DG warmup by gradually loading the DG. This change is consistent with current practice and is not precluded by CTS. This change is consistent with the recommendations of Generic Letter (GL) 93-05, "Line- Item Technical Specifications Improvements to Reduce Surveillance Requirements for Testing During Power Operation." GL 93-05, Section 10.1, states that DGs "should be loaded in accordance with vendor recommendations for all test purposes other than the refueling outage loss of offsite power tests." The change is acceptable, because it will ensure the DGs will continue to be operated consistent with manufacturer recommendations. This change is designated as administrative, because it does not result in a technical change to the CTS.

A05 CTS 4.8.1.1.2.a.4 footnote ** includes the phrase, “so that mechanical stress and wear on the diesel generator is minimized” in addressing the allowed use of manufacturer recommended procedures. ITS does not include this additional clarifying information. Deleting this text does not change the allowance of engine prelube periods and warmup procedures as recommended by the manufacturer for performance of the applicable surveillance requirements. | R1

The purpose of the phrase “minimizing mechanical stress and wear on the diesel generator” is to provide additional clarification for the allowance. This change is designated as administrative because it does not result in technical changes to the CTS.

A06 CTS 4.8.1.1.2.a.5 footnote *** includes the statement, “The indicated load band is meant as guidance to avoid routine overloading.” Unit 1 CTS 4.8.1.1.2.e.6, Unit 2 CTS 4.8.1.1.2.e.7 and Unit 2 CTS 4.8.1.1.2.e.13 footnote # includes the statement, “This band is meant as guidance to avoid routine overloading of the engine.” ITS does not include this additional clarifying information. Deleting this text does not change the allowance for variations in loads outside of the stated band due to changing bus loads when meeting the surveillance criteria. | R1

The purpose of the statements is clarification of the load band in justifying the allowance of variations in loads due to bus load changes during performance of the surveillance. This change is designated as administrative because it does not result in technical changes to the CTS.

A07 Unit 1 CTS 4.8.1.1.2.e.4 and Unit 2 CTS 4.8.1.1.2.e.5 require verification that on an ESF actuation signal (without loss of offsite power), each DG starts and operates for greater than or equal to 5 minutes. ITS SR 3.8.1.11 require a similar test but do not specify that the DG auto-start on an ESF actuation signal is "without loss of offsite power." This changes the CTS by not specifying the DG auto-start on an ESF actuation signal is without a loss of offsite power signal.

The purpose of Unit 1 CTS 4.8.1.1.2.e.4 and Unit 2 CTS 4.8.1.1.2.e.5 is to demonstrate that each DG automatically starts on an actual or simulated ESF actuation signal. The requirements of this Surveillance are retained in the ITS as SR 3.8.1.11. This change is acceptable, because it is understood that the CTS Unit 1 4.8.1.1.2.e.4 and Unit 2 CTS 4.8.1.1.2.e.5 required DG start on an ESF

actuation signal is without a loss of offsite power signal. Therefore, it is unnecessary to provide this information in ITS SR 3.8.1.11. This change is designated as administrative because it does not result in a technical change to the CTS.

A08 Unit 1 CTS 4.8.1.1.2.e.6 and Unit 2 CTS 4.8.1.1.2.e.7 require the DG to operate for at least 24 hours and contains a **** footnote indicating the test may be conducted in accordance with manufacturer's recommendation concerning engine prelube period. ITS SR 3.8.1.13 does not retain this note because the note is related to DG start tests and not associated with the DG 24 hour load run test. ITS Surveillances related to DG starting contain a similar note allowing engine prelube prior to the DG start. This change is designated as administrative because it does not result in a technical change to the CTS.

A09 **Unit 1 only**: CTS page 3/4.8-6b contains a # footnote not associated with any requirement on the page. ITS does not retain this footnote. The change is designated as administrative and does not result in technical changes to the CTS.

A10 **Unit 2 only**: CTS 4.8.1.1.2.e.13 requires performing Surveillance Requirement 4.8.1.1.2a.4 within 5 minutes of shutting down the diesel generator following a load run (i.e., DG hot restart test). ITS SR 3.8.1.20 retains this requirement as Note 2 to the Surveillance and instead of referencing another Surveillance to perform, ITS SR 3.8.1.20 explicitly provides the DG start requirements. Refer to DOC L04 for changes to CTS 4.8.1.1.2.a.4. The change is designated as administrative because explicitly stating the requirements of a Surveillance instead of referencing the Surveillance does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 The St. Lucie Plant (PSL) CTS do not contain a Condition for three or more AC sources inoperable. ITS ACTION H requires immediate entry into LCO 3.0.3 when three or more AC sources are inoperable. This changes the CTS by adding a specific Action requiring entry into LCO 3.0.3 when three or more AC sources are inoperable.

The addition of ITS ACTION is acceptable because it addresses a level of degradation in which all redundancy in AC electrical power supplies has been lost and any further losses in the AC electrical power system will result in loss of safety function. This change is designated as more restrictive because additional requirements are being imposed that limit unit operation in the event of 3 or more AC sources inoperable.

M02 CTS 4.8.1.1.2.a.3 requires verification that the fuel transfer pump can be started and transfer fuel from the storage system to the day tank. ITS SR 3.8.1.6 requires verification the fuel oil transfer system operates to automatically transfer fuel oil from the storage tanks to the day tanks. This changes the CTS requirement from verifying that the fuel oil transfer pump can be started and transfer fuel from the storage system to requiring verification that the fuel oil

transfer system operates to automatically transfer fuel oil from the storage tanks to the day tanks.

The purpose of CTS 4.8.1.1.2.a.3 is to demonstrate that each fuel oil transfer pump operates and transfers fuel oil from the storage tanks to the day tanks. The proposed change demonstrates that the fuel oil transfer system operates to automatically transfer fuel to the day tank of each DG engine to support continuous operation of the standby power source. The change is acceptable because the fuel transfer system consists of a transfer pump, day tank isolation valves and day tank level switches that operate in conjunction to automatically maintain DG engine day tank level in standby conditions and also ensure adequate fuel supply to an operating diesel generator for continuous operation. In addition, this change demonstrates that the controls and control system for automatic fuel transfer is OPERABLE. This change is designated as more restrictive because it requires demonstration of automatic operation of the fuel oil transfer system.

M03 CTS 4.8.1.1.2.a.5 requires each DG to be synchronized, loaded, and operated for at least 60 minutes. ITS SR 3.8.1.3 requires the same test however an additional Note has been added that places a restriction on the test. ITS SR 3.8.1.3 Note 3 modifies the CTS requirements by stating that the SR shall be on only one DG at a time. This changes the CTS by adding a restriction when performing this test.

The purpose of CTS 4.8.1.1.2.a.5 is to ensure the DG can supply the emergency loads. This change is acceptable because DG loading during performance of CTS 4.8.1.1.2.a.5 is usually conducted one DG at a time. This change is designated as more restrictive because an explicit restriction is added to the DG load test.

M04 CTS 4.8.1.1.2.a.5 requires each DG to be synchronized, loaded, and operated for at least 60 minutes. ITS SR 3.8.1.3 requires the same test however an additional Note has been added that places a restriction on the test. ITS SR 3.8.1.3 Note 4 modifies the CTS requirements by stating that the SR shall be preceded by and immediately follow, without a shutdown of the DG, a successful performance of ITS SR 3.8.1.2 or ITS SR 3.8.1.7. This changes the CTS by adding a restriction when performing this test.

The purpose of CTS 4.8.1.1.2.a.5 is to ensure the DG can supply the emergency loads. This change is acceptable because DG loading during performance of CTS 4.8.1.1.2.a.5 is usually conducted without shut down after a successful start during performance of CTS 4.8.1.1.2.a.4. This change is designated as more restrictive because an explicit restriction is added to the DG load test.

M05 Unit 1 CTS 4.8.1.1.2.e.2, Unit 1 CTS 4.8.1.1.2.e.6, Unit 2 CTS 4.8.1.1.2.e.2 and Unit 2 CTS 4.8.1.1.2.e.7 require the testing of each DG with a load rejection greater than or equal to the single largest post-accident load. The respective CTS requires verifying the diesel generator operates for at least 24 hours under specific loaded conditions. The Surveillances do not specify that the testing be performed under certain unit conditions, nor that a DG shall be tested at a specific power factor. ITS SR 3.8.1.9 requires the verification that each DG can

reject a load equal to or greater than its associated single largest post-accident load. Unit 1 ITS SR 3.8.1.13 requires verifying each DG operates for ≥ 24 hours; for ≥ 2 hours loaded ≥ 3800 kW and ≤ 3860 kW and for the remaining hours of the test loaded ≥ 3300 kW and ≤ 3500 kW. Unit 2 ITS SR 3.8.1.13 requires verifying each DG operated for ≥ 24 hours; for ≥ 2 hours loaded ≥ 3800 kW and ≤ 3934 kW and for the remaining hours of the test loaded ≥ 3450 kW and ≤ 3669 kW. Two Notes modify these SRs. ITS SR 3.8.1.9 Note 1 states that for the associated unit's DGs, the Surveillance shall not normally be performed in MODE 1 or 2. However, this Surveillance may be performed to reestablish OPERABILITY provided an assessment determines the safety of the plant is maintained or enhanced. ITS SR 3.8.1.9 Note 2 and Unit 1 ITS SR 3.8.1.13 and Unit 2 ITS 3.8.1.13 Note 3 state that if the Surveillance is performed with DG synchronized with offsite power, it shall be performed at a power factor ≤ 0.9. However, if grid conditions do not permit, the power factor limit is not required to be met. Under this condition the power factor shall be maintained as close to the limit as practicable. This changes the CTS requirement by specifying conditions for when the associated unit DGs are normally tested and by specifying a power factor of ≤ 0.9 if the testing is conducted by synchronizing with the offsite sources. Other changes to Unit 1 and Unit 2 CTS 4.8.1.1.2.e.2 (ITS SR 3.8.1.9), Unit 1 CTS 4.8.1.1.2.e.6 (ITS 3.8.1.13) and Unit 2 CTS 4.8.1.1.2.e.7 (ITS 3.8.1.13) are discussed in DOC L08 and DOC L10.

The addition of ITS SR 3.8.1.9 Notes 1 and 2, ITS SR 3.8.1.13 Note 3 is acceptable, because performance of the Surveillance for the associated unit's DGs could cause perturbations to the electrical distribution systems. Restricting normal performance of the Surveillance on the associated unit's DGs during MODES 1 and 2 minimizes challenges to continued steady state operation and, as a result, the unit's safety systems. However, if an assessment of the risks indicates plant safety is maintained or enhanced, the Surveillance can be performed to reestablish OPERABILITY. The addition of ITS SR 3.8.1.9 Note 2, Unit 1 ITS SR 3.8.1.13 Notes 2 Note 3, and Unit 2 ITS SR 3.8.1.14 Notes 2 and 3 is acceptable, because the testing should be conducted as close as possible to the conditions that would be experienced by a DG following an accident. Loading the DG solely with the inductive characteristics of a large motor will create a power factor less than unity. The design of the DG is set for full power operation with a power factor of ≥ 0.8. Therefore, testing of the DG for a loss of the single largest load and at full load is acceptable with a power factor ≤ 0.9. This change is designated as more restrictive because the testing required by the CTS does not currently contain these limitations.

M06 Unit CTS 4.8.1.1.2.e.4 and Unit 2 CTS 4.8.1.1.2.e.5 require each DG to auto-start on an ESF actuation signal and operate for greater than or equal to 5 minutes. ITS SR 3.8.1.11 requires the verification that each DG auto-start from standby condition and, in part, verify d) permanently connected loads remain energized from the offsite power system; and e) emergency loads are energized from the offsite power system. This changes the CTS by adding additional performance requirements for the ESF actuation test.

The purpose of the Unit 1 CTS 4.8.1.1.2.e.4 and Unit 2 CTS 4.8.1.1.2.e.5 is to test the performance of each DG on an ESF actuation signal. The proposed change adds explicit requirements to verify the permanently connected loads and

emergency loads are energized from the offsite electrical power system on an ESF signal without loss of offsite power. The change is acceptable because verifying the connection of the permanent loads and emergency loads will confirm the DG loading logic. This change is designated as more restrictive because additional acceptance criteria have been added to the CTS.

M07 CTS 4.8.1.1.2.f requires the diesel generators to be started simultaneously and accelerate to approximately 900 rpm in less than or equal to 10 seconds. ITS SR 3.8.1.18 requires the diesel generators to achieve voltage ≥ 3950 V and frequency ≥ 59.4 Hz and steady state voltage ≥ 3950 V and ≤ 4370 V and frequency ≥ 59.4 Hz and ≤ 60.6 Hz in ≤ 10 seconds. This changes the CTS by replacing the 900 rpm criterion with generator voltage and frequency requirements.

The purpose of CTS 4.8.1.1.2.f is to demonstrate that diesel generator starting independence has not been compromised and that each engine can achieve proper generator output within the specified time when the diesel generators are started simultaneously. The proposed changes add explicit requirements that verify the engine achieves design speed (i.e., proper frequency) and the generator output satisfies the design voltage and frequency requirements. The change is acceptable because verification that proper diesel generator voltage and frequency is achieved within 10 seconds confirms diesel generator starting independence has not been compromised. This change is designated as more restrictive because additional acceptance criteria is added to the CTS. Additional changes to CTS 4.8.1.1.2.f are discussed in DOC L11 and DOC L12.

M08 **Unit 2 only:** CTS 4.8.1.1.2.e.3 requires verification of generator capability to reject a load of 3685 kW without tripping and shall not exceed 4784 volts during and following the load rejection. The Surveillance does not specify that the testing be performed under certain unit conditions, nor that a DG shall be tested at a specific power factor. ITS SR 3.8.1.19 requires the verification that each DG does not trip, and voltage is maintained ≤ 4784 V during and following a load rejection of ≥ 3669 kW. Two Notes modify the SR. Note 1 states that the Surveillance shall not normally be performed in MODE 1 or 2. However, this Surveillance may be performed to reestablish OPERABILITY provided an assessment determines the safety of the plant is maintained or enhanced. Finally, credit may be taken for unplanned events that satisfy this SR. Note 2 states that if the Surveillance is performed with DG synchronized with offsite power, it shall be performed at a power factor ≤ 0.9. However, if grid conditions do not permit, the power factor limit is not required to be met. Under this condition the power factor shall be maintained as close to the limit as practicable. This changes the CTS requirement by specifying conditions for when the DGs are normally tested and by specifying a power factor of ≤ 0.9, if the testing is conducted by synchronizing with the offsite sources.

The addition of Note 1 is acceptable, because performance of the Surveillance for the DG could cause perturbations to the electrical distribution systems. Restricting normal performance of the Surveillance on the DG during MODES 1 and 2 minimizes challenges to continued steady state operation and, as a result, the unit's safety systems. However, if an assessment of the risks indicates plant safety is maintained or enhanced, the Surveillance can be performed to

reestablish OPERABILITY. The addition of Note 2 is acceptable, because the testing should be conducted as close as possible to the conditions that would be experienced by a DG following an accident. Loading the DG solely with the inductive characteristics of a large motor will create a power factor less than unity. The design of the DG is set for full power operation with a power factor of ≥ 0.8. Therefore, testing of the DG for a loss of the single largest load and at full load is acceptable with a power factor ≤ 0.9. This change is designated as more restrictive because the testing required by the CTS does not currently contain these limitations.

M09 Unit 1 CTS 4.8.1.1.2.e.6 and Unit 2 CTS 4.8.1.1.2.e.7 require verification that each DG can operate for at least 24 hours within a specified load band. For the first two hours the Unit 1 load band is specified as 3800 kW to 3960 kW and 3800 kW to 3985 kW for Unit 2. ITS 3.8.1.13 specifies a two hour load band of 3800 kW to 3860 kW for Unit 1 DGs and 3800 kW to 3934 kW for the Unit 2 DGs. This changes the CTS by lowering the required upper load limit for the initial 2 hours of the DG 24 hour load run.

The purpose of Unit 1 CTS 4.8.1.1.2.e.6 and Unit 2 CTS 4.8.1.1.2.e.7 is to demonstrate that the DG can start and run continuously for not less than 24 hours at a full load capability with greater than or equal to 2 hours of the run at a load approximately equivalent to the 109% of the DG continuous rating for Unit 1 and approximately 104% of the DG continuous rating for Unit 2. The remainder of the run time is at a load equivalent to the continuous duty rating of the DG. The proposed change restricts the 2 hour band to a lower upper load band limit. The change is acceptable because the test loading is maintained consistent with the intent of RG 1.108 and within the 4 hour rating of the Unit 1 DGs and the 2000 hour rating of the Unit 2 DGs. This change is designated as more restrictive because it imposes a more restrictive load band on the DG test in lowering the upper band limit of the 2 hour load run. See DOC M11 for discussion of additional changes to the Unit 2 DG loading criteria.

M10 **Unit 2 only:** CTS 4.8.1.1.2.a.5, 4.8.1.1.2.e.7 and 4.8.1.1.2.e.13 specify a load band of 3450 kW to 3685 kW and CTS 4.8.1.1.2.e.3 specifies a generator load of 3685 kW for the full load rejection test. ITS SR 3.8.1.3, SR 3.8.1.13 and SR 3.8.1.20 specify bands of 3450 kW to 3669 kW, respectively. ITS SR 3.8.1.19 specifies a generator load of 3669 kW for the full load rejection test. This changes the CTS by changing the full load limit for testing of the Unit 2 DGs from 3685 kW to 3669 kW for the listed tests.

Analysis of the Unit 2 DGs identified the machines are engine limited (due to temperature limitations) at a continuous generator rating of 3669.4 kW and the DGs were derated. The change is acceptable because ITS retains testing of the DGs at the full load capability of the respective machine and is consistent with the RG 1.108 criteria. This change is designated more restrictive because it imposes a more restrictive load limit on the Unit 2 DGs.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.8.1.1.a requires two "physically independent" circuits between the offsite network and the onsite Class 1E AC Electrical Distribution System to be OPERABLE. CTS 3.8.1.1.b requires two "separate and independent" DG sets to be OPERABLE each with, in part, a separate fuel transfer pump. CTS 4.8.1.1.1 requires the determination of OPERABILITY for each "independent" circuit between the offsite transmission network and the onsite Class 1E AC Electrical Distribution System. In addition, a number of Surveillance Requirements in CTS have an **** footnote that states, “This test may be conducted in accordance with the manufacturer’s recommendations concerning engine prelube period.” ITS LCO 3.8.1 requires two qualified circuits between the offsite network and the onsite Class 1E AC Electrical Distribution System, two DGs capable of supplying the onsite Class 1E AC Electrical Distribution System. ITS SR 3.8.1.1 requires verification of the correct breaker alignment for each offsite circuit. The ITS SR Note regarding engine prelube for DG start Surveillances states, “All DG starts may be preceded by an engine prelube period.” This changes the CTS by moving the details that the offsite circuits are "independent" or "physically independent," that the DGs are "separate and independent" with a separate fuel transfer pump, and that engine prelube is conducted “in accordance with the manufacturer’s recommendations,” from the CTS to the ITS Bases.

The removal of these details related to system design from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for OPERABLE offsite sources and DGs and Surveillance Requirements to periodically verify the AC sources are OPERABLE. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.8.1.1 Action f describes specific Required Actions with one Unit 1 (Unit 2) startup transformer inoperable and with a Unit 2 (Unit 1) startup transformer connected to the same A or B offsite power circuit but administratively available to both units. ITS does not include specific Required Actions for a plant configuration utilizing the other unit’s startup transformer. This changes the CTS by moving the description of the plant configuration that is acceptable for a qualified offsite circuit using the opposite unit’s startup transformer from the CTS to the ITS Bases.

CTS 3.8.1.1 Action f was implemented as part of Amendment No. 103, “St. Lucie Unit 1 – Issuance of Amendment Re: Diesel Generator Reliability (TAC No.

75505)," dated June 7, 1990 (ADAMS Accession No. ML013550091) and Amendment No. 39, "St. Lucie Unit 2 – Issuance of Amendment Re: Diesel Generator Reliability (TAC Nos. 59634 and 64190)," dated February 7, 1989 (ADAMS Accession No. ML013600246). As stated in the safety evaluation supporting the amendments, the NRC determined the change was acceptable.

The described configuration relies on a two-unit facility design that allows for alignment of one unit's startup transformer to satisfy one of the two qualified offsite circuits requirement of CTS 3.8.1.1 for the other unit. The opposite unit startup transformer may be available to both units provided it is not supplying power to its respective unit Class 1E Electrical Distribution System. The design allows this alternate alignment as an acceptable qualified offsite circuit for the operating unit.

The removal of this detail related to system design from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. This change is acceptable because the ITS continues to require two qualified circuits between the offsite transmission network to the onsite Class 1E Electrical Distribution System to be OPERABLE and the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications. See DOC L01 for additional discussion of changes to CTS 3.8.1.1 Action f.

LA03 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS Actions 3.8.1.1.b.2 and 3.8.1.1.c.2 include detail addressing the steam driven auxiliary feed pump as a required redundant feature. ITS Required Actions B.2 and C.2 do not include detail for specific redundant required features. This changes the CTS by moving the steam driven auxiliary feed pump detail from the CTS to the ITS Bases.

The removal of this detail related to system design from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA04 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS Actions 3.8.1.1.b.3 and 3.8.1.1.c.3 require demonstration of the OPERABILITY of the OPERABLE DG by performance of Surveillance Requirement 4.8.1.1.2.a.4 within 8 hours and clarifies the requirement by stating "If the EDG became inoperable due to any cause other than an inoperable

support system, an independently testable component, or preplanned preventative maintenance or testing." ITS Required Actions B.3.1 and B.3.2 do not include the clarifying detail. This changes the CTS by moving the clarifying detail from the CTS to the ITS Bases. | R1

The removal of this detail related to system design from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA05 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 4.8.1.1.2.a.6 requires the verification that each DG is aligned to provide standby power to the associated emergency busses. ITS 3.8.1 does not contain this requirement. This changes the CTS by moving the detail that each DG is aligned to provide standby power to the associated emergency busses from the CTS to the ITS Bases.

The removal of these details that are related to system design from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for OPERABLE DGs. An OPERABLE DG must be capable of providing power to the associated emergency busses as indicated in the Bases. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA06 *(Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program)* Unit 1 CTS 4.8.1.1.2.e.5.c and Unit 2 CTS 4.8.1.1.2.e.6.c require all automatic diesel generator trips, except engine overspeed and generator differential, are automatically bypassed upon loss of voltage on the emergency bus concurrent with a safety injection signal. ITS SR 3.8.1.12 requires a similar verification, but instead of specifying the DG automatic trips that are not bypassed, the Surveillance refers to the trips that are bypassed as "noncritical." This changes the CTS by moving the detail of the specific DG trips that are not bypassed to the UFSAR. | R1

The removal of these details related to system design from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement to verify that the

noncritical DG trips are bypassed on a loss of voltage signal concurrent with a safety injection signal. This change is acceptable because the UFSAR contains a complete listing of the DG electrical and mechanical trips and indicates the trips that are required whenever the DGs are required and the trips that are only required during the exercise mode of operation. In addition, PSL procedures periodically verify the capability of the DG trip relays and associated instrumentation to actuate a DG trip. The removed requirements will be adequately controlled in the UFSAR as any changes to the UFSAR are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA07 *(Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program)* CTS 4.8.1.1.2.g requires the performance of pressure tests of those portions of the diesel fuel oil system designed to USAS B31.7 Class 3 requirements in accordance with the Inservice Inspection Program. Performance of the requirement is in accordance with the Surveillance Frequency Control Program. ITS 3.8.1 does not include this requirement. This changes the CTS by moving this requirement for the diesel fuel oil system to the Inservice Inspection Program.

The removal of these details from the Technical Specifications is acceptable because this type of information is not necessary to provide adequate protection of public health and safety. Section XI of the ASME Boiler and Pressure Vessel Code contains the inservice inspection requirements addressed by this detail and the St. Lucie Inservice Inspection (ISI) Program implements the requirements. This change is acceptable because the removed information will be adequately controlled in the ISI Program. Any changes to the ISI Program are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information is being removed from the Technical Specifications.

LA08 *(Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program)* CTS 4.8.1.1.4 requires that the Class 1E underground cable system be demonstrated OPERABLE within 30 days after the movement of any load in excess of 80% of the ground surface design basis load over the cable ducts with the method of test specifically described in the Surveillance Requirement. ITS 3.8.1 does not include this Surveillance Requirement. This changes the CTS by moving this requirement for the underground cable system to the UFSAR.

The removal of these details from the Technical Specifications is acceptable because this type of information is not necessary to provide adequate protection of public health and safety. This change is acceptable because the removed information will be adequately controlled in the UFSAR. Any changes to the UFSAR are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* CTS 3.8.1.1 Actions b and c are modified by a NOTE requiring the completion of Surveillance Requirement 4.8.1.1.2.a.4 regardless of when the inoperable diesel generator is restored to operability if the absence of a common-cause failure cannot be confirmed. ITS 3.8.1 ACTION B requires a determination that the OPERABLE DG is not inoperable due to common cause failure through performance of SR 3.8.1.2 (CTS 4.8.1.1.2.a.4) unless it can be confirmed that the cause of the inoperable diesel generator does not exist on the OPERABLE diesel generator. However, ITS does not specify that the Required Action be completed if the Condition is exited. This changes the CTS by removing a requirement to complete the Surveillance Requirement once the ACTION is entered.

The purpose of CTS 3.8.1.1 Actions b and c is to provide compensatory measures to be taken in response to inoperable DG set(s), including demonstration that the OPERABLE DG is not inoperable due to a common cause. The Note requiring completion of the actions to verify the remaining DG is OPERABLE once the CTS Action is entered was added to the CTS with License Amendments 103 (Unit 1) and 39 (Unit 2) as part of the change to reflect the recommendations contained in Generic Letter 84-15. The requirement to complete the DG start test on the OPERABLE DG regardless of when the inoperable DG is restored to OPERABLE status was not included in ISTS 3.8.1 ACTION B. The requirement to complete the actions to demonstrate the OPERABLE DGs are not inoperable is not a required exception to ITS LCO 3.0.2 (CTS 3.0.2). Completing the ACTIONS to verify the OPERABILITY of the remaining OPERABLE DGs is not a required action to restore compliance with the LCO. Once a DG is restored to OPERABLE status, the need to start the OPERABLE DG if it cannot be determined the inoperable DG was not inoperable due to a common cause failure becomes unnecessary. Common cause failure evaluations are required by the PSL corrective action program pursuant to the requirements of 10 CFR 50, Appendix B. This change is acceptable because performance of a common cause failure evaluation is tracked in the plant's corrective action program, which if necessary, could require testing of the OPERABLE DG to confirm OPERABILITY. Additionally, deletion of the requirement to perform a start of the OPERABLE DG following restoration of the inoperable DG minimizes mechanical stress and wear on the OPERABLE DG engine and components. This change is designated as less restrictive, because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 (*Category 3 - Relaxation of Completion Time*) CTS 3.8.1.1 Action b.3 specifies the compensatory actions for one inoperable DG and CTS 3.8.1.1 Action c.3 specifies the compensatory actions for one inoperable offsite circuit and one inoperable DG. The Actions include a requirement to demonstrate the OPERABILITY of the remaining OPERABLE EDG by performing Surveillance Requirement 4.8.1.1.2.a.4 within 8 hours. ITS 3.8.1 Required Action B.3.2 allows 24 hours to perform a similar check (ITS SR 3.8.1.2) on the remaining

OPERABLE DG. This changes the CTS by extending the time to perform this check from 8 hours to 24 hours.

The purpose of the CTS Action requirements to perform CTS 4.8.1.1.2.a.4 is to ensure that the other EDG is not inoperable because of a similar, yet undetected, failure (i.e., due to a common mode failure). The proposed 24 hour Completion time to start the OPERABLE DG is acceptable because it is considered a reasonable time to complete the DG start test on the other DG. Generic Letter 84-15 identified that a 24 hour time limit was acceptable to perform common mode failure checks or verify the DG start capability. In addition, the change is considered acceptable since the vast majority of DG start tests demonstrate that the DG is in fact OPERABLE. This change is designated as less restrictive because more time will be allowed to complete a Required Action in the ITS than is allowed in the CTS.

L03 *(Category 4 – Relaxation of Required Action)* CTS 3.8.1.1 Action f requires actions consistent with CTS 3.8.1.1 Action a except when the CTS 3.8.1.1.f actions are not met, the unit must be placed in COLD SHUTDOWN within the following 30 hours instead of HOT SHUTDOWN within the following 6 hours as required by CTS 3.8.1.1 Action a. ITS 3.8.1, ACTION G requires the unit to be placed in MODE 4 within 12 hours (i.e., HOT SHUTDOWN within 6 hours following HOT STANDBY in 6 hours) when the Required Actions and associated Completion Times of Condition A (i.e., one offsite circuit inoperable) are not met. This changes the CTS by changing the end state of CTS 3.8.1.1 Action f from "COLD SHUTDOWN within the following 30 hours" to "MODE 4 within 12 hours." (See DOC LA02 for discussion of removal of detail from CTS 3.8.1.1 Action f.)

The purpose of CTS 3.8.1.1 Actions a and f is to ensure that the remaining required AC source is OPERABLE when it is the only available offsite circuit to the affected unit and ensures that the inoperable startup transformer (offsite circuit) is restored to OPERABLE status within a reasonable time. CTS 3.8.1.1 Action f allows an opposite unit startup transformer to be used as an alternative AC source to support the qualified offsite circuit when the unit startup transformer is inoperable provided the opposite unit startup transformer is not supplying power to its own loads. If the opposite unit startup transformer is subsequently needed to supply its own loads, CTS 3.8.1.1 Action f duplicates Required Actions provided in CTS 3.8.1.1.a.1 and 3.8.1.1.a.3 and contrary to the Required Actions for one offsite circuit inoperable provided in Action a requires the unit to be in COLD SHUTDOWN within 36 hours if the Required Actions of CTS 3.8.1.1.f cannot be satisfied. This change is acceptable because the impact of not restoring the offsite circuit to Operable status is not changed based on the AC source (unit startup transformer or opposite unit startup transformer). The change to the end state from MODE 5 to MODE 4 is consistent with the Required Actions of CTS 3.8.1.1 Action a as revised in Amendments 234 and 184 (Units 1 and 2, respectively), "St. Lucie Plant, Unit Nos. 1 and 2 – Issuance of Amendments Regarding Changes in Selected Technical Specifications End States (CAC Nos. MF8106 and MF8107; Formerly CAC NOS. MF6683 AND MF6684)," dated August 30, 2016, (ADAMS Accession No. ML16210A374). In addition, the change of the end state from MODE 5 to MODE 4 is acceptable because the modification is consistent with CE-NPSD-1186-A, Revision 00, "Technical Justification for the Risk-Informed Modification to Selected Required

Action End States for CEOG Member PWRs," dated October 2001 (ADAMS Accession No. 110410539). This change is designated as less restrictive because instead of requiring the plant to achieve MODE 5 (COLD SHUTDOWN), the ITS end state is MODE 4 (HOT SHUTDOWN) with LCO 3.0.4.a allowance not applicable.

L04 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* CTS 4.8.1.1.2.a.4 and CTS 4.8.1.1.2.f require verification that the DG starts from ambient condition and accelerates to approximately 900 rpm in less than or equal to 10 seconds. ITS SR 3.8.1.2, SR 3.8.1.7 and SR 3.8.1.18 require similar tests but do not include the specific criteria to accelerate to 900 rpm. In addition, the voltage and frequency criteria during the 10 second start is modified in CTS 4.8.1.1.2.a.4, CTS 4.8.1.1.2.e.4.a (Unit 1), and CTS 4.8.1.1.2.e.5.a (Unit 2). ITS SR 3.8.1.2 (DG slow start test) requires that each DG starts from standby conditions and achieves a steady state voltage of ≥ 3950 V and ≤ 4370 V and ≥ 59.4 Hz and ≤ 60.6 Hz. ITS SR 3.8.1.7 (DG quick start test), ITS SR 3.8.1.18, and ITS SR 3.8.1.20 (Unit 2), in part, requires the verification that each DG starts from standby conditions and achieves a voltage of ≥ 3950 V and frequency ≥ 59.4 Hz within 10 seconds and achieves a steady state voltage of ≥ 3950 V and ≤ 4370 V and ≥ 59.4 Hz and ≤ 60.6 Hz. ITS SR 3.8.1.11 (DG ESF actuation test), in part, requires the verification that each DG starts from standby conditions and achieves a voltage of ≥ 3950 V and frequency ≥ 59.4 Hz within 10 seconds and achieves a steady state voltage of ≥ 3950 V and ≤ 4370 V and ≥ 59.4 Hz and ≤ 60.6 Hz. This changes CTS 4.8.1.1.2.a.4 by removing the 900 rpm and the 10 seconds to achieve the steady state voltage and frequency range as addressed in ITS SR 3.8.1.2 criterion. It changes CTS 4.8.1.1.2.a.4, CTS 4.8.1.1.2.e.4.a (Unit 1), and CTS 4.8.1.1.2.e.5.a (Unit 2) by specifying a minimum voltage and frequency to be achieved within 10 seconds instead of requiring the voltage and frequency to be within range in 10 seconds. This effectively allows the upper voltage and frequency limits to be exceeded during DG acceleration and stabilization.

The purpose of the CTS 4.8.1.1.2.a.4, CTS 4.8.1.1.2.e.4.a (Unit 1), and CTS 4.8.1.1.2.e.5.a (Unit 2) is to test for the OPERABILITY of each DG to start and load on an ESF signal, respectively. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria (i.e., upper voltage and frequency limits) are not necessary for verification that the equipment used to meet the LCO can perform its required functions. This change includes narrowing the current voltage and frequency ranges consistent with the DG steady state voltage and frequency ranges specified in other CTS Surveillances (e.g., CTS 4.8.1.1.2.e.3.b (Unit 1) and CTS 4.8.1.1.2.e.4.b (Unit 2)). This changes the CTS by specifying a minimum voltage and frequency limit to be achieved within 10 seconds instead of a voltage and frequency range. This effectively allows the upper voltage and frequency limits to be exceeded during DG acceleration and stabilization. As stated herein, proposed SR 3.8.1.7, SR 3.8.11 and SR 3.8.18 will require only the establishment of the minimum frequency and voltage within the given time frame. The accident analyses and other Surveillances require that the DGs be capable of being loaded within 10 seconds. This can be accomplished at the lowest level in the frequency and voltage ranges. While the upper level requirement regarding the frequency and voltage acceptance criterion is being eliminated during the 10 second start, the

requirement to establish a steady state voltage and frequency has been retained. Once steady state conditions are reached, the minimum and maximum voltage and frequency limits must be maintained. Verification that the minimum voltage and frequency limits are met within the proper time is sufficient to ensure the DG can perform its design function. When called upon, the DG must start and accept load within the proper time. Once the minimum voltage and frequency limits are met, the DG can connect to the bus. When a test is performed that does not result in connecting the DG to the bus, a voltage or frequency overshoot can occur since no loads are connected (the loading tends to minimize overshoot). This overshoot could be such that the voltage or frequency is outside the band high when the time limit expires. However, this condition is not indicative of an inoperable DG, provided that steady state voltage and frequency are maintained. The DG start times are monitored and trend evaluated to identify degradation of DG governor and voltage regulator performance as described in the ITS Bases. This change is designated as less restrictive because less stringent Surveillance test criteria are being applied in the ITS than were applied in the CTS.

L05 *(Category 5 – Deletion of Surveillance Requirement)* CTS 4.8.1.1.2.a.4 requires verification that each DG starts and achieves voltage and frequency within the specified limits. Additionally, the Surveillance requires the DG to be started for the test by using one of the following signals with startup on each signal verified in accordance with the Surveillance Frequency Control Program: manual/local, simulated loss-of-offsite power by itself, simulated loss-of-offsite power in conjunction with an ESF actuation signal, and an ESF actuation signal by itself. ITS SR 3.8.1.2 requires a similar test but does not include the requirement to vary the start signal between manual, loss of offsite power, simulated loss-of-offsite power in conjunction with an ESF actuation signal, and ESF actuation. This changes the CTS by deleting the requirement to use different start signals in the performance of the DG start Surveillance.

The purpose of CTS 4.8.1.1.2.a.4 is to verify the capability of each DG to start and achieve voltage and frequency with the specified limits. This change is acceptable because the deleted requirement is not necessary to verify that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between the origin of the start signal. Therefore, the results of the test are unaffected by the type of signal used to initiate the test. Each DG will continue to be tested in a manner to ensure the safety analyses assumption will be met. This change is designated as less restrictive because a Surveillance which is required in the CTS will not be required in the ITS.

L06 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.8.1.1.2.a.5 requires verification that each DG is synchronized, loaded to greater than or equal to 3500 kW in accordance with manufacturer's recommendations and operates within a load band of 3300 to 3500 kW for at least an additional 60 minutes. Unit 2 CTS 4.8.1.1.2.a.5 requires verification that each DG is synchronized, loaded to greater than or equal to 3685 kW in accordance with manufacturer's recommendations and operates within a load band of 3450 to 3685 kW for at least an additional 60 minutes. ITS SR 3.8.1.3 requires a similar test but does not include the requirement to initially load the diesel generator to greater than or equal to 3500 kW (Unit 1) or 3685 kW (Unit 2). This changes the CTS by deleting the requirement to initially load the diesel

generator to greater than or equal to 3500 kW (Unit 1) and 3685 kW (Unit 2). See DOC M11 for additional discussion of changes.

The purpose of CTS 4.8.1.1.2.a.5 (Unit 1 and Unit 2) is to verify the capability of each DG to synchronize to the offsite electrical system and accept loads greater than or equal to the equivalent of the maximum expected accident loads with a minimum run time to stabilize temperatures. This change is acceptable because the relaxed Surveillance Requirement acceptance criterion is not necessary to verify that the equipment used to meet the LCO can perform its required functions. This change is designated as less restrictive because a Surveillance test criterion, which is required in the CTS, will not be required in the ITS.

L07 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.8.1.1.2.b.1 requires the removal of accumulated water from the engine-mounted fuel tanks at least in accordance with the Surveillance Frequency Control Program and "after each occasion when the diesel is operated for greater than 1 hour." ITS SR 3.8.1.5 requires the same Surveillance but does not include requirement of after each occasion when the diesel is operated for greater than 1 hour. This changes the CTS by deleting the conditional requirement to test for accumulated water after each operation of the DG for greater than one hour.

The purpose of CTS 4.8.1.1.2.b.1 is to provide a degree of assurance that the engine-mounted fuel tanks are free of accumulated water each time the associated DG is operated for an hour or more.

This change is acceptable because the requirement to check for and remove accumulated water is retained in the ITS. Water condensation within the engine-mounted fuel tanks is a time dependent process, not a process dependent on the transfer of fuel oil during DG operation. Since it is the expectation that the DG will not be operated except for the nominal monthly OPERABILITY tests (based on experience), and that the fuel oil storage tanks are also periodically checked for water, no increased Frequency is necessary. This change is designated as less restrictive because the explicit requirement to remove accumulated water in the engine-mounted fuel tanks after a DG run of greater than one hour has been deleted.

L08 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* CTS 4.8.1.1.2.e.2 requires verification of the generator capability to reject a load greater than or equal to the specified value while maintaining voltage within ± 10 percent of the initial pretest voltage and frequency at 60 ± 1.2 Hz. ITS SR 3.8.1.9 requires verification that following load rejection, frequency is ≤ 66.7 Hz, and within 1.8 seconds following load rejection voltage is maintained ≥ 3950 V and ≤ 4370 V and frequency is maintained ≥ 59.4 Hz and ≤ 60.6 Hz. This changes the CTS in that the maximum frequency is relaxed to 66.7 Hz following load rejection and the time to reach the DG steady state frequency and voltage range is added. The voltage and frequency ranges are consistent with the DG steady state voltage and frequency ranges specified in other CTS Surveillances (e.g., CTS 4.8.1.1.2.e.3.b (Unit 1) and CTS 4.8.1.1.2.e.4.b (Unit 2)).

The purpose of CTS 4.8.1.1.2.e.2 is to ensure the proper operation of the DG governor and load control circuits. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria is not necessary for verification that the equipment used to meet the LCO can perform its required functions. These changes the CTS allow the transient frequency following load rejection and time to recover the voltage and frequency. Consistent with Regulatory Guide 1.9, the load rejection test is acceptable if the diesel speed does not exceed 75% of the difference between nominal speed and the overspeed trip setpoint, or 15% above nominal speed, whichever is lower. The overspeed trip of the PSL DGs is 1035 rpm, which is 115% of the DG synchronous speed. A frequency of 66.7 Hz equates to the synchronous speed plus 75% of the difference between synchronous speed and the overspeed trip setpoint (i.e., 1001.25 rpm). Consistent with Regulatory Guide 1.9, the time allowed to recover the voltage and frequency to within the nominal range is calculated based on 60% of the load sequence interval of the largest single load. The proposed timing of 1.8 seconds equates to 60% of the load sequence interval of the single largest load; 3 seconds. This change is acceptable since the DG continues to be tested consistent with the recommendations of Regulatory Guide 1.9. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L09 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.8.1.1.2.e.5 and Unit 2 CTS 4.8.1.1.2.e.6 require verification of DG performance following an actual or simulated loss of offsite power in conjunction with an ESF actuation signal. ITS SR 3.8.1.12 and ITS SR 3.8.1.17 specify that the signal may be from either "actual or simulated" actuation signals. This changes the CTS by explicitly allowing the use of either an actual or simulated signal for the actuation signals and changes the specific actuation signal (i.e., safety injection) to ESF.

The purpose of Unit 1 CTS 4.8.1.1.2.e.5 and Unit 2 CTS 4.8.1.1.2.e.6 is to ensure that the AC Sources operate correctly upon receipt of an actuation signal. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Equipment cannot discriminate between an actual or simulated signal therefore the results of the testing are unaffected by the type of signal used to initiate the test. This change allows taking credit for unplanned actuation if sufficient information is collected to satisfy the Surveillance test requirements. The change also allows a simulated signal to be used, if necessary. In addition, ITS retains the specific ESF actuation signal (i.e., safety injection signal) information in the ITS Bases. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L10 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.8.1.1.2.e.6 and Unit 2 CTS 4.8.1.1.2.e.7 requires verification that each DG can operate for at least 24 hours, with loading within the specified load bands.

The CTS further requires that voltage and frequency be 4160 ± 240 volts and 60 ± 1.2 Hz within 10 seconds after the start signal and steady state generator voltage and frequency shall be maintained within these limits during this test. ITS SR 3.8.1.13 requires similar tests however it does not specify voltage and frequency limits for the test. This changes the CTS by removing the voltage and frequency limits from the Surveillance.

The purpose of Unit 1 CTS 4.8.1.1.2.e.6 and Unit 2 CTS 4.8.1.1.2.e.7 is to verify the capability of each DG to start and run continuously at full load for at least 24 hours. DG operation with voltage and frequency within the specified limits will continue to be verified during performance of Unit 1 ITS SR 3.8.1.2, SR 3.8.1.7, SR 3.8.1.9, SR 3.8.1.10, SR 3.8.1.11, SR 3.8.1.17, and SR 3.8.1.18; and Unit 2 ITS SR 3.8.1.2, SR 3.8.1.7, SR 3.8.1.9, SR 3.8.1.10, SR 3.8.1.11, SR 3.8.1.17, SR 3.8.1.18 and SR 3.8.1.20. This change is acceptable because it has been determined that the relaxed Surveillance Requirement acceptance criteria are not necessary for verification that the equipment used to meet the LCO can perform its required functions. The Surveillance will continue to verify that the DG is capable of running continuously at full load for an interval of not less than 24 hours. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L11 *(Category 5 – Deletion of Surveillance Requirement)* CTS 4.8.1.1.2.f requires verification that the DGs accelerate to 900 rpm within 10 seconds when started simultaneously in accordance with the Surveillance Frequency Control Program or after any modification which could affect DG interdependence. ITS SR 3.8.1.18 does not include the requirement to test simultaneous start of the DGs after any modifications which could affect DG interdependence. This changes the CTS by deleting the requirement to simultaneously start the DGs after any modifications which could affect DG interdependence.

This change is acceptable because the deleted Surveillance Requirement is not necessary to verify that the equipment used to meet the LCO is consistent with the safety analyses. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to give confidence that the assumptions in the safety analyses are protected. Following repair, maintenance, modification, or replacement of a component that may affect OPERABILITY, post maintenance testing is required to demonstrate OPERABILITY of the system or component. This is described in the Bases of ITS SR 3.0.1 and required under SR 3.0.1. The OPERABILITY requirements of the DGs are described in the Bases for Specification 3.8.1. In addition, the requirements of 10 CFR 50, Appendix B, Section XI (Test Control) provide adequate controls for test programs to ensure that testing incorporates applicable acceptance criteria. Compliance with 10 CFR 50 is required under the unit's operating license. As a result, post maintenance testing will continue to be performed and an explicit requirement in the Technical Specifications is not necessary. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS. Additional changes to CTS 4.8.1.1.2.f are discussed in DOC M07, DOC L04 and DOC L12.

L12 *(Category 8 – Deletion of Surveillance Requirement Shutdown Performance Requirements)* CTS 4.8.1.1.2.f contains the requirement to perform the test "during shutdown." ITS SR 3.8.1.18 does not specify conduct of the test to occur during shutdown. This changes the CTS by deleting the requirement to perform the Surveillance during shutdown.

The purpose of CTS 4.8.1.1.2.f is to demonstrate that diesel generator starting independence has not been compromised and that each engine can achieve proper speed within the specified time when the diesel generators are started simultaneously. The proposed Surveillance does not include the restriction that it be performed during shutdown. The control of unit conditions appropriate to perform the test is an issue for procedures and scheduling and has been determined by the NRC Staff to be unnecessary as a Technical Specification restriction. As indicated in Generic Letter 91-04, removal of this specific restriction is consistent with the vast majority of other Technical Specification Surveillances that do not dictate unit conditions for the Surveillance. This change is designated as less restrictive because the Surveillance may be performed during plant conditions other than shutdown. Additional changes to CTS 4.8.1.1.2.f are discussed in DOC M07, DOC L04 and DOC L11.

DOC L12

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.1, AC SOURCES - OPERATING

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. ISTS LCO 3.8.1.c and ISTS 3.8.1 ACTION F have been deleted since St. Lucie Plant (PSL) Units 1 and 2 do not use automatic load sequencers. Each load or load block is sequenced by the use of its associated time delay relay (i.e., load sequence timers). Each major ESF component has an individual time delay relay that operates individual components, instead of an electronic load sequencer that sequences the required ESF components on a bus. Thus, if a single time delay relay fails, only the affected component and the DG are impacted. ISTS SR 3.8.1.11 (ITS SR 3.8.1.10), ISTS SR 3.8.1.12 (ITS SR 3.8.1.11), ISTS SR 3.8.1.18 (ITS SR 3.8.1.16), and ISTS SR 3.8.1.19 (ITS SR 3.8.1.17) have been revised to reflect the use of load sequence timers.

3. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. Changes made to reflect the current licensing basis approved in PSL Unit 1 License Amendment 170 and PSL Unit 2 License Amendment 115.

5. ITS 3.8.1 ACTION F has been added to reflect CTS 3.8.1.1 Action d.2. ITS 3.8.1 Condition F applies when the Required Action and associated Completion Time of Condition C is not met with a Required Action to be in MODE 3 and a Completion Time of 6 hours. When two offsite circuits are inoperable, the original PSL Unit 1 and Unit 2 Technical Specifications only require the unit to be placed in Hot Standby (MODE 3) within 6 hours when one of two offsite circuits cannot be restored to OPERABLE status within 24 hours.

   When both offsite circuits are inoperable, the DGs are supplying power to the loads necessary to maintain the reactor shutdown. This change is acceptable because remaining in MODE 3 allows operators to focus on restoration of at least one offsite circuit to OPERABLE status instead of shifting their attention to a plant cooldown. In MODE 3, the steam generators continue to be available for steaming to maintain RCS parameters and steam generator makeup can be provided by the turbine driven auxiliary feedwater pump. This can minimize DG loading while attempts are made to restore offsite power. If one or more offsite circuits remains inoperable for > 72 hours while in MODE 3, the actions of Condition A (one offsite circuit inoperable) would not be met and Condition H would apply. Required Action H.2 will further require action to place the unit in MODE 4. Voluntary entry into MODE 4 or 5 is not restricted as these MODES are also acceptable low risk states. Concomitant changes are made to ISTS 3.8.1, Condition G.

6. ISTS SR 3.8.1.10 is not included in the Unit 1 PSL ITS. This SR is not included in the Unit 1 PSL current licensing basis and has not been retained in ITS. ISTS SR 3.8.1.10 requires verification that each DG will not trip and will maintain voltage within a maximum limit on a full load rejection test. A full load rejection test is not required by the CTS requirements. ITS retains the CTS requirement to

perform the largest post-accident load rejection test (SR 3.8.1.9). This change is acceptable because the DG output breaker current trip is greater than the current trip of the individual load breakers. Therefore, on a system fault, the breaker of the individual loads will trip before the DG output breaker trips. Tripping of the DG output breaker with all loads connected is the most likely way to cause a 100% load rejection. Therefore, testing of the largest post-accident load rejection is sufficient to ensure DG reliability. To maintain consistency between Unit 1 and Unit 2 SRs, ISTS SR 3.8.1.10 has been renumbered as SR 3.8.1.19 in the Unit 2 ITS. Subsequent ISTS Surveillances have been renumbered in the Unit 1 and Unit 2 ITS, as applicable.

7. ISTS SR 3.8.1.11, ISTS SR 3.8.1.17, ISTS SR 3.8.1.18 and ISTS SR 3.8.1.19 include a NOTE modifying the respective surveillance stating that the Surveillance shall not normally be performed in MODE 1, 2, 3, or 4. These ISTS SRs are changed to state that the Surveillance shall not normally be performed in MODE 1 or 2, as approved in Unit 1 License Amendment 250 and Unit 2 License Amendment 202.

8. ISTS SR 3.8.1.15 is not included in the Unit 1 PSL ITS. ISTS SR 3.8.1.15 requires the hot fast re-start of each DG to rated voltage and frequency after operating for at least 2 hours. This test is normally associated with the requirement to perform a 24-hour run to establish the required “hot” conditions. ISTS SR 3.8.1.15 has not been included in the Unit 1 ITS since it is not consistent with current licensing basis and testing practices for the DGs. ISTS SR 3.8.1.15 tests a design feature (the hot restart capability of the DG) that is not credited in the PSL accident analysis. No postulated design basis event results in the need to restart the DG following a shutdown from hot conditions and the potential consequences of failure of DG to restart from hot condition are bounded by the potential consequences that would result from an immediate failure of the DG itself. Since the accident analysis assumes no operator actions associated with the Emergency Core Cooling System take place in the first 10 minutes following an accident, verification of this design feature does not materially contribute to the demonstration of DG OPERABILITY. To maintain consistency between Unit 1 and Unit 2 SRs, ISTS SR 3.8.1.15 has been renumbered as SR 3.8.1.20 in the Unit 2 ITS. Subsequent ISTS Surveillances have been renumbered in the Unit 1 and Unit 2 ITS, as applicable.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.1 AC Sources - Operating

BASES

BACKGROUND

The unit Class 1E Electrical Power Distribution System AC sources consist of the offsite power sources (preferred power sources, normal and alternate(s)), and the onsite standby power sources (Train A and Train B diesel generators (DGs)). As required by 10 CFR 50, Appendix A, GDC 17 (Ref. 1), the design of the AC electrical power system provides independence and redundancy to ensure an available source of power to the Engineered Safety Feature (ESF) systems.

The onsite Class 1E AC Distribution System is divided into redundant load groups (trains) so that the loss of any one group does not prevent the minimum safety functions from being performed. Each train has connections to two preferred offsite power sources and a single DG.

four

startup

Offsite power is supplied to the unit switchyard(s) from the transmission network by ~~[two]~~ transmission lines. From the switchyard(s), two electrically and physically separated circuits provide AC power, through ~~[~~step down ~~station auxiliary~~ transformers~~]~~, to the 4.16 kV ESF buses. A detailed description of the offsite power network and the circuits to the Class 1E ESF buses is found in the FSAR, Chapter ~~[~~8~~]~~ (Ref. 2).

2

Insert 1

1

U

An offsite circuit consists of all breakers, transformers, switches, interrupting devices, cabling, and controls required to transmit power from the offsite transmission network to the onsite Class 1E ESF bus or buses.

Insert 2

~~Certain required unit loads are returned to service in a predetermined sequence in order to prevent overloading the transformer supplying offsite power to the onsite Class 1E Distribution System. Within [1 minute] after the initiating signal is received, all automatic and permanently connected loads needed to recover the unit or maintain it in a safe condition are returned to service via the load sequencer~~.

1

3

actuation signal

1B

1A3

1A

1B3

-low

4.16kV

The onsite standby power source for each 4.16 kV ESF bus is a dedicated DG. DGs ~~[1]~~ and ~~[2]~~ are dedicated to ESF buses ~~[1]~~ and ~~[2]~~, respectively. A DG starts automatically on a safety injection (SI) ~~signal~~ (i.e., low pressurizer pressure or high containment pressure signals) or on an ~~[~~ESF bus degraded voltage or undervoltage signal~~]~~. After the DG has started, it will automatically tie to its respective bus after offsite power is tripped as a consequence of ESF bus undervoltage or

AS

2

1

St. Lucie – Unit 1

1

1

Insert 1

The circuit between each startup transformer and the associated 4.16 kV ESF bus includes two non-ESF buses: 2A4 and 1A2 buses for Train A; and 2B4 and 1B2 buses for Train B. Alternately, AC power can be supplied from a Unit 2 startup transformer; 2A or 2B via the non-ESF buses, by manually aligning the opposite unit startup transformer (i.e., removing and installing the startup transformer feeder breaker in a different breaker cubicle) to the unit 4.16 kV ESF bus.

1

Insert 2

Normal power for the onsite Class 1E AC Distribution System is supplied through the unit auxiliary transformers. If the normal onsite power source is lost to the onsite Class 1E AC Electrical Distribution System (i.e., main generator trip) an automatic fast transfer is initiated to transfer the 4.16 kV ESF buses from the unit auxiliary transformers to the startup transformers (offsite power). The transfer occurs in approximately three cycles.

BASES

BACKGROUND (continued)

degraded voltage, independent of or coincident with an SI signal. The DGs will also start and operate in the standby mode without tying to the ESF bus on an SI signal alone. Following the trip of offsite power, [a sequencer/an undervoltage signal] strips nonpermanent loads from the ESF bus. When the DG is tied to the ESF bus, loads are then sequentially connected to its respective ESF bus by the automatic load sequencer. The sequencing logic controls the permissive and starting signals to motor breakers to prevent overloading the DG by automatic load application.

In the event of a loss of preferred power, the ESF electrical loads are automatically connected to the DGs in sufficient time to provide for safe reactor shutdown and to mitigate the consequences of a Design Basis Accident (DBA) such as a loss of coolant accident (LOCA).

Certain required unit loads are returned to service in a predetermined sequence in order to prevent overloading the DG in the process. Within [1] minute after the initiating signal is received, all loads needed to recover the unit or maintain it in a safe condition are returned to service.

Ratings for Train A and Train B DGs satisfy the requirements of Regulatory Guide 1.9 (Ref. 3). The continuous service rating of each DG is [7000] kW with [10]% overload permissible for up to 2 hours in any 24 hour period. The ESF loads that are powered from the 4.16 kV ESF buses are listed in Reference 2.

APPLICABLE SAFETY ANALYSES

The initial conditions of DBA and transient analyses in the FSAR, Chapter [6] (Ref. 4) and Chapter [15] (Ref. 5), assume ESF systems are OPERABLE. The AC electrical power sources are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to ESF systems so that the fuel, Reactor Coolant System (RCS), and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, Power Distribution Limits; Section 3.4, Reactor Coolant System (RCS); and Section 3.6, Containment Systems.

The OPERABILITY of the AC electrical power sources is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This results in maintaining at least one train of the onsite or offsite AC sources OPERABLE during accident conditions in the event of:

BASES

APPLICABLE SAFETY ANALYSES (continued)

a. An assumed loss of all offsite power or all onsite AC power and

b. A worst case single failure.

The AC sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Two qualified circuits between the offsite transmission network and the onsite Class 1E Electrical Power Distribution System and separate and independent DGs for each train ensure availability of the required power to shut down the reactor and maintain it in a safe shutdown condition after an anticipated operational occurrence (AOO) or a postulated DBA.

U

Qualified offsite circuits are those that are described in the FSAR and are part of the licensing basis for the unit. 1

~~[In addition, one required automatic load sequencer per train must be OPERABLE.]~~ 2

qualified physically independent, 1

Each offsite circuit must be capable of providing three phases of AC power, maintaining rated frequency and voltage, and accepting required loads during an accident, while connected to the ESF buses.

Insert 3

~~[Offsite circuit #1 consists of Safeguards Transformer B, which is supplied from Switchyard Bus B, and is fed through breaker 52-3 powering the ESF transformer XNB01, which, in turn, powers the #1 ESF bus through its normal feeder breaker. Offsite circuit #2 consists of the Startup Transformer, which is normally fed from the Switchyard Bus A, and is fed through breaker PA 0201 powering the ESF transformer, which, in turn, powers the #2 ESF bus through its normal feeder breaker.]~~ 2

Each DG must be capable of starting, accelerating to rated speed and voltage, and connecting to its respective ESF bus on detection of bus undervoltage. This will be accomplished within ~~[~~10~~]~~ seconds. Each DG must also be capable of accepting required loads within the assumed loading sequence intervals~~,~~ and continue to operate until offsite power can be restored to the ESF buses. These capabilities are required to be met from a variety of initial conditions such as DG in standby with the engine hot and DG in standby with the engine at ambient conditions. Additional DG capabilities must be demonstrated to meet required Surveillances, e.g., capability of the DG to revert to standby status on an ECCS signal while operating in parallel test mode. 2 5

Insert 3 (1)

Each offsite circuit consists of a unit startup transformer (i.e., 1A, 1B) and the associated circuit path, including non-ESF buses (i.e., 2A4 and 1A2 buses; 2B4 and 1B2 buses), up to and including the feeder breaker to the respective unit 4.16 kV ESF bus (i.e., 1A3 bus, 1B3 bus). Alternately, when one unit startup transformer is unavailable, the associated offsite circuit may consist of an opposite unit startup transformer (i.e., 2A or 2B) and the associated circuit path, including non-ESF buses, up to and including the feeder breaker to the respective unit 4.16 kV ESF bus.

BASES

LCO (continued)

Proper sequencing of loads, ~~[~~including tripping of nonessential loads,~~]~~ is a required function for DG OPERABILITY. 2

The AC sources in one train must be separate and independent (to the extent possible) of the AC sources in the other train. For the DGs, separation and independence are complete.

For the offsite AC sources, separation and independence are to the extent practical. ~~A circuit may be connected to more than one ESF bus, with fast transfer capability to the other circuit OPERABLE, and not violate separation criteria.~~ A circuit that is not connected to an ESF bus is required to have OPERABLE fast transfer interlock mechanisms to at least ~~two~~ ESF bus~~es~~ to support OPERABILITY of that circuit. 1

one

Insert 4

APPLICABILITY

The AC sources ~~[and sequencers]~~ are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure that: 3 2

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients and

b. Adequate core cooling is provided and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

The AC power requirements for MODES 5 and 6 are covered in LCO 3.8.2, "AC Sources - Shutdown."

ACTIONS

A Note prohibits the application of LCO 3.0.4.b to an inoperable DG. There is an increased risk associated with entering a MODE or other specified condition in the Applicability with an inoperable DG and the provisions of LCO 3.0.4.b, which allow entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, should not be applied in this circumstance.

A.1

To ensure a highly reliable power source remains with the one offsite circuit inoperable, it is necessary to verify the OPERABILITY of the remaining required offsite circuit on a more frequent basis. Since the Required Action only specifies "perform," a failure of SR 3.8.1.1

1

Insert 4

Each startup transformer set (1A-2A, 1B-2B) is provided with a manual switching arrangement that permits powering the associated Class 1E electrical distribution subsystem from either unit's startup transformer. A single startup transformer is adequate to accommodate the emergency and auxiliary loads of a unit during a postulated DBA. Therefore, when utilized as a qualified offsite AC source to Unit 1, the Unit 2 startup transformer may be aligned to ESF buses of both units and not violate the criterion for shared systems between units provided the Unit 2 startup transformer is not supplying power to a Unit 2 bus.

BASES

ACTIONS (continued)

acceptance criteria does not result in a Required Action not met. However, if a second required circuit fails SR 3.8.1.1, the second offsite circuit is inoperable, and Condition C, for two offsite circuits inoperable, is entered.

~~REVIEWER'S NOTE~~

~~The turbine driven auxiliary feedwater pump is only required to be considered a redundant required feature, and, therefore, required to be determined OPERABLE by this Required Action, if the design is such that the remaining OPERABLE motor or turbine driven auxiliary feedwater pump(s) is not by itself capable (without any reliance on the motor driven auxiliary feedwater pump powered by the emergency bus associated with the inoperable diesel generator) of providing 100% of the auxiliary feedwater flow assumed in the safety analysis.~~

4

A.2

Required Action A.2, which only applies if the train cannot be powered from an offsite source, is intended to provide assurance that an event coincident with a single failure of the associated DG will not result in a complete loss of safety function of critical redundant required features. These features are powered from the redundant AC electrical power train. This includes motor and steam driven auxiliary feedwater pumps~~. Single train systems, such as turbine driven auxiliary feedwater pumps, may not be included~~.

The steam driven auxiliary feedwater pump is only considered a redundant required feature in MODES 1, 2, and 3 because it is not required to be OPERABLE in MODE 4.

1

The Completion Time for Required Action A.2 is intended to allow the operator time to evaluate and repair any discovered inoperabilities. This Completion Time also allows for an exception to the normal "time zero" for beginning the allowed outage time "clock." In this Required Action, the Completion Time only begins on discovery that both:

a. The train has no offsite power supplying its loads and

b. A required feature on the other train is inoperable.

If at any time during the existence of Condition A (one offsite circuit inoperable) a redundant required feature subsequently becomes inoperable, this Completion Time begins to be tracked.

BASES

ACTIONS (continued)

Discovering no offsite power to one train of the onsite Class 1E Electrical Power Distribution System coincident with one or more inoperable required support or supported features, or both, that are associated with the other train that has offsite power, results in starting the Completion Times for the Required Action. Twenty-four hours is acceptable because it minimizes risk while allowing time for restoration before subjecting the unit to transients associated with shutdown.

The remaining OPERABLE offsite circuit and DGs are adequate to supply electrical power to Train A and Train B of the onsite Class 1E Distribution System. The 24 hour Completion Time takes into account the component OPERABILITY of the redundant counterpart to the inoperable required feature. Additionally, the 24 hour Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period.

A.3

According to Regulatory Guide 1.93 (Ref. 6), operation may continue in Condition A for a period that should not exceed 72 hours. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ With one offsite circuit inoperable, the reliability of the offsite system is degraded, and the potential for a loss of offsite power is increased, with attendant potential for a challenge to the unit safety systems. In this Condition, however, the remaining OPERABLE offsite circuit and DGs are adequate to supply electrical power to the onsite Class 1E Distribution System. 2

The 72 hour Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period.

B.1

To ensure a highly reliable power source remains with an inoperable DG, it is necessary to verify the availability of the offsite circuits on a more frequent basis. Since the Required Action only specifies "perform," a failure of SR 3.8.1.1 acceptance criteria does not result in a Required Action being not met. However, if a circuit fails to pass SR 3.8.1.1, it is inoperable. Upon offsite circuit inoperability, additional Conditions and Required Actions must then be entered.

BASES

ACTIONS (continued)

~~REVIEWER'S NOTE~~

~~The turbine driven auxiliary feedwater pump is only required to be considered a redundant required feature, and, therefore, required to be determined OPERABLE by this Required Action, if the design is such that the remaining OPERABLE motor or turbine driven auxiliary feedwater pump(s) is not by itself capable (without any reliance on the motor driven auxiliary feedwater pump powered by the emergency bus associated with the inoperable diesel generator) of providing 100% of the auxiliary feedwater flow assumed in the safety analysis.~~

4

B.2

Required Action B.2 is intended to provide assurance that a loss of offsite power, during the period that a DG is inoperable, does not result in a complete loss of safety function of critical systems. These features are designed with redundant safety related trains. This includes motor driven auxiliary feedwater pumps~~. Single train systems, such as turbine driven auxiliary feedwater pumps, are not included~~. Redundant required feature failures consist of inoperable features with a train, redundant to the train that has an inoperable DG.

and steam

1

The steam driven auxiliary feedwater pump is only considered a redundant required feature in MODES 1, 2, and 3 because it is not required to be OPERABLE in MODE 4.

The Completion Time for Required Action B.2 is intended to allow the operator time to evaluate and repair any discovered inoperabilities. This Completion Time also allows for an exception to the normal "time zero" for beginning the allowed outage time "clock." In this Required Action, the Completion Time only begins on discovery that both:

a. An inoperable DG exists and

b. A required feature on the other train is inoperable.

If at any time during the existence of this Condition (one DG inoperable) a required feature subsequently becomes inoperable, this Completion Time begins to be tracked.

St. Lucie – Unit 1

1

BASES

ACTIONS (continued)

Discovering one required DG inoperable coincident with one or more inoperable required support or supported features, or both, that are associated with the OPERABLE DG, results in starting the Completion Time for the Required Action. Four hours from the discovery of these events existing concurrently, is acceptable because it minimizes risk while allowing time for restoration before subjecting the unit to transients associated with shutdown.

In this Condition, the remaining OPERABLE DG and offsite circuits are adequate to supply electrical power to the onsite Class 1E Distribution System. Thus, on a component basis, single failure protection for the required feature's function may have been lost; however, function has not been lost. The 4 hour Completion Time takes into account the OPERABILITY of the redundant counterpart to the inoperable required feature. Additionally, the 4 hour Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period.

B.3.1 and B.3.2

Required Action B.3.1 provides an allowance to avoid unnecessary testing of OPERABLE DGs. If it can be determined that the cause of the inoperable DG does not exist on the OPERABLE DG, SR 3.8.1.2 does not have to be performed. If the cause of inoperability exists on other DG~~(s)~~, the other DG~~(s)~~ would be declared inoperable upon discovery and Condition E of LCO 3.8.1 would be entered. Once the failure is repaired, the common cause failure no longer exists and Required Action B.3.1 is satisfied. If the cause of the initial inoperable DG cannot be confirmed not to exist on the remaining DG~~(s)~~, performance of SR 3.8.1.2 suffices to provide assurance of continued OPERABILITY of that DG.

For example: if the DG inoperability is due to an inoperable support system, an independently testable component, preplanned preventative maintenance or testing.

the

1

1

In the event the inoperable DG is restored to OPERABLE status prior to completing either B.3.1 or B.3.2, the ~~[~~plant corrective action program~~]~~ will continue to evaluate the common cause possibility. This continued evaluation, however, is no longer under the 24 hour constraint imposed while in Condition B.

2

9

According to Generic Letter 84-15 (Ref. ~~7~~), ~~[~~24~~]~~ hours is reasonable to confirm that the OPERABLE DG~~(s)~~ is not affected by the same problem as the inoperable DG.

1 2

1

BASES

ACTIONS (continued)

B.4

Insert 5

~~According to Regulatory Guide 1.93 (Ref. 6), operation may continue in Condition B for a period that should not exceed 72 hours.~~ 1

In Condition B, the remaining OPERABLE DG and offsite circuits are adequate to supply electrical power to the onsite Class 1E Distribution System. The ~~72-hour~~ Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~

14 day 1

2

C.1 and C.2

Required Action C.1, which applies when two offsite circuits are inoperable, is intended to provide assurance that an event with a coincident single failure will not result in a complete loss of redundant required safety functions. The Completion Time for this failure of redundant required features is reduced to 12 hours from that allowed for one train without offsite power (Required Action A.2). The rationale for the reduction to 12 hours is that Regulatory Guide 1.93 (Ref. 6) allows a Completion Time of 24 hours for two required offsite circuits inoperable, based upon the assumption that two complete safety trains are OPERABLE. When a concurrent redundant required feature failure exists, this assumption is not the case, and a shorter Completion Time of 12 hours is appropriate. These features are powered from redundant AC safety trains. This includes motor driven auxiliary feedwater pumps. ~~Single train features, such as turbine driven auxiliary pumps, are not included in the list.~~

and steam 1

The steam driven auxiliary feedwater pump is only considered a redundant required feature in MODES 1, 2, and 3 because it is not required to be OPERABLE in MODE 4.

The Completion Time for Required Action C.1 is intended to allow the operator time to evaluate and repair any discovered inoperabilities. This Completion Time also allows for an exception to the normal "time zero" for beginning the allowed outage time "clock." In this Required Action, the Completion Time only begins on discovery that both:

a. All required offsite circuits are inoperable and

b. A required feature is inoperable.

Insert 5 (1)

The 14-day Completion Time is based on the findings of a deterministic and probabilistic safety analysis. The risk impact of the Completion Time has been evaluated pursuant to the risk assessment and management provisions of the Maintenance Rule, 10 CFR 50.65(a)(4), and the associated implementation guidance, Regulatory Guide 1.160. Per NRC Letter, "St. Lucie Unit 1 – Issuance of Amendment Regarding Diesel Generator Allowed Outage Time Extension (TAC No. MA7205)," dated January 19, 2001, (Ref. 7) operation may continue in Condition B for a period of 14 days provided compensatory measures are taken.

BASES

ACTIONS (continued)

If at any time during the existence of Condition C (two offsite circuits inoperable) and a required feature becomes inoperable, this Completion Time begins to be tracked.

According to Regulatory Guide 1.93 (Ref. 6), operation may continue in Condition C for a period that should not exceed 24 hours. This level of degradation means that the offsite electrical power system does not have the capability to effect a safe shutdown and to mitigate the effects of an accident; however, the onsite AC sources have not been degraded. This level of degradation generally corresponds to a total loss of the immediately accessible offsite power sources.

Because of the normally high availability of the offsite sources, this level of degradation may appear to be more severe than other combinations of two AC sources inoperable that involve one or more DGs inoperable. However, two factors tend to decrease the severity of this level of degradation:

a. The configuration of the redundant AC electrical power system that remains available is not susceptible to a single bus or switching failure and

b. The time required to detect and restore an unavailable offsite power source is generally much less than that required to detect and restore an unavailable onsite AC source.

With both of the required offsite circuits inoperable, sufficient onsite AC sources are available to maintain the unit in a safe shutdown condition in the event of a DBA or transient. In fact, a simultaneous loss of offsite AC sources, a LOCA, and a worst case single failure were postulated as a part of the design basis in the safety analysis. Thus, the 24 hour Completion Time provides a period of time to effect restoration of one of the offsite circuits commensurate with the importance of maintaining an AC electrical power system capable of meeting its design criteria. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ 2

According to Reference 6, with the available offsite AC sources, two less than required by the LCO, operation may continue for 24 hours. If two offsite sources are restored within 24 hours, unrestricted operation may continue. If only one offsite source is restored within 24 hours, power operation continues in accordance with Condition A.

BASES

ACTIONS (continued)

D.1 and D.2

Pursuant to LCO 3.0.6, the Distribution System ACTIONS would not be entered even if all AC sources to it were inoperable resulting in de-energization. Therefore, the Required Actions of Condition D are modified by a Note to indicate that when Condition D is entered with no AC source to any train, the Conditions and Required Actions for LCO 3.8.9, "Distribution Systems - Operating," must be immediately entered. This allows Condition D to provide requirements for the loss of one offsite circuit and one DG without regard to whether a train is de-energized. LCO 3.8.9 provides the appropriate restrictions for a de-energized train.

According to Regulatory Guide 1.93 (Ref. 6), operation may continue in Condition D for a period that should not exceed 12 hours. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ 2

In Condition D, individual redundancy is lost in both the offsite electrical power system and the onsite AC electrical power system. Since power system redundancy is provided by two diverse sources of power, however, the reliability of the power systems in this Condition may appear higher than that in Condition C (loss of both required offsite circuits). This difference in reliability is offset by the susceptibility of this power system configuration to a single bus or switching failure. The 12 hour Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ 2

E.1

With Train A and Train B DGs inoperable, there are no remaining standby AC sources. Thus, with an assumed loss of offsite electrical power, insufficient standby AC sources are available to power the minimum required ESF functions. Since the offsite electrical power system is the only source of AC power for this level of degradation, the risk associated with continued operation for a short time could be less than that associated with an immediate controlled shutdown (the immediate shutdown could cause grid instability, which could result in a total loss of AC power). Since any inadvertent generator trip could also result in a total loss of offsite AC power, however, the time allowed for continued

BASES

ACTIONS (continued)

operation is severely restricted. The intent here is to avoid the risk associated with an immediate controlled shutdown and to minimize the risk associated with this level of degradation.

According to Regulatory Guide 1.93 (Ref. 6), with both DGs inoperable, operation may continue for a period that should not exceed 2 hours.

Insert 6

~~[F.1~~

~~The sequencer(s) is an essential support system to [both the offsite circuit and the DG associated with a given ESF bus]. [Furthermore, the sequencer is on the primary success path for most major AC electrically powered safety systems powered from the associated ESF bus.] Therefore, loss of an [ESF bus sequencer] affects every major ESF system in the [division]. The [12] hour Completion Time provides a period of time to correct the problem commensurate with the importance of maintaining sequencer OPERABILITY. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.] This time period also ensures that the probability of an accident (requiring sequencer OPERABILITY) occurring during periods when the sequencer is inoperable is minimal.~~

~~This Condition is preceded by a Note that allows the Condition to be deleted if the unit design is such that any sequencer failure mode will only affect the ability of the associated DG to power its respective safety loads under any conditions. Implicit in this Note is the concept that the Condition must be retained if any sequencer failure mode results in the inability to start all or part of the safety loads when required, regardless of power availability, or results in overloading the offsite power circuit to a safety bus during an event, thereby causing its failure. Also implicit in the Note, is that the Condition is not applicable to any train that does not have a sequencer.]~~

1

2

G.1 and G.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

4

St. Lucie – Unit 1

1

1

Insert 6

If a Required Action of Condition C cannot be performed within its associated Completion Time, the unit must be brought to a MODE in which plant risk is minimized. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours.

When both offsite circuits are inoperable, the DGs are supplying power to the loads necessary to maintain the reactor shutdown. Remaining in MODE 3 allows operators to focus on restoration of at least one offsite circuit to OPERABLE status instead of shifting their attention to a plant cooldown. In MODE 3, the steam generators continue to be available for steaming to maintain RCS parameters and steam generator makeup can be provided by the turbine driven auxiliary feedwater pump. This can minimize DG loading while attempts are made to restore offsite power. If one or more offsite circuits remains inoperable for > 72 hours while in MODE 3, the actions of Condition A would not be met and Condition H would apply. Required Action H.2 will further require action to place the unit in MODE 4. However, voluntary entry into MODE 4 or 5 may be made as these MODES are also acceptable low risk states.

The allowed Completion Time is reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

BASES

ACTIONS (continued)

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

4

~~If the inoperable AC electrical power sources cannot be restored to OPERABLE status within the required Completion Time,~~ the unit must be brought to a MODE in which plant risk is minimized. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

1

If a Required Action of Conditions A, B, D, or E cannot be performed within its associated Completion Time,

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~7~~). In MODE 5, it is likely that increased plant maintenance activities (particularly those involving the switchyard) will make the plant more susceptible to loss of offsite power events. In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

8

1

Required Action G.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

St. Lucie – Unit 1

1

BASES

ACTIONS (continued)

H.1

Condition H corresponds to a level of degradation in which all redundancy in the AC electrical power supplies has been lost. At this severely degraded level, any further losses in the AC electrical power system will cause a loss of function. Therefore, no additional time is justified for continued operation. The unit is required by LCO 3.0.3 to commence a controlled shutdown.

SURVEILLANCE REQUIREMENTS

The AC sources are designed to permit inspection and testing of all important areas and features, especially those that have a standby function, in accordance with 10 CFR 50, Appendix A, GDC 18 (Ref. ~~9~~ 10).

Periodic component tests are supplemented by extensive functional tests during refueling outages (under simulated accident conditions). The SRs for demonstrating the OPERABILITY of the DGs are in accordance with the recommendations of Regulatory Guide 1.9 (Ref. 3), Regulatory Guide 1.108 (Ref. 1~~0~~), and Regulatory Guide 1.137 (Ref. 1~~1~~), as addressed in the FSAR.

Where the SRs discussed herein specify voltage and frequency tolerances, the following is applicable. The minimum steady state output voltage of ~~[3740] V is 90% of the nominal 4160 V output voltage. This value, which is specified in ANSI C84.1-1982 (Ref. 12), allows for voltage drop to the terminals of 4000 V motors whose minimum operating voltage is specified as 90% or 3600 V. It also allows for voltage drops to motors and other equipment down through the 120 V level where minimum operating voltage is also usually specified as 80% of name plate rating. The specified maximum steady state output voltage of [4756] V is equal to the maximum operating voltage specified for 4000 V motors. It ensures that for a lightly loaded distribution system, the voltage at the terminals of 4000 V motors is no more than the maximum rated operating voltages. The specified minimum and maximum frequencies of the DG are 58.8 Hz and 61.2 Hz, respectively. These values are equal to ± 2% of the 60 Hz nominal frequency and are derived from the recommendations given in Regulatory Guide 1.9 (Ref. 3).~~

SR 3.8.1.1

This SR ensures correct breaker alignment for each ~~[required]~~ offsite circuit to ensure that distribution buses and loads are connected to their preferred power source, and that appropriate independence of offsite circuits is maintained. The SR also verifies the indicated availability of three-phase AC electrical power from each ~~[required]~~ offsite circuit to the

Insert 7 (1)

3950 V is 95% of the nominal 4160 V output voltage. This value, which is conservative with respect to the value specified in ANSI C84.1-1989 (Ref. 13), allows for voltage drop to the terminals of 4000 V motors whose minimum operating voltage is specified as 90% or 3600 V. It also allows for voltage drops to motors and other equipment down through the 120 V level. The minimum steady state output voltage ensures the operating system voltage for the 480 V switchgear is ≥ 90% of nominal bus voltage, which bounds the 90% criterion of the safety related motor voltage ratings. The specified maximum steady state output voltage of 4370 V bounds the maximum operating bus voltage. It ensures that for a lightly loaded distribution system, the voltage at the terminals of 4000 V motors is such that continuous operation of motor loads does not result in a failure of the load due to overheating. The specified minimum and maximum frequencies of the DG are 59.4 Hz and 60.6 Hz, respectively. These values are equal to ± 1% of the 60 Hz nominal frequency and are conservative with respect to the recommendations given in Regulatory Guide 1.9 (Ref. 3). The under frequency limit considers reduced pump flow and discharge pressure and reduced motor operated valve stroke times during accident sequences. The over frequency limit considers net positive suction head of safety related pumps, increased differential pressure across closed valves, and increased DG fuel oil and lube oil consumption.

BASES

SURVEILLANCE REQUIREMENTS (continued)

onsite distribution network. [The 7 day Frequency is adequate since breaker position is not likely to change without the operator being aware of it and because its status is displayed in the control room.

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

SR 3.8.1.2 and SR 3.8.1.7

These SRs help to ensure the availability of the standby electrical power supply to mitigate DBAs and transients and to maintain the unit in a safe shutdown condition.

To minimize the wear on moving parts that do not get lubricated when the engine is not running, these SRs are modified by a Note (Note 1 for SR 3.8.1.2 and Note for SR 3.8.1.7) to indicate that all DG starts for these Surveillances may be preceded by an engine prelube period and followed by a warmup period prior to loading by an engine prelube period.

For the purposes of SR 3.8.1.2 and SR 3.8.1.7 testing, the DGs are started from standby conditions. Standby conditions for a DG mean the diesel engine coolant and oil are being continuously circulated and temperature is being maintained consistent with manufacturer recommendations.

[In order to reduce stress and wear on diesel engines, the DG manufacturers recommend a modified start in which the starting speed of DGs is limited, warmup is limited to this lower speed, and the DGs are gradually accelerated to synchronous speed prior to loading. This is the intent of Note 2, which is only applicable when such modified start procedures are recommended by the manufacturer.

SR 3.8.1.7 requires that the DG starts from standby conditions and achieves required voltage and frequency within 10 seconds. The 10 second start requirement supports the assumptions of the design basis LOCA analysis in the FSAR, Chapter [15] (Ref. 5).]

BASES

SURVEILLANCE REQUIREMENTS (continued)

The 10 second start requirement is not applicable to SR 3.8.1.2 (see Note 2) when a modified start procedure as described above is used. If a modified start is not used, 10 second start requirement of SR 3.8.1.7 applies.

Since SR 3.8.1.7 requires a 10 second start, it is more restrictive than SR 3.8.1.2, and it may be performed in lieu of SR 3.8.1.2.

In addition to the SR requirements, the time for the DG to reach steady state operation, unless the modified DG start method is employed, is periodically monitored and the trend evaluated to identify degradation of governor and voltage regulator performance.

~~[The 31 day Frequency for SR 3.8.1.2 is consistent with Regulatory Guide 1.9 (Ref. 3). The 184 day Frequency for SR 3.8.1.7 is a reduction in cold testing consistent with Generic Letter 84-15 (Ref. 8). These Frequencies provide adequate assurance of DG OPERABILITY, while minimizing degradation resulting from testing.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

SR 3.8.1.3

This Surveillance verifies that the DGs are capable of synchronizing with the offsite electrical system and accepting loads greater than or equal to the equivalent of the maximum expected accident loads. A minimum run time of 60 minutes is required to stabilize engine temperatures, while minimizing the time that the DG is connected to the offsite source.

Although no power factor requirements are established by this SR, the DG is normally operated at a power factor between ~~[~~0.8 lagging~~]~~ and ~~[~~1.0~~]~~. The 0.8 value is the design rating of the machine, while ~~[~~1.0~~]~~ is an operational limitation ~~[~~to ensure circulating currents are minimized~~]~~. ~~[The 31 day Frequency for this Surveillance is consistent with Regulatory Guide 1.9 (Ref. 3).~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

This SR is modified by four Notes. Note 1 indicates that diesel engine runs for this Surveillance may include gradual loading, as recommended by the manufacturer, so that mechanical stress and wear on the diesel engine are minimized. Note 2 states that momentary transients because of changing bus loads do not invalidate this test. Similarly, momentary power factor transients above the limit will not invalidate the test. Note 3 indicates that this Surveillance should be conducted on only one DG at a time in order to avoid common cause failures that might result from offsite circuit or grid perturbations. Note 4 stipulates a prerequisite requirement for performance of this SR. A successful DG start must precede this test to credit satisfactory performance.

SR 3.8.1.4

engine mounted day tanks (one tank per engine)

This SR provides verification that the level of fuel oil in the ~~day tank [and engine mounted tank]~~ is at or above the level at which fuel oil is automatically added. The level is expressed as an equivalent volume in gallons, and is selected to ensure adequate fuel oil ~~for a minimum of 1 hour of DG operation at full load plus 10%~~.

to operate the engine at rated capacity for a sufficient duration to allow maintenance or valve realignment

~~[The 31 day Frequency is adequate to assure that a sufficient supply of fuel oil is available, since low level alarms are provided and unit operators would be aware of any large uses of fuel oil during this period.~~

SR 3.8.1.5

Microbiological fouling is a major cause of fuel oil degradation. There are numerous bacteria that can grow in fuel oil and cause fouling, but all must have a water environment in order to survive. Removal of water from the fuel oil day ~~[and engine mounted]~~ tanks eliminates the necessary environment for bacterial survival. This is the most effective means of controlling microbiological fouling. In addition, it eliminates the potential for water entrainment in the fuel oil during DG operation. Water may come from any of several sources, including condensation, ground water, rain water, contaminated fuel oil, and from breakdown of the fuel oil by bacteria. Frequent checking for and removal of accumulated water minimizes fouling and provides data regarding the watertight integrity of the fuel oil system. ~~[The Surveillance Frequency of 31 days is established by Regulatory Guide 1.137 (Ref. 11). This SR is for preventive maintenance.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

The presence of water does not necessarily represent failure of this SR provided the accumulated water is removed during the performance of this Surveillance.

SR 3.8.1.6

This Surveillance demonstrates that each required fuel oil transfer pump operates and transfers fuel oil from ~~its associated storage tank~~ the fuel oil storage system to its associated day tank~~s~~. This is required to support continuous operation of

BASES

SURVEILLANCE REQUIREMENTS (continued)

transfer system

standby power sources. This Surveillance provides assurance that the fuel oil transfer pump is OPERABLE, the fuel oil piping ~~system~~ is intact, the fuel delivery piping is not obstructed, and the controls and control systems for automatic fuel transfer systems are OPERABLE. 1

~~[[The Frequency for this SR is variable, depending on individual system design, with up to a [92] day interval. The [92] day Frequency corresponds to the testing requirements for pumps as contained in the ASME Code (Ref. 13); however, the design of fuel transfer systems is such that pumps will operate automatically or must be started manually in order to maintain an adequate volume of fuel oil in the day [and engine mounted] tanks during or following DG testing. In such a case, a 31 day Frequency is appropriate. Since proper operation of fuel transfer systems is an inherent part of DG OPERABILITY, the Frequency of this SR should be modified to reflect individual designs.~~ 2

~~This SR is modified by a Note. The reason for the Note is that during operation with the reactor critical, performance of this SR could cause perturbations to the electrical distribution systems that could challenge continued steady state operation and, as a result, unit safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed Surveillance, a successful Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when the Surveillance is performed in MODE 1 or 2. Risk insights or deterministic methods may be used for this assessment. Credit may be taken for unplanned events that satisfy this SR .]~~

SR 3.8.1.9

Each DG is provided with an engine overspeed trip to prevent damage to the engine. Recovery from the transient caused by the loss of a large load could cause diesel engine overspeed, which, if excessive, might result in a trip of the engine. This Surveillance demonstrates the DG load response characteristics and capability to reject the largest single load without exceeding predetermined voltage and frequency and while maintaining a specified margin to the overspeed trip. ~~[~~For this unit, the single load for each DG and its horsepower rating is ~~as follows:]~~. This Surveillance may be accomplished by:

an intake cooling water pump with a nameplate rating of 600 hp

BASES

SURVEILLANCE REQUIREMENTS (continued)

a. Tripping the DG output breaker with the DG carrying greater than or equal to its associated single largest post-accident load while paralleled to offsite power or while solely supplying the bus, or

b. Tripping its associated single largest post-accident load with the DG solely supplying the bus.

As required by IEEE-308 (Ref. 14), the load rejection test is acceptable if the increase in diesel speed does not exceed 75% of the difference between synchronous speed and the overspeed trip setpoint, or 15% above synchronous speed, whichever is lower.

The time, voltage, and frequency tolerances specified in this SR are derived from Regulatory Guide 1.9 (Ref. 3) recommendations for response during load sequence intervals. The ~~[3]~~ seconds specified is equal to 60% of a ~~typical 5~~ second load sequence interval associated with sequencing of the largest load. The voltage and frequency specified are consistent with the design range of the equipment powered by the DG. SR 3.8.1.9.a corresponds to the maximum frequency excursion, while SR 3.8.1.9.b and SR 3.8.1.9.c are steady state voltage and frequency values to which the ~~system~~ must recover following load rejection~~. [The [18 month] Frequency is consistent with the recommendation of Regulatory Guide 1.108 (Ref. 10).~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

This SR is modified by two Notes. The reason for Note 1 is that during operation with the reactor critical, performance of this SR could cause perturbations to the electrical distribution systems that could challenge continued steady state operation and, as a result, unit safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns)

BASES

SURVEILLANCE REQUIREMENTS (continued)

provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed Surveillance, a successful Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when the Surveillance is performed in MODE 1 or 2. Risk insights or deterministic methods may be used for this assessment. Credit may be taken for unplanned events that satisfy this SR. Note 2 ensures that the DG is tested under load conditions that are as close to design basis conditions as possible. When synchronized with offsite power, testing should be performed at a power factor of ≤ ~~[~~0.9~~]~~. This power factor is representative of the actual inductive loading a DG would see under design basis accident conditions. Under certain conditions, however, Note 2 allows the Surveillance to be conducted at a power factor other than ≤ ~~[~~0.9~~]~~. These conditions occur when grid voltage is high, and the additional field excitation needed to get the power factor to ≤ ~~[~~0.9~~]~~ results in voltages on the emergency busses that are too high. Under these conditions, the power factor should be maintained as close as practicable to ~~[~~0.9~~]~~ while still maintaining acceptable voltage limits on the emergency busses. In other circumstances, the grid voltage may be such that the DG excitation levels needed to obtain a power factor of ~~[~~0.9~~]~~ may not cause unacceptable voltages on the emergency busses, but the excitation levels are in excess of those recommended for the DG. In such cases, the power factor shall be maintained as close as practicable to ~~[~~0.9~~]~~ without exceeding the DG excitation limits. 2

~~REVIEWER'S NOTE~~

~~The above MODE restrictions may be deleted if it can be demonstrated to the staff, on a plant specific basis, that performing the SR with the reactor in any of the restricted MODES can satisfy the following criteria, as applicable~~:

~~a. Performance of the SR will not render any safety system or component inoperable,~~

~~b. Performance of the SR will not cause perturbations to any of the electrical distribution systems that could result in a challenge to steady state operation or to plant safety systems, and~~

~~c. Performance of the SR or failure of the SR will not cause or result in an AOO with attendant challenge to plant safety systems.~~ 4

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.8.1.10

This Surveillance demonstrates the DG capability to reject a full load without overspeed tripping or exceeding the predetermined voltage limits. The DG full load rejection may occur because of a system fault or inadvertent breaker tripping. This Surveillance ensures proper engine generator load response under the simulated test conditions. This test simulates the loss of the total connected load that the DG experiences following a full load rejection and verifies that the DG will not trip upon loss of the load. These acceptance criteria provide DG damage protection. While the DG is not expected to experience this transient during an event and continues to be available, this response ensures that the DG is not degraded for future application, including reconnection to the bus if the trip initiator can be corrected or isolated.

[The [18 month] Frequency is consistent with the recommendation of Regulatory Guide 1.108 (Ref. 10) and is intended to be consistent with expected fuel cycle lengths.

c. Performance of the SR or failure of the SR will not cause or result in an AOO with attendant challenge to plant safety systems.

4

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.8.1.1~~1~~

As required by Regulatory Guide 1.108 (Ref. 1~~0~~), paragraph 2.a.(1), this Surveillance demonstrates the as designed operation of the standby power sources during loss of the offsite source. This test verifies all actions encountered from the loss of offsite power, including shedding of the nonessential loads and energization of the emergency buses and respective loads from the DG. It further demonstrates the capability of the DG to automatically achieve the required voltage and frequency within the specified time.

The DG auto-start time of ~~[~~10~~]~~ seconds is derived from requirements of the accident analysis to respond to a design basis large break LOCA. The Surveillance should be continued for a minimum of 5 minutes in order to demonstrate that all starting transients have decayed and stability has been achieved.

The requirement to verify the connection and power supply of permanent and auto-connected loads is intended to satisfactorily show the relationship of these loads to the DG loading logic. In certain circumstances, many of these loads cannot actually be connected or loaded without undue hardship or potential for undesired operation. For instance, Emergency Core Cooling Systems (ECCS) injection valves are not desired to be stroked open, high pressure injection systems are not capable of being operated at full flow, or shutdown cooling (SDC) systems performing a decay heat removal function are not desired to be realigned to the ECCS mode of operation. In lieu of actual demonstration of connection and loading of loads, testing that adequately shows the capability of the DG system to perform these functions is acceptable. This testing may include any series of sequential, overlapping, or total steps so that the entire connection and loading sequence is verified.

~~[The Frequency of [18 months] is consistent with the recommendations of Regulatory Guide 1.108 (Ref. 10), paragraph 2.a.(1), takes into consideration unit conditions required to perform the Surveillance, and is intended to be consistent with expected fuel cycle lengths.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

This SR is modified by two Notes. The reason for Note 1 is to minimize wear and tear on the DGs during testing. For the purpose of this testing, the DGs must be started from standby conditions, that is, with the engine coolant and oil continuously circulated and temperature maintained consistent with manufacturer recommendations. The reason for Note 2 is that performing the Surveillance would remove a required offsite circuit from service, perturb the electrical distribution system, and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed partial Surveillance, a successful partial Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the partial Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when portions of the Surveillance are performed in MODE 1 or 2. Risk insights or deterministic methods may be used for the assessment. Credit may be taken for unplanned events that satisfy this SR.

~~[~~SR 3.8.1.1~~2~~

This Surveillance demonstrates that the DG automatically starts and achieves the required voltage and frequency within the specified time (~~[~~10~~]~~ seconds) from the ~~design basis~~ actuation signal ~~(LOCA signal)~~ and operates for ≥ 5 minutes. The 5 minute period provides sufficient time to demonstrate stability. SR 3.8.1.1~~2~~.d and SR 3.8.1.1~~2~~.e ensure that permanently connected loads and emergency loads are energized from the offsite electrical power system on an ESF signal without loss of offsite power.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The requirement to verify the connection of permanent and autoconnected loads is intended to satisfactorily show the relationship of these loads to the DG loading logic. In certain circumstances, many of these loads cannot actually be connected or loaded without undue hardship or potential for undesired operation. For instance, ECCS injection valves are not desired to be stroked open, high pressure injection systems are not capable of being operated at full flow, or SDC systems performing a decay heat removal function are not desired to be realigned to the ECCS mode of operation. In lieu of actual demonstration of connection and loading of loads, testing that adequately shows the capability of the DG system to perform these functions is acceptable. This testing may include any series of sequential, overlapping, or total steps so that the entire connection and loading sequence is verified.

~~[The Frequency of [18 months] takes into consideration unit conditions required to perform the Surveillance and is intended to be consistent with the expected fuel cycle lengths. Operating experience has shown that these components usually pass the SR when performed at the [18 month] Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 4
~~]~~ 2

This SR is modified by two Notes. The reason for Note 1 is to minimize wear and tear on the DGs during testing. For the purpose of this testing, the DGs must be started from standby conditions, that is, with the engine coolant and oil continuously circulated and temperature maintained consistent with manufacturer recommendations. The reason for Note 2 is that during operation with the reactor critical, performance of this Surveillance could cause perturbations to the electrical distribution systems that could challenge continued steady state operation and, as a result, unit safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing

BASES

SURVEILLANCE REQUIREMENTS (continued)

OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed partial Surveillance, a successful partial Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the partial Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when portions of the Surveillance are performed in MODE 1 or 2. Risk insights or deterministic methods may be used for the assessment. Credit may be taken for unplanned events that satisfy this SR.~~]~~ 2

SR 3.8.1.1~~3~~ 2 6

This Surveillance demonstrates that DG noncritical protective functions (e.g., high jacket water temperature) are bypassed on a loss of voltage signal concurrent with an ESF actuation ~~test~~ signal. Noncritical automatic trips are all automatic trips except: 1

a. Engine overspeed; and 1

b. Generator differential current~~;~~

~~[c. Low lube oil pressure;~~

~~d. High crankcase pressure; and~~ 2

~~e. Start failure relay.]~~

The noncritical trips are bypassed during DBAs and provide an alarm on an abnormal engine condition. This alarm provides the operator with sufficient time to react appropriately. The DG availability to mitigate the DBA is more critical than protecting the engine against minor problems that are not immediately detrimental to emergency operation of the DG.

~~[The [18 month] Frequency is based on engineering judgment, taking into consideration unit conditions required to perform the Surveillance, and is intended to be consistent with expected fuel cycle lengths. Operating experience has shown that these components usually pass the SR when performed at the [18 month] Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.~~ 2

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4 2

The SR is modified by a Note. The reason for the Note is that performing the Surveillance would remove a required DG from service. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed Surveillance, a successful Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when the Surveillance is performed in MODE 1 or 2. Risk insights or deterministic methods may be used for this assessment. Credit may be taken for unplanned events that satisfy this SR.

~~---------- REVIEWER'S NOTE ----------~~
~~The above MODE restrictions may be deleted if it can be demonstrated to the staff, on a plant specific basis, that performing the SR with the reactor in any of the restricted MODES can satisfy the following criteria, as applicable:~~

~~a. Performance of the SR will not render any safety system or component inoperable,~~

~~b. Performance of the SR will not cause perturbations to any of the electrical distribution systems that could result in a challenge to steady state operation or to plant safety systems, and~~ 4

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~c. Performance of the SR or failure of the SR will not cause or result in an AOO with attendant challenge to plant safety systems.~~

SR 3.8.1.1~~4~~

Regulatory Guide 1.108 (Ref. 1~~0~~), paragraph 2.a.(3), requires demonstration that the DGs can start and run continuously at full load capability for an interval of not less than 24 hours, ~~≥ [~~2~~]~~ hours of which is at a load equivalent to 110% of the continuous duty rating) and the remainder of the time at a load equivalent to the continuous duty rating of the DG. The DG starts for this Surveillance can be performed either from standby or hot conditions. The provisions for prelubricating and warmup, discussed in SR 3.8.1.2, and for gradual loading, discussed in SR 3.8.1.3, are applicable to this SR.

the 2 hour rating (i.e.,

This SR meets the intent of this requirement to the extent practical by loading the DG to approximately 109% of the generator continuous duty rating not to exceed the 4 hour rating. This loading requirement challenges the full loading capability of the DG without unnecessarily overloading the DG.

The load band is provided to avoid routine overloading of the DG. Routine overloading may result in more frequent teardown inspections in accordance with vendor recommendations in order to maintain DG OPERABILITY.

~~[The [18 month] Frequency is consistent with the recommendations of Regulatory Guide 1.108 (Ref. 8), paragraph 2.a.(3), takes into consideration unit conditions required to perform the Surveillance, and is intended to be consistent with expected fuel cycle lengths.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

This Surveillance is modified by three Notes. Note 1 states that momentary transients due to changing bus loads do not invalidate this test. Similarly, momentary power factor transients above the power factor limit will not invalidate the test. ~~The reason for Note 2 is that during operation with the reactor critical, performance of this Surveillance could cause perturbations to the electrical distribution systems that could challenge continued steady state operation and, as a result, unit safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed Surveillance, a successful Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when the Surveillance is performed in MODE 1 or 2. Risk insights or deterministic methods may be used for this assessment.~~ 2

Note 2 provides an allowance that c

~~C~~redit may be taken for unplanned events that satisfy this SR. Note 3 ensures that the DG is tested under load conditions that are as close to design basis conditions as possible. When synchronized with offsite power, testing should be performed at a power factor of ≤ ~~[~~0.9~~]~~. This power factor is representative of the actual inductive loading a DG would see under design basis accident conditions. Under certain conditions, however, Note 3 allows the Surveillance to be conducted at a power factor other than ≤ ~~[~~0.9~~]~~. These conditions occur when grid voltage is high, and the additional field excitation needed to get the power factor to ≤ ~~[~~0.9~~]~~ results in voltages on the emergency busses that are too high. Under these conditions, the power factor should be maintained as close as practicable to ~~[~~0.9~~]~~ while still maintaining acceptable voltage limits on the emergency busses. In other circumstances, the grid voltage may be such that the DG excitation levels needed to obtain a power factor of ~~[~~0.9~~]~~ may not cause unacceptable voltages on the emergency busses, but the excitation levels are in excess of those recommended for the DG. In such cases, the power factor shall be maintained as close practicable to ~~[~~0.9~~]~~ without exceeding the DG excitation limits. 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~SR 3.8.1.15~~

~~This Surveillance demonstrates that the diesel engine can restart from a hot condition, such as subsequent to shutdown from normal Surveillances, and achieve the required voltage and frequency within [10] seconds. The [10] second time is derived from the requirements of the accident analysis to respond to a design basis large break LOCA. [The [18 month] Frequency is consistent with the recommendations of Regulatory Guide 1.108 (Ref. 10), paragraph 2.a.(5).~~

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

~~This SR is modified by two Notes. Note 1 ensures that the test is performed with the diesel sufficiently hot. The load band is provided to avoid routine overloading of the DG. Routine overloads may result in more frequent teardown inspections in accordance with vendor recommendations in order to maintain DG OPERABILITY. The requirement that the diesel has operated for at least [2] hours at full load conditions prior to performance of this Surveillance is based on manufacturer recommendations for achieving hot conditions. Momentary transients due to changing bus loads do not invalidate this test. Note 2 allows all DG starts to be preceded by an engine prelube period to minimize wear and tear on the diesel during testing.~~

SR 3.8.1.1~~6~~

As required by Regulatory Guide 1.108 (Ref. 1~~0~~), paragraph 2.a.(6), this Surveillance ensures that the manual synchronization and automatic load transfer from the DG to the offsite source can be made and that the DG can be returned to ready to load status when offsite power is restored. It also ensures that the auto-start logic is reset to allow the DG to reload if a

BASES

SURVEILLANCE REQUIREMENTS (continued)

subsequent loss of offsite power occurs. The DG is considered to be in ready to load status when the DG is at rated speed and voltage, the output breaker is open and can receive and autoclose signal on bus undervoltage, and the load sequence timers are reset. 5

~~[The Frequency of [18 months] is consistent with the recommendations of Regulatory Guide 1.108 (Ref. 10), paragraph 2.a.(6), and takes into consideration unit conditions required to perform the Surveillance.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 4
~~]~~ 2

This SR is modified by a Note. The reason for the Note is that performing the Surveillance would remove a required offsite circuit from service, perturb the electrical distribution system, and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed Surveillance, a successful Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when the Surveillance is performed in MODE 1 or 2. Risk insights or deterministic methods may be used for this assessment. Credit may be taken for unplanned events that satisfy this SR.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[~~SR 3.8.1.1~~7~~

Demonstration of the test mode override ensures that the DG availability under accident conditions will not be compromised as the result of testing and the DG will automatically reset to ready to load operation if a ~~LOCA~~ actuation signal is received during operation in the test mode. Ready to load operation is defined as the DG running at rated speed and voltage with the DG output breaker open. These provisions for automatic switchover are required by IEEE-308 (Ref. 14), paragraph 6.2.6(2).

The requirement to automatically energize the emergency loads with offsite power is essentially identical to that of SR 3.8.1.1~~2~~. The intent in the requirement associated with SR 3.8.1.1~~7~~.b is to show that the emergency loading was not affected by the DG operation in test mode. In lieu of actual demonstration of connection and loading of loads, testing that adequately shows the capability of the emergency loads to perform these functions is acceptable. This testing may include any series of sequential, overlapping, or total steps so that the entire connection and loading sequence is verified.

~~[The [18 month] Frequency is consistent with the recommendations of Regulatory Guide 1.108 (Ref. 10), paragraph 2.a.(8); takes into consideration unit conditions required to perform the Surveillance; and is intended to be consistent with expected fuel cycle lengths.~~

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.1 AC Sources - Operating

BASES

BACKGROUND

The unit Class 1E Electrical Power Distribution System AC sources consist of the offsite power sources (preferred power sources, normal and alternate(s)), and the onsite standby power sources (Train A and Train B diesel generators (DGs)). As required by 10 CFR 50, Appendix A, GDC 17 (Ref. 1), the design of the AC electrical power system provides independence and redundancy to ensure an available source of power to the Engineered Safety Feature (ESF) systems.

The onsite Class 1E AC Distribution System is divided into redundant load groups (trains) so that the loss of any one group does not prevent the minimum safety functions from being performed. Each train has connections to two preferred offsite power sources and a single DG.

Offsite power is supplied to the unit switchyard(s) from the transmission network by ~~[two]~~ four transmission lines. From the switchyard(s), two electrically and physically separated circuits provide AC power, through ~~[~~step down ~~station auxiliary~~ startup transformers~~]~~, to the 4.16 kV ESF buses. A detailed description of the offsite power network and the circuits to the Class 1E ESF buses is found in the FSAR, Chapter ~~[~~8~~]~~ U (Ref. 2). Insert 1 2 1

An offsite circuit consists of all breakers, transformers, switches, interrupting devices, cabling, and controls required to transmit power from the offsite transmission network to the onsite Class 1E ESF bus or buses.

Insert 2

~~Certain required unit loads are returned to service in a predetermined sequence in order to prevent overloading the transformer supplying offsite power to the onsite Class 1E Distribution System. Within [1 minute] after the initiating signal is received, all automatic and permanently connected loads needed to recover the unit or maintain it in a safe condition are returned to service via the load sequencer.~~ 1

The onsite standby power source for each 4.16 kV ESF bus is a dedicated DG. DGs ~~[1]~~ 2A and ~~[2]~~ 2B are dedicated to ESF buses ~~[1]~~ 2A3 and ~~[2]~~ 2B3, respectively. A DG starts automatically on a safety injection (SI) ~~signal~~ -low (i.e., low pressurizer pressure or high containment pressure signals) or on an ~~[~~ESF~~]~~ 4.16kV bus degraded voltage or undervoltage ~~signal~~ actuation signal AS. After the DG has started, it will automatically tie to its respective bus after offsite power is tripped as a consequence of ESF bus undervoltage or 3 1 2 1

1

Insert 1

The circuit between each startup transformer and the associated 4.16 kV ESF bus includes two non-ESF buses: 2A4 and 2A2 buses for Train A; and 2B4 and 2B2 buses for Train B. Alternately, AC power can be supplied from a Unit 1 startup transformer, 1A or 1B via the non-ESF buses, by manually aligning the opposite unit startup transformer (i.e., removing and installing the startup transformer feeder breaker in a different breaker cubicle) to the unit 4.16 kV ESF bus.

1

Insert 2

Normal power for the onsite Class 1E AC Distribution System is supplied through the unit auxiliary transformers. If the normal onsite power source is lost to the onsite Class 1E AC Electrical Distribution System (i.e., main generator trip) an automatic fast transfer is initiated to transfer the 4.16 kV ESF buses from the unit auxiliary transformers to the startup transformers (offsite power). The transfer occurs in approximately three cycles.

BASES

BACKGROUND (continued)

degraded voltage, independent of or coincident with an SI signal. The DGs will also start and operate in the standby mode without tying to the ESF bus on an SI signal alone. Following the trip of offsite power, ~~[a sequencer/an undervoltage signal] strips~~ nonpermanent loads from the ESF bus. When the DG is tied to the ESF bus, loads are then sequentially connected to its respective ESF bus ~~by the automatic load sequencer~~. ~~The sequencing logic controls the permissive and starting signals to motor breakers~~to prevent overloading the DG by automatic load application.

In the event of a loss of preferred power, the ESF electrical loads are automatically connected to the DGs in sufficient time to provide for safe reactor shutdown and to mitigate the consequences of a Design Basis Accident (DBA) such as a loss of coolant accident (LOCA).

Certain required unit loads are returned to service in a predetermined sequence in order to prevent overloading the DG in the process. Within ~~[~~1~~]~~ minute after the initiating signal is received, all loads needed to recover the unit or maintain it in a safe condition are returned to service.

Ratings for Train A and Train B DGs satisfy the requirements of Regulatory Guide 1.9 (Ref. 3). The continuous service rating of each DG is ~~[7000]~~ kW with ~~[10]% overload permissible for up to 2 hours in any 24 hour period~~. The ESF loads that are powered from the 4.16 kV ESF buses are listed in Reference 2.

APPLICABLE SAFETY ANALYSES

The initial conditions of DBA and transient analyses in the FSAR, Chapter ~~[~~6~~]~~ (Ref. 4) and Chapter ~~[~~15~~]~~ (Ref. 5), assume ESF systems are OPERABLE. The AC electrical power sources are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to ESF systems so that the fuel, Reactor Coolant System (RCS), and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, Power Distribution Limits; Section 3.4, Reactor Coolant System (RCS); and Section 3.6, Containment Systems.

The OPERABILITY of the AC electrical power sources is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the unit. This results in maintaining at least one train of the onsite or offsite AC sources OPERABLE during accident conditions in the event of:

BASES

APPLICABLE SAFETY ANALYSES (continued)

a. An assumed loss of all offsite power or all onsite AC power and

b. A worst case single failure.

The AC sources satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Two qualified circuits between the offsite transmission network and the onsite Class 1E Electrical Power Distribution System and separate and independent DGs for each train ensure availability of the required power to shut down the reactor and maintain it in a safe shutdown condition after an anticipated operational occurrence (AOO) or a postulated DBA.

Qualified offsite circuits are those that are described in the U FSAR and are part of the licensing basis for the unit. (1)

~~[In addition, one required automatic load sequencer per train must be OPERABLE.]~~ (2)

Each qualified offsite circuit must be physically independent, capable of providing three phases of AC power, maintaining rated frequency and voltage, and accepting required loads during an accident, while connected to the ESF buses. (1)

Insert 3

~~[Offsite circuit #1 consists of Safeguards Transformer B, which is supplied from Switchyard Bus B, and is fed through breaker 52-3 powering the ESF transformer XNB01, which, in turn, powers the #1 ESF bus through its normal feeder breaker. Offsite circuit #2 consists of the Startup Transformer, which is normally fed from the Switchyard Bus A, and is fed through breaker PA 0201 powering the ESF transformer, which, in turn, powers the #2 ESF bus through its normal feeder breaker.]~~ (2)

Each DG must be capable of starting, accelerating to rated speed and voltage, and connecting to its respective ESF bus on detection of bus undervoltage. This will be accomplished within ~~[~~10~~]~~ seconds. (2) Each DG must also be capable of accepting required loads within the assumed loading sequence intervals~~,~~ and continue to operate until offsite power can be restored to the ESF buses. (5) These capabilities are required to be met from a variety of initial conditions such as DG in standby with the engine hot and DG in standby with the engine at ambient conditions. Additional DG capabilities must be demonstrated to meet required Surveillances, e.g., capability of the DG to revert to standby status on an ECCS signal while operating in parallel test mode.

Insert 3 (1)

Each offsite circuit consists of a unit startup transformer (i.e., 2A, 2B) and the associated circuit path, including non-ESF buses (i.e., 2A4 and 2A2 buses; 2B4 and 2B2 buses), up to and including the feeder breaker to the respective unit 4.16 kV ESF bus (i.e., 2A3 bus, 2B3 bus). Alternately, when one unit startup transformer is unavailable, the associated offsite circuit may consist of an opposite unit startup transformer (i.e., 1A or 1B) and the associated circuit path, including non-ESF buses, up to and including the feeder breaker to the respective unit 4.16 kV ESF bus.

BASES

LCO (continued)

Proper sequencing of loads, ~~[~~including tripping of nonessential loads,~~]~~ is a required function for DG OPERABILITY. 2

The AC sources in one train must be separate and independent (to the extent possible) of the AC sources in the other train. For the DGs, separation and independence are complete.

For the offsite AC sources, separation and independence are to the extent practical. ~~A circuit may be connected to more than one ESF bus, with fast transfer capability to the other circuit OPERABLE, and not violate separation criteria.~~ A circuit that is not connected to an ESF bus is required to have OPERABLE fast transfer interlock mechanisms to at least ~~two~~ ESF bus~~es~~ to support OPERABILITY of that circuit. 1

one

Insert 4

APPLICABILITY

The AC sources ~~[and sequencers]~~ are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure that: 3 2

a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients and

b. Adequate core cooling is provided and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

The AC power requirements for MODES 5 and 6 are covered in LCO 3.8.2, "AC Sources - Shutdown."

ACTIONS

A Note prohibits the application of LCO 3.0.4.b to an inoperable DG. There is an increased risk associated with entering a MODE or other specified condition in the Applicability with an inoperable DG and the provisions of LCO 3.0.4.b, which allow entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, should not be applied in this circumstance.

A.1

To ensure a highly reliable power source remains with the one offsite circuit inoperable, it is necessary to verify the OPERABILITY of the remaining required offsite circuit on a more frequent basis. Since the Required Action only specifies "perform," a failure of SR 3.8.1.1

1

Insert 4

Each startup transformer set (1A-2A, 1B-2B) is provided with a manual switching arrangement that permits powering the associated Class 1E electrical distribution subsystem from either unit's startup transformer. A single startup transformer is adequate to accommodate the emergency and auxiliary loads of a unit during a postulated DBA. Therefore, when utilized as a qualified offsite AC source to Unit 2, the Unit 1 startup transformer may be aligned to ESF buses of both units and not violate the shared system criterion between units provided the Unit 1 startup transformer is not supplying power to a Unit 1 bus.

BASES

ACTIONS (continued)

acceptance criteria does not result in a Required Action not met. However, if a second required circuit fails SR 3.8.1.1, the second offsite circuit is inoperable, and Condition C, for two offsite circuits inoperable, is entered.

~~REVIEWER'S NOTE~~

~~The turbine driven auxiliary feedwater pump is only required to be considered a redundant required feature, and, therefore, required to be determined OPERABLE by this Required Action, if the design is such that the remaining OPERABLE motor or turbine driven auxiliary feedwater pump(s) is not by itself capable (without any reliance on the motor driven auxiliary feedwater pump powered by the emergency bus associated with the inoperable diesel generator) of providing 100% of the auxiliary feedwater flow assumed in the safety analysis.~~

4

A.2

Required Action A.2, which only applies if the train cannot be powered from an offsite source, is intended to provide assurance that an event coincident with a single failure of the associated DG will not result in a complete loss of safety function of critical redundant required features. These features are powered from the redundant AC electrical power train. This includes motor and steam driven auxiliary feedwater pumps~~. Single train systems, such as turbine driven auxiliary feedwater pumps, may not be included~~.

The steam driven auxiliary feedwater pump is only considered a redundant required feature in MODES 1, 2, and 3 because it is not required to be OPERABLE in MODE 4.

1

The Completion Time for Required Action A.2 is intended to allow the operator time to evaluate and repair any discovered inoperabilities. This Completion Time also allows for an exception to the normal "time zero" for beginning the allowed outage time "clock." In this Required Action, the Completion Time only begins on discovery that both:

a. The train has no offsite power supplying its loads and

b. A required feature on the other train is inoperable.

If at any time during the existence of Condition A (one offsite circuit inoperable) a redundant required feature subsequently becomes inoperable, this Completion Time begins to be tracked.

BASES

ACTIONS (continued)

Discovering no offsite power to one train of the onsite Class 1E Electrical Power Distribution System coincident with one or more inoperable required support or supported features, or both, that are associated with the other train that has offsite power, results in starting the Completion Times for the Required Action. Twenty-four hours is acceptable because it minimizes risk while allowing time for restoration before subjecting the unit to transients associated with shutdown.

The remaining OPERABLE offsite circuit and DGs are adequate to supply electrical power to Train A and Train B of the onsite Class 1E Distribution System. The 24 hour Completion Time takes into account the component OPERABILITY of the redundant counterpart to the inoperable required feature. Additionally, the 24 hour Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period.

A.3

According to Regulatory Guide 1.93 (Ref. 6), operation may continue in Condition A for a period that should not exceed 72 hours. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ With one offsite circuit inoperable, the reliability of the offsite system is degraded, and the potential for a loss of offsite power is increased, with attendant potential for a challenge to the unit safety systems. In this Condition, however, the remaining OPERABLE offsite circuit and DGs are adequate to supply electrical power to the onsite Class 1E Distribution System. 2

The 72 hour Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period.

B.1

To ensure a highly reliable power source remains with an inoperable DG, it is necessary to verify the availability of the offsite circuits on a more frequent basis. Since the Required Action only specifies "perform," a failure of SR 3.8.1.1 acceptance criteria does not result in a Required Action being not met. However, if a circuit fails to pass SR 3.8.1.1, it is inoperable. Upon offsite circuit inoperability, additional Conditions and Required Actions must then be entered.

BASES

ACTIONS (continued)

~~REVIEWER'S NOTE~~

~~The turbine driven auxiliary feedwater pump is only required to be considered a redundant required feature, and, therefore, required to be determined OPERABLE by this Required Action, if the design is such that the remaining OPERABLE motor or turbine driven auxiliary feedwater pump(s) is not by itself capable (without any reliance on the motor driven auxiliary feedwater pump powered by the emergency bus associated with the inoperable diesel generator) of providing 100% of the auxiliary feedwater flow assumed in the safety analysis.~~

4

B.2

Required Action B.2 is intended to provide assurance that a loss of offsite power, during the period that a DG is inoperable, does not result in a complete loss of safety function of critical systems. These features are designed with redundant safety related trains. This includes motor driven auxiliary feedwater pumps~~. Single train systems, such as turbine driven auxiliary feedwater pumps, are not included~~. Redundant required feature failures consist of inoperable features with a train, redundant to the train that has an inoperable DG.

and steam

1

The steam driven auxiliary feedwater pump is only considered a redundant required feature in MODES 1, 2, and 3 because it is not required to be OPERABLE in MODE 4.

The Completion Time for Required Action B.2 is intended to allow the operator time to evaluate and repair any discovered inoperabilities. This Completion Time also allows for an exception to the normal "time zero" for beginning the allowed outage time "clock." In this Required Action, the Completion Time only begins on discovery that both:

a. An inoperable DG exists and

b. A required feature on the other train is inoperable.

If at any time during the existence of this Condition (one DG inoperable) a required feature subsequently becomes inoperable, this Completion Time begins to be tracked.

BASES

ACTIONS (continued)

Discovering one required DG inoperable coincident with one or more inoperable required support or supported features, or both, that are associated with the OPERABLE DG, results in starting the Completion Time for the Required Action. Four hours from the discovery of these events existing concurrently, is acceptable because it minimizes risk while allowing time for restoration before subjecting the unit to transients associated with shutdown.

In this Condition, the remaining OPERABLE DG and offsite circuits are adequate to supply electrical power to the onsite Class 1E Distribution System. Thus, on a component basis, single failure protection for the required feature's function may have been lost; however, function has not been lost. The 4 hour Completion Time takes into account the OPERABILITY of the redundant counterpart to the inoperable required feature. Additionally, the 4 hour Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period.

B.3.1 and B.3.2

Required Action B.3.1 provides an allowance to avoid unnecessary testing of OPERABLE DGs. If it can be determined that the cause of the inoperable DG does not exist on the OPERABLE DG, SR 3.8.1.2 does not have to be performed. If the cause of inoperability exists on other DG~~(s)~~, the other DG~~(s)~~ would be declared inoperable upon discovery and Condition E of LCO 3.8.1 would be entered. Once the failure is repaired, the common cause failure no longer exists and Required Action B.3.1 is satisfied. If the cause of the initial inoperable DG cannot be confirmed not to exist on the remaining DG~~(s)~~, performance of SR 3.8.1.2 suffices to provide assurance of continued OPERABILITY of that DG.

For example: if the DG inoperability is due to an inoperable support system, an independently testable component, preplanned preventative maintenance or testing.

the

1

1

In the event the inoperable DG is restored to OPERABLE status prior to completing either B.3.1 or B.3.2, the ~~[~~plant corrective action program~~]~~ will continue to evaluate the common cause possibility. This continued evaluation, however, is no longer under the 24 hour constraint imposed while in Condition B.

2

9

According to Generic Letter 84-15 (Ref. ~~7~~), ~~[~~24~~]~~ hours is reasonable to confirm that the OPERABLE DG~~(s)~~ is not affected by the same problem as the inoperable DG.

2

1

St. Lucie – Unit 2

1

BASES

ACTIONS (continued)

B.4

Insert 5

~~According to Regulatory Guide 1.93 (Ref. 6), operation may continue in Condition B for a period that should not exceed 72 hours.~~ 1

In Condition B, the remaining OPERABLE DG and offsite circuits are adequate to supply electrical power to the onsite Class 1E Distribution System. The ~~72-hour~~ Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~

14 day 1

2

C.1 and C.2

Required Action C.1, which applies when two offsite circuits are inoperable, is intended to provide assurance that an event with a coincident single failure will not result in a complete loss of redundant required safety functions. The Completion Time for this failure of redundant required features is reduced to 12 hours from that allowed for one train without offsite power (Required Action A.2). The rationale for the reduction to 12 hours is that Regulatory Guide 1.93 (Ref. 6) allows a Completion Time of 24 hours for two required offsite circuits inoperable, based upon the assumption that two complete safety trains are OPERABLE. When a concurrent redundant required feature failure exists, this assumption is not the case, and a shorter Completion Time of 12 hours is appropriate. These features are powered from redundant AC safety trains. This includes motor driven auxiliary feedwater pumps. ~~Single train features, such as turbine driven auxiliary pumps, are not included in the list.~~

and steam 1

The steam driven auxiliary feedwater pump is only considered a redundant required feature in MODES 1, 2, and 3 because it is not required to be OPERABLE in MODE 4.

The Completion Time for Required Action C.1 is intended to allow the operator time to evaluate and repair any discovered inoperabilities. This Completion Time also allows for an exception to the normal "time zero" for beginning the allowed outage time "clock." In this Required Action, the Completion Time only begins on discovery that both:

a. All required offsite circuits are inoperable and

b. A required feature is inoperable.

Insert 5 (1)

The 14-day Completion Time is based on the findings of a deterministic and probabilistic safety analysis. The risk impact of the Completion Time has been evaluated pursuant to the risk assessment and management provisions of the Maintenance Rule, 10 CFR 50.65(a)(4), and the associated implementation guidance, Regulatory Guide 1.160. Per NRC Letter, "St. Lucie Unit No. 2 – Issuance of Amendment Regarding Diesel Generator Allowed Outage Time Extension (TAC No. MA7206)," dated April 26, 2001, (Ref. 7) operation may continue in Condition B for a period of 14 days provided compensatory measures are taken.

BASES

ACTIONS (continued)

If at any time during the existence of Condition C (two offsite circuits inoperable) and a required feature becomes inoperable, this Completion Time begins to be tracked.

According to Regulatory Guide 1.93 (Ref. 6), operation may continue in Condition C for a period that should not exceed 24 hours. This level of degradation means that the offsite electrical power system does not have the capability to effect a safe shutdown and to mitigate the effects of an accident; however, the onsite AC sources have not been degraded. This level of degradation generally corresponds to a total loss of the immediately accessible offsite power sources.

Because of the normally high availability of the offsite sources, this level of degradation may appear to be more severe than other combinations of two AC sources inoperable that involve one or more DGs inoperable. However, two factors tend to decrease the severity of this level of degradation:

a. The configuration of the redundant AC electrical power system that remains available is not susceptible to a single bus or switching failure and

b. The time required to detect and restore an unavailable offsite power source is generally much less than that required to detect and restore an unavailable onsite AC source.

With both of the required offsite circuits inoperable, sufficient onsite AC sources are available to maintain the unit in a safe shutdown condition in the event of a DBA or transient. In fact, a simultaneous loss of offsite AC sources, a LOCA, and a worst case single failure were postulated as a part of the design basis in the safety analysis. Thus, the 24 hour Completion Time provides a period of time to effect restoration of one of the offsite circuits commensurate with the importance of maintaining an AC electrical power system capable of meeting its design criteria. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ (2)

According to Reference 6, with the available offsite AC sources, two less than required by the LCO, operation may continue for 24 hours. If two offsite sources are restored within 24 hours, unrestricted operation may continue. If only one offsite source is restored within 24 hours, power operation continues in accordance with Condition A.

BASES

ACTIONS (continued)

D.1 and D.2

Pursuant to LCO 3.0.6, the Distribution System ACTIONS would not be entered even if all AC sources to it were inoperable resulting in de-energization. Therefore, the Required Actions of Condition D are modified by a Note to indicate that when Condition D is entered with no AC source to any train, the Conditions and Required Actions for LCO 3.8.9, "Distribution Systems - Operating," must be immediately entered. This allows Condition D to provide requirements for the loss of one offsite circuit and one DG without regard to whether a train is de-energized. LCO 3.8.9 provides the appropriate restrictions for a de-energized train.

According to Regulatory Guide 1.93 (Ref. 6), operation may continue in Condition D for a period that should not exceed 12 hours. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ 2

In Condition D, individual redundancy is lost in both the offsite electrical power system and the onsite AC electrical power system. Since power system redundancy is provided by two diverse sources of power, however, the reliability of the power systems in this Condition may appear higher than that in Condition C (loss of both required offsite circuits). This difference in reliability is offset by the susceptibility of this power system configuration to a single bus or switching failure. The 12 hour Completion Time takes into account the capacity and capability of the remaining AC sources, a reasonable time for repairs, and the low probability of a DBA occurring during this period. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ 2

E.1

With Train A and Train B DGs inoperable, there are no remaining standby AC sources. Thus, with an assumed loss of offsite electrical power, insufficient standby AC sources are available to power the minimum required ESF functions. Since the offsite electrical power system is the only source of AC power for this level of degradation, the risk associated with continued operation for a short time could be less than that associated with an immediate controlled shutdown (the immediate shutdown could cause grid instability, which could result in a total loss of AC power). Since any inadvertent generator trip could also result in a total loss of offsite AC power, however, the time allowed for continued

BASES

ACTIONS (continued)

operation is severely restricted. The intent here is to avoid the risk associated with an immediate controlled shutdown and to minimize the risk associated with this level of degradation.

According to Regulatory Guide 1.93 (Ref. 6), with both DGs inoperable, operation may continue for a period that should not exceed 2 hours.

Insert 6

~~[F.1~~

~~The sequencer(s) is an essential support system to [both the offsite circuit and the DG associated with a given ESF bus]. [Furthermore, the sequencer is on the primary success path for most major AC electrically powered safety systems powered from the associated ESF bus.] Therefore, loss of an [ESF bus sequencer] affects every major ESF system in the [division]. The [12] hour Completion Time provides a period of time to correct the problem commensurate with the importance of maintaining sequencer OPERABILITY. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.] This time period also ensures that the probability of an accident (requiring sequencer OPERABILITY) occurring during periods when the sequencer is inoperable is minimal.~~

~~This Condition is preceded by a Note that allows the Condition to be deleted if the unit design is such that any sequencer failure mode will only affect the ability of the associated DG to power its respective safety loads under any conditions. Implicit in this Note is the concept that the Condition must be retained if any sequencer failure mode results in the inability to start all or part of the safety loads when required, regardless of power availability, or results in overloading the offsite power circuit to a safety bus during an event, thereby causing its failure. Also implicit in the Note, is that the Condition is not applicable to any train that does not have a sequencer.]~~

1
2

G.1 and G.2

~~---------- REVIEWER'S NOTE ----------~~
~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

4

Insert 6 (1)

If a Required Action of Condition C cannot be performed within its associated Completion Time, the unit must be brought to a MODE in which plant risk is minimized. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours.

When both offsite circuits are inoperable, the DGs are supplying power to the loads necessary to maintain the reactor shutdown. Remaining in MODE 3 allows operators to focus on restoration of at least one offsite circuit to OPERABLE status instead of shifting their attention to a plant cooldown. In MODE 3, the steam generators continue to be available for steaming to maintain RCS parameters and steam generator makeup can be provided by the turbine driven auxiliary feedwater pump. This can minimize DG loading while attempts are made to restore offsite power. If one or more offsite circuits remains inoperable for > 72 hours while in MODE 3, the actions of Condition A would not be met and Condition H would apply. Required Action H.2 will further require action to place the unit in MODE 4. However, voluntary entry into MODE 4 or 5 may be made as these MODES are also acceptable low risk states.

The allowed Completion Time is reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

BASES

ACTIONS (continued)

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~ 4

~~If the inoperable AC electrical power sources cannot be restored to OPERABLE status within the required Completion Time,~~ the unit must be brought to a MODE in which plant risk is minimized. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. 1

If a Required Action of Conditions A, B, D, or E cannot be performed within its associated Completion Time,

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~7~~ 8). In MODE 5, it is likely that increased plant maintenance activities (particularly those involving the switchyard) will make the plant more susceptible to loss of offsite power events. In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 1

Required Action G.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

BASES

ACTIONS (continued)

H.1

Condition H corresponds to a level of degradation in which all redundancy in the AC electrical power supplies has been lost. At this severely degraded level, any further losses in the AC electrical power system will cause a loss of function. Therefore, no additional time is justified for continued operation. The unit is required by LCO 3.0.3 to commence a controlled shutdown.

SURVEILLANCE REQUIREMENTS

The AC sources are designed to permit inspection and testing of all important areas and features, especially those that have a standby function, in accordance with 10 CFR 50, Appendix A, GDC 18 (Ref. ~~9~~).

Periodic component tests are supplemented by extensive functional tests during refueling outages (under simulated accident conditions). The SRs for demonstrating the OPERABILITY of the DGs are in accordance with the recommendations of Regulatory Guide 1.9 (Ref. 3), Regulatory Guide 1.108 (Ref. 1~~0~~), and Regulatory Guide 1.137 (Ref. 1~~1~~), as addressed in the FSAR.

Where the SRs discussed herein specify voltage and frequency tolerances, the following is applicable. The minimum steady state output voltage of ~~[3740] V is 90% of the nominal 4160 V output voltage. This value, which is specified in ANSI C84.1-1982 (Ref. 12), allows for voltage drop to the terminals of 4000 V motors whose minimum operating voltage is specified as 90% or 3600 V. It also allows for voltage drops to motors and other equipment down through the 120 V level where minimum operating voltage is also usually specified as 80% of name plate rating. The specified maximum steady state output voltage of [4756] V is equal to the maximum operating voltage specified for 4000 V motors. It ensures that for a lightly loaded distribution system, the voltage at the terminals of 4000 V motors is no more than the maximum rated operating voltages. The specified minimum and maximum frequencies of the DG are 58.8 Hz and 61.2 Hz, respectively. These values are equal to ± 2% of the 60 Hz nominal frequency and are derived from the recommendations given in Regulatory Guide 1.9 (Ref. 3)~~.

SR 3.8.1.1

This SR ensures correct breaker alignment for each ~~[required]~~ offsite circuit to ensure that distribution buses and loads are connected to their preferred power source, and that appropriate independence of offsite circuits is maintained. The SR also verifies the indicated availability of three-phase AC electrical power from each ~~[required]~~ offsite circuit to the

Insert 7 (1)

3950 V is 95% of the nominal 4160 V output voltage. This value, which is conservative with respect to the value specified in ANSI C84.1-1989 (Ref. 13), allows for voltage drop to the terminals of 4000 V motors whose minimum operating voltage is specified as 90% or 3600 V. It also allows for voltage drops to motors and other equipment down through the 120 V level. The minimum steady state output voltage ensures the operating system voltage for the 480 V switchgear is ≥ 90% of nominal bus voltage, which bounds the 90% criterion of the safety related motor voltage ratings. The specified maximum steady state output voltage of 4370 V bounds the maximum operating bus voltage. It ensures that for a lightly loaded distribution system, the voltage at the terminals of 4000 V motors is such that continuous operation of motor loads does not result in a failure of the load due to overheating. The specified minimum and maximum frequencies of the DG are 59.4 Hz and 60.6 Hz, respectively. These values are equal to ± 1% of the 60 Hz nominal frequency and are conservative with respect to the recommendations given in Regulatory Guide 1.9 (Ref. 3). The under frequency limit considers reduced pump flow and discharge pressure and reduced motor operated valve stroke times during accident sequences. The over frequency limit considers net positive suction head of safety related pumps, increased differential pressure across closed valves, and increased DG fuel oil and lube oil consumption.

BASES

SURVEILLANCE REQUIREMENTS (continued)

onsite distribution network. [The 7 day Frequency is adequate since breaker position is not likely to change without the operator being aware of it and because its status is displayed in the control room. 2

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement. 4
----------] 2

SR 3.8.1.2 and SR 3.8.1.7

These SRs help to ensure the availability of the standby electrical power supply to mitigate DBAs and transients and to maintain the unit in a safe shutdown condition.

To minimize the wear on moving parts that do not get lubricated when the engine is not running, these SRs are modified by a Note (Note 1 for SR 3.8.1.2 and Note for SR 3.8.1.7) to indicate that all DG starts for these Surveillances may be preceded by an engine prelube period and followed by a warmup period prior to loading by an engine prelube period. 1

For the purposes of SR 3.8.1.2 and SR 3.8.1.7 testing, the DGs are started from standby conditions. Standby conditions for a DG mean the diesel engine coolant and oil are being continuously circulated and temperature is being maintained consistent with manufacturer recommendations.

[In order to reduce stress and wear on diesel engines, the DG manufacturers recommend a modified start in which the starting speed of DGs is limited, warmup is limited to this lower speed, and the DGs are gradually accelerated to synchronous speed prior to loading. This is the intent of Note 2, which is only applicable when such modified start procedures are recommended by the manufacturer. 2

s

SR 3.8.1.2

SR 3.8.1.7 requires that the DG starts from standby conditions and achieves required voltage and frequency within 10 seconds. The 10 second start requirement supports the assumptions of the design basis LOCA analysis in the FSAR, Chapter [15] (Ref. 5).]

U

Chapter 6 (Ref. 4) and

BASES

SURVEILLANCE REQUIREMENTS (continued)

The 10 second start requirement is not applicable to SR 3.8.1.2 (see Note 2) when a modified start procedure as described above is used. If a modified start is not used, 10 second start requirement of SR 3.8.1.7 applies.

Since SR 3.8.1.7 requires a 10 second start, it is more restrictive than SR 3.8.1.2, and it may be performed in lieu of SR 3.8.1.2.

In addition to the SR requirements, the time for the DG to reach steady state operation, unless the modified DG start method is employed, is periodically monitored and the trend evaluated to identify degradation of governor and voltage regulator performance.

~~[The 31 day Frequency for SR 3.8.1.2 is consistent with Regulatory Guide 1.9 (Ref. 3). The 184 day Frequency for SR 3.8.1.7 is a reduction in cold testing consistent with Generic Letter 84-15 (Ref. 8). These Frequencies provide adequate assurance of DG OPERABILITY, while minimizing degradation resulting from testing.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

SR 3.8.1.3

This Surveillance verifies that the DGs are capable of synchronizing with the offsite electrical system and accepting loads greater than or equal to the equivalent of the maximum expected accident loads. A minimum run time of 60 minutes is required to stabilize engine temperatures, while minimizing the time that the DG is connected to the offsite source.

Although no power factor requirements are established by this SR, the DG is normally operated at a power factor between ~~[~~0.8 lagging~~]~~ and ~~[~~1.0~~]~~. The 0.8 value is the design rating of the machine, while ~~[~~1.0~~]~~ is an operational limitation ~~[~~to ensure circulating currents are minimized~~]~~. ~~[The 31 day Frequency for this Surveillance is consistent with Regulatory Guide 1.9 (Ref. 3).~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 4 2

This SR is modified by four Notes. Note 1 indicates that diesel engine runs for this Surveillance may include gradual loading, as recommended by the manufacturer, so that mechanical stress and wear on the diesel engine are minimized. Note 2 states that momentary transients because of changing bus loads do not invalidate this test. Similarly, momentary power factor transients above the limit will not invalidate the test. Note 3 indicates that this Surveillance should be conducted on only one DG at a time in order to avoid common cause failures that might result from offsite circuit or grid perturbations. Note 4 stipulates a prerequisite requirement for performance of this SR. A successful DG start must precede this test to credit satisfactory performance.

to operate the engine at rated capacity for a sufficient duration to prevent cycling of the fuel oil transfer pump and maintain 60 minutes of operation at rated capacity.

SR 3.8.1.4

engine mounted day tanks (one tank per engine)

This SR provides verification that the level of fuel oil in the day tank ~~[and engine mounted tank]~~ is at or above the level at which fuel oil is automatically added. The level is expressed as an equivalent volume in gallons, and is selected to ensure adequate fuel oil ~~for a minimum of 1 hour of DG operation at full load plus 10%~~. 2 1

~~[The 31 day Frequency is adequate to assure that a sufficient supply of fuel oil is available, since low level alarms are provided and unit operators would be aware of any large uses of fuel oil during this period.~~ 2

SR 3.8.1.5

Microbiological fouling is a major cause of fuel oil degradation. There are numerous bacteria that can grow in fuel oil and cause fouling, but all must have a water environment in order to survive. Removal of water from the fuel oil day ~~[and engine mounted]~~ tanks eliminates the necessary environment for bacterial survival. This is the most effective means of controlling microbiological fouling. In addition, it eliminates the potential for water entrainment in the fuel oil during DG operation. Water may come from any of several sources, including condensation, ground water, rain water, contaminated fuel oil, and from breakdown of the fuel oil by bacteria. Frequent checking for and removal of accumulated water minimizes fouling and provides data regarding the watertight integrity of the fuel oil system. ~~[The Surveillance Frequency of 31 days is established by Regulatory Guide 1.137 (Ref. 11). This SR is for preventive maintenance.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

The presence of water does not necessarily represent failure of this SR provided the accumulated water is removed during the performance of this Surveillance.

SR 3.8.1.6

This Surveillance demonstrates that each required fuel oil transfer pump operates and transfers fuel oil from its associated storage tank to its associated day tank. This is required to support continuous operation of

s

BASES

SURVEILLANCE REQUIREMENTS (continued)

standby power sources. This Surveillance provides assurance that the fuel oil transfer pump is OPERABLE, the fuel oil piping system is intact, the fuel delivery piping is not obstructed, and the controls and control systems for automatic fuel transfer systems are OPERABLE.

[[The Frequency for this SR is variable, depending on individual system design, with up to a [92] day interval. The [92] day Frequency corresponds to the testing requirements for pumps as contained in the ASME Code (Ref. 13); however, the design of fuel transfer systems is such that pumps will operate automatically or must be started manually in order to maintain an adequate volume of fuel oil in the day [and engine mounted] tanks during or following DG testing. In such a case, a 31 day Frequency is appropriate. Since proper operation of fuel transfer systems is an inherent part of DG OPERABILITY, the Frequency of this SR should be modified to reflect individual designs.

~~This SR is modified by a Note. The reason for the Note is that during operation with the reactor critical, performance of this SR could cause perturbations to the electrical distribution systems that could challenge continued steady state operation and, as a result, unit safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed Surveillance, a successful Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when the Surveillance is performed in MODE 1 or 2. Risk insights or deterministic methods may be used for this assessment. Credit may be taken for unplanned events that satisfy this SR .]~~

SR 3.8.1.9

Each DG is provided with an engine overspeed trip to prevent damage to the engine. Recovery from the transient caused by the loss of a large load could cause diesel engine overspeed, which, if excessive, might result in a trip of the engine. This Surveillance demonstrates the DG load response characteristics and capability to reject the largest single load without exceeding predetermined voltage and frequency and while maintaining a specified margin to the overspeed trip. ~~[~~For this unit, the single load for each DG and its horsepower rating is ~~as follows:]~~. This Surveillance may be accomplished by:

an intake cooling water pump with a nameplate rating of 600 hp

St. Lucie – Unit 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

a. Tripping the DG output breaker with the DG carrying greater than or equal to its associated single largest post-accident load while paralleled to offsite power or while solely supplying the bus, or

b. Tripping its associated single largest post-accident load with the DG solely supplying the bus.

As required by IEEE-308 (Ref. 14), the load rejection test is acceptable if the increase in diesel speed does not exceed 75% of the difference between synchronous speed and the overspeed trip setpoint, or 15% above synchronous speed, whichever is lower.

The time, voltage, and frequency tolerances specified in this SR are derived from Regulatory Guide 1.9 (Ref. 3) recommendations for response during load sequence intervals. The ~~[3]~~ seconds specified is equal to 60% of a ~~typical 5~~ second load sequence interval associated with sequencing of the largest load. The voltage and frequency specified are consistent with the design range of the equipment powered by the DG. SR 3.8.1.9.a corresponds to the maximum frequency excursion, while SR 3.8.1.9.b and SR 3.8.1.9.c are steady state voltage and frequency values to which the ~~system~~ must recover following load rejection~~. [The [18 month] Frequency is consistent with the recommendation of Regulatory Guide 1.108 (Ref. 10).~~

Move Bases discussion to after SR 3.8.1.18

This Surveillance demonstrates the DG capability to reject a full load without overspeed tripping or exceeding the predetermined voltage limits. The DG full load rejection may occur because of a system fault or inadvertent breaker tripping. This Surveillance ensures proper engine generator load response under the simulated test conditions. This test simulates the loss of the total connected load that the DG experiences following a full load rejection and verifies that the DG will not trip upon loss of the load. These acceptance criteria provide DG damage protection. While the DG is not expected to experience this transient during an event and continues to be available, this response ensures that the DG is not degraded for future application, including reconnection to the bus if the trip initiator can be corrected or isolated.

~~----------~~ 4

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.8.1.1~~1~~

As required by Regulatory Guide 1.108 (Ref. 1~~0~~), paragraph 2.a.(1), this Surveillance demonstrates the as designed operation of the standby power sources during loss of the offsite source. This test verifies all actions encountered from the loss of offsite power, including shedding of the nonessential loads and energization of the emergency buses and respective loads from the DG. It further demonstrates the capability of the DG to automatically achieve the required voltage and frequency within the specified time.

The DG auto-start time of ~~[~~10~~]~~ seconds is derived from requirements of the accident analysis to respond to a design basis large break LOCA. The Surveillance should be continued for a minimum of 5 minutes in order to demonstrate that all starting transients have decayed and stability has been achieved.

The requirement to verify the connection and power supply of permanent and auto-connected loads is intended to satisfactorily show the relationship of these loads to the DG loading logic. In certain circumstances, many of these loads cannot actually be connected or loaded without undue hardship or potential for undesired operation. For instance, Emergency Core Cooling Systems (ECCS) injection valves are not desired to be stroked open, high pressure injection systems are not capable of being operated at full flow, or shutdown cooling (SDC) systems performing a decay heat removal function are not desired to be realigned to the ECCS mode of operation. In lieu of actual demonstration of connection and loading of loads, testing that adequately shows the capability of the DG system to perform these functions is acceptable. This testing may include any series of sequential, overlapping, or total steps so that the entire connection and loading sequence is verified.

~~[The Frequency of [18 months] is consistent with the recommendations of Regulatory Guide 1.108 (Ref. 10), paragraph 2.a.(1), takes into consideration unit conditions required to perform the Surveillance, and is intended to be consistent with expected fuel cycle lengths.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

This SR is modified by two Notes. The reason for Note 1 is to minimize wear and tear on the DGs during testing. For the purpose of this testing, the DGs must be started from standby conditions, that is, with the engine coolant and oil continuously circulated and temperature maintained consistent with manufacturer recommendations. The reason for Note 2 is that performing the Surveillance would remove a required offsite circuit from service, perturb the electrical distribution system, and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed partial Surveillance, a successful partial Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the partial Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when portions of the Surveillance are performed in MODE 1 or 2. Risk insights or deterministic methods may be used for the assessment. Credit may be taken for unplanned events that satisfy this SR.

~~[~~ SR 3.8.1.1~~2~~

This Surveillance demonstrates that the DG automatically starts and achieves the required voltage and frequency within the specified time (~~[~~10~~]~~ seconds) from the ~~design basis~~ actuation signal ~~(LOCA signal)~~ and operates for ≥ 5 minutes. The 5 minute period provides sufficient time to demonstrate stability. SR 3.8.1.1~~2~~.d and SR 3.8.1.1~~2~~.e ensure that permanently connected loads and emergency loads are energized from the offsite electrical power system on an ESF signal without loss of offsite power.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The requirement to verify the connection of permanent and autoconnected loads is intended to satisfactorily show the relationship of these loads to the DG loading logic. In certain circumstances, many of these loads cannot actually be connected or loaded without undue hardship or potential for undesired operation. For instance, ECCS injection valves are not desired to be stroked open, high pressure injection systems are not capable of being operated at full flow, or SDC systems performing a decay heat removal function are not desired to be realigned to the ECCS mode of operation. In lieu of actual demonstration of connection and loading of loads, testing that adequately shows the capability of the DG system to perform these functions is acceptable. This testing may include any series of sequential, overlapping, or total steps so that the entire connection and loading sequence is verified.

SR 3.8.1.1~~3~~ 2 6

This Surveillance demonstrates that DG noncritical protective functions (e.g., high jacket water temperature) are bypassed on a loss of voltage signal concurrent with an ESF actuation ~~test~~ signal. Noncritical automatic trips are all automatic trips except: 1

a. Engine overspeed; and 1

b. Generator differential current~~;~~

~~[c. Low lube oil pressure;~~

~~d. High crankcase pressure; and~~

~~e. Start failure relay.]~~ 2

The noncritical trips are bypassed during DBAs and provide an alarm on an abnormal engine condition. This alarm provides the operator with sufficient time to react appropriately. The DG availability to mitigate the DBA is more critical than protecting the engine against minor problems that are not immediately detrimental to emergency operation of the DG.

~~[The [18 month] Frequency is based on engineering judgment, taking into consideration unit conditions required to perform the Surveillance, and is intended to be consistent with expected fuel cycle lengths. ~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 4
~~]~~ 2

This SR is modified by a Note. The reason for the Note is that performing the Surveillance would remove a required offsite circuit from service, perturb the electrical distribution system, and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed Surveillance, a successful Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when the Surveillance is performed in MODE 1 or 2. Risk insights or deterministic methods may be used for this assessment. Credit may be taken for unplanned events that satisfy this SR.

BASES

SURVEILLANCE REQUIREMENTS (continued)

[SR 3.8.1.17

Demonstration of the test mode override ensures that the DG availability under accident conditions will not be compromised as the result of testing and the DG will automatically reset to ready to load operation if a LOCA actuation signal is received during operation in the test mode. Ready to load operation is defined as the DG running at rated speed and voltage with the DG output breaker open. These provisions for automatic switchover are required by IEEE-308 (Ref. 14), paragraph 6.2.6(2).

The requirement to automatically energize the emergency loads with offsite power is essentially identical to that of SR 3.8.1.12. The intent in the requirement associated with SR 3.8.1.17.b is to show that the emergency loading was not affected by the DG operation in test mode. In lieu of actual demonstration of connection and loading of loads, testing that adequately shows the capability of the emergency loads to perform these functions is acceptable. This testing may include any series of sequential, overlapping, or total steps so that the entire connection and loading sequence is verified.

[The [18 month] Frequency is consistent with the recommendations of Regulatory Guide 1.108 (Ref. 10), paragraph 2.a.(8); takes into consideration unit conditions required to perform the Surveillance; and is intended to be consistent with expected fuel cycle lengths.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

This SR is modified by a Note. The reason for the Note is that performing the Surveillance would remove a required offsite circuit from service, perturb the electrical distribution system, and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow portions of the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing

SURVEILLANCE REQUIREMENTS (continued)

This SR is modified by a Note. The reason for the Note is that performing the Surveillance would remove a required offsite circuit from service, perturb the electrical distribution system, and challenge safety systems. This restriction from normally performing the Surveillance in MODE 1 or 2 is further amplified to allow the Surveillance to be performed for the purpose of reestablishing OPERABILITY (e.g., post work testing following corrective maintenance, corrective modification, deficient or incomplete surveillance testing, and other unanticipated OPERABILITY concerns) provided an assessment determines plant safety is maintained or enhanced. This assessment shall, as a minimum, consider the potential outcomes and transients associated with a failed Surveillance, a successful Surveillance, and a perturbation of the offsite or onsite system when they are tied together or operated independently for the Surveillance; as well as the operator procedures available to cope with these outcomes. These shall be measured against the avoided risk of a plant shutdown and startup to determine that plant safety is maintained or enhanced when the Surveillance is performed in MODE 1 or 2. Risk insights or deterministic methods may be used for this assessment. Credit may be taken for unplanned events that satisfy this SR.

~~REVIEWER'S NOTE~~

~~The above MODE restrictions may be deleted if it can be demonstrated to the staff, on a plant specific basis, that performing the SR with the reactor in any of the restricted MODES can satisfy the following criteria, as applicable:~~

~~a. Performance of the SR will not render any safety system or component inoperable,~~

~~b. Performance of the SR will not cause perturbations to any of the electrical distribution systems that could result in a challenge to steady state operation or to plant safety systems, and~~

~~c. Performance of the SR or failure of the SR will not cause or result in an AOO with attendant challenge to plant safety systems.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.1 BASES, AC SOURCES - OPERATING

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. Discussions regarding load sequencers have been deleted, because PSL does not use load sequencers. Each load is sequenced with the use of its associated load sequence timer.

4. The Reviewer's Note has been deleted, because it is not meant to be retained in the plant specific ITS submittal.

5. Editorial/grammatical error corrected.

6. Changes have been made to be consistent with changes made to the Specifications.

7. Corrections have been made consistent with the Writer’s Guide for the Improved Technical Specifications, TSTF-GG-05-01, Section 3.

DISCUSSION OF CHANGES
ITS 3.8.2, AC SOURCES - SHUTDOWN

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.8.1.2.a states one circuit between the offsite transmission network and the onsite Class 1E distribution system shall be OPERABLE. ITS 3.8.2.a states one qualified circuit between the offsite transmission network and the onsite Class 1E AC Electrical Power Distribution System shall be OPERABLE. This changes the CTS requirement by modifying the description of the offsite circuit to the ITS requirement for the circuit description of “qualified.”

The change is acceptable because the ITS requirement for the offsite circuit remains consistent with the intent of the CTS requirement. The ITS requirement of being “qualified” provides a clarification for the offsite circuit requirements consistent with the existing design requirements for these circuits. The change in wording does not modify the technical requirement for the CTS. The ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as administrative because the technical requirements of the specifications have not changed.

A03 CTS 3.8.1.2.b requires one diesel generator set to be OPERABLE. ITS LCO 3.8.2 b states “One diesel generator (DG) capable of supplying one train of the onsite Class 1E AC electrical power distribution subsystem(s) required by LCO 3.8.10,” shall be OPERABLE. This changes the CTS by stating that the DG set is capable of supplying the required electrical power to the distribution subsystem(s) required by LCO 3.8.10.

This change is acceptable because the ITS requirement for the DG set remains consistent with the intent of the less explicit CTS requirement. The addition of the ISTS wording, “capable of supplying one train of the onsite Class 1E AC electrical power distribution subsystem(s) required by LCO 3.8.10,” provides a clarifying statement for the CTS requirements that is consistent with the DG OPERABILITY requirements in these MODES. The ITS requirement is consistent with the ISTS wording for this requirement. This change is designated as administrative because the technical requirements of the specifications have not changed.

MORE RESTRICTIVE CHANGES

M01 CTS 3.8.1.2 is applicable during MODES 5 and 6. ITS 3.8.2 is applicable in MODES 5 and 6, and during the movement of irradiated fuel assemblies. In addition, a Note has been added to the ACTIONS of ITS 3.8.2 that states

LCO 3.0.3 is not applicable. This changes the CTS by requiring the AC Sources to be OPERABLE under more conditions than is currently required.

The purpose of CTS 3.8.1.2 is to ensure that sufficient AC Sources are available to mitigate the consequences of an analyzed event during shutdown modes. This change also provides an explicit requirement that the AC Sources must be OPERABLE during the movement of irradiated fuel assemblies. The movement of irradiated fuel assemblies may occur during MODE 5 or 6, however movement of irradiated fuel assemblies could also occur while the unit is operating or defueled if moving fuel only in the spent fuel pool. CTS 3.8.1.1 (ITS 3.8.1) does not provide the appropriate compensatory actions under this condition. The activity should be suspended immediately when the AC Sources are not available consistent with the immediate actions for CORE ALTERATIONS in the CTS 3.8.1.2 Action. Because the actions provided in LCO 3.0.3 will not place the unit in a safe condition with respect to the applicable condition, a modifying Note is added to the ITS ACTIONS. This change is acceptable because the proposed Applicability is consistent with the Applicability in the AC Distribution System – Shutdown Specification (ITS 3.8.10). AC Sources provide the power for the AC Electrical Distribution System. This change is designated as more restrictive because the Applicability of the Specification, although modified, has been expanded.

M02 The Unit 1 CTS 3.8.1.2 Action requires, in part, immediate initiation of corrective action to restore the sources to OPERABLE status with less than the minimum AC electrical power sources in MODE 5 with reactor coolant loops not filled or in MODE 6 with water level less than 23 feet above the top of irradiated fuel assemblies seated within the reactor vessel. Unit 2 CTS 3.8.1.2 Action requires, in part, immediate initiation of corrective action to restore the sources to OPERABLE status with less than the minimum AC electrical power sources in MODE 5 with reactor coolant loops not filled or in MODE 6 with water level less than 23 feet above the reactor vessel flange. ITS 3.8.2 Required Actions A.2.3 and B.3 require the immediate initiation of action to restore the required AC Sources to OPERABLE status. This changes the CTS by expanding the Action requirement to restore the inoperable AC Sources to OPERABLE status regardless of fill status of the reactor coolant loops or the water level above the top of irradiated fuel (Unit 1) or reactor vessel flange (Unit 2).

The purpose of ITS 3.8.1.2 Required Actions A.2.3 and B.3 is to promptly initiate action to restore the LCO requirements. When a required offsite circuit or one required DG is inoperable, the actions imposed by the CTS 3.8.1.2 ACTION do not necessarily place the unit in a MODE or other specified condition in which CTS 3.8.1.2 is not applicable. Therefore, proposed ITS 3.8.2 Required Actions A.2.3 and B.3 are being expanded to apply in all plant configurations in MODES 5 and 6. When in MODE 5 with the reactor coolant loops filled and MODE 6 with water level ≥ 23 ft above the reactor vessel flange, at least one shutdown cooling loop is required to be OPERABLE and in operation and two trains of the Control Room Emergency Ventilation System are required to be OPERABLE during movement of irradiated fuel assemblies. Therefore, AC Sources are, at a minimum, required to be OPERABLE to support these required systems to avoid immediate difficulty, assuming either a loss of all offsite power or a loss of all onsite diesel generator (DG) power. These additional restrictions will ensure

action is immediately taken to restore compliance with the LCO requirements. This change is designated as more restrictive because the CTS Required Actions are expanded apply to all plant configurations in MODES 5 and 6 and during movement of irradiated fuel assemblies.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* The CTS 3.8.1.2 ACTION requires the suspension of certain activities when the minimum required AC electrical power sources are inoperable. ITS 3.8.2 provides an alternate Required Action (ITS 3.8.2 Required Action A.1) that allows the declaration of affected required feature(s) with no offsite power available inoperable instead of requiring the specified activities to be suspended. This changes the CTS by allowing the affected required feature(s) with no offsite power available to be declared inoperable instead of suspending the specified activities.

The purpose of CTS 3.8.1.2 is to ensure the appropriate offsite circuit is OPERABLE. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a loss of offsite power occurring during the repair period. This changes the CTS by allowing the affected required feature(s) with no offsite power available to be declared inoperable instead of suspending specified activities (i.e., movement of irradiated fuel assemblies). Since the ITS 3.8.2 circuit OPERABILITY requirements are proposed to require supplying power to all required electrical power distribution subsystems, if one or more subsystems are not powered by an offsite circuit, that circuit is inoperable. Conservative actions can be assured if required equipment with no offsite power is declared inoperable and the associated ACTIONS of the individual equipment taken (ITS 3.8.2 Required Action A.1). This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.8.1.2 ACTION states, in part, with less than the above minimum required A.C. electrical power sources OPERABLE, immediately suspend all operations involving CORE ALTERATIONS …or crane operation with loads over the fuel storage pool. ITS 3.8.2 ACTIONS do not include these actions. This changes the CTS Actions by

removing actions to immediately suspend all operations involving CORE ALTERATIONS or crane operation with loads over the fuel storage pool.

The purpose of the CTS 3.8.1.2 ACTION is to minimize the possibility of an event that may require the AC source to mitigate the consequences of a design basis event. CORE ALTERATIONS is defined in CTS 1.9, in part, as "the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity, within the reactor vessel with the head removed and fuel in the vessel." CORE ALTERATIONS only occur when the reactor vessel head is removed - it only applies in MODE 6. There is only one accident considered during MODE 6 that involves a CORE ALTERATION: a fuel handling accident. According to the Unit 1 UFSAR Section 15.4.3 and Unit 2 UFSAR Section 15.7.4.1.2, a fuel handling accident is initiated by the dropping of an irradiated fuel assembly either in the containment or in the fuel building. Suspension of CORE ALTERATIONS, except for suspension of movement of irradiated fuel, will not prevent or impair the mitigation of a fuel handling accident.

Crane travel related requirements were relocated from the CTS in Unit 1 and Unit 2 PSL Amendments 190 and 134, respectively, ("St. Lucie Units 1 and 2 – Issuance of Amendments Regarding the Relocation of Spent Fuel Pool Crane Technical Specification Requirements (TAC NOS. MB5667 and MB5668)," dated April 28, 2004 (ADAMS Accession No. ML 040440111)) to the respective unit Updated Final Safety Analysis Report where the operational detail is controlled under 10 CFR 50.59 criteria. As cited in the NRC Safety Evaluation associated with Amendments 190 (Unit 1) and 134 (Unit 2), NUREG-0612, "Control of Heavy Loads at Nuclear Power Plants," regulatory guidelines for control of heavy load lifts provide assurance of safe handling of heavy loads in areas where a load drop could impact stored spent fuel, fuel in the reactor core, or equipment that may be required to achieve safe shutdown or permit continued decay heat removal. Section 5.1.1 of NUREG-0612 provides guidelines for reducing the likelihood of dropping heavy loads and provides criteria for establishing safe load paths; procedures for load-handling operations; training of crane operators; design, testing, inspection, and maintenance of cranes and lifting devices; and analyses of the impact of heavy load drops. The guidelines in Sections 5.1.2 through 5.1.6 address alternatives to either further reduce the probability of a load-handling accident or mitigate the consequences of heavy load drops. These alternatives include using a single-failure-proof crane to improve reliability through increased factors of safety and through redundancy or duality in certain active components. Criteria for design of single-failure-proof cranes are included in NUREG-0554, "Single-Failure-Proof Cranes for Nuclear Power Plants."

This change is acceptable because the possibility of damage to a fuel assembly as a consequence of mishandling components other than an irradiated fuel assembly is minimized by thorough training, detailed procedures and equipment design. The PSL crane design precludes the handling of heavy objects, such as shipping casks, over the spent fuel pool storage racks. Administrative controls prevent the movement of heavy loads over the cask pit whenever the cask pit rack is installed in the cask area of the spent fuel storage pool. In addition, the cask handling crane design meets the regulatory guidance for single-failure-proof cranes in NUREG-0554, "Single-Failure-Proof Cranes for Nuclear Power Plants" and NUREG-0612. Administrative controls that control of movement of light

loads or prevent movement of light loads over irradiated fuel assemblies are similar to those used for control of heavy loads, to the extent practicable, as advised in NUREG-0612. Consequently, the possibility of dropping a load other than an irradiated fuel assembly and damaging of fuel assemblies in the spent fuel storage pool is remote. Therefore, the CTS 3.8.1.2 action related to suspension of crane operation with loads over the fuel storage pool is not necessary to be included in the technical specifications and are removed.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 **Unit 2 Only** *(Category 4 – Relaxation of Required Action)* CTS 3.8.1.2 ACTION requires, in part, with less than the minimum required AC electrical power sources OPERABLE, the Reactor Coolant System (RCS) to be depressurized and vented through a greater than or equal to 3.58 square inch vent within 8 hours. ITS 3.8.2 does not include this required action.

The purpose of CTS is to ensure the minimum AC electrical power sources are OPERABLE. CTS 3.4.9.3 provides specific OPERABILITY requirements for overpressure protection systems when in MODE 5 and MODE 6 with the reactor vessel head on. The definition of OPERABLE in CTS 1.19 requires necessary electrical power to components so they can perform their required safety function. This change is acceptable because CTS 3.4.9.3 Action a.1 requires depressurization and venting of the RCS when adequate pressure relief methods are inoperable, including the loss of electrical power necessary to support the required pressure relief components. ITS 3.4.12 retains the requirement to depressurize and establish the required RCS vent size (Refer to ITS 3.4.12 for any changes to CTS 3.4.9.3 requirements). Therefore, the CTS 3.8.1.2 action to depressurize the RCS and vent through a greater than or equal to 3.58 square inch vent is unnecessary. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L04 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.8.1.2.1 requires the AC electrical power sources to be demonstrated OPERABLE by the performance of each of the Surveillance Requirements of 4.8.1.1.1 and 4.8.1.1.2 except for requirement 4.8.1.1.2.a.5. ITS SR 3.8.2.1 includes the performance exception in the Note to SR 3.8.2.1. However, the Note provides additional ITS 3.8.1 SRs exempt from being required to be performed. ITS SR 3.8.2.1 Note states the following SRs are not required to be performed: SR 3.8.1.3, SR 3.8.1.9, SR 3.8.1.10, SR 3.8.1.12 through SR 3.8.1.14, and SR 3.8.1.16. The Note to Unit 2 ITS SR 3.8.2.1 also includes SR 3.8.1.19 and SR 3.8.1.20.

This changes the performance Frequency of specific CTS 4.8.1.1 Surveillances required by CTS 4.8.1.2.1 by suspending the performance requirement of the Surveillances in MODES 5 and 6 and other specified conditions in the Applicability until the AC Source is no longer required to meet the AC Sources – Shutdown LCO.

The purpose of CTS 3.8.1.2 is to ensure the AC Sources required when in MODE 5 or 6 or during movement of irradiated fuel assemblies are demonstrated

to be OPERABLE. Currently CTS 4.8.1.1.2.a.5 is not required to be performed (however it must be met). CTS 4.8.1.1.2.e.2 (ITS SR 3.8.1.9) demonstrates the DG capability to reject the single largest load, Unit 1 CTS 4.8.1.1.2.e.3 and Unit 2 CTS 4.8.1.1.2.e.4 (ITS SR 3.8.1.10) verifies a DG start on a loss of offsite power, Unit 2 CTS 4.8.1.1.2.e.3 (ITS SR 3.8.1.19) verifies that the DG does not trip on a load reject, Unit 1 CTS 4.8.1.1.2.e.5.c and Unit 2 CTS 4.8.1.1.2.e.6.c (ITS 3.8.1.12) demonstrates the DG noncritical protective functions are bypassed on a loss of voltage signal concurrent with an ESF actuation test signal, Unit 1 CTS 4.8.1.1.2.e.6 and Unit 2 CTS 4.8.1.1.2.e.7 (ITS SR 3.8.1.13) is the DG 24 hour run test, Unit 2 CTS 4.8.1.1.2.e.13 (ITS SR 3.8.1.20) is the DG hot restart test, Unit 1 CTS 4.8.1.1.2.e.8 and Unit 2 CTS 4.8.1.1.2.e.9 (ITS SR 3.8.1.14) ensures manual synchronization and automatic load transfer from the DG to the offsite source can be made and the DG can be returned to ready to load status when offsite power is restored, and Unit 1 CTS 4.8.1.1.2.e.11 and Unit 2 CTS 4.8.1.1.2.e.12 (ITS SR 3.8.1.16) is a test of the individual load sequence timers.

The tests listed in the proposed SR 3.8.2.1 Note normally require the DG to be paralleled with offsite power. With limited AC Sources available, a single event could compromise both the required offsite circuit and the DG, which presents a significant risk of a station blackout. The NRC has previously recognized this in the exception of CTS 4.8.1.1.2.a.5 in CTS 4.8.1.2.1. In an effort to consistently address this concern and to avoid potential conflicting Technical Specifications, the Surveillances that would require a DG to be connected to the offsite source or would require disconnection of the required offsite circuit and de-energization of required buses are excepted from being performed. The exception does not remove the requirement for the required DG to be capable of performing its related support function. The exception only removes the requirement to demonstrate the capability while that source of power is being relied on to meet the supporting LCO.

This change is acceptable because the SR specified in the Note will continue to be required to be capable of being met. Historically, the most probable result of performing a Surveillance is the verification of conformance with the requirements while failure to meet a Surveillance is typically discovered when not performing a surveillance test. Therefore, any risk of suspending Surveillance performance until the AC Source is no longer required to meet the AC Sources Shutdown LCO is offset by minimizing the risk of losing both required AC sources. This change is designated as less restrictive because Surveillances will be performed less frequently under the ITS than under the CTS.

L05 *(Category 5 – Deletion of Surveillance Requirement)* CTS 4.8.1.2.1 requires the AC electrical power sources to be demonstrated OPERABLE by the performance of each of the Surveillance Requirements of CTS 4.8.1.1.1 and CTS 4.8.1.1.2 except for CTS 4.8.1.1.2.a.5. ITS SR 3.8.2.1 has included a similar allowance to waive performance of the current Surveillance (ITS SR 3.8.1.3) in the Note to SR 3.8.2.1. However, ITS SR 3.8.2.1 exempts SRs from being required. ITS SR 3.8.2.1 does not require the following ITS 3.8.1 SRs: SR 3.8.1.8, SR 3.8.1.11, SR 3.8.1.15, SR 3.8.17, and SR 3.8.1.18.

This changes the CTS by not requiring specific CTS 4.8.1.1 Surveillances in MODES 5 and 6 and other specified conditions in the Applicability.

DISCUSSION OF CHANGES
ITS 3.8.2, AC SOURCES - SHUTDOWN

The purpose of CTS 3.8.1.2 is to ensure the AC Sources required when in MODE 5 or 6 or during movement of irradiated fuel assemblies are demonstrated OPERABLE. This change is acceptable because the deleted Surveillance Requirements are not necessary to verify that the required AC Sources can perform their required support function. Thus, the required AC Sources continue to be tested in a manner and at a Frequency necessary to give confidence that the equipment can perform its assumed electrical support function.

This change deletes the following CTS 4.8.1.1 Surveillances from being required in MODE 5 or 6 or during movement of irradiated fuel assemblies: CTS 4.8.1.1.1.b (ITS SR 3.8.1.8), the automatic and manual transfer of power sources from normal circuit (unit auxiliary transformer) to the offsite circuit (startup transformer), Unit 1 CTS 4.8.1.1.2.e.4 and Unit 2 CTS 4.8.1.1.2.e.5 (ITS SR 3.8.1.11), the ESF actuation signal DG start test, Unit 1 CTS 4.8.1.1.2.e.9 and Unit 2 CTS 4.8.1.1.2.e.10 (ITS SR 3.8.1.15), ESF signal override with DG operating in test mode test, Unit 1 CTS 4.8.1.1.2.e.5 and Unit 2 CTS 4.8.1.1.2.e.6 (ITS SR 3.8.1.17), ESF concurrent with loss of offsite power signal test, and CTS 4.8.1.1.2.f (ITS SR 3.8.1.18), the simultaneous DG start test.

ITS SR 3.8.1.8 is not required to be met since only one offsite circuit is required by ITS LCO 3.8.2. ITS SR 3.8.1.11 and SR 3.8.1.17 are not required to be met because the ESF actuation signal is not required to be OPERABLE in MODE 5 or 6 or during movement of irradiated fuel assemblies. A single event could compromise both the required offsite circuit and the DG, which presents a significant risk of a station blackout. Therefore, SR 3.8.1.15 is not required to be met so the DG is not required to synchronize to the offsite circuit. SR 3.8.1.18 is excepted because starting independence is not required for the DG that is not required to be OPERABLE. The required DG is required to start if a loss of offsite power occurs. Thus, the requirement to autostart the required DG on a loss of offsite power signal (ITS SR 3.8.1.10) continues to be required by ITS SR 3.8.2.1. This change is designated as less restrictive because Surveillances that are required in CTS will not be required in the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.8.2, AC SOURCES - SHUTDOWN

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

3. The SRs have been changed to be consistent with the changes made to the Surveillance Requirements in ITS 3.8.1.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.2 AC Sources - Shutdown

BASES

BACKGROUND

A description of the AC sources is provided in the Bases for LCO 3.8.1, "AC Sources - Operating."

APPLICABLE SAFETY ANALYSES

The OPERABILITY of the minimum AC sources during MODES 5 and 6 and during movement of ~~[recently]~~ irradiated fuel assemblies ensures that: (2)

a. The unit can be maintained in the shutdown or refueling condition for extended periods,

b. Sufficient instrumentation and control capability is available for monitoring and maintaining the unit status, and

c. Adequate AC electrical power is provided to mitigate events postulated during shutdown, such as a fuel handling accident ~~[involving handling recently irradiated fuel~~. ~~Due to radioactive decay, AC electrical power is only required to mitigate fuel handling accidents involving handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~. (2)

In general, when the unit is shut down, the Technical Specifications requirements ensure that the unit has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. The rationale for this is based on the fact that many Design Basis Accidents (DBAs) that are analyzed in MODES 1, 2, 3, and 4 have no specific analyses in MODES 5 and 6. Worst case bounding events are deemed not credible in MODES 5 and 6 because the energy contained within the reactor pressure boundary, reactor coolant temperature and pressure, and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and in minimal consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCO for required systems.

During MODES 1, 2, 3, and 4, various deviations from the analysis assumptions and design requirements are allowed within the Required Actions. This allowance is in recognition that certain testing and maintenance activities must be conducted provided an acceptable level of risk is not exceeded. During MODES 5 and 6, performance of a

BASES

APPLICABLE SAFETY ANALYSES (continued)

significant number of required testing and maintenance activities is also required. In MODES 5 and 6, the activities are ~~generally~~ planned and administratively controlled. Relaxations from MODE 1, 2, 3, and 4 LCO requirements are acceptable during shutdown modes based on: 1

a. The fact that time in an outage is limited. This is a risk prudent goal as well as a utility economic consideration.

b. Requiring appropriate compensatory measures for certain conditions. These may include administrative controls, reliance on systems that do not necessarily meet typical design requirements applied to systems credited in operating MODE analyses, or both.

c. Prudent utility consideration of the risk associated with multiple activities that could affect multiple systems.
