If one ESFAS channel is inoperable, startup or power operation is allowed to continue, providing the inoperable channel is placed in bypass or trip within 1 hour (Required Action B.1). With one channel in bypass, no additional random failure of a single channel could spuriously cause an actuation and a valid trip signal can still cause an actuation. With one channel in trip, an additional random failure of a single channel could spuriously cause an actuation. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to bypass or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.

The failed channel is restored to OPERABLE status within 48 hours (Required Action B.2). Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program (Required Action B.2). The 48 hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the 48 hour period is a low probability event.

1

INSERT C

C.1, C.2.1, C.2.2.1, C.2.2.2

Condition C applies to the failure of a single channel of one or more input parameters in the Auxiliary Feedwater Actuation Signal (AFAS) ESFAS Function.

AFAS coincidence logic is normally two-out-of-four. If one AFAS channel is inoperable, startup or power operation is allowed to continue as long as action is taken to restore the design level of redundancy.

If one AFAS channel is inoperable, startup or power operation is allowed to continue, providing the inoperable channel is placed in bypass or trip within 1 hour (Required Action C.1). With one channel in bypass, no additional random failure of a single channel could spuriously cause an actuation and a valid trip signal can still cause an actuation. With one channel in trip, an additional random failure of a single channel could spuriously cause an actuation. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to bypass or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.

One failed channel is restored to OPERABLE status or is placed in bypass within 48 hours (Required Action C.2.1 or C.2.2.1). Required Action C.2.1 restores the full capability of the function. Required Action C.2.2.1 places the function in a two-out-of-three configuration. In this configuration, common cause failure of the dependent channel cannot prevent AFAS actuation. The 48 hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the 48 hour period is a low probability event. R1

Additionally, the failed channel must be restored to OPERABLE status prior to entering MODE 3 following the next MODE 5 entry. The Completion Time of Required Action C.2.2.2 is based on adequate channel to channel independence, which allows a two-out-of-three channel operation since no single failure will cause or prevent a reactor trip. However, it is expected that the inoperable channel will be restored to OPERABLE status at the first reasonable opportunity. The determination of the first reasonable opportunity should include consideration of the impact on plant risk (from delaying restoration of the channel as well as any plant configuration changes required or shutting the plant down to repair the channel) and impact on any analysis assumptions, in addition to unit conditions, planning, availability of personnel, and the time required to repair the channel. This risk impact should be managed through the program in place to implement 10 CFR 50.65(a)(4) and NRC Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants."

Condition C is modified by a Note requiring Required Action C.2.2.2 to be completed whenever the Condition is entered even when the LCO is no longer applicable to ensure the channel is restored to OPERABLE prior to the next reactor startup from MODE 5 conditions.

BASES

ACTIONS (continued)

4. Main Steam Isolation Signal
   Steam Generator Pressure - Low

5. ~~Recirculation Actuation Signal~~
   ~~Refueling Water Tank Level - Low~~

6. ~~Auxiliary Feedwater Actuation Signal~~
   ~~Steam Generator Level - Low~~
   ~~Steam Generator Pressure Difference - High~~

ESFAS coincidence logic is normally two-out-of-four. If one ESFAS channel is inoperable, startup or power operation is allowed to continue as long as action is taken to restore the design level of redundancy.

If one ESFAS channel is inoperable, startup or power operation is allowed to continue, providing the inoperable channel is placed in bypass or trip within 1 hour (Required Action ~~B~~.1). With one channel in bypass, no additional random failure of a single channel could spuriously ~~trip the reactor~~ cause an actuation and a valid trip signal can still ~~trip the reactor~~. With one channel in trip, an additional random failure of a single channel could spuriously ~~trip the reactor~~ cause an actuation. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to bypass or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.

INSERT D

~~One failed channel is restored to OPERABLE status or is placed in trip within [48] hours [or in accordance with the Risk Informed Completion Time Program] (Required Action B.2.1 or B.2.2). Required Action B.2.1 restores the full capability of the function. Required Action B.2.2 places the function in a one-out-of three configuration. In this configuration, common cause failure of the dependent channel cannot prevent ESFAS actuation. The [48] hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the [48] hour period is a low probability event. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~

INSERT E

~~C~~.1 and ~~C~~.2

Condition ~~C~~ applies to the failure of two channels in any of the following ESFAS functions:

1

INSERT D

Additionally, the failed channel must be restored to OPERABLE status prior to entering MODE 3 following the next MODE 5 entry. The Completion Time of Required Action D.2 is based on adequate channel to channel independence, which allows a two-out-of-three channel operation since no single failure will cause or prevent a reactor trip. However, it is expected that the inoperable channel will be restored to OPERABLE status at the first reasonable opportunity. The determination of the first reasonable opportunity should include consideration of the impact on plant risk (from delaying restoration of the channel as well as any plant configuration changes required or shutting the plant down to repair the channel) and impact on any analysis assumptions, in addition to unit conditions, planning, availability of personnel, and the time required to repair the channel. This risk impact should be managed through the program in place to implement 10 CFR 50.65(a)(4) and NRC Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants."

Condition D is modified by a Note requiring Required Action D.2 to be completed whenever the Condition is entered even when the LCO is no longer applicable to ensure the channel is restored to OPERABLE prior to the next reactor startup from MODE 5 conditions.

1

INSERT E

E.1 and E.2

Condition E applies to failure of two or more channels in the Auxiliary Feedwater Actuation Signal (AFAS) ESFAS Function or two channel in the Containment Spray Actuation System (CSAS) ESAFS Function.

With two inoperable channels, one channel should be placed in bypass, and the other channel should be placed in trip within the 1 hour Completion Time. With one channel of protective instrumentation bypassed, the ESFAS Function is in two-out-of-three logic, but with another channel failed the ESFAS may be operating with a two-out-of-two logic. This is outside the assumptions made in the analyses and should be corrected. To correct the problem, the second channel is placed in trip. This places the ESFAS in a one-out-of-two logic. If any of the other OPERABLE channels receives a trip signal, ESFAS actuation will occur.

One of the failed channels should be restored to OPERABLE status within 48 hours. The 48 hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the 48 hour period is a low probability event. After one channel is restored to OPERABLE status, the provisions of Condition C still apply to the remaining inoperable channel. Therefore, the channel that is still inoperable after completion of Required Action E.2 must be placed in bypass if more than 48 hours has elapsed since the initial channel failure. Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.

BASES

ACTIONS (continued)

1. Safety Injection Actuation Signal
   Containment Pressure - High
   Pressurizer Pressure - Low

3. Containment Isolation Actuation Signal
   Containment Pressure - High
   Containment Radiation - High

4. Main Steam Isolation Signal
   Steam Generator Pressure - Low
   Containment Pressure - High
5. Recirculation Actuation Signal
   Refueling Water Tank Level - Low

~~6. Auxiliary Feedwater Actuation Signal~~
~~Steam Generator Level - Low~~
~~Steam Generator Pressure Difference - High~~

With two inoperable channels, one channel should be placed in bypass, and the other channel should be placed in trip within the 1 hour Completion Time. With one channel of protective instrumentation bypassed, the ESFAS Function is in two-out-of-three logic, but with another channel failed the ESFAS may be operating with a two-out-of-two logic. This is outside the assumptions made in the analyses and should be corrected. To correct the problem, the second channel is placed in trip. This places the ESFAS in a one-out-of-two logic. If any of the other OPERABLE channels receives a trip signal, ESFAS actuation will occur.

One of the failed channels should be restored to OPERABLE status within ~~[~~48~~]~~ hours, for reasons similar to those stated under Condition ~~B~~. After one channel is restored to OPERABLE status, the provisions of Condition ~~B~~ still apply to the remaining inoperable channel. Therefore, except for Function 5 - RAS the channel that is still inoperable after completion of Required Action ~~C~~.2 must be placed in trip if more than ~~[~~48~~]~~ hours has elapsed since the initial channel failure. Function 1 - SIAS, Function 3 – CIAS, Function 4 – MSIS

After one Function 5 – RAS channel is restored to OPERABLE status, the provisions of Condition B still apply to the remaining inoperable channel. The RAS channel that is still inoperable after completion of Required Action F.2 must be restored to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time since the initial channel failure.

~~D~~.1, ~~D~~.2.1, ~~D~~.2.2.1, and ~~D~~.2.2.2

Condition ~~D~~ applies to the failure of one bypass removal channel.

The bypass removal channels consist of four sensor subsystems and two actuation subsystems. Condition ~~D~~ applies to failures in one of the four sensor subsystems, including sensors, bistables, and associated

BASES

ACTIONS (continued)

equipment. Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in LCO 3.3.~~5~~.

In Condition ~~D~~, it is permissible to continue operation with one bypass permissive removal channel failed, providing the bypass is disabled (Required Action ~~D~~.1). This can be accomplished by removing the bypass with the manual bypass key switch, which disables the bypass in its respective ~~both~~ train~~s~~. Since the bypass Function must be manually enabled, the bypass permissive Function will not by itself cause an undesired bypass insertion.

Alternatively, the bypass may be disabled by defeating the bypass permissive input in one of the four channels to the two-out-of-four bypass removal logic, placing the bypass removal feature in one-out-of-three logic. Thus, any of the remaining three channels is capable of removing the bypass feature when the bypass enable conditions are no longer valid.

If the bypass removal feature in the inoperable channel cannot be defeated, actions to address the inoperability of the affected automatic trip channel must be taken. Required Action ~~D~~.2.1, Required Action ~~D~~.2.2.1, and Required Action ~~D~~.2.2.2 are equivalent to the Required Actions for a single automatic trip channel failure (Condition ~~B~~). The Completion Times have the same bases as discussed for Condition ~~B~~. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~

~~E~~.1, ~~E~~.2.1, and ~~E~~.2.2

Condition ~~E~~ applies to two inoperable bypass removal channels. The bypass removal channels consist of four sensor subsystems and two actuation subsystems. This Condition applies to failures in two of the four sensor subsystems. With two of the four sensor subsystems failed in a nonconservative direction (enabling the bypass Function), the bypass removal feature is in two-out-of-two logic. Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in LCO 3.3.~~5~~.

In Condition ~~E~~, it is permissible to continue operation with two bypass permissive channels failed, providing the bypasses are disabled in a similar manner as discussed for Condition ~~D~~.

BASES

ACTIONS (continued)

If the failed bypasses cannot be disabled, actions to address the inoperability of the affected automatic trip channels must be taken. Required Action ~~E~~.2.1 and Required Action ~~E~~.2.2 are equivalent to the Required Actions for a two automatic trip channel failure (Condition ~~C~~). Also similar to Condition ~~C~~, after one set of inoperable channels is restored, the provisions of Condition ~~D~~ still apply to the remaining inoperable channel, with the Completion Time measured from the point of the initial bypass channel failure. The Completion Times have the same bases as discussed for Condition ~~C~~. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~

~~F~~.1 and ~~F~~.2

If the Required Actions and associated Completion Times of Condition A, B, C, D, ~~or~~ E are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

The SRs for any particular ESFAS Function are found in the SRs column of Table 3.3.~~4~~-1 for that Function. Most functions are subject to CHANNEL CHECK, CHANNEL FUNCTIONAL TEST, CHANNEL CALIBRATION, and response time testing.

~~REVIEWER'S NOTE~~

~~In order for a unit to take credit for topical reports as the basis for justifying Frequencies, topical reports should be supported by an NRC staff Safety Evaluation Report that establishes the acceptability of each topical report for that unit.~~

~~REVIEWER'S NOTE~~

~~Notes a and b are applied to the setpoint verification Surveillances for each ESFAS Instrumentation (Analog) Function in Table 3.3.4-1 unless one or more of the following exclusions apply:~~

~~1. Manual actuation circuits, automatic actuation logic circuits or instrument functions that derive input from contacts which have no associated sensor or adjustable device, e.g., limit switches, breaker position switches, manual actuation switches, float switches, proximity~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~detectors, etc. are excluded. In addition, those permissives and interlocks that derive input from a sensor or adjustable device that is tested as part of another TS function are excluded.~~

~~2. Settings associated with safety relief valves are excluded. The performance of these components is already controlled (i.e., trended with as-left and as-found limits) under the ASME Code for Operation and Maintenance of Nuclear Power Plants testing program.~~ 4

~~3. Functions and Surveillance Requirements which test only digital components are normally excluded. There is no expected change in result between SR performances for these components. Where separate as-left and as-found tolerance is established for digital component SRs, the requirements would apply.~~

3

SR 3.3.~~4~~.1 3

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit. If the channels are within the criteria, it is an indication that the channels are OPERABLE. If the channels are normally off scale during times when Surveillance is required, the CHANNEL CHECK will only verify that they are off scale in the same direction. Offscale low current loop channels are verified to be reading at the bottom of the range and not failed downscale.

~~[The Frequency of about once every shift is based on operating experience that demonstrates channel failure is rare. Since the probability of two random failures in redundant channels in any 12 hour period is extremely low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The~~ 2

~~]~~

Move to end of this SR 3.3.3.2 description

A CHANNEL FUNCTIONAL TEST on each ESFAS instrument channel is performed to ensure the entire channel will perform its intended function when needed.

A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. 1

The CHANNEL FUNCTIONAL TEST tests the individual sensor subsystems using an analog test input to each bistable.

BASES

SURVEILLANCE REQUIREMENTS (continued)

A test signal is superimposed on the input in one channel at a time to verify that the bistable trips within the specified ~~tolerance~~ around the setpoint. Any setpoint adjustment shall be consistent with the assumptions of the plant specific setpoint analysis.

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the surveillance interval extension analysis. ~~The requirements for this review are outlined in Reference [10].~~

SR 3.3.~~4~~.2 is modified by two Notes as identified in Table 3.3.~~4~~-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value. Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition. The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[~~LTSP~~]~~. Where a setpoint more conservative than the ~~[~~LTSP~~]~~ is used in the plant surveillance procedures ~~[~~NTSP~~]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and/or Analytical Limit is maintained. If the as-left channel setting cannot be returned to a setting within the as-left ~~tolerance~~ of the ~~[~~LTSP~~]~~, then the channel shall be declared inoperable.

The second Note also requires that ~~[~~LTSP~~]~~ and the methodologies for calculating the as-left and the as-found ~~tolerances~~ be in ~~[insert the facility FSAR reference or the name of any document incorporated into the facility FSAR by reference]~~.

SR 3.3.~~4~~.3

SR 3.3.~~4~~.3 is a CHANNEL FUNCTIONAL TEST similar to SR 3.3.~~4~~.2, except 3.3.~~4~~.3 is ~~performed within 92 days prior to startup and is~~ only applicable to bypass Functions. These include the Pressurizer Pressure - Low bypass and the MSIS Steam Generator Pressure - Low bypass. A successful test of the required contact(s) of a channel relay may be

SURVEILLANCE REQUIREMENTS (continued)

performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

~~The CHANNEL FUNCTIONAL TEST for proper operation of the bypass removal Functions is critical during plant heatups because the bypasses may be in place prior to entering MODE 3 but must be removed at the appropriate points during plant startup to enable the ESFAS Function. Consequently, just prior to startup is the appropriate time to verify bypass removal Function OPERABILITY. Once the bypasses are removed, the bypasses must not fail in such a way that the associated ESFAS Function is inappropriately bypassed. This feature is verified by the appropriate ESFAS Function CHANNEL FUNCTIONAL TEST.~~ 1

~~The allowance to conduct this Surveillance within 92 days of startup is based upon the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 11).~~ 1

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. 1

3

SR 3.3.~~4~~.4 3

CHANNEL CALIBRATION is a complete check of the instrument channel, including the sensor. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive surveillances. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the extension analysis. ~~The requirements for this review are outlined in Reference [10].~~ 1

~~[The Frequency is based upon the assumption of an [18] month calibration interval for the determination of the magnitude of equipment drift in the setpoint analysis.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

Move to end of this SR 3.3.3.4 description

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

3 3

SR 3.3.4.4 is modified by two Notes as identified in Table 3.3.4-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value. Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition. The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[~~LTSP~~]~~. Where a setpoint more conservative than the ~~[~~LTSP~~]~~ is used in the plant surveillance procedures ~~[~~NTSP~~]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and~~/or~~ Analytical Limit is maintained. If the as-left channel setting cannot be returned to a setting within the as-left ~~tolerance~~ of the ~~[~~LTSP~~]~~, then the channel shall be declared inoperable.

3

SR 3.3.4.5

This Surveillance ensures that the train actuation response times are the maximum values assumed in the safety analyses. Individual component response times are not modeled in the analyses. The analysis models the overall or total elapsed time, from the point at which the parameter exceeds the trip setpoint value at the sensor to the point at which the equipment in both trains reaches the required functional state (e.g.,

SURVEILLANCE REQUIREMENTS (continued)

pumps at rated discharge pressure, valves in full open or closed position). Response time testing acceptance criteria are included in Reference 5. The test may be performed in one measurement or in overlapping segments, with verification that all components are measured.

~~---------- REVIEWER'S NOTE ----------~~
~~Applicable portions of the following TS Bases are applicable to plants adopting CEOG Topical Report CE NPSD-1167-1, "Elimination of Pressure Sensor Response Time Testing Requirements," and the methodology contained in Attachment 1 to TSTF-569.~~
~~----------~~ 2

Response time may be verified by any series of sequential, overlapping or total channel measurements, including allocated sensor response time, such that the response time is verified. Allocations for sensor response times may be obtained from records of test results, vendor test data, or vendor engineering specifications. ~~Topical Report CE NPSD-1167-A, "Elimination of Pressure Sensor Response Time Testing Requirements," (Ref. 12) provides the basis and methodology for using allocated sensor response times in the overall verification of the channel response time for specific sensors identified in the Topical Report. The response time may be verified for components that replace the components that were previously evaluated in Ref. 12 provided that the components have been evaluated in accordance with the NRC approved methodology as discussed in Attachment 1 to TSTF-569, "Methodology to Eliminate Pressure Sensor and Protection Channel (for Westinghouse Plants only) Response Time Testing," (Ref. 13). Response time verification for other sensor types must be demonstrated by test. The allocation of sensor response times must be verified prior to placing a new component in operation and reverified after maintenance that may adversely affect the sensor response time.~~ 1

~~[ESF RESPONSE TIME tests are conducted on a STAGGERED TEST BASIS of once every [18] months. This results in the interval between successive tests of a given channel of n x 18 months, where n is the number of channels in the Function. Surveillance of the final actuation devices, which make up the bulk of the response time, is included in the testing of each channel. Therefore, staggered testing results in response time verification of these devices every [18] months. The [18] month STAGGERED TEST BASIS Frequency is based upon plant operating experience, which shows that random failures of instrumentation components causing serious response time degradation, but not channel failure, are infrequent occurrences.~~ 2

~~OR~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.3, BASES, ENGINEERED SAFETY FEATURES ACTUATION SYSTEM (ESFAS) INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The heading for ISTS 3.3.4 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2). Therefore, ISTS 3.3.2 is not included in the PSL ITS. The successive Specifications are renumbered as necessary.

4. PSL does not use the terms “as-found tolerance” and “Limiting Trip Setpoint (LTSP)” in plant specific instrument calculations or the Updated Final Safety Analysis Report. Therefore, the use of these terms in Footnotes (a) and (b) in ISTS Table 3.3.1-1 are revised in the ITS to include the plant specific terminology. To comply with the guidance provided in NRC Regulatory Issue Summary 2006-17, “NRC Staff Position on the Requirements of 10 CFR 50.36, ‘Technical Specifications,’ Regarding Limiting Safety System Settings During Periodic Testing and Calibration of Instrument Channels,” the PSL setpoint calculations have been structured to include a Nominal Trip Setpoint (NTSP), also known as the field trip setpoint, and determination of an OPERABILITY limit range, referred to in CTS as acceptance criteria band. For PSL, the Nominal Trip Setpoint (NTSP) is synonymous with the Limiting Trip Setpoint (LTSP) and the as-found acceptance criteria band (i.e., OPERABILITY limit range) is synonymous with the as-found tolerance.

ACTION:

Table 3.3.4-1

~~a.~~ With an ESFAS instrumentation channel trip setpoint less conservative than the value shown in the Allowable Values column of Table 3.3-4, ~~declare the channel inoperable and~~ apply the applicable ACTION requirement of Table 3.3-3 ~~until the channel is restored to OPERABLE status~~ with the trip setpoint adjusted consistent with the Trip Setpoint value.

ACTIONS for associated Table 3.3.4-1 Functions 1-6

ACTIONS for associated Table 3.3.4-1 Functions 1-6

~~b.~~ With an ESFAS instrumentation channel inoperable, take the ACTION shown in Table 3.3-3.

SURVEILLANCE REQUIREMENTS

SR 3.3.4.1
SR 3.3.4.2

4.3.2.1.1 Each ESFAS instrumentation channel shall be demonstrated OPERABLE by the performance of the CHANNEL CHECK, CHANNEL CALIBRATION and CHANNEL FUNCTIONAL TEST operations during the modes ~~and at the frequencies~~ shown in Table 4.3-2.

In accordance with the Surveillance Frequency Control Program

4.3.2.1.2 The logic for the bypasses shall be demonstrated OPERABLE during the at power CHANNEL FUNCTIONAL TEST of channels affected by bypass operation. The total bypass function shall be demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program during CHANNEL CALIBRATION testing of each channel affected by bypass operation.

See ITS 3.3.3

4.3.2.1.3 The ENGINEERED SAFETY FEATURES RESPONSE TIME of each ESFAS function shall be demonstrated to be within the limit in accordance with the Surveillance Frequency Control Program. Each test shall include at least one channel per function.

Add proposed LCO 3.3.4 ACTIONS C and D — L02

ACTION STATEMENTS

One or more Functions with one Manual Actuation or Actuation Logic channel inoperable except AFAS and MSIS.

ACTION 8 - ~~With the number of OPERABLE channels one less than the Total Number of Channels,~~ restore ~~the inoperable~~ channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in ~~at least~~ ~~HOT STANDBY~~ within ~~the next~~ 6 hours and ~~in~~ ~~COLD SHUTDOWN~~ within ~~the following~~ ~~30~~ hours.

ACTION E

ACTION F

MODE 5

MODE 3

36

Add proposed ACTION F Condition: One or more Functions with two Manual Actuation or Actuation Logic channels inoperable except AFAS and MSIS. — A04

ACTION 9 - With the number of OPERABLE channels one less than the Total Number of Channels, operation may proceed provided the following conditions are satisfied:

a. The inoperable channel is placed in either the bypassed or tripped condition within 1 hour. For the purposes of testing and maintenance, the inoperable channel may be bypassed for up to 48 hours from time of initial loss of OPERABILITY; however, the inoperable channel shall then be either restored to OPERABLE status or placed in the tripped condition.

b. Within one hour, all functional units receiving an input from the inoperable channel are also bypassed or tripped.

c. The Minimum Channels OPERABLE requirement is met; however, one additional channel may be bypassed for up to 48 hours while performing tests and maintenance on that channel provided the other inoperable channel is placed in the tripped condition.

See ITS 3.3.3

A01

TABLE 3.3-3 (continued)

TABLE NOTATION

ACTION 10A - With the number of OPERABLE channels one less than the Total Number of Channels, operation may proceed provided the following conditions are satisfied:

See ITS 3.3.3

a. The inoperable channel is placed in the bypassed or tripped condition and the Minimum Channels OPERABLE requirement is demonstrated within 1 hour. If the inoperable channel can not be restored to OPERABLE status within 48 hours, then place the inoperable channel in the tripped condition.

b. Within 1 hour, all functional units receiving an input from the inoperable channel are also bypassed or tripped.

ACTION 10B - With the number of channels OPERABLE one less than the Minimum Channels OPERABLE, operation may proceed provided one of the inoperable channels has been bypassed and the other inoperable channel has been placed in the tripped condition within 1 hour. Restore one of the inoperable channels to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours.

One or more Functions with one Auxiliary Feedwater Actuation Signal (AFAS) Manual Actuation or Actuation Logic channel inoperable.

ACTION 11 - ~~With the number of OPERABLE channels one less than the Total Number of Channels,~~ restore ~~the inoperable~~ channel~~s~~ to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in ~~at least HOT STANDBY~~ within 6 hours and ~~in HOT SHUTDOWN~~ within ~~the following~~ ~~6~~ hours. ~~LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.~~

MODE 4

A07

ACTION 12 - With the number of OPERABLE Channels one less than the Total Number of Channels, operation may proceed until performance of the next required CHANNEL FUNCTIONAL TEST provided the inoperable channel is placed in the tripped condition within 1 hour.

See ITS 3.3.5

Add proposed ACTION B Condition: Two AFAS Manual Actuation or Actuation Logic channels inoperable.

A04

A01

TABLE 3.3-3 (continued)

TABLE NOTATION

ACTION 13 - With the number of OPERABLE channels one less than the Total Number of Channels, operation may proceed provided the following conditions are satisfied:

See ITS 3.3.3

a. The inoperable channel is placed in either the bypassed or tripped condition within 1 hour. If OPERABILITY cannot be restored within 48 hours or in accordance with the Risk Informed Completion Time Program, be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours.

b. The Minimum Channels OPERABLE requirement is met; however, one additional channel may be bypassed for up to 2 hours while performing tests and maintenance on that channel provided the other inoperable channel is placed in the tripped condition.

ACTION 14 - With the number of channels OPERABLE one less than the Total Number of Channels, operation may proceed provided the following conditions are satisfied:

a. The inoperable channel is placed in either the bypassed or tripped condition within 1 hour. If an inoperable SG level channel can not be restored to OPERABLE status within 48 hours, then AFAS-1 or AFAS-2 as applicable in the inoperable channel shall be placed in the bypassed condition. If an inoperable SG DP or FW Header DP channel can not be restored to OPERABLE status within 48 hours, then both AFAS-1 and AFAS-2 in the inoperable channel shall be placed in the bypassed condition. The channel shall be returned to OPERABLE status no later than during the next COLD SHUTDOWN.

b. Within 1 hour, all functional units receiving an input from the inoperable channel are also bypassed or tripped.

ACTION 15 - With the number of channels OPERABLE one less than the Minimum Channels OPERABLE, operation may proceed provided one of the inoperable channels has been bypassed and the other inoperable channel has been placed in the tripped condition within 1 hour. Restore one of the inoperable channels to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours.

INSTRUMENTATION

3/4.3.2 ENGINEERED SAFETY FEATURES ACTUATION SYSTEM INSTRUMENTATION

LIMITING CONDITION FOR OPERATION

LCO 3.3.4
Table 3.3.4-1

3.3.2 The Engineered Safety Features Actuation System (ESFAS) instrumentation channels and bypasses shown in Table 3.3-3 shall be OPERABLE with their trip setpoints set consistent with the values shown in the Trip Setpoint column of Table 3.3-4.

LCO 3.3.4
Table 3.3.4-1

APPLICABILITY: As shown in Table 3.3-3.

ACTION:

Table 3.3.4-1
ACTIONS for
Table 3.3.4-1 Functions 1-6

~~a.~~ With an ESFAS instrumentation channel trip setpoint less conservative than the value shown in the Allowable Values column of Table 3.3-4, ~~declare the channel inoperable and~~ apply the applicable ACTION requirement of Table 3.3-3 ~~until the channel is restored to OPERABLE status~~ with the trip setpoint adjusted consistent with the Trip Setpoint value.

ACTIONS for
Table 3.3.4-1 Functions 1-6

~~b.~~ With an ESFAS instrumentation channel inoperable, take the ACTION shown in Table 3.3-3.

SURVEILLANCE REQUIREMENTS

SR 3.3.4.1
SR 3.3.4.2

~~4.3.2.1~~ Each ESFAS instrumentation channel shall be demonstrated OPERABLE by the performance of the CHANNEL CHECK, CHANNEL CALIBRATION and CHANNEL FUNCTIONAL TEST operations during the MODES ~~and at the frequencies~~ shown in Table 4.3-2.

In accordance with the Surveillance Frequency Control Program

4.3.2.2 The logic for the bypasses shall be demonstrated OPERABLE during the at power CHANNEL FUNCTIONAL TEST of channels affected by bypass operation. The total bypass function shall be demonstrated OPERABLE in accordance with the Surveillanc Frequency Control Program during CHANNEL CALIBRATION testing of each channel affected by bypass operation.

See ITS 3.3.3

4.3.2.3 The ENGINEERED SAFETY FEATURES RESPONSE TIME of each ESFAS function shall be demonstrated to be within the limit in accordance with the Surveillance Frequency Control Program. Each test shall include at least one channel per function.

A06

ACTION OF STATEMENTS

One or more Functions with one Manual Actuation or Actuation Logic channel inoperable except AFAS and MSIS.

ACTION E

ACTION F

ACTION 12 - ~~With the number of OPERABLE channels one less than the Total Number of Channels,~~ restore ~~the inoperable~~ channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in ~~at least~~ ~~HOT STANDBY~~ within ~~the next~~ 6 hours and ~~in~~ ~~COLD SHUTDOWN~~ within ~~the following~~ ~~30~~ hours.

MODE 3

36

MODE 5

ACTION 13 - With the number of channels OPERABLE one less than the Total Number of Channels, STARTUP and/or POWER OPERATION may continue provided the inoperable channel is placed in the bypassed or tripped condition within 1 hour. The channel shall be returned to OPERABLE status no later than during the next COLD SHUTDOWN.

With a channel process measurement circuit that affects multiple functional units inoperable or in test, bypass or trip all associated functional units as listed below.

See ITS 3.3.3

Process Measurement Circuit	Functional Unit Bypassed
1. Containment Pressure -	Containment Pressure – High (SIAS, CIAS, CSAS) Containment Pressure – High (RPS)
2. Steam Generator Pressure -	Steam Generator Pressure – Low (MSIS) AFAS-1 and AFAS-2 (AFAS) Thermal Margin/Low Pressure (RPS) Steam Generator Pressure – Low (RPS)
3. Steam Generator Level -	Steam Generator Level – Low (RPS) If SG-2A, then AFAS-1 (AFAS) If SG-2B, then AFAS-2 (AFAS)
4. Pressurizer Pressure -	Pressurizer Pressure – High (RPS) Pressurizer Pressure – Low (SIAS) Thermal Margin/Low Pressure (RPS)

in accordance with the Risk Informed Completion Time Program

One Main Steam Isolation Signal (MSIS) Manual Actuation or Actuation Logic channel inoperable.

ACTION 17A - With the number of OPERABLE Channels one less than the Total Number of Channels, restore the inoperable channel to OPERABLE status within 48 hours or place the inoperable channel in the tripped condition and verify that the Minimum Channels OPERABLE requirement is demonstrated within 1 hour; one additional channel may be bypassed for up to 2 hours for surveillance testing per Specification 4.3.2.1.

See ITS 3.3.5

A01

TABLE 3.3-3 (Continued)

TABLE NOTATION

ACTION 17B - With the number of OPERABLE Channels one less than the Total Number of Channels, restore the inoperable channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or place the inoperable channel in the tripped condition and verify that the Minimum Channels OPERABLE requirement is demonstrated within 1 hour; one additional channel may be bypassed for up to 2 hours for surveillance testing per Specification 4.3.2.1.

See ITS 3.3.5

ACTION 18A - With the number of OPERABLE Channels one less than the Total Number of Channels, operation may proceed provided the following conditions are satisfied:

a. The inoperable channel is placed in either the bypassed or tripped condition and the Minimum Channels OPERABLE requirement is demonstrated within 1 hour. If the inoperable channel can not be restored to OPERABLE status within 48 hours, then place the inoperable channel in the tripped condition.

b. With a channel process measurement circuit that affects multiple functional units inoperable or in test, bypass or trip all associated functional units as listed in ACTION 13.

See ITS 3.3.3

ACTION 18B - With the number of channels OPERABLE one less than the Minimum Channels OPERABLE, operation may proceed provided one of the inoperable channels has been bypassed and the other inoperable channel has been placed in the tripped condition within 1 hour. Restore one of the inoperable channels to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours.

ACTION 19 - With the number of OPERABLE Channels one less than the Total Number of Channels, operation may proceed provided the following conditions are satisfied:

a. Within 1 hour the inoperable channel is placed in either the bypassed or tripped condition. If OPERABILITY cannot be restored within 48 hours or in accordance with the Risk Informed Completion Time Program, be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours.

b. The Minimum Channels OPERABLE requirement is met; however, one additional channel may be bypassed for up to 2 hours for surveillance testing per Specification 4.3.2.1.

A01

TABLE NOTATION

ACTION 20 - With the number of channels OPERABLE one less than the Total Number of Channels, operation may proceed provided the following conditions are satisfied:

See ITS 3.3.3

a. The inoperable channel is placed in either the bypassed or tripped condition within 1 hour. If an inoperable SG level channel can not be restored to OPERABLE status within 48 hours, then AFAS-1 or AFAS-2 as applicable in the inoperable channel shall be placed in the bypassed condition. If an inoperable SG DP or FW Header DP channel can not be restored to OPERABLE status within 48 hours, then both AFAS-1 and AFAS-2 in the inoperable channel shall be placed in the bypassed condition. The channel shall be returned to OPERABLE status no later than during the next COLD SHUTDOWN.

b With a channel process measurement circuit that affects multiple functional units inoperable or in test, bypass or trip all associated functional units as listed in ACTION 13.

ACTION 21 - With the number of channels OPERABLE one less than the Minimum Channels OPERABLE, operation may proceed provided one of the inoperable channels has been bypassed and the other inoperable channel placed in the tripped condition within 1 hour. Restore one of the inoperable channels to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours.

DISCUSSION OF CHANGES
ITS 3.3.4, ENGINEERED SAFETY FEATURES ACTUATION SYSTEM (ESFAS)
LOGIC AND MANUAL ACTUATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.3.2 specify requirements for ESFAS instrumentation and list the requirements for each functional unit in CTS Tables 3.3-3, 3.3-4, and 4.3-2, including the manual channels and automatic actuation logic (Unit 2 only). ITS 3.3.4 provides requirements for the ESFAS Actuation Logic and Manual Actuation channels and provides the requirements in the LCO, Applicability, ACTIONS, and Surveillance Requirements. Additionally, ITS Table 3.3.4-1 does not retain the "TOTAL NO. OF CHANNELS" or "CHANNELS TO TRIP" columns. DOC LA01 describes the change that moves the information of the "TOTAL NO. OF CHANNELS" and "CHANNELS TO TRIP" columns to the Bases. This changes the CTS by moving the "MINIMUM CHANNELS OPERABLE" requirements to the LCO statement and reformatting the content consistent with the ISTS. This change is designated as administrative because it does not result in a technical change to the CTS.

A03 **Unit 1 only:** CTS Table 3.3-3 Functional Unit 1 (SIAS), Functional Unit 2 (CSAS), Functional Unit 3 (CIS), Functional Unit 4 (MSIS) and Functional Unit 5 (RAS) do not specifically include the Automatic Actuation Logic and Actuation Relay Function. However, CTS Table 4.3-2 list Surveillance Requirements for the ESFAS automatic actuation logic associated with these Functions. Therefore, per the requirements of CTS 4.0.1 (ITS SR 3.0.1), CTS 3.3.2.1 encompasses the ESFAS automatic actuation logic. ITS LCO 3.3.4 requires two ESFAS Actuation Logic channels to be OPERABLE in the MODES specified for each Function. This changes the CTS by explicitly requiring two channels of the ESFAS Actuation Logic Functions for SIAS, CSAS, CIS, MSIS, and RAS to be OPERABLE.

This change is considered acceptable because the SIAS, CSAS, CIS, MSIS and RAS Functions require the Actuation Logic channels to operate properly in order to actuate the associated function response. Two channels are required to be OPERABLE to ensure a single failure of a logic channel does not prevent the actuation of the associated SIAS, CSAS, CIS, MSIS or RAS function response. The proposed Applicability is consistent with the Applicability of the Functions listed under CTS Table 3.3-3 Functional Units 1.a, 2.a, 3.a, 5.a and 4.a as modified by DOC L02. This change is designated as administrative because it does not result in a technical change to the CTS.

A04 Unit 1 CTS 3.3.2.1 does not currently contain an ACTION when two Manual Actuation channels are inoperable and Unit 2 CTS 3.3.2 does not currently

contain an ACTION when two Manual Actuation or Actuation Logic channels are inoperable; therefore, an LCO 3.0.3 entry would be required. ITS 3.3.4 ACTION B requires the unit to be in MODE 3 in 6 hours and MODE 4 in 12 hours when two Auxiliary Feedwater Actuation Signal (AFAS) Manual Actuation or Actuation Logic channels are inoperable. ITS 3.3.4 ACTION F requires the unit to be in MODE 3 in 6 hours and MODE 5 in 36 hours when either two Safety Injection Actuation Signal (SIAS), two Containment Spray actuation Signal (CSAS), two Containment Isolation Signal (CIS – Unit 1), two Containment Isolation Actuation Signal (CIAS – Unit 2), or two Containment Sump Recirculation Actuation Signal (RAS) Manual Actuation or Actuation Logic channels are inoperable. This changes the CTS by explicitly stating shutdown ACTIONS when two Manual Actuation or Actuation Logic channels are inoperable for an ESFAS Function.

The purpose of ITS 3.3.4 ACTIONS B, and F when two Manual Actuation or Actuation Logic channels are inoperable, is to ensure the plant is brought to a MODE in which the LCO for the ESFAS Functions does not apply within a reasonable amount of time in a controlled manner. Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.3.2 are silent on these actions, deferring to CTS 3.0.3 for the actions to accomplish this. The proposed change is acceptable because the ACTIONS specified in ITS 3.3.4 adopt ISTS structure for placing the unit outside the MODE of Applicability without changing the time specified to enter MODE 3, MODE 4, or MODE 5, as applicable. This change is designated as administrative because it does not result in a technical change to the CTS.

A05 **Unit 1 only:** CTS Table 3.3-3 Functional Unit 4.a provides requirements for MSIS manual actuation. The Total No. Of Channels and Minimum Channels Operable columns specify 2 channels per steam generator (SG) and the Channels to Trip column specifies 1 channel per SG. ITS LCO 3.3.4, in part, requires two channels of ESFAS Manual Actuation for each Function listed in Table 3.3.4-1 to be OPERABLE, which includes the main steam isolation signal (MSIS) Function. This changes the CTS by requiring two MSIS Manual Actuation channels instead of two channels per SG.

The purpose of the required number of channels is to ensure a manual MSIS trip can be initiated coincident with a single failure. The MSIS manual actuation function is comprised of one manual actuation push button per MSIS actuation logic. A single pushbutton associated with either Manual Actuation channel is required to initiate an isolation of both MSIVs. Each Manual Actuation channel actuates its associated MSIS Actuation Logic channel and each MSIS Actuation Logic channel provides a signal to both MSIVs via interposing relays. CTS Table 3.3-3 Functional Unit 4.a specifies each logic input to each MSIV as a Manual Actuation channel (i.e., two Manual Actuation channels to each SG). ISTS LCO 3.3.5 (ITS LCO 3.3.4) and the associated ACTIONS and Surveillances are formatted to address each individual manual actuation push button circuit to the MSIS logic channel as a channel. Actuating either MSIS Manual Actuation will result in a full main steam isolation. Therefore, changing the minimum number of required channels from 2 per steam generator to 2 results in an equivalent requirement; two manual push buttons must be OPERABLE and one manual push button is required to initiate a main steam isolation.

This change is a presentation preference is consistent with NUREG-1432, Rev. 5 and PSL Unit 2 CTS Table 3.3-1 Functional Unit 1 Total No. of Channels, Minimum Channels Operable, and Channels to Trip columns. This change is designated as administrative because it does not result in technical changes to the CTS.

A06 CTS Table 3.3-3 Actions describe the Actions to be taken when ESFAS Function manual actuations or actuation logic channels are inoperable. ITS 3.3.4 also describes Actions to be taken when ESFAS Function manual actuations or actuation logic channels are inoperable and contains a note that separate condition entry is allowed for each ESFAS Function. This changes the CTS by adding a Note stating that separate condition entry is allowed for each ESFAS Function, those Functions being the SIAS, CSAS, CIS (Unit 1) and CIAS (Unit 2), MSIS, RAS, and AFAS Functions.

The purpose of the CTS Actions is to provide the appropriate compensatory actions for inoperable ESFAS Functions. This proposed change will allow separate condition entry for each ESFAS Function. The Note clarifies that ESFAS Functions are treated as separate entities, each with separate Completion Times. This change is acceptable because it clearly states the current requirement. The CTS considers each ESFAS Function to be separate and independent from the others including on a per steam generator basis. This change is designated as administrative because it does not result in technical changes to the CTS.

A07 Unit 1 CTS Table 3.3-3 Action 11 and Unit 2 CTS Table 3.3-3 Action 15 describe the actions to be taken when one Manual Actuation or Actuation Logic channel associated with an AFAS Functional Unit cannot be restored to OPERABLE status within the required Completion Time. ACTION 15 includes a statement that “LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.” ITS 3.3.4 ACTION B also describes actions to be taken when one Manual Actuation or Actuation Logic channel associated with an AFAS Function cannot be restored to OPERABLE status within the required Completion Time but does not include the CTS statement regarding LCO 3.0.4.a because the AFAS instrumentation is not applicable in HOT SHUTDOWN (MODE 4). This changes the CTS by eliminating a note that is unnecessary for Technical Specification compliance.

The purpose of the CTS Actions is to provide the appropriate compensatory actions for inoperable AFAS Functions. This CTS statement that LCO 3.0.4.a is not appliable when entering Hot Shutdown is unnecessary. The purpose of CTS 3.0.4 (ITS LCO 3.0.4) is to prohibit entry into a MODE or other specified condition in which the LCO is applicable when the LCO is not met except as allowed by LCO 3.0.4.a, b, or c. CTS Table 3.3-3 Action 11 (Unit 1) and Action 15 (Unit 2) are only related to the AFAS Functions (CTS Table 3.3-3 Functional Units 7.a and 7.b). These Functions are not applicable in MODE 4 (Hot Shutdown). Therefore, LCO 3.0.4 does not apply to the AFAS Functions when in MODE 4 resulting in the statement related to LCO 3.0.4.a not being applicable meaningless. This change is designated as administrative because it removes a requirement that serves no purpose and does not result in technical changes to the CTS.

A08 **Unit 1 only:** CTS Table 4.3-2 requires CHANNEL FUNCTIONAL TEST requirements for each ESFAS Functional Unit, including ESFAS automatic actuation logic channels. ITS SR 3.3.4.1 also requires a CHANNEL FUNCTIONAL TEST on each ESFAS logic channel and includes a Note (Note 1) that states, "Testing of Actuation Logic shall include verification of the proper operation of each initiation relay." The added Note is consistent with the ISTS. This changes the CTS by explicitly stating that proper operation of each initiation relay is required to satisfy the CHANNEL FUNCTIONAL TEST requirement.

The purpose of the additional Note is to explicitly clarify the intent of the CHANNEL FUNCTIONAL TEST to include the initiation relays of the equipment. CTS 1.6 definition of a CHANNEL FUNCTIONAL TEST requires the injection of a simulated signal into the channel as close to the primary sensor as practicable to verify OPERABILITY including alarm and/or trip functions. Similarly, the ITS definition of a CHANNEL FUNCTIONAL TEST states, in part, "…the injection of a simulated or actual signal into the channel as close to the sensor as practicable to verify OPERABILITY of all devices in the channel required for channel OPERABILITY." Although it is inferred by the definition of a CHANNEL FUNCTIONAL TEST that testing the associated initiation relays is required to verify logic OPERABILITY, Note 1 to SR 3.3.4.1 provides explicit clarification of the requirement. This change is designated as administrative because it does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS Table 3.3-3 for ESFAS instrumentation has three columns stating various requirements for each function. These columns are labeled, "TOTAL NO. OF CHANNELS," "CHANNELS TO TRIP," and "MINIMUM CHANNELS OPERABLE." ITS Table 3.3.4-1 does not retain the "TOTAL NO. OF CHANNELS" or "CHANNELS TO TRIP" columns. This changes the CTS by moving the information of the "TOTAL NO. OF CHANNELS" and "CHANNELS TO TRIP" columns to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required

channel becomes inoperable. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS Table 4.3-2 contains Note (1) requiring, in part, that "logic circuits to be tested manually." Unit 2 CTS Table 4.3-2 contains Notes (2) and (3) modifying the Automatic Actuation Logic Channel Functional Test requirements. Note (2) requires an actuation relay test to be performed including the energization/de-energization of each actuation relay and verification of the OPERABILITY of each actuation relay. Note (3) requires a subgroup relay test to be performed including the energization/de-energization of each subgroup relay and verification of the OPERABILITY of each subgroup relay. ITS 3.3.4 does not retain these Notes, but rather, includes this testing procedural guidance in the ITS Bases. This changes the CTS by moving procedural details regarding testing to the Bases.

The purpose of the CTS Notes is to ensure the appropriate components are tested to demonstrate OPERABILITY of instrumentation actuation logic. The removal of these details, which are procedural details, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the CHANNEL FUNCTIONAL TEST requirement and the definition of a CHANNEL FUNCTIONAL TEST which ensures the appropriate components are tested to verify instrumentation OPERABILITY. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 (*Category 2 – Relaxation of Applicability*) Unit 1 CTS 3.3.2.1, Table 3.3-3 Functional Unit 4 – main steam isolation signal (MSIS) manual actuation is applicable in MODES 1, 2, 3, and 4 and Table 4.3-2 Functional Unit 4 – MSIS automatic actuation logic is applicable in MODES 1, 2, and 3. Unit 2 CTS 3.3.2, Tables 3.3-3 and 4.3-2 Functional Unit 4 –MSIS manual and automatic actuation logic are applicable in MODES 1, 2, and 3. When one MSIS manual actuation channel (or one automatic actuation logic channel for Unit 2) is inoperable, CTS Table 3.3-3 Action 8 (Unit 1) and Action 12 (Unit 2) require, in part, to restore the channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program.

ITS LCO 3.3.4 (Table 3.3.4-1) requires the MSIS manual actuation and automatic actuation channel to be OPERABLE in MODES 1, 2, and 3 except in MODES 2 and 3 when valves isolated by the MSIS Function are closed as specified in Footnote (a). Consistent with CTS, ITS 3.3.4 ACTION C requires restoring a channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program when one MSIS Manual Actuation or Actuation Logic channel is inoperable. However, ITS 3.3.4 ACTION D requires closing the main steam isolation valves (MSIVs) and the main feedwater isolation valves (MFIVs) in 6 hours, or be in MODE 3 in 6 hours and MODE 4 in 12 hours when two MSIS Manual Actuation or Actuation Logic channels are inoperable or when the action to restore one MSIS Manual Actuation or Actuation Logic channel cannot be completed within the required Completion Time. This changes the CTS by deleting the MODE 4 applicability requirement for Unit 1 MSIS, and changing the MODE 2 and 3 Applicability for Unit 1 and Unit 2 to include “except when valves isolated by the MSIS Function are closed.” This change aligns the Applicability of the MSIS actuation instrumentation with the applicability requirements of the associated MSIS instrument channels (i.e., steam generator low pressure instrument channels and the Unit 2 containment high pressure instrument channels) and the supported equipment (i.e., the MSIVs and MFIVs). This change also revises the CTS Actions to add appropriate actions to reflect the change to the Applicability, which provides sufficient remedial actions to safely continue operation in lieu of a plant cooldown.

The purpose of the MSIS manual and automatic instrumentation in CTS Table 3.3-3 is to ensure the ESFAS MSIS Functions are OPERABLE when the supported equipment is required to be OPERABLE. Automatic steam line and feedwater line isolation is assumed in the mitigation of a major secondary system pipe rupture accident (e.g., main steam line break or feedwater line break). The MSIS manual actuation instrumentation is not credited in the safety analysis and a safety analysis limit is not specified for this actuation function. MSIS automatic actuation instrumentation is credited in the safety analysis.

In MODES 1, 2, and 3, there is sufficient energy in the primary and secondary systems to warrant automatic ESF System response to ensure the main steam and feedwater lines can be isolated in the event of a high energy secondary system pipe rupture. The exception to MODE 2 and 3 is added to clarify that the MSIS manual and automatic actuation instrumentation is not required to be OPERABLE when the valves actuated by the MSIS instrumentation are in positions that support the safety analyses. When the valves isolated by the MSIS function are in the closed position, they are in their assumed accident position. This change is acceptable, because when the MSIVs and MFIVs are closed, the adverse effects of a high energy secondary system pipe rupture are precluded and the requirements continue to ensure that the structures, systems, and components are maintained in the MODES and other specified conditions assumed in the safety analyses. The proposed applicability and actions provide the same level of protection as the current requirements for the supported equipment.

Since the proposed actions provide the allowance to place the MSIVs and MFIVs in their accident position with the option to continue a plant cooldown, sufficient remedial measures continue to be provided to allow safe operation pursuant the requirements of 10 CFR 50.36(c)(2). Proposed ITS 3.3.4 ACTION D is acceptable because, if not restricted by plant operation, the action of closing the associated MSIVs and MFIVs isolates the affected secondary system line, which accomplishes the safety function of the inoperable MSIS manual and automatic actuation logic channel(s). This action is similar to the ACTIONS provided in ITS 3.7.2, "Main Steam Isolation Valves (MSIVs)," and ITS 3.7.3, "Main Feedwater Isolation Valves (MFIVs)," and may be preferable instead of placing the plant in an unnecessary plant cooldown transient. Alternately, if it is necessary to maintain the MSIVs and MFIVs open to support plant cooldown, the actions continue to allow the plant to be placed in MODE 3 within 6 hours and in MODE 4 within 12 hours consistent with the current time to reach these MODES in CTS 3.0.3 (ITS LCO 3.0.3) and the times used throughout the CTS and ITS to reach MODES 3 and 4. The Completion Time to close the associated MSIVs and MFIVs corresponds to the time to be in MODE 3. These Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. This change is designated as less restrictive because the ITS LCO requirements are applicable in fewer operating conditions than in the CTS.

L02 **Unit 1 only:** *(Category 4 – Relaxation of Required Action)* CTS Table 3.3-3 Functional Unit 1 (SIAS), Functional Unit 2 (CSAS), Functional Unit 3 (CIS), Functional Unit 4 (MSIS) and Functional Unit 5 (RAS) do not specifically include requirements for the automatic actuation logic channels, including actions when one or more automatic actuation logic channels are inoperable. However, CTS Table 4.3-2 list Surveillance Requirements for the ESFAS automatic actuation logic associated with these Functions. Therefore, per the requirements of CTS 4.0.1 (ITS SR 3.0.1), CTS 3.3.2.1 encompasses the ESFAS automatic actuation logic. ITS LCO 3.3.4 requires the two automatic actuation logic channels to be OPERABLE in the MODES specified for each Function. Additionally, ITS 3.3.4 provides ACTIONS for one actuation logic channel inoperable and for two actuation logic channels inoperable. For CTS, if an automatic actuation channel is inoperable, CTS 3.0.3 is entered since there is no Condition and Action specified in the CTS. This changes the CTS by explicitly requiring the two ESFAS actuation logic channels be OPERABLE for each ESAFS Function and providing time to restore an automatic actuation channel to OPERABLE status when one channel (per Function) is inoperable. ITS ACTION C and ACTION E provide a Completion Time of 48 hours or in accordance with the Risk Informed Completion Time Program to restore an inoperable actuation logic channel to OPERABLE status before entry into ACTION D or F, respectively, which provide shutdown requirements. ACTION D requires the MSIVs and MFIVs be closed within 6 hours or be in MODE 3 within 6 hours and MODE 4 within 12 hours. ACTION F requires the unit be in MODE 3 within 6 hours and MODE 5 within 36 hours. This changes the CTS by providing specific ACTIONS to take when an actuation logic channel is inoperable before a shutdown ACTION is entered. CTS 3.0.3 requires the unit to be in MODE 5 within 37 hours from the time that one ESFAS actuation logic channel is discovered inoperable, whereas the ITS

ACTIONS allow a Completion Time of 48 hours or in accordance with the Risk Informed Completion Time Program to restore the inoperable actuation logic channel to OPERABLE status before a shutdown ACTION is required.

The purpose of ITS 3.3.4 ACTIONS C and E is to provide a period of time to restore an inoperable actuation logic channel to OPERABLE status and the purpose of ITS 3.3.4 ACTIONS D and F is to place the unit outside the Applicability of the ESFAS Function with the inoperable actuation logic channel. Currently, an inoperable automatic actuation logic channel requires entry into CTS 3.0.3 since no Action is provided for this case. CTS 3.0.3 allows 1 hour to initiate action, 7 hours for the unit to be placed in MODE 3, and 13 hours for the unit to be placed in MODE 4, and 37 hours for the unit to be in MODE 5.

ITS ACTION C and ACTION E provide a Completion Time of 48 hours or in accordance with the Risk Informed Completion Time Program to restore an inoperable actuation logic channel to OPERABLE status before entry into ACTION D or F, respectively. ACTION D requires the MSIVs and MFIVs closed within 6 hours or be in MODE 3 within 6 hours and MODE 4 within 12 hours. ACTION F requires the unit be in MODE 3 within 6 hours and MODE 5 within 36 hours. The proposed ACTIONS result in extending the time an ESFAS channel may be inoperable, which is less restrictive than the CTS 3.0.3 times of 13 hours for the unit to be placed in MODE 4, and 37 hours for the unit to be in MODE 5.

This change is considered acceptable because the SIAS, CSAS, CIS, MSIS and RAS Functions require the automatic actuation logic channels to operate properly in order to actuate the associated Function response. Two channels are required to be OPERABLE to ensure a single failure of a logic channel does not prevent the actuation of the associated SIAS, CSAS, CIS, MSIS or RAS Function response. The proposed Applicability is consistent with the Applicability of the Functions listed under CTS Table 3.3-3 Functional Units 1.a, 2.a, 3.a, 5.a and 4.a as modified by DOC L01. This change is designated as less restrictive because the ITS Actions are less restrictive than the CTS Actions

L03 (*Category 7 - Relaxation of Surveillance Frequency*) CTS Table 4.3-2 requires CHANNEL FUNCTIONAL TEST requirements for each ESFAS Functional Unit, including ESFAS automatic actuation logic channels. ITS SR 3.3.4.1 also requires a CHANNEL FUNCTIONAL TEST on each ESFAS logic channel and includes a Note (Note 2) that states, “Relays associated with plant equipment that cannot be operated during plant operation are only required to be tested during each MODE 5 entry exceeding 24 hours unless tested during the previous 6 months.” This changes the CTS by providing allowance to test components required to satisfy the CHANNEL FUNCTIONAL TEST at a frequency other than the frequency specified in accordance with the Surveillance Frequency Control Program.

The purpose of the additional Note is to allow certain components required to satisfy the CHANNEL FUNCTIONAL TEST to be tested during plant shutdown conditions. The allowance is necessary to allow for the fact that operating certain relays during power operation could cause plant transients or equipment damage. This change is acceptable because during plant operation actuation of

certain systems and components could result in a plant transient. For example, isolation of the Component Cooling Water System valves to and from the reactor coolant pumps or closure of the MSIVs and feedwater isolation valves. Appropriate equipment continues to be tested in a manner and at a frequency necessary to give confidence that the equipment can perform its assumed safety function and assure that the necessary quality of systems and components is maintained, and that facility operation will be within safety limits. Additionally, the relaxation of the testing frequency is offset by reducing the likelihood of a plant transient as a result of testing certain actuating relays during at-power conditions. This change is also consistent with Note 2 in ISTS SR 3.3.5.1. This change is designated as less restrictive because portions of the Surveillance will be performed less frequently under the ITS than under the CTS.

L04 **Unit 2 only**: (*Category 4 – Relaxation of Required Action*) When one MSIS manual trip button channel is inoperable, CTS Table 3.3-3 Action 16 requires the channel to be restored to OPERABLE status within 48 hours or declare the associated valve inoperable and take the ACTION required by Specification 3.7.1.5 (i.e., Main Steam Line Isolation Valves Specification). ITS 3.3.4 ACTION C requires restoring a channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program. This changes the CTS by optionally allowing the manual channel to be restored in accordance with the Risk Informed Completion Time (RICT) Program and eliminating the requirement to declare the associated valve inoperable and take ACTION required by the supported system Specification. This change aligns the action for one inoperable Unit 2 MSIS manual channel with the action for one inoperable Unit 1 MSIS manual channel and an inoperable channel for the other ESFAS manual actuation channels.

The purpose of the actions associated with the MSIS manual actuation instrumentation in CTS Table 3.3-3 is to ensure sufficient remedial measures are provided to allow safe operation pursuant the requirements of 10 CFR 50.36(c)(2). Automatic steam line and feedwater line isolation is assumed in the mitigation of a major secondary system pipe rupture accident (e.g., main steam line break (MSLB) or feedwater line break (FWLB)). The consequences of a MSLB inside containment bounds the consequences of a FWLB accident. This change is acceptable because, in part, the MSIS manual actuation instrumentation is not credited in the safety analysis and a safety analysis limit is not specified for this actuation function. This change is also acceptable considering redundant manual actuation logic channels are available to ensure the required equipment supported by the MSIS (i.e., MSIVs and MFIVs) will be capable of actuating, diverse automatic actuation channels are available, and a Completion Time beyond 48 hours will be evaluated, and the risk managed in accordance with the RICT Program. Extending the time to restore a single ESFAS manual actuation channel to OPERABLE status has been previously evaluated and approved by the NRC for the other ESFAS manual channels and the Unit 1 ESFAS manual channels, including the Unit 1 MSIS manual channel. In the NRC safety evaluation (SE) accompanying PSL Unit 2 License Amendment 199 (RICT Amendment), dated July 2, 2019, (NRC ADAMS Accession No. ML19113A099) the NRC concluded that the proposed RICT for the manual ESFAS channels does not impede accomplishing their safety

function and does not alter the existing diversity of the affected functions. The NRC staff stated that the change is consistent with the defense-in-depth philosophy, and therefore acceptable. The acceptability was based, in part, on confirmation that more than one diverse means existed to accomplish the safety function for each identified accident condition, as indicated in the Tables provided in FPL to NRC supplement letter, "Fourth Response to Request for Additional Information Regarding License Amendment Request to Adopt Risk Informed Completion Times TSTF-505, Revision 1, 'Provide Risk-Informed Extended Completion Times – RITSTF Initiative 4b,'" dated March 15, 2018 (NRC ADAMS Accession No. ML18074A116). Tables 2 and 4 of the supplement letter provided the Instrumentation Diversity for each Unit 1 and Unit 2 ESFAS Instrument Function, respectively. As indicated in Table 4 of the RICT supplement letter, ESFAS diversity for the MSIS manual actuation instrumentation is provided by the Steam Generator Pressure – Low Function for a MSLB outside containment. ESFAS diversity for the MSIS manual actuation instrumentation for a MSLB inside containment is provided by the Steam Generator Pressure – Low Function and the Containment Pressure – High Function. This diversity is equivalent or better than the diversity for the Unit 1 MSIS manual actuation instrumentation, which has been approved to restore one inoperable channel to OPERABLE status in accordance with the RICT Program.

The NRC-approved RICT Program required by CTS 6.8.4.s (ITS 5.5.17) provides controls to calculate a RICT as implemented in accordance with NEI 06-09-A, Revision 0, "Risk-Managed Technical Specifications (RMTS) Guidelines." In the NRC SE accompanying the RICT Amendment, the NRC found that the PSL PRA maintenance and change process ensures that the configuration risk management program models used in the RICT calculations will continue to use PRA methods acceptable to the NRC and that the PRA model will be updated as necessary to reflect the as-built and as-operated plant. The NRC also found that appropriate programmatic and procedural controls for the RICT Program are consistent with the guidance of NEI 06-09, Revision 0-A. Therefore, use of the RICT Program specified in the Technical Specifications to determine a RICT to restore an inoperable MSIS manual actuation channel is acceptable.

Based on the considerations described herein, the change to the actions associated with one inoperable MSIS manual actuation channel continues to provide sufficient remedial measures to allow safe operation pursuant the requirements of 10 CFR 50.36(c)(2). This change is designated as less restrictive because the ITS Actions are less restrictive than the CTS Actions.

L05 **Unit 1 only**: (*Category 4 – Relaxation of Required Action*) CTS Table 3.3-3 Functional Unit 1 (SIAS), Functional Unit 2 (CSAS), Functional Unit 3 (CIS), Functional Unit 4 (MSIS) and Functional Unit 5 (RAS) do not specifically include requirements for the automatic actuation logic channels, including actions when one or more automatic actuation logic channels are inoperable. However, CTS Table 4.3-2 list Surveillance Requirements for the ESFAS automatic actuation logic associated with these Functions. Therefore, per the requirements of CTS 4.0.1 (ITS SR 3.0.1), CTS 3.3.2.1 encompasses the ESFAS automatic actuation logic. ITS LCO 3.3.4 requires the two automatic actuation logic channels to be OPERABLE in the MODES specified for each Function. Additionally, ITS 3.3.4

provides ACTIONS for inoperable actuation logic channels. For CTS, if an automatic actuation channel is inoperable, CTS 3.0.3 is entered since there is no Condition and Action specified in the CTS. When one MSIS automatic logic channel is inoperable, ITS 3.3.4 ACTION C requires restoring a channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time (RICT) Program. When one automatic logic channel associated with one or more ESFAS Functions (except MSIS and AFAS) is inoperable, ITS 3.3.4 ACTION E also requires restoring a channel to OPERABLE status within 48 hours or in accordance with the RICT Program. This changes the CTS by providing time to restore one automatic logic channel of each ESFAS actuation Function within 48 hours or in accordance with the RICT Program. This change aligns the action for one inoperable SIAS, CSAS, CIS, MSIS, and RAS automatic actuation logic channel with the action for one inoperable AFAS automatic actuation logic channel, one inoperable ESFAS manual channel, and an inoperable channel for the Unit 2 ESFAS automatic logic actuation channels.

The purpose of the actions associated with the SIAS, CSAS, CIS, MSIS, and RAS automatic actuation instrumentation in CTS Table 3.3-3 is to ensure sufficient remedial measures are provided to allow safe operation pursuant the requirements of 10 CFR 50.36(c)(2). The SIAS, CSAS, CIS, MSIS, and RAS automatic actuation logic channels are implicitly assumed to be functional to support automatic actuation of the supported ESF equipment during design basis accidents and transients. This change is acceptable considering redundant automatic actuation logic channels are available to ensure the required equipment supported by the ESFAS (e.g., ECCS and Containment Spray System) will be capable of automatically actuating, diverse manual actuation channels are available, and a Completion Time beyond 48 hours will be evaluated, and the risk managed in accordance with the RICT Program. Extending the time to restore a single ESFAS automatic actuation logic channel to OPERABLE status has been previously evaluated and approved by the NRC for one inoperable AFAS automatic actuation logic channel, the ESFAS manual channels, and the Unit 2 ESFAS automatic actuation logic channels. In the NRC safety evaluation (SE) accompanying PSL Unit 1 License Amendment 247 (RICT Amendment), dated July 2, 2019, (NRC ADAMS Accession No. ML19113A099) the NRC concluded that the proposed RICT for the manual ESFAS channels and the Unit 2 automatic actuation logic channels does not impede accomplishing their safety function and does not alter the existing diversity of the affected functions. The NRC staff stated that the change is consistent with the defense-in-depth philosophy, and therefore acceptable. The acceptability was based, in part, on confirmation that more than one diverse means existed to accomplish the safety function for each identified accident condition, as indicated in the tables provided in FPL to NRC supplement letter, “Fourth Response to Request for Additional Information Regarding License Amendment Request to Adopt Risk Informed Completion Times TSTF-505, Revision 1, ‘Provide Risk-Informed Extended Completion Times – RITSTF Initiative 4b,’” dated March 15, 2018 (NRC ADAMS Accession No. ML18074A116). Tables 2 and 4 of the supplement letter provided the Instrumentation Diversity for each Unit 1 and Unit 2 ESFAS Instrument Function, respectively. As indicated in Table 2 of the RICT supplement letter, ESFAS diversity for the SIAS, CSAS, CIS, MSIS, and RAS automatic actuation instrumentation is provided by the respective manual

actuation channels for each specified accident condition. Equivalent actions in Unit 2 CTS (Table 3.3-3, Action 12) allow restoration of one inoperable automatic actuation channel to OPERABLE status in 48 hours or in accordance with the RICT Program.

The NRC-approved RICT Program required by CTS 6.8.4.r (ITS 5.5.17) provides controls to calculate a RICT as implemented in accordance with NEI 06-09-A, Revision 0, "Risk-Managed Technical Specifications (RMTS) Guidelines." In the NRC SE accompanying the RICT Amendment, the NRC found that the PSL PRA maintenance and change process ensures that the configuration risk management program models used in the RICT calculations will continue to use PRA methods acceptable to the NRC and that the PRA model will be updated as necessary to reflect the as-built and as-operated plant. The NRC also found that appropriate programmatic and procedural controls for the RICT Program are consistent with the guidance of NEI 06-09, Revision 0-A. Therefore, use of the RICT Program specified in the Technical Specifications to determine a RICT to restore an inoperable SIAS, CSAS, CIS, MSIS, or RAS automatic actuation logic channel is acceptable.

Based on the considerations described herein, the change to the Unit 1 CTS actions associated with one inoperable SIAS, CSAS, CIS, MSIS, or RAS automatic actuation logic channel continues to provide sufficient remedial measures to allow safe operation pursuant the requirements of 10 CFR 50.36(c)(2). This change is designated as less restrictive because the ITS Actions are less restrictive than the CTS Actions.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.4, ENGINEERED SAFETY FEATURES ACTUATION SYSTEM (ESFAS) LOGIC AND MANUAL ACTUATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The heading for ISTS 3.3.5 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2). Therefore, ISTS 3.3.2 is not included in the PSL ITS. The successive Specifications are renumbered as necessary.

4. ISTS Table 3.3.5-1, Function 4, Main Steam Isolation Signal, specifies an Applicability of MODES 1, 2, 3, and 4. ITS 3.3.4-1 (ISTS 3.3.5-1) requires the same function in MODES 1, 2, and 3 consistent with Unit 2 CTS for the same function. MODES 2 and 3 are also modified by Footnote (a) that states, “except when valves isolated by the MSIS Function are closed.” As a result of the change to the Applicability, ITS 3.3.4 includes proposed ACTIONS C and D. When one MSIS Manual Actuation or Actuation Logic channels is inoperable, proposed ACTION C requires restoring the channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program consistent with the Unit 1 CTS Actions. Discussion of Change L04 provides justification for the change to the Completion Time to restore the manual channel to OPERABLE status in the Unit 2 CTS Actions. When two MSIS Manual Actuation or Actuation Logic channels are inoperable or when the action to restore one MSIS Manual Actuation or Actuation Logic channel cannot be completed within the required Completion Time, proposed ACTION D requires closing the main steam isolation valves and the main feedwater isolation valves in 6 hours, or be in MODE 3 in 6 hours and MODE 4 in 12 hours.

   This ISTS deviation aligns the Applicability of the MSIS actuation instrumentation with the applicability requirements of the associated MSIS instrument channels (i.e., Footnote (f) to ISTS 3.3.4-1 (ITS 3.3.3-1), Function 4.a) and similar to the applicability of the supported equipment Specifications ITS 3.7.2, “Main Steam Isolation Valves (MSIVs)” and ITS 3.7.4, “Main Feedwater Isolation Valves (MFIVs).” Proposed ITS 3.3.4 ACTION C is added to differentiate the ACTIONS for the MSIS from the ACTIONS of the other ESFAS Logic and Manual Actuation signals. ITS 3.3.4 ACTION D is added to provide appropriate actions to reflect the change to the Applicability, which provides sufficient remedial actions to safely continue operation in lieu of a plant cooldown. Discussion of Change L01 provides justification for the change to the CTS Applicability for the MSIS and proposed actions to close the MSIVs and MFIVs.

   The purpose of the MSIS in ISTS Table 3.3.5-1 (ITS 3.3.4-1) is to ensure the ESFAS MSIS Functions are OPERABLE when the supported equipment is required to be

OPERABLE. The exception to MODE 2 and 3 is added to clarify that the MSIS manual and automatic actuation instrumentation is not required to be OPERABLE when the valves actuated by the MSIS instrumentation are in the closed position. Proposed ACTION D places the unit in a MODE or other specified condition in which the LCO does not apply by either closing the MSIVs and MFIVs within 6 hours (proposed Required Actions D.1.1 and D.1.2) or in MODE 3 within 6 hours and in MODE 4 within 12 hours (proposed Required Actions D.2.1 and D.2.2). The Completion Time of Required Actions D.1.1 and D.1.2 is consistent with the Completion Time to be in MODE 3. The 6-hour and 12-hour Completion Times of Required Actions D.2.1 and D.2.2, respectively, are based on the Completion Times to reach MODES 3 and 4 elsewhere in the ISTS and are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. Subsequent Conditions and Required Actions are renumerated, as applicable.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.~~5~~ 4 Engineered Safety Features Actuation System (ESFAS) Logic and Manual ~~Trip~~ Actuation ~~(Analog)~~

BASES

BACKGROUND

The ESFAS initiates necessary safety systems, based upon the values of selected unit parameters, to protect against violating core design limits and the Reactor Coolant System (RCS) pressure boundary and to mitigate accidents.

The ESFAS contains devices and circuitry that generate the following signals when the monitored variables reach levels that are indicative of conditions requiring protective action:

1. Safety Injection Actuation Signal (SIAS),
2. Containment Spray Actuation Signal (CSAS),
3. Containment Isolation ~~Actuation~~ Signal (CI~~A~~S),
4. Main Steam Isolation Signal (MSIS),
5. Recirculation Actuation Signal (RAS), and
6. Auxiliary Feedwater Actuation Signal (AFAS).

Equipment actuated by each of the above signals is identified in the FSAR (Ref. 1).

Each of the above ESFAS actuation systems is segmented into four sensor subsystems addressed by LCO 3.3.~~4~~ 5, "Engineered Safety Features Actuation System (ESFAS) Instrumentation," and two actuation subsystems addressed by this LCO. Each sensor subsystem includes measurement channels and bistables. The SIAS actuation subsystems include two logic subsystems for sequentially loading the diesel generators.

Each of the four sensor subsystem channels monitors redundant and independent process measurement channels. Each sensor is monitored by at least one bistable. The bistable associated with each ESFAS Function will trip when the monitored variable exceeds the trip setpoint. When tripped, the sensor subsystems provide outputs to the two actuation subsystems.

BASES

BACKGROUND (continued)

The two independent actuation subsystems each compare the four associated sensor subsystem outputs. If a trip occurs in two or more sensor subsystem channels, the two-out-of-four logic in each actuation subsystem will initiate one train of ESFAS. Each has sufficient equipment to provide protection to the public in the case of a Design Basis Event. The sensor subsystem is addressed in LCO 3.3.~~4~~ 3. This LCO addresses the actuation subsystem. 3

Each of the four sensor subsystems is mounted in a separate cabinet, excluding the sensors and field wiring.

The role of the sensor subsystem (measurement channels and bistables) is discussed in LCO 3.3.~~4~~ 3. That of the actuation subsystem is discussed below. 3

ESFAS Logic

The two independent actuation subsystems compare the four sensor subsystem outputs. If a trip occurs in the same parameter in two or more sensor subsystem channels, the two-out-of-four logic in each actuation subsystem initiates one train of ESFAS. Either train controls sufficient redundant and independent equipment.

INSERT 1

Each actuation subsystem channel is housed in two cabinets. One cabinet contains the logic circuitry for the actuation channel, while the other cabinet contains the power relay equipment. This power relay equipment includes the power relays (initiation relays) that actuate the ESFAS equipment in response to a signal from the Actuation Logic.

It is possible to change the two-out-of-four ESFAS Logic to a two-out-of-three logic for a given input parameter in one channel at a time by disabling one channel input to the logic. Thus, the bistables will function normally, producing normal trip indication and annunciation, but ESFAS actuation will not occur since the bypassed channel is effectively removed from the coincidence logic. Maintenance bypassing can be simultaneously performed on any number of parameters in any number of channels, providing each parameter is bypassed in only one channel at a time. ~~At some plants an interlock prevents simultaneous maintenance bypassing of the same parameter in more than one channel.~~ Maintenance bypassing is normally employed during maintenance or testing. 1

1

INSERT 1

Each ESFAS consists of four measurement channels (designated MA, MB, MC, and MD) for each input parameter, two logic matrix systems (SA and SB) and two actuation channels (A and B).

Each measurement channel consists of a sensor, power supply and bistable unit arranged in a current flow loop circuit. The bistable unit provides a digital signal to logic matrices where signals from all four measurement channels for that parameter are combined in a two-out-of-four logic network. Isolation devices are provided to maintain separation between the measurement channels and the logic matrices. Logic matrices (SA or SB) provide initiation signals to their associated actuation channels (A or B) when the logic for the particular signal is satisfied.

BASES

BACKGROUND (continued)

~~For plants that have demonstrated sufficient channel to channel independence,~~ two-out-of-three logic is the minimum that is required to provide adequate plant protection, since a failure of one channel still ensures that ESFAS actuation would be generated by the two remaining OPERABLE channels. Two-out-of-three logic also prevents inadvertent actuation caused by any single channel failure in a trip condition. 1

In addition to the maintenance bypasses, there are operating bypasses (blocks) on the Pressurizer Pressure - Low input to the SIAS and on the Steam Generator Pressure - Low input to the MSIS when these inputs are no longer required for protection. These bypasses are enabled manually when the enabling conditions are satisfied in three of the four sensor subsystem channels. The operating bypass circuitry employs four bistable channels in the sensor subsystems, sensing pressurizer pressure (for the SIAS) and steam generator pressure (for the MSIS). These bistables provide contact output to the three-out-of-four logic in the two actuation subsystem channels. When the logic is satisfied, manual bypassing is permitted. There are two manual bypass actuation controls for each Function, one per train.

All operating bypasses are automatically removed when enabling bypass conditions are no longer satisfied.

Manual ESFAS initiation capability is provided to permit the operator to manually actuate an Engineered Safety Features (ESF) System when necessary. Two push buttons are provided in the control room for each ESFAS Function. Each push button actuates one train via the ESFAS Logic.

The Actuation Logic is tested by inserting a local test signal. A coincidence logic trip will occur if there is the simultaneous presence of a sensor channel trip, either legitimate or due to testing. Most ESFAS Functions employ several separate parallel two-out-of-four Actuation Logic modules, with each module actuating a subset of the ESFAS equipment associated with that Function. Each of these subchannels can be tested individually so that simultaneous actuation of an entire train can be avoided during testing.

INSERT 2 → ~~Except in the case of actuation subchannels SIAS Nos. 5 and 10, CIAS No. 5, and MSIS No. 1, all Actuation Logic channels can be tested at power. The above designated subchannels must be tested when shut down because they actuate the following equipment, which cannot be actuated at power:~~ 1

1

INSERT 2

Some logic channels are testable during reactor operation without affecting the operability or safety of the plant. These devices are tested by imposing an ESFAS during reactor operation. Other logic channels are not testable during reactor operation and must be tested when shutdown to prevent affecting the operability or safety of the plant. Testing Criteria are identified in the UFSAR (Ref. 1).

- ~~CCW from RCPs,~~
- ~~Main steam isolation valves (MSIVs),~~
- ~~Feedwater isolation valves, and~~
- ~~Instrument air containment isolation valves.~~

1

APPLICABLE SAFETY ANALYSES

Each of the analyzed accidents can be detected by one or more ESFAS Functions. One of the ESFAS Functions is the primary actuation signal for that accident. An ESFAS Function may be the primary actuation signal for more than one type of accident. An ESFAS Function may also be a secondary, or backup, actuation signal for one or more other accidents. Functions such as Manual Initiation, not specifically credited in the accident analysis, serve as backups to Functions and are part of the NRC staff approved licensing basis for the plant.

ESFAS protective Functions are as follows:

1. Safety Injection Actuation Signal

   The SIAS ensures acceptable consequences during loss of coolant accident (LOCA) events, including steam generator tube rupture, and main steam line breaks (MSLBs) or feedwater line breaks (FWLBs) (inside containment). To provide the required protection, either a high containment pressure or a low pressurizer pressure signal will initiate SIAS. SIAS initiates the Emergency Core Cooling Systems (ECCS) and performs several other Functions, such as initiating control room isolation and starting the diesel generators.

BASES

APPLICABLE SAFETY ANALYSES (continued)

2. Containment Spray Actuation Signal

The CSAS initiates containment spray, preventing containment overpressurization during a LOCA or MSLB. ~~At some plants,~~ both a high containment pressure signal and an SIAS have to actuate to provide the required protection. This configuration reduces the likelihood of inadvertent containment spray. 1

3. Containment Isolation ~~Actuation~~ Signal 1

The CI~~A~~S actuates the Containment Isolation System, ensuring acceptable consequences during LOCAs and MSLBs or FWLBs (inside containment). To provide protection, a high containment pressure signal will initiate CI~~A~~S at the same setpoint at which an SIAS is initiated. 1 1

4. Main Steam Isolation Signal

The MSIS ensures acceptable consequences during an MSLB or FWLB by isolating both steam generators if either generator indicates a low steam generator pressure. The MSIS, concurrent with or following a reactor trip, minimizes the rate of heat extraction and subsequent cooldown of the RCS during these events.

5. Recirculation Actuation Signal

At the end of the injection phase of a LOCA, the refueling water tank (RWT) will be nearly empty. Continued cooling must be provided by the ECCS to remove decay heat. The source of water for the ECCS pumps is automatically switched to the containment recirculation sump. Switchover from RWT to containment sump must occur before the RWT empties to prevent damage to the ECCS pumps and a loss of core cooling capability. For similar reasons, switchover must not occur before there is sufficient water in the containment sump to support pump suction. Furthermore, early switchover must not occur to ensure sufficient borated water is injected from the RWT to ensure the reactor remains shut down in the recirculation mode. An RWT Level - Low signal initiates the RAS.

BASES

APPLICABLE SAFETY ANALYSES (continued)

6. Auxiliary Feedwater Actuation Signal

the affected

An AFAS initiates feedwater flow to ~~both~~ steam generator~~s~~ if a low level is indicated in ~~either~~ steam generator, unless the generator is ~~ruptured~~.

the affected

faulted

The AFAS maintains a steam generator heat sink during the following events:

- MSLB,
- FWLB,
- Inadvertent opening of a steam generator atmospheric dump valve, and
- Loss of feedwater.

A low steam generator water level signal will initiate auxiliary feed to the affected steam generator.

INSERT 3

1

Secondary steam generator (SG) differential pressure (SG-A > SG-B) or (SG-B > SG-A) inhibits auxiliary feed to a generator identified as being ~~ruptured~~. This input to the AFAS logic prevents loss of the intact generator while preventing feeding a ~~ruptured~~ generator during MSLBs and FWLBs. This prevents containment overpressurization during these events.

faulted

faulted

INSERT 4

1

The ESFAS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires that all components necessary to provide an ESFAS actuation be OPERABLE.

Actions allow maintenance bypass of individual channels. Plants are restricted to 48 hours in a maintenance bypass condition before either restoring the Function to four channel operation (two-out-of-four logic) or placing the channel in trip (one-out-of-three logic).

The Bases for the LCO on ESFAS automatic actuation Functions are addressed in the Bases for LCO 3.3.~~4~~. Those associated with the Manual ~~Trip~~ or Actuation Logic are addressed below.

3

Actuation

3

1

INSERT 3

A separate auxiliary feedwater actuation signal is generated for each steam generator (AFAS-1, AFAS-2). For each AFAS-1 and AFAS-2 there are four independent level transmitters for steam generator level, four independent steam generator pressure transmitters, and four independent feedwater header pressure transmitters. The AFAS actuation logic actuates auxiliary feedwater to a steam generator on low level after a time delay period unless that steam generator or its associated auxiliary feedwater supply header have been identified as being faulted. R1

1

INSERT 4

The AFAS actuation logic isolates auxiliary feedwater flow to a steam generator upon recovery of steam generator level.

BASES

LCO (continued)

1. Safety Injection Actuation Signal

a. Manual ~~Trip~~ Actuation

1

This LCO requires two channels of SIAS Manual Trip Actuation to be OPERABLE in MODES 1, 2, 3, and 4.

1

b. Actuation Logic

This LCO requires two channels of SIAS Actuation Logic to be OPERABLE in MODES 1, 2, 3, and 4.

~~Failures in the actuation subsystems, including the manual bypass key switches, are Actuation Logic failures and are addressed in this LCO.~~

1

Actuation Logic consists of all circuitry housed within the actuation subsystems, including the initiating relay contacts responsible for actuating the ESF equipment.

2. Containment Spray Actuation Signal

CSAS is initiated either manually or automatically. ~~At many plants~~ it is also necessary to have an automatic or manual SIAS for a complete actuation. ~~The SIAS opens the containment spray valves, whereas the CSAS actuates other required components.~~ The SIAS requirement should always be satisfied on a legitimate CSAS, since the Containment Pressure - High signal used in the SIAS ~~is the same~~ setpoint used in the CSAS. ~~The transmitters used to initiate CSAS are independent of those used in the SIAS to prevent inadvertent containment spray due to failures in two sensor channels.~~

1

1

1

setpoint is less than the Containment Pressure – High High

a. Manual ~~Trip~~ Actuation

1

Actuation

This LCO requires two channels of CSAS Manual ~~Trip~~ to be OPERABLE in MODES 1, 2, 3, and 4.

b. Actuation Logic

This LCO requires two channels of CSAS Actuation Logic to be OPERABLE in MODES 1, 2, 3, and 4.

Actuation Logic consists of all circuitry housed within the actuation subsystems, including the initiating relay contacts responsible for actuating the ESF equipment.

BASES

LCO (continued)

3. Containment Isolation ~~Actuation~~ Signal

a. Manual ~~Trip~~ (Actuation) 1

This LCO requires two channels of CI~~A~~S Manual ~~Trip~~ (Actuation) to be OPERABLE in MODES 1, 2, 3, and 4. 1

b. Actuation Logic

This LCO requires two channels of Actuation Logic for CI~~A~~S to be OPERABLE in MODES 1, 2, 3, and 4. 1

Actuation Logic consists of all circuitry housed within the actuation subsystems, including the initiating relay contacts responsible for actuating the ESF equipment.

4. Main Steam Isolation Signal

a. Manual ~~Trip~~ (Actuation) 1

This LCO requires two channels ~~per steam generator~~ of the MSIS Manual ~~Trip~~ (Actuation) to be OPERABLE in MODES 1, 2, 3~~, and 4~~ (and except when all MSIVs are closed). 1

Each channel actuates its associated MSIS Actuation Logic channel. Actuating either MSIS Manual Actuation will result in a full main steam isolation.

b. Actuation Logic 1

This LCO requires two channels of MSIS Actuation Logic to be OPERABLE in MODE~~S~~ 1, 2~~,~~ 3~~, and 4~~ (and MODES and except when all MSIVs are closed). 1

Each MSIS Actuation Logic channel provides a signal to its respective MSIV. An interposing relay will cause the opposite train MSIV to close.

~~Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in the logic LCO.~~

5. Recirculation Actuation Signal

a. Manual ~~Trip~~ (Actuation) 1

This LCO requires two channels of RAS Manual ~~Trip~~ (Actuation) to be OPERABLE in MODES 1, 2, 3, and 4. 1

b. Actuation Logic

This LCO requires two channels of RAS Actuation Logic to be OPERABLE in MODES 1, 2, 3, and 4.

BASES

LCO (continued)

6. Auxiliary Feedwater Actuation Signal

the affected steam
steam

A low level in ~~either~~ generator, as sensed by a two-out-of-four coincidence of four wide range sensors for each generator, will its generate an auxiliary feedwater actuation signal (AFAS), which starts the affected ~~both~~ train~~s~~ of auxiliary feedwater (AFW) pumps and feeds ~~both~~ steam generator~~s~~. The AFAS also monitors the secondary differential pressure in both steam generators and initiates an AFAS block signal to a ~~ruptured~~ generator if the pressure in that generator is lower than the other generator by the differential pressure setpoint.

faulted

a. Manual ~~Trip~~

Actuation

This LCO requires two channels of AFAS Manual ~~Trip~~ to be OPERABLE in MODES 1, 2, and 3.

Actuation

b. Actuation Logic

This LCO requires two channels of AFAS Actuation Logic to be OPERABLE in MODES 1, 2, and 3.

Actuation Logic consists of all circuitry housed within the actuation subsystems, including the initiating relay contacts responsible for actuating the ESF equipment.

1
1
1
1
1

APPLICABILITY All ESFAS Functions are required to be OPERABLE in MODES 1, 2, and 3. In MODES 1, 2, and 3, there is sufficient energy in the primary and secondary systems to warrant automatic ESF System responses to:

- Close the MSIVs to preclude a positive reactivity addition,
- Actuate AFW to preclude the loss of the steam generators as a heat sink (in the event the normal feedwater system is not available),
- Actuate ESF systems to prevent or limit the release of fission product radioactivity to the environment by isolating containment and limiting the containment pressure from exceeding the containment design pressure during a design basis LOCA or MSLB, and
- Actuate ESF systems to ensure sufficient borated inventory to permit adequate core cooling and reactivity control during a design basis LOCA or MSLB accident.

BASES

APPLICABILITY (continued)

In MODES 4, 5, and 6, automatic actuation of ESFAS Functions is not required, because adequate time is available for plant operators to evaluate plant conditions and respond by manually operating the ESF components if required. ESFAS Manual ~~Trip~~ capability is required for Functions other than AFAS and MSIS in MODE 4 even though automatic actuation is not required. Because of the large number of components actuated on each ESFAS, actuation is simplified by the use of the Manual ~~Trip~~ push buttons. Manual ~~Trip~~ of AFAS is not required in MODE 4 because AFW or shutdown cooling will already be in operation in this MODE.

The ESFAS Actuation Logic must be OPERABLE in the same MODES as the Automatic and Manual ~~Trips~~. In MODE 4, only the portion of the ESFAS logic responsible for the required Manual ~~Trip~~ must be OPERABLE.

In MODES 5 and 6, ESFAS initiated systems are either reconfigured or disabled for shutdown cooling operation. Accidents in these MODES are slow to develop and would be mitigated by manual operation of individual components.

ACTIONS

When the number of inoperable channels in a trip Function exceeds those specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered, if applicable in the current MODE of operation.

A Note has been added to the ACTIONS to clarify the application of the Completion Time rules. The Conditions of this Specification may be entered independently for each Function in Table 3.3.~~5~~-1 in the LCO. Completion Times for the inoperable channel of a Function will be tracked separately.

A.1

Condition A applies to one AFAS Manual ~~Trip~~ or AFAS Actuation Logic channel inoperable. It is ~~identical~~ to Condition ~~C~~ for the other ESFAS Functions, except for the shutdown track imposed by Condition ~~D~~.

The channel must be restored to OPERABLE status to restore redundancy of the AFAS Function. The 48 hour Completion Time is commensurate with the importance of avoiding the vulnerability of a single failure in the only remaining OPERABLE channel. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~

BASES

ACTIONS (continued)

B.1 and B.2

Actuation

If two Manual ~~Trip~~ or Actuation Logic channels are inoperable or the Required Action and associated Completion Time of Condition A cannot be met, the reactor should be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

1
2

INSERT 5

1

~~C~~.1

E
E
F
Actuation
and MSIS

Condition ~~C~~ applies to one Manual ~~Trip~~ or Actuation Logic channel inoperable for those ESFAS Functions that must be OPERABLE in MODES 1, 2, 3, and 4 (all Functions except AFAS). The shutdown track imposed by Condition ~~D~~ requires entry into MODE 5, where the LCO does not apply to the affected Functions. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~

3
1
2

The channel must be restored to OPERABLE status to restore redundancy of the affected Functions. The 48 hour Completion Time is commensurate with the importance of avoiding the vulnerability of a single failure in the only remaining OPERABLE channel.

~~D.1 and D.2~~

1

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

2

1

INSERT 5

C.1

Condition C applies when one MSIS Manual Actuation or Actuation Logic channel is inoperable.

The 48 hour Completion Time is commensurate with the importance of avoiding the vulnerability of a single failure in the remaining OPERABLE MSIS Manual Actuation or Actuation Logic channel. Alternatively, the Completion Time can be determined in accordance with the Risk Informed Completion Time Program.

D.1.1, D.1.2, D.2.1, and D.2.2

If both MSIS Manual Actuation or Actuation Logic channels are inoperable or if the Required Actions and associated Conditions of Condition C are not met, the plant must be placed in a MODE or other specified condition in which the LCO does not apply. This is done by closing the MSIVs and MFIVs within 6 hours (Required Actions D.1.1 and D.1.2). If allowed, operation in MODES 2 or 3 with MSIVs and MFIVs closed may continue because isolating the affected main steam line and main feedwater line accomplishes the safety function of the inoperable channel. Alternately, if the MSIVs and MFIVs cannot be closed, the plant must be placed in MODE 3 within 6 hours and in MODE 4 within 12 hours (Required Actions D.2.1 and D.2.2).

The Completion Times of Required Actions D.1.1 and D.1.2 is consistent with the Completion Time to be in MODE 3 for similar conditions and correspond to the Completion Time of D.2.1. The Completion Times of Required Actions D.2.1 and D.2.2 are based on the Completion Time to reach MODE 3 (i.e., 6 hours) and allow an additional 6 hours to reach MODE 4, respectively, if the MSIVs and MFIVs are not closed within 12 hours. These Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

ACTIONS (continued)

~~Condition D is entered when the Required Action and associated Completion Time of Condition C is not met. The plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.~~ 1

~~Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 2). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.~~

~~Required Action D.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.~~

F

F F

~~E~~.1 and ~~E~~.2

Condition ~~E~~ is entered when one or more Functions have two Manual ~~Trip~~ or Actuation Logic channels inoperable except AFAS. The plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.3.~~5~~.1

4

A CHANNEL FUNCTIONAL TEST is performed to ensure the entire channel will perform its intended function when needed. Sensor subsystem tests are addressed in LCO 3.3.4. This SR addresses Actuation Logic tests. A successful test of the required contact(s) of a

3

4

SURVEILLANCE REQUIREMENTS (continued)

channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

Actuation Logic Tests

Actuation subsystem testing includes injecting one trip signal into each two-out-of-four logic subsystem in each ESFAS Function and using a bistable trip input to satisfy the trip logic. Initiation relays associated with the affected channel will then actuate the individual ESFAS components. Since each ESFAS Function employs subchannels of Actuation Logic, it is possible to actuate individual components without actuating an entire ESFAS Function.

Note 1 requires that Actuation Logic tests include operation of initiation relays. Note 2 allows deferred at power testing of certain relays to allow for the fact that operating certain relays during power operation could cause plant transients or equipment damage. ~~Those initiation relays that cannot be tested at power must be tested in accordance with Note 2. These include [SIAS No. 5, SIAS No. 10, CIAS No. 5, and MSIS No. 1.]~~ 1 2

~~These relays actuate the following components, which cannot be tested at power:~~

- ~~RCP seal bleedoff isolation valves,~~
- ~~Service water isolation valves,~~ 1
- ~~VCT discharge valves,~~
- ~~Letdown stop valves,~~
- ~~CCW to and from the RCPs,~~
- ~~MSIVs and feedwater isolation valves, and~~
- ~~Instrument air containment isolation valves.~~

~~The reasons that each of the above cannot be fully tested at power are stated in Reference 1.~~

These tests verify that the ESFAS is capable of performing its intended function, from bistable input through the actuated components.

Actuation

A CHANNEL FUNCTIONAL TEST is performed on the manual ESFAS actuation circuitry, de-energizing relays and providing Manual ~~Trip~~ of the Function. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

Actuation

This Surveillance verifies that the trip push buttons are capable of opening contacts in the Actuation Logic as designed, de-energizing the initiation relays and providing Manual ~~Trip~~ of the Function. ~~[The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed at a Frequency of once every [18] months.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.~~5~~ Engineered Safety Features Actuation System (ESFAS) Logic and Manual ~~Trip~~ ~~(Analog)~~

BASES

BACKGROUND

The ESFAS initiates necessary safety systems, based upon the values of selected unit parameters, to protect against violating core design limits and the Reactor Coolant System (RCS) pressure boundary and to mitigate accidents.

The ESFAS contains devices and circuitry that generate the following signals when the monitored variables reach levels that are indicative of conditions requiring protective action:

1. Safety Injection Actuation Signal (SIAS),
2. Containment Spray Actuation Signal (CSAS),
3. Containment Isolation Actuation Signal (CIAS),
4. Main Steam Isolation Signal (MSIS),
5. Recirculation Actuation Signal (RAS), and
6. Auxiliary Feedwater Actuation Signal (AFAS).

Equipment actuated by each of the above signals is identified in the FSAR (Ref. 1).

Each of the above ESFAS actuation systems is segmented into four sensor subsystems addressed by LCO 3.3.~~4~~, "Engineered Safety Features Actuation System (ESFAS) Instrumentation," and two actuation subsystems addressed by this LCO. Each sensor subsystem includes measurement channels and bistables. The SIAS actuation subsystems include two logic subsystems for sequentially loading the diesel generators.

Each of the four sensor subsystem channels monitors redundant and independent process measurement channels. Each sensor is monitored by at least one bistable. The bistable associated with each ESFAS Function will trip when the monitored variable exceeds the trip setpoint. When tripped, the sensor subsystems provide outputs to the two actuation subsystems.

BASES

BACKGROUND (continued)

The two independent actuation subsystems each compare the four associated sensor subsystem outputs. If a trip occurs in two or more sensor subsystem channels, the two-out-of-four logic in each actuation subsystem will initiate one train of ESFAS. Each has sufficient equipment to provide protection to the public in the case of a Design Basis Event. The sensor subsystem is addressed in LCO 3.3.~~4~~ 3. This LCO addresses the actuation subsystem. 3

Each of the four sensor subsystems is mounted in a separate cabinet, excluding the sensors and field wiring.

The role of the sensor subsystem (measurement channels and bistables) is discussed in LCO 3.3.~~4~~ 3. That of the actuation subsystem is discussed below. 3

ESFAS Logic

The two independent actuation subsystems compare the four sensor subsystem outputs. If a trip occurs in the same parameter in two or more sensor subsystem channels, the two-out-of-four logic in each actuation subsystem initiates one train of ESFAS. Either train controls sufficient redundant and independent equipment.

INSERT 1

Each actuation subsystem channel is housed in two cabinets. One cabinet contains the logic circuitry for the actuation channel, while the other cabinet contains the power relay equipment. This power relay equipment includes the power relays (initiation relays) that actuate the ESFAS equipment in response to a signal from the Actuation Logic.

It is possible to change the two-out-of-four ESFAS Logic to a two-out-of-three logic for a given input parameter in one channel at a time by disabling one channel input to the logic. Thus, the bistables will function normally, producing normal trip indication and annunciation, but ESFAS actuation will not occur since the bypassed channel is effectively removed from the coincidence logic. Maintenance bypassing can be simultaneously performed on any number of parameters in any number of channels, providing each parameter is bypassed in only one channel at a time. ~~At some plants an interlock prevents simultaneous maintenance bypassing of the same parameter in more than one channel.~~ Maintenance bypassing is normally employed during maintenance or testing. 1

1

INSERT 1

Each ESFAS consists of four measurement channels (designated MA, MB, MC, and MD) for each input parameter, two logic matrix systems (SA and SB) and two actuation channels (A and B).

Each measurement channel consists of a sensor, power supply and bistable unit arranged in a current flow loop circuit. The bistable unit provides a digital signal to logic matrices where signals from all four measurement channels for that parameter are combined in a two-out-of-four logic network. Isolation devices are provided to maintain separation between the measurement channels and the logic matrices. Logic matrices (SA or SB) provide initiation signals to their associated actuation channels (A or B) when the logic for the particular signal is satisfied.

BASES

BACKGROUND (continued)

~~For plants that have demonstrated sufficient channel to channel independence,~~ two-out-of-three logic is the minimum that is required to provide adequate plant protection, since a failure of one channel still ensures that ESFAS actuation would be generated by the two remaining OPERABLE channels. Two-out-of-three logic also prevents inadvertent actuation caused by any single channel failure in a trip condition. 1

In addition to the maintenance bypasses, there are operating bypasses (blocks) on the Pressurizer Pressure - Low input to the SIAS and on the Steam Generator Pressure - Low input to the MSIS when these inputs are no longer required for protection. These bypasses are enabled manually when the enabling conditions are satisfied in three of the four sensor subsystem channels. The operating bypass circuitry employs four bistable channels in the sensor subsystems, sensing pressurizer pressure (for the SIAS) and steam generator pressure (for the MSIS). These bistables provide contact output to the three-out-of-four logic in the two actuation subsystem channels. When the logic is satisfied, manual bypassing is permitted. There are two manual bypass actuation controls for each Function, one per train.

All operating bypasses are automatically removed when enabling bypass conditions are no longer satisfied.

Manual ESFAS initiation capability is provided to permit the operator to manually actuate an Engineered Safety Features (ESF) System when necessary. Two push buttons are provided in the control room for each ESFAS Function. Each push button actuates one train via the ESFAS Logic.

The Actuation Logic is tested by inserting a local test signal. A coincidence logic trip will occur if there is the simultaneous presence of a sensor channel trip, either legitimate or due to testing. Most ESFAS Functions employ several separate parallel two-out-of-four Actuation Logic modules, with each module actuating a subset of the ESFAS equipment associated with that Function. Each of these subchannels can be tested individually so that simultaneous actuation of an entire train can be avoided during testing.

INSERT 2

~~Except in the case of actuation subchannels SIAS Nos. 5 and 10, CIAS No. 5, and MSIS No. 1, all Actuation Logic channels can be tested at power. The above designated subchannels must be tested when shut down because they actuate the following equipment, which cannot be actuated at power:~~ 1

1

INSERT 2

Some logic channels are testable during reactor operation without affecting the operability or safety of the plant. These devices are tested by imposing an ESFAS during reactor operation. Other logic channels are not testable during reactor operation and must be tested when shutdown to prevent affecting the operability or safety of the plant. Testing Criteria are identified in the UFSAR (Ref. 1).

1

APPLICABLE SAFETY ANALYSES

Each of the analyzed accidents can be detected by one or more ESFAS Functions. One of the ESFAS Functions is the primary actuation signal for that accident. An ESFAS Function may be the primary actuation signal for more than one type of accident. An ESFAS Function may also be a secondary, or backup, actuation signal for one or more other accidents. Functions such as Manual Initiation, not specifically credited in the accident analysis, serve as backups to Functions and are part of the NRC staff approved licensing basis for the plant.

ESFAS protective Functions are as follows:

1. Safety Injection Actuation Signal

   The SIAS ensures acceptable consequences during loss of coolant accident (LOCA) events, including steam generator tube rupture, and main steam line breaks (MSLBs) or feedwater line breaks (FWLBs) (inside containment). To provide the required protection, either a high containment pressure or a low pressurizer pressure signal will initiate SIAS. SIAS initiates the Emergency Core Cooling Systems (ECCS) and performs several other Functions, such as initiating control room isolation and starting the diesel generators.

BASES

APPLICABLE SAFETY ANALYSES (continued)

2. Containment Spray Actuation Signal

The CSAS initiates containment spray, preventing containment overpressurization during a LOCA or MSLB. ~~At some plants,~~ both a high containment pressure signal and an SIAS have to actuate to provide the required protection. This configuration reduces the likelihood of inadvertent containment spray. 1

3. Containment Isolation Actuation Signal

The CIAS actuates the Containment Isolation System, ensuring acceptable consequences during LOCAs and MSLBs or FWLBs (inside containment). To provide protection, a high containment pressure signal will initiate CIAS at the same setpoint at which an SIAS is initiated.

4. Main Steam Isolation Signal

The MSIS ensures acceptable consequences during an MSLB or FWLB by isolating both steam generators if either generator indicates a low steam generator pressure. The MSIS, concurrent with or following a reactor trip, minimizes the rate of heat extraction and subsequent cooldown of the RCS during these events.

5. Recirculation Actuation Signal

At the end of the injection phase of a LOCA, the refueling water tank (RWT) will be nearly empty. Continued cooling must be provided by the ECCS to remove decay heat. The source of water for the ECCS pumps is automatically switched to the containment recirculation sump. Switchover from RWT to containment sump must occur before the RWT empties to prevent damage to the ECCS pumps and a loss of core cooling capability. For similar reasons, switchover must not occur before there is sufficient water in the containment sump to support pump suction. Furthermore, early switchover must not occur to ensure sufficient borated water is injected from the RWT to ensure the reactor remains shut down in the recirculation mode. An RWT Level - Low signal initiates the RAS.

BASES

APPLICABLE SAFETY ANALYSES (continued)

6. Auxiliary Feedwater Actuation Signal

the affected

An AFAS initiates feedwater flow to ~~both~~ steam generator~~s~~ if a low level is indicated in ~~either~~ steam generator, unless the generator is ~~ruptured~~.

the affected

faulted

The AFAS maintains a steam generator heat sink during the following events:

- MSLB,
- FWLB,
- Inadvertent opening of a steam generator atmospheric dump valve, and
- Loss of feedwater.

A low steam generator water level signal will initiate auxiliary feed to the affected steam generator.

INSERT 3

1

Secondary steam generator (SG) differential pressure (SG-A > SG-B) or (SG-B > SG-A) inhibits auxiliary feed to a generator identified as being ~~ruptured~~. This input to the AFAS logic prevents loss of the intact generator while preventing feeding a ~~ruptured~~ generator during MSLBs and FWLBs. This prevents containment overpressurization during these events.

faulted

faulted

INSERT 4

1

The ESFAS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires that all components necessary to provide an ESFAS actuation be OPERABLE.

Actions allow maintenance bypass of individual channels. Plants are restricted to 48 hours in a maintenance bypass condition before either restoring the Function to four channel operation (two-out-of-four logic) or placing the channel in trip (one-out-of-three logic).

The Bases for the LCO on ESFAS automatic actuation Functions are addressed in the Bases for LCO 3.3.~~4~~. Those associated with the Manual ~~Trip~~ or Actuation Logic are addressed below.

3

Actuation

3

1

INSERT 3

A separate auxiliary feedwater actuation signal is generated for each steam generator (AFAS-1, AFAS-2). For each AFAS-1 and AFAS-2 there are four independent level transmitters for steam generator level, four independent steam generator pressure transmitters, and four independent feedwater header pressure transmitters. The AFAS actuation logic actuates auxiliary feedwater to a steam generator on low level after a time delay period unless that steam generator or its associated auxiliary feedwater supply header have been identified as being faulted. R1

1

INSERT 4

The AFAS actuation logic isolates auxiliary feedwater flow to a steam generator upon recovery of steam generator level.

BASES

LCO (continued)

1. Safety Injection Actuation Signal

   a. Manual ~~Trip~~

   This LCO requires two channels of SIAS Manual ~~Trip~~ to be OPERABLE in MODES 1, 2, 3, and 4.

   b. Actuation Logic

   This LCO requires two channels of SIAS Actuation Logic to be OPERABLE in MODES 1, 2, 3, and 4.

   ~~Failures in the actuation subsystems, including the manual bypass key switches, are Actuation Logic failures and are addressed in this LCO.~~

   Actuation Logic consists of all circuitry housed within the actuation subsystems, including the initiating relay contacts responsible for actuating the ESF equipment.

2. Containment Spray Actuation Signal

   CSAS is initiated either manually or automatically. ~~At many plants~~ it is also necessary to have an automatic or manual SIAS for a complete actuation. ~~The SIAS opens the containment spray valves, whereas the CSAS actuates other required components~~. The SIAS requirement should always be satisfied on a legitimate CSAS, since the Containment Pressure - High signal used in the SIAS ~~is the same~~ setpoint used in the CSAS. ~~The transmitters used to initiate CSAS are independent of those used in the SIAS to prevent inadvertent containment spray due to failures in two sensor channels.~~

   a. Manual ~~Trip~~

   This LCO requires two channels of CSAS Manual ~~Trip~~ to be OPERABLE in MODES 1, 2, 3, and 4.

   b. Actuation Logic

   This LCO requires two channels of CSAS Actuation Logic to be OPERABLE in MODES 1, 2, 3, and 4.

   Actuation Logic consists of all circuitry housed within the actuation subsystems, including the initiating relay contacts responsible for actuating the ESF equipment.

BASES

LCO (continued)

3. Containment Isolation Actuation Signal

a. Manual ~~Trip~~ (Actuation) 1

This LCO requires two channels of CIAS Manual ~~Trip~~ (Actuation) to be OPERABLE in MODES 1, 2, 3, and 4. 1

b. Actuation Logic

This LCO requires two channels of Actuation Logic for CIAS to be OPERABLE in MODES 1, 2, 3, and 4.

Actuation Logic consists of all circuitry housed within the actuation subsystems, including the initiating relay contacts responsible for actuating the ESF equipment.

4. Main Steam Isolation Signal

a. Manual ~~Trip~~ (Actuation) 1

This LCO requires two channels ~~per steam generator~~ of the MSIS Manual ~~Trip~~ (Actuation) to be OPERABLE in MODES 1, 2, 3~~, and 4~~ (and except when all MSIVs are closed). 1

Each channel actuates its associated MSIS Actuation Logic channel. Actuating either MSIS Manual Actuation will result in a full main steam isolation.

b. Actuation Logic 1

This LCO requires two channels of MSIS Actuation Logic to be OPERABLE in MODE~~S~~ 1, 2~~,~~ 3~~, and 4~~ (and MODES and except when all MSIVs are closed). 1

Each MSIS Actuation Logic channel provides a signal to its respective MSIV. An interposing relay will cause the opposite train MSIV to close.

~~Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in the logic LCO.~~

5. Recirculation Actuation Signal

a. Manual ~~Trip~~ (Actuation) 1

This LCO requires two channels of RAS Manual ~~Trip~~ (Actuation) to be OPERABLE in MODES 1, 2, 3, and 4. 1

b. Actuation Logic

This LCO requires two channels of RAS Actuation Logic to be OPERABLE in MODES 1, 2, 3, and 4.

BASES

LCO (continued)

6. Auxiliary Feedwater Actuation Signal

the affected steam
steam
its
the affected
faulted
Actuation
Actuation

A low level in ~~either~~ generator, as sensed by a two-out-of-four coincidence of four wide range sensors for each generator, will generate an auxiliary feedwater actuation signal (AFAS), which starts ~~both~~ train~~s~~ of auxiliary feedwater (AFW) pumps and feeds ~~both~~ steam generator~~s~~. The AFAS also monitors the secondary differential pressure in both steam generators and initiates an AFAS block signal to a ~~ruptured~~ generator if the pressure in that generator is lower than the other generator by the differential pressure setpoint.

1
1
1
1
1

a. Manual ~~Trip~~

This LCO requires two channels of AFAS Manual ~~Trip~~ to be OPERABLE in MODES 1, 2, and 3.

b. Actuation Logic

This LCO requires two channels of AFAS Actuation Logic to be OPERABLE in MODES 1, 2, and 3.

Actuation Logic consists of all circuitry housed within the actuation subsystems, including the initiating relay contacts responsible for actuating the ESF equipment.

APPLICABILITY All ESFAS Functions are required to be OPERABLE in MODES 1, 2, and 3. In MODES 1, 2, and 3, there is sufficient energy in the primary and secondary systems to warrant automatic ESF System responses to:

- Close the MSIVs to preclude a positive reactivity addition,
- Actuate AFW to preclude the loss of the steam generators as a heat sink (in the event the normal feedwater system is not available),
- Actuate ESF systems to prevent or limit the release of fission product radioactivity to the environment by isolating containment and limiting the containment pressure from exceeding the containment design pressure during a design basis LOCA or MSLB, and
- Actuate ESF systems to ensure sufficient borated inventory to permit adequate core cooling and reactivity control during a design basis LOCA or MSLB accident.

BASES

APPLICABILITY (continued)

In MODES 4, 5, and 6, automatic actuation of ESFAS Functions is not required, because adequate time is available for plant operators to evaluate plant conditions and respond by manually operating the ESF components if required. ESFAS Manual ~~Trip~~ capability is required for Functions other than AFAS and MSIS in MODE 4 even though automatic actuation is not required. Because of the large number of components actuated on each ESFAS, actuation is simplified by the use of the Manual ~~Trip~~ push buttons. Manual ~~Trip~~ of AFAS is not required in MODE 4 because AFW or shutdown cooling will already be in operation in this MODE.

The ESFAS Actuation Logic must be OPERABLE in the same MODES as the Automatic and Manual ~~Trips~~. In MODE 4, only the portion of the ESFAS logic responsible for the required Manual ~~Trip~~ must be OPERABLE.

In MODES 5 and 6, ESFAS initiated systems are either reconfigured or disabled for shutdown cooling operation. Accidents in these MODES are slow to develop and would be mitigated by manual operation of individual components.

ACTIONS

When the number of inoperable channels in a trip Function exceeds those specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered, if applicable in the current MODE of operation.

A Note has been added to the ACTIONS to clarify the application of the Completion Time rules. The Conditions of this Specification may be entered independently for each Function in Table 3.3.~~5~~-1 in the LCO. Completion Times for the inoperable channel of a Function will be tracked separately.

A.1

Condition A applies to one AFAS Manual ~~Trip~~ or AFAS Actuation Logic channel inoperable. It is ~~identical~~ to Condition ~~C~~ for the other ESFAS Functions, except for the shutdown track imposed by Condition ~~D~~.

The channel must be restored to OPERABLE status to restore redundancy of the AFAS Function. The 48 hour Completion Time is commensurate with the importance of avoiding the vulnerability of a single failure in the only remaining OPERABLE channel. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~

Actuation

4

3

BASES

ACTIONS (continued)

B.1 and B.2

Actuation

If two Manual ~~Trip~~ or Actuation Logic channels are inoperable or the Required Action and associated Completion Time of Condition A cannot be met, the reactor should be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

1

2

INSERT 5

1

E

~~C~~.1

E

F

Actuation

and MSIS

3

Condition ~~C~~ applies to one Manual ~~Trip~~ or Actuation Logic channel inoperable for those ESFAS Functions that must be OPERABLE in MODES 1, 2, 3, and 4 (all Functions except AFAS). The shutdown track imposed by Condition ~~D~~ requires entry into MODE 5, where the LCO does not apply to the affected Functions. ~~[~~Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.~~]~~

1

2

The channel must be restored to OPERABLE status to restore redundancy of the affected Functions. The 48 hour Completion Time is commensurate with the importance of avoiding the vulnerability of a single failure in the only remaining OPERABLE channel.

~~D.1 and D.2~~

1

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

2

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

4

3

1

St. Lucie – Unit 2

Revision XXX

1

INSERT 5

C.1

Condition C applies when one MSIS Manual Actuation or Actuation Logic channel is inoperable.

The 48 hour Completion Time is commensurate with the importance of avoiding the vulnerability of a single failure in the remaining OPERABLE MSIS Manual Actuation or Actuation Logic channel. Alternatively, the Completion Time can be determined in accordance with the Risk Informed Completion Time Program.

D.1.1, D.1.2, D.2.1, and D.2.2

If both MSIS Manual Actuation or Actuation Logic channels are inoperable or if the Required Actions and associated Conditions of Condition C are not met, the plant must be placed in a MODE or other specified condition in which the LCO does not apply. This is done by closing the MSIVs and MFIVs within 6 hours (Required Actions D.1.1 and D.1.2). If allowed, operation in MODES 2 or 3 with MSIVs and MFIVs closed may continue because isolating the affected main steam line and main feedwater line accomplishes the safety function of the inoperable channel. Alternately, if the MSIVs and MFIVs cannot be closed, the plant must be placed in MODE 3 within 6 hours and in MODE 4 within 12 hours (Required Actions D.2.1 and D.2.2).

The Completion Times of Required Actions D.1.1 and D.1.2 is consistent with the Completion Time to be in MODE 3 for similar conditions and correspond to the Completion Time of D.2.1. The Completion Times of Required Actions D.2.1 and D.2.2 are based on the Completion Time to reach MODE 3 (i.e., 6 hours) and allow an additional 6 hours to reach MODE 4, respectively, if the MSIVs and MFIVs are not closed within 12 hours. These Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

BASES

ACTIONS (continued)

~~Condition D is entered when the Required Action and associated Completion Time of Condition C is not met. The plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.~~ 1

~~Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 2). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.~~

~~Required Action D.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.~~

F
F
F
~~E~~.1 and ~~E~~.2

Condition ~~E~~ is entered when one or more Functions have two Manual ~~Trip~~ or Actuation Logic channels inoperable except AFAS. The plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.3.~~5~~.1
4

A CHANNEL FUNCTIONAL TEST is performed to ensure the entire channel will perform its intended function when needed. Sensor subsystem tests are addressed in LCO 3.3.~~4~~. This SR addresses Actuation Logic tests. A successful test of the required contact(s) of a

3

BASES

SURVEILLANCE REQUIREMENTS (continued)

channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

Actuation Logic Tests

Actuation subsystem testing includes injecting one trip signal into each two-out-of-four logic subsystem in each ESFAS Function and using a bistable trip input to satisfy the trip logic. Initiation relays associated with the affected channel will then actuate the individual ESFAS components. Since each ESFAS Function employs subchannels of Actuation Logic, it is possible to actuate individual components without actuating an entire ESFAS Function.

Note 1 requires that Actuation Logic tests include operation of initiation relays. Note 2 allows deferred at power testing of certain relays to allow for the fact that operating certain relays during power operation could cause plant transients or equipment damage. ~~Those initiation relays that cannot be tested at power must be tested in accordance with Note 2. These include [SIAS No. 5, SIAS No. 10, CIAS No. 5, and MSIS No. 1.]~~ 1 2

~~These relays actuate the following components, which cannot be tested at power:~~

- ~~RCP seal bleedoff isolation valves,~~
- ~~Service water isolation valves,~~ 1
- ~~VCT discharge valves,~~
- ~~Letdown stop valves,~~
- ~~CCW to and from the RCPs,~~
- ~~MSIVs and feedwater isolation valves, and~~
- ~~Instrument air containment isolation valves.~~

~~The reasons that each of the above cannot be fully tested at power are stated in Reference 1.~~

These tests verify that the ESFAS is capable of performing its intended function, from bistable input through the actuated components.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[The Frequency of [92] days is based on the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 3).~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

SR 3.3.~~5~~.2

A CHANNEL FUNCTIONAL TEST is performed on the manual ESFAS actuation circuitry, de-energizing relays and providing Manual ~~Trip~~ of the Function. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

This Surveillance verifies that the trip push buttons are capable of opening contacts in the Actuation Logic as designed, de-energizing the initiation relays and providing Manual ~~Trip~~ of the Function. ~~[The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed at a Frequency of once every [18] months.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The heading for ISTS 3.3.5 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2). Therefore, ISTS 3.3.2 is not included in the PSL ITS. The successive Specifications are renumbered as necessary.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.3.4, ENGINEERED SAFETY FEATURES ACTUATION SYSTEM (ESFAS)
LOGIC AND MANUAL ACTUATION

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGE L01

Florida Power & Light Company (FPL) is converting the St. Lucie Plant (PSL) Unit 1 and Unit 2 Technical Specifications to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, "Standard Technical Specifications, Combustion Engineering Plants," Revision 5. The proposed change involves making the current technical specifications (CTS) less restrictive. Below is the description of the change and the determination of No Significant Hazards Considerations for conversion to NUREG-1432.

Unit 1 CTS 3.3.2.1, Table 3.3-3 Functional Unit 4 – main steam isolation signal (MSIS) manual actuation is applicable in MODES 1, 2, 3, and 4 and Table 4.3-2 Functional Unit 4 – MSIS automatic actuation logic is applicable in MODES 1, 2, and 3. Unit 2 CTS 3.3.2, Tables 3.3-3 and 4.3-2 Functional Unit 4 – MSIS manual and automatic actuation logic are applicable in MODES 1, 2, and 3. When one Unit 1 MSIS manual actuation channel is inoperable or one Unit 2 MSIS automatic actuation logic channel is inoperable, CTS Table 3.3-3 Action 8 (Unit 1) and Action 12 (Unit 2) require, in part, to restore the channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program.

ITS Limiting Condition for Operation (LCO) 3.3.4 (Table 3.3.4-1) requires the MSIS manual actuation and automatic actuation channel to be OPERABLE in MODES 1, 2, 3 except in MODES 2 and 3 when valves isolated by the MSIS Function are closed as specified in Footnote (a). ITS actions require closing the main steam isolation valves (MSIVs) and the main feedwater isolation valves (MFIVs) in 6 hours, or be in MODE 3 in 6 hours and MODE 4 in 12 hours when two MSIS Manual Actuation or Actuation Logic channels are inoperable or when the action to restore one MSIS Manual Actuation or Actuation Logic channel cannot be completed within the required Completion Time. This changes the CTS by deleting the MODE 4 applicability requirement for Unit 1 MSIS, and changing the MODE 2 and 3 Applicability for both units to include “except when valves isolated by the MSIS Function are closed.” This change aligns the Applicability of the MSIS actuation instrumentation with the applicability requirements of the associated MSIS instrument channels (i.e., steam generator low pressure instrument channels and the Unit 2 containment high pressure instrument channels) and the supported equipment (i.e., the MSIVs and MFIVs). The change also revises the CTS Actions to add appropriate actions to reflect the change to the Applicability, which provides sufficient remedial actions to safely continue operation in lieu of a plant cooldown.

The purpose of the MSIS manual and automatic instrumentation in CTS Table 3.3-3 is to ensure the Engineered Safety Features Actuation System (ESFAS) MSIS Functions are OPERABLE when the supported equipment is required to be OPERABLE. Automatic steam line and feedwater line isolation is assumed in the mitigation of a major secondary system pipe rupture accident (e.g., main steam line break or feedwater line break). The MSIS manual actuation instrumentation is not credited in the safety analysis and a safety analysis limit is not specified for this actuation function. MSIS automatic actuation instrumentation is credited in the safety analysis.

In MODES 1, 2, and 3, there is sufficient energy in the primary and secondary systems to warrant automatic ESF System response to ensure the main steam and feedwater

lines can be isolated in the event of a high energy secondary system pipe rupture. The exception to MODE 2 and 3 are added to clarify that the MSIS manual and automatic actuation instrumentation is not required to be OPERABLE when the valves actuated by the MSIS instrumentation are in positions that support the safety analyses. When the valves isolated by the MSIS function are in the closed position, they are in their assumed accident position. This change is acceptable, because when the MSIVs and MFIVs are closed, the adverse effects of a high energy secondary system pipe rupture are precluded and the requirements continue to ensure that the structures, systems, and components (SSCs) are maintained in the MODES and other specified conditions assumed in the safety analyses. The proposed applicability and actions provide the same level of protection as the current requirements for the supported equipment.

Since the proposed actions provide the allowance to place the MSIVs and MFIVs in their accident position with the option to continue a plant cooldown, sufficient remedial measures continue to be provided to allow safe operation pursuant to the requirements of 10 CFR 50.36(c)(2).

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. Does the proposed change involve a significant increase in the probability or consequences of any accident previously evaluated?

   Response: No.

   The proposed change does not affect accident initiators or precursors nor adversely alter the design assumptions, conditions, and configuration of the facility. The proposed change does not alter any plant equipment or operating practices with respect to such initiators or precursors in a manner that the probability of an accident is increased. The proposed change revises the applicability requirements for the ESFAS MSIS actuation instrumentation to align with the applicability requirements of the associated instrument channels and the supported equipment. Changing the applicability requirements of the MSIS actuation instrumentation to be consistent with the applicability requirements of the associated instrument channels and the supported equipment does not alter the probability or consequences of previously evaluated accidents. In addition, the proposed actions provide sufficient remedial measures to continue safe operation in lieu of a plant cooldown. The proposed change does not involve a physical change to the ESFAS, nor does it change the safety function of the ESFAS instrumentation or the equipment supported by the ESFAS instrumentation. Automatic steam line and feedwater line isolation is assumed in the mitigation of a major secondary system pipe rupture accident. When the valves are in the closed position, they are in their assumed accident position. Therefore, the adverse effects of a high energy secondary system pipe rupture are precluded. As a result, the proposed change does not alter assumptions relative to the mitigation of a previously evaluated accident.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any previously evaluated?

   Response: No

   With respect to a new or different kind of accident, there are no proposed design changes to the ESFAS; nor are there any changes in the method by which safety related plant SSCs perform their specified safety functions. The proposed change will not affect the normal method of plant operation or revise any operating parameters. No new accident scenarios, transient precursor, failure mechanisms, or limiting single failures will be introduced as a result of this proposed change and the failure modes and effects analyses of SSCs important to safety are not altered as a result of this change.

   The proposed change does not alter the design or performance of the ESFAS, rather, the change aligns the applicability requirements of the MSIS actuation instrumentation with the applicability requirements of the associated instrument channels and the supported equipment. The proposed actions provide sufficient remedial measures to continue safe operation in lieu of a plant cooldown. The process to close the MSIVs and the MFIVs or place the unit in a shutdown condition uses current procedures, methods, and processes already established and currently in use and, therefore, does not constitute a new type of test.

   No changes are being proposed to the procedures that operate the plant equipment and the change does not have a detrimental impact on the manner in which plant equipment operates or responds to an actuation signal.

   Therefore, the proposed change will not create the possibility of a new or different accident previously evaluated.

3. Does the proposed change involve a significant reduction in the margin of safety?

   Response: No.

   The margin of safety is related to the ability of the fission product barriers to perform their design functions during and following an accident. These barriers include the fuel cladding, the reactor coolant system, and the containment. The performance of these fission product barriers is not affected by the proposed change.

   Instrumentation safety margin is established by ensuring the limiting safety system settings (LSSSs) automatically actuate the applicable design function to correct an abnormal situation before a safety limit is exceeded. Safety analysis limits are established for reactor trip system and ESFAS instrumentation functions related to those variables having significant safety functions. The proposed change aligns the applicability requirements of the MSIS actuation instrumentation with the applicability requirements of the associated instrument channels and the supported equipment. The proposed actions provide sufficient remedial measures to continue safe operation in lieu of a plant cooldown. The MSIS manual actuation instrumentation is not credited in the safety analysis and a safety analysis limit is not specified for this actuation function. Therefore, the MSIS manual actuation instrumentation does not

represent an LSSS because this instrumentation does not monitor a plant variable on which a safety limit has been placed. In addition, the change to the applicability and actions of the MSIS automatic actuation logic does not alter the capability of the LSSSs to automatically actuate the applicable design function to correct an abnormal situation before a safety limit is exceeded because the applicability and optional remedial actions to close the associated valves ensure the components are in their safety position precluding adverse effects of a high energy secondary system pipe rupture. The proposed change does not alter the instrumentation used to monitor a plant variable on which a safety limit has been placed.

The controlling parameters established to isolate the steam and feedwater lines during an accident or transient are not affected by the proposed change and no design basis or safety limit is altered as a result of the proposed change. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based upon the above analysis, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and accordingly, a finding of no significant hazards consideration is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.3.4, ENGINEERED SAFETY FEATURES ACTUATION SYSTEM (ESFAS)
LOGIC AND MANUAL ACTUATION

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGE L04 – UNIT 2
LESS RESTRICTIVE CHANGE L05 – UNIT 1

Florida Power & Light Company (FPL) is converting the St. Lucie Plant (PSL) Unit 1 and Unit 2 Technical Specifications to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, "Standard Technical Specifications, Combustion Engineering Plants," Revision 5. The proposed change involves making the current technical specifications (CTS) less restrictive. Below is the description of the change and the determination of No Significant Hazards Considerations for conversion to NUREG-1432.

When one Unit 2 main steam isolation signal (MSIS) manual trip button channel is inoperable, CTS actions require the channel to be restored to OPERABLE status within 48 hours or declare the associated valve inoperable and take the actions required by the supported system specification. ITS requires restoring the channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time (RICT) Program. This changes the CTS by optionally allowing the manual channel to be restored in accordance with the RICT Program provided the associated risk is assessed and managed and in accordance with an NRC approved RICT Program. This change aligns the action for one inoperable Unit 2 MSIS manual channel with the action for one inoperable Unit 1 MSIS manual channel and the action for one inoperable channel of the other Engineered Safety Features Actuation System (ESFAS) manual actuation channels.

Unit 1 CTS does not specifically include requirements for the ESFAS automatic actuation logic channels, including actions when one or more automatic actuation logic channels are inoperable. However, Surveillance Requirements associated with the ESFAS automatic actuation logic is included in the Unit 1 CTS. Because no actions are provided for the Unit 1 ESFAS automatic actuation logic channels, a plant shutdown is required when an automatic actuation channel is inoperable. When an ESFAS automatic actuation logic channel is inoperable, Unit 1 ITS actions allow restoring a channel to OPERABLE status within 48 hours or in accordance with the RICT Program consistent with the Unit 2 ITS actions. This changes the Unit 1 CTS by providing time to restore the redundant automatic actuation logic channel to OPERABLE status provided the associated risk is assessed and managed in accordance with an NRC approved RICT Program.

License Amendments 247 and 199, dated July 2, 2019, for PSL Unit 1 and Unit 2, respectively (NRC ADAMS Accession No. ML19113A099) incorporated an NRC approved RICT Program in the PSL Unit 1 and Unit 2 technical specifications. The RICT Program provides controls to assess and manage risk during the extended time to restore the redundant automatic actuation logic channel or manual actuation channel to OPERABLE status.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.3.4, ENGINEERED SAFETY FEATURES ACTUATION SYSTEM (ESFAS) LOGIC AND MANUAL ACTUATION

1. Does the proposed change involve a significant increase in the probability or consequences of any accident previously evaluated?

   Response: No.

   The proposed change does not affect accident initiators or precursors nor adversely alter the design assumptions, conditions, and configuration of the facility. The proposed change does not alter any plant equipment or operating practices with respect to such initiators or precursors in a manner that the probability of an accident is increased. In addition, the actions continue to provide sufficient remedial measures to continue safe operation in lieu of a plant shutdown. The proposed change does not involve a physical change to the ESFAS, nor does it change the safety function of the ESFAS instrumentation or the equipment supported by the ESFAS instrumentation.

   The proposed change permits the extension of the time to restore the redundant automatic actuation logic channel or manual actuation channel to OPERABLE status provided the associated risk is assessed and managed in accordance with an NRC approved RICT Program. The proposed change does not involve a significant increase in the probability of an accident previously evaluated because the change involves no change to the plant or its modes of operation. The proposed change does not increase the consequences of an accident because the design basis mitigation function of the ESFAS instrumentation and supported systems is not changed and the consequences of an accident during the extended Completion Time are no different from those during the existing Completion Time

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any previously evaluated?

   Response: No

   With respect to a new or different kind of accident, there are no proposed design changes to the ESFAS; nor are there any changes in the method by which safety related plant structures systems and components perform their specified safety functions. The proposed change will not affect the method of plant operation or revise any operating parameters. No new accident scenarios, transient precursor, failure mechanisms, or limiting single failures will be introduced as a result of this proposed change and the failure modes and effects analyses of SSCs important to safety are not altered as a result of this change.

   The proposed change does not alter the design or performance of the ESFAS, rather, the change permits the extension of the time to restore the redundant automatic actuation logic channel or manual actuation channel to OPERABLE status provided the associated risk is assessed and managed in accordance with an NRC approved RICT Program. The proposed actions provide sufficient remedial measures to continue safe operation in lieu of a plant shutdown. The process to return inoperable instrumentation to service or place the unit in a shutdown condition

uses current procedures, methods, and processes already established and currently in use and, therefore, does not constitute a new type of test.

No changes are being proposed to the procedures that operate the plant equipment and the change does not have a detrimental impact on the manner in which plant equipment operates or responds to an actuation signal.

Therefore, the proposed change will not create the possibility of a new or different accident previously evaluated.

3. Does the proposed change involve a significant reduction in the margin of safety?

   Response: No.

   The margin of safety is related to the ability of the fission product barriers to perform their design functions during and following an accident. These barriers include the fuel cladding, the reactor coolant system, and the containment. The performance of these fission product barriers is not affected by the proposed change.

   Instrumentation safety margin is established by ensuring the limiting safety system settings (LSSSs) automatically actuate the applicable design function to correct an abnormal situation before a safety limit is exceeded. Safety analysis limits are established for reactor trip system and ESFAS instrumentation functions related to those variables having significant safety functions. The proposed actions provide sufficient remedial measures to continue safe operation in lieu of a plant shutdown. In addition, the change does not allow continued operation with a loss of the actuation capability, and therefore, does not alter the capability of the LSSSs to automatically actuate the applicable design function to correct an abnormal situation before a safety limit is exceeded.

   The proposed change does not alter the instrumentation used to monitor a plant variable on which a safety limit has been placed. The change permits the extension of the time to restore the redundant automatic actuation logic channel or manual actuation channel to OPERABLE status provided the associated risk is assessed and managed in accordance with an NRC approved RICT Program.

   The controlling parameters established to actuate supporting systems during an accident or transient are not affected by the proposed change and no design basis or safety limit is altered as a result of the proposed change. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based upon the above analysis, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and accordingly, a finding of no significant hazards consideration is justified.

ACTION 14 - With the number of channels OPERABLE one less than the Minimum Channels OPERABLE, STARTUP and/or POWER OPERATION may continue provided the following conditions are satisfied:

See ITS 3.3.3

a. Verify that one of the inoperable channels has been bypassed and place the other inoperable channel in the tripped condition within 1 hour.

b. All functional units affected by the bypassed/tripped channel shall also be placed in the bypassed/tripped condition as listed below.

Process Measurement Circuit	Functional Unit Bypassed/Tripped
1. Containment Pressure -	Containment Pressure – High (SIAS, CIAS, CSAS) Containment Pressure – High (RPS)
2. Steam Generator Pressure -	Steam Generator Pressure – Low (MSIS) AFAS-1 and AFAS-2 (AFAS) Thermal Margin/Low Pressure (RPS) Steam Generator Pressure – Low (RPS)
3. Steam Generator Level -	Steam Generator Level – Low (RPS) If SG-2A, then AFAS-1 (AFAS) If SG-2B, then AFAS-2 (AFAS)
4. Pressurizer Pressure -	Pressurizer Pressure – High (RPS) Pressurizer Pressure – Low (SIAS) Thermal Margin/Low Pressure (RPS)

ACTION 15 - With the number of OPERABLE channels one less than the Total Number of Channels, restore the inoperable channels to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

See ITS 3.3.4

ACTION 16 - With the number of OPERABLE channels one less than the Total Number of Channels, restore the inoperable channel to OPERABLE status within 48 hours or declare the associated valve inoperable and take the ACTION required by Specification 3.7.1.5.

ACTION 17A - ~~With the number of OPERABLE Channels one less than the Total Number of Channels,~~ restore the inoperable channel to OPERABLE status within 48 hours or place ~~the inoperable~~ channel in ~~the~~ tripped ~~condition and verify that the Minimum Channels OPERABLE requirement is demonstrated~~ within ~~1~~ hour; one ~~additional~~ channel may be bypassed for up to 2 hours for surveillance testing ~~per Specification 4.3.2.1.~~

ACTION 18A - With the number of OPERABLE Channels one less than the Total Number of Channels, operation may proceed provided the following conditions are satisfied:

See ITS 3.3.3

a. The inoperable channel is placed in either the bypassed or tripped condition and the Minimum Channels OPERABLE requirement is demonstrated within 1 hour. If the inoperable channel can not be restored to OPERABLE status within 48 hours, then place the inoperable channel in the tripped condition.

b. With a channel process measurement circuit that affects multiple functional units inoperable or in test, bypass or trip all associated functional units as listed in ACTION 13.

ACTION 18B - With the number of channels OPERABLE one less than the Minimum Channels OPERABLE, operation may proceed provided one of the inoperable channels has been bypassed and the other inoperable channel has been placed in the tripped condition within 1 hour. Restore one of the inoperable channels to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours.

ACTION 19 - With the number of OPERABLE Channels one less than the Total Number of Channels, operation may proceed provided the following conditions are satisfied:

a. Within 1 hour the inoperable channel is placed in either the bypassed or tripped condition. If OPERABILITY cannot be restored within 48 hours or in accordance with the Risk Informed Completion Time Program, be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours.

b. The Minimum Channels OPERABLE requirement is met; however, one additional channel may be bypassed for up to 2 hours for surveillance testing per Specification 4.3.2.1.

(1) Testing of Automatic Actuation Logic shall include energization/de-energization of each initiation relay (solid-state component) and verification of the OPERABILITY of each initiation relay (solid-state component).

(2) An actuation relay test shall be performed which shall include the energization/de-energization of each actuation relay and verification of the OPERABILITY of each actuation relay.

(3) A subgroup relay test shall be performed which shall include the energization/de-energization of each subgroup relay and verification of the OPERABILITY of each subgroup relay. Testing of the ESFAS subgroup relays shall be performed in accordance with the Surveillance Frequency Control Program.

See ITS 3.3.4

DISCUSSION OF CHANGES
ITS 3.3.5, DIESEL GENERATOR (DG) – LOSS OF VOLTAGE START (LOVS)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 *(Category 4 – Relaxation of Required Action)* CTS Table 3.3-3 Actions describe the Actions to be taken when diesel generator (DG) loss of voltage start (LOVS) Function instrument channels are inoperable. ITS 3.3.5 also describes Actions to be taken when DG – LOVS Function instrument channels are inoperable and contains a note that separate condition entry is allowed for each DG – LOVS Function. This changes the CTS by adding a Note stating that separate condition entry is allowed for each Function, those Functions being DG – LOVS 4.16 kV and 480 V loss of voltage and degraded voltage Functions.

The purpose of the CTS Actions is to provide the appropriate compensatory actions for inoperable DG-LOVS Functions. This proposed change will allow separate condition entry for each DG-LOVS Function. The Note clarifies that DG-LOVS Functions are treated as separate entities, each with separate Completion Times. The Conditions of this Specification may be entered independently for each DG-LOVS Function in the LCO. Completion Times for the inoperable channel of a Function will be tracked separately. These changes are acceptable since the proposed Required Actions provide sufficient time to satisfy the Required Actions. Inoperable instrument channels are normally found one at a time, not concurrently. Therefore, the Actions to be taken when DG-LOVS Function instrument channels are inoperable apply as each Function is found to be inoperable and not at the same time. This change is designated as an administrative change and is acceptable because it does not result in technical changes to the CTS.

A03 Unit 1 CTS 4.3.2.1.3 and Unit 2 CS 4.3.2.3 require ENGINEERED SAFETY FEATURES RESPONSE TIME testing of "each" ESFAS function. ITS 3.3.5 does not include response time testing for the DG-LOVS Instrumentation Functions. This changes the CTS by clearly identifying that the ENGINEERED SAFETY FEATURES RESPONSE TIME testing does not apply to the DG-LOVS Instrumentation Functions.

The purpose of Unit 1 CTS 4.3.2.1.3 and Unit 2 CTS 4.3.2.3 is to ensure that the actuation response times, when applicable to a Function, are less than or equal to the maximum values assumed in the accident analysis. The Unit 1 UFSAR Table 13.8.2-2, states that the ENGINEERED SAFETY FEATURES RESPONSE TIME testing is not applicable to the 4.16 kV Loss of Voltage and Degraded Voltage Functions, and the 480 V Degraded Voltage Function. The Unit 2 UFSAR Table 13.7.2-2, states that the ENGINEERED SAFETY FEATURES RESPONSE TIME testing is not applicable to the 4.16 kV Loss of Voltage and

Degraded Voltage Functions, and the 480 V Loss of Voltage and Degraded Voltage Functions. The response time surveillance test acceptance criteria for Technical Specification 3/4.3.2 was relocated by License Amendment No. 128 (Unit 1) and License Amendment No. 67 (Unit 2) and NRC Safety Evaluation dated July 12, 1994. The measurement of engineered safety features actuation systems instrumentation response times at the specified frequencies provides assurance that the ESF action function associated with each channel is completed within the time limit assumed in the accident analyses. No credit is taken in the analyses for those channels with response times indicated as not applicable. Therefore, this change is acceptable since ENGINEERED SAFETY FEATURES RESPONSE TIME testing of the Loss of Voltage and Degraded Voltage Functions is not required. This change is designated as administrative because it does not result in technical changes to the CTS.

A04 CTS Table 3.3-3 for ESFAS instrumentation has three columns stating various requirements for each function. These columns are labeled, "TOTAL NO. OF CHANNELS," "CHANNELS TO TRIP," and "MINIMUM CHANNELS OPERABLE." ITS 3.3.5 does not retain the "TOTAL NO. OF CHANNELS" or "CHANNELS TO TRIP" columns. DOC LA01 describes the change that moves the information of the "TOTAL NO. OF CHANNELS" and "CHANNELS TO TRIP" columns to the Bases. This changes the CTS by changing the "MINIMUM CHANNELS OPERABLE" column to "REQUIRED CHANNELS OPERABLE" and changes the number of channels to 2 per bus for Unit 1 Functional Units 6.a, 6.b, and 6.c, and changes the number of channels to 2 per bus for Unit 2 Functional Unit 6.a.(1) and to 3 per bus for Unit 2 Functional Units 6.a.(2), 6.b.(1), and 6.b.(2). Additionally, the revised "MINIMUM CHANNELS OPERABLE" criteria are moved to the ITS 3.3.5 LCO statement and the "MINIMUM CHANNELS OPERABLE" column is deleted from CTS Table 3.3-3. This change is designated as administrative because it does not result in a technical change to the CTS. | R1

MORE RESTRICTIVE CHANGES

M01 CTS Tables 3.3-3 and 4.3-2 requirements for the Degraded Voltage and Loss of Voltage Functional Units are applicable in MODES 1, 2, and 3. ITS 3.3.5 requires the Degraded Voltage and Loss of Voltage Functions to be OPERABLE in MODES 1, 2, 3, and 4, and when the associated EDG is required to be OPERABLE by LCO 3.8.2, "AC Sources - Shutdown." This changes the CTS by expanding the conditions under which the Degraded Voltage and Loss of Voltage Functions must be OPERABLE.

This change is acceptable because requiring the Degraded Voltage and Loss of Voltage Functions to be OPERABLE when LCO 3.8.2 requires an EDG to be OPERABLE ensures that the automatic loss of power start of the EDG is available when needed. This change is designated as more restrictive because it expands the applicability in which equipment is required to be OPERABLE.

M02 **Unit 2 only:** *(Category 3 - Relaxation of Completion Time)* CTS Table 3.3-3 Action 17A requires that, with the number of OPERABLE channels one less than the total number of channels per DG, restore the inoperable channel to

OPERABLE status within 48 hours (2 channels per DG Function) or place the inoperable channel in trip within 1 hour. Action 17A applies to the 2 channels per DG 4.16 kV Loss of Voltage Function. CTS Table 3.3-3 Action 17B requires that, with the number of OPERABLE channels one less than the total number of channels per DG, restore the inoperable channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time (3 channels per DG Functions), or place the inoperable channel in trip within 1 hour. Action 17B applies to the 3 channels per DG 4.16 kV Degraded Voltage Function, 3 channels per DG 480 Loss of Voltage Function, and 3 channels per DG 480V Degraded Voltage Function.

ITS 3.3.5 retains the current licensing basis with time allotted to restore the inoperable channel to OPERABLE status before requiring the inoperable channel be placed in trip. ITS 3.3.5 ACTION A is consistent with CTS Action 17A. ITS 3.3.5 ACTION B is consistent with CTS Action 17B. The CTS Actions use an "or" connector. ITS ACTIONS that use an "OR" connector use the same Completion Time. This changes the CTS by eliminating the allowance to place the channel in trip within 1 hour after the channel is not restored within the required Completion Time and instead requires the channel to be placed in trip within 48 hours (ACTION A), and within the same 48 hours or in accordance with the Risk Informed Completion Time (ACTION B), consistent with the time currently allotted to restore the inoperable channel to OPERABLE status. If the actions (i.e., restore or trip the inoperable channel) cannot be completed within the required Completion Time, the associated DG must be immediately declared inoperable. This change is acceptable because if the inoperable channel is not restored to OPERABLE status within the associated Completion Time, the channel is placed in trip. However, the ITS 3.3.5 time to trip the channel is 1 hour less than the time allotted in CTS. If the inoperable channel is not restored to OPERABLE status with 48 hours (ACTION A), or within 48 hours or in accordance with the Risk Informed Completion Time (ACTION B), the DG is immediately declared inoperable (ACTION D). This change is designated as more restrictive because it reduces the Completion Time for a CTS Required Action.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.2.1 Table 3.3-4, ESFAS Instrumentation Trip Values, has two columns stating trip setpoints and allowable values for each Function. Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.2.1 require the ESFAS instrumentation setpoints to be set consistent with the Trip Setpoint values shown in Table 3.3-4. However, the CTS Action is only required to be taken when the setpoint is less conservative than the Allowable Value column of Table 3.3-4. When the setpoint is less conservative than the Allowable Value, the channel is to be declared inoperable and adjusted consistent with the

Trip Setpoint value. CTS Table 3.3-4 specifies both the Trip Setpoints and Allowable Values for the ESFAS Actuation Instrumentation DG-LOVS Functional Units. ITS 3.3.5 requires the instrumentation for each DG-LOVS Function in the LCO to be OPERABLE. ITS SR 3.3.5.3 specifies only the Allowable Values for the DG-LOVS Instrumentation Functions. The Allowable Values represent the OPERABILITY limit of the channels in ITS. This changes the CTS by moving the Trip Setpoints to the Technical Requirements Manual (TRM).

The purpose of the trip setpoint requirements is to ensure required automatic safety systems are actuated to protect against violating core design limits, breaching the Reactor Coolant System pressure boundary, and to mitigate accidents. Pursuant to 10 CFR 50.36(c)(1)(ii)(A), if it is determined that an automatic protective device for a variable on which a safety limit has been placed (i.e., limiting safety system setting) does not function as required, appropriate action is taken to ensure the abnormal situation is corrected before a safety limit is exceeded, which may include shutting down the reactor. The PSL Instrument Setpoint Methodology calculates nominal trip setpoints (NTSPs) using methods consistent with the guidance provided in NRC Regulatory Guide 1.105, “Setpoints For Safety-Related Instrumentation,” and ANSI/ISA Standard 67.04, "Setpoints for Nuclear Safety-Related Instrumentation." Additionally, pre-defined limits (double-sided Operability limits and as-left limits) are determined for each instrument consistent with the guidance provided in NRC Regulatory Guide 1.105 and ANSI/ISA–RP67.04, “Methodologies for the Determination of Setpoints for Nuclear Safety-Related Instrumentation.” The instrument Operability limit band in plant uncertainty calculations is synonymous with the as-found acceptance criteria band specified in ITS and is centered about the nominal equipment setting (clarified in calculations as the field trip setpoint or NTSP). The PSL Instrument Setpoint Methodology, including the method of determining instrument uncertainties, was reviewed by the NRC during the review of Extended Power Uprate (EPU) as documented in the EPU safety evaluations for License Amendments 213 (Unit 1) and 163 (Unit 2), dated July 9, 2012 and September 24, 2012, respectively (NRC ADAMS Accession Nos. ML12181A019 and ML12235A463). The NRC staff determined that the PSL Instrument Setpoint Methodology described in the EPU license request meets the requirements of 10 CFR 50, Appendix A, General Design Criterion 13 and the regulatory guidance in RG 1.105 (EPU SE pg. 92 (Unit 1) and 95 (Unit 2)). The NRC staff also determined that the application of the clarifications of RG 1.105 in Regulatory Issue Summary 2006-17 “NRC Staff Position on the Requirements of 10 CFR 50.36, ‘Technical Specifications,’ Regarding Limiting Safety System Settings During Periodic Testing and Calibration of Instrument Channels,” is acceptable (EPU SE pg. 94 (Unit 1) and 97 (Unit 2)). | R1

The removal of these details for meeting Technical Specification requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the Allowable Values associated with the DG-LOVS Instrumentation, which are designated as the Operability limits for the required instrument Functions. Also, this change is acceptable because these types of procedural details will be adequately controlled in the TRM. Any changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is

designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS Table 3.3-3 for ESFAS instrumentation has three columns stating various requirements for each function. These columns are labeled, "TOTAL NO. OF CHANNELS," "CHANNELS TO TRIP," and "MINIMUM CHANNELS OPERABLE." ITS 3.3.5 does not retain the "TOTAL NO. OF CHANNELS" or "CHANNELS TO TRIP" columns. This changes the CTS by moving the information of the "TOTAL NO. OF CHANNELS" and "CHANNELS TO TRIP" columns to the Bases. The MINIMUM CHANNELS OPERABLE" column is deleted as described in discussion of change (DOC) A03. | R1

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS 3.3.5 LCO still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS Table 3.3-3 Functional Units 6.a - 4.16 kV Loss of Voltage, 6.b – 4.16 kV Degraded Voltage, and 6.c – 480 V Degraded Voltage require 2 channels per DG for each Function. Unit 2 CTS Table 3.3-3 Functional Units 6.a.(1) - 4.16 kV Loss of Voltage requires 2 channels per DG. Unit 2 CTS Functional Units 6.a.(2) 480 V Loss of Voltage, 6.b.(1) – 4.16 kV Degraded Voltage, and 6.b.(2) – 480 V Degraded Voltage each require 3 channels per DG. However, CTS Table 3.3-3 only describes the Actions to be taken when one channel per DG is inoperable for a DG-LOVS Function. ITS LCO 3.3.5 states the DG-LOVS Functions and maintains the same operable channels per DG requirements as CTS. ITS also provides actions to be taken when one diesel generator (DG) loss of voltage start (LOVS) Function instrument channel is inoperable (Unit 1 ACTION A and Unit 2 ACTIONS A and B). Note that the Unit 2 DG-LOVS Function channel operability requirements differ for the Unit 2 CTS Functional Units: 6.a.(1)) - 4.16 kV Loss of Voltage requires 2 channels per DG (Unit 2 ACTION A), and Functional Units 6.a.(2) 480 V Loss of Voltage, 6.b.(1) – 4.16 kV Degraded Voltage, and 6.b.(2) – 480 V Degraded Voltage each require 3 channels per DG (Unit 2 ACTION B).

Additionally, ITS provides Actions for one or more DG-LOVS Functions with two channels per DG inoperable requiring one inoperable channel be restored to OPERABLE status within 1 hour (Unit 1 ACTION B and Unit 2 ACTION C). ITS also provides Actions if the Required Actions and Associated Completion Times are not met requiring the associated DG be declared inoperable immediately (Unit 1 ACTION C and Unit 2 ACTION D). For CTS, if one or more Functions with two or more channels per DG are inoperable, or if the Required Action is not Completed in the associated Completion Time, CTS 3.0.3 is entered since there is no Condition and Action specified in the CTS. This changes the CTS by explicitly providing an ACTION for one or more Functions with two or more channels per DG inoperable, and an ACTION if the Required Action is not Completed in the associated Completion Time.

The purpose of CTS is to ensure that the LOVS-DG logic is in a known configuration either by restoring the inoperable channel to OPERABLE status or by placing the inoperable channel in trip. This change is acceptable because the Completion Time is consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the allowed Completion Time. ITS 3.3.5 retains the CTS requirement to either restore the inoperable channel to OPERABLE status or place the channel in trip when one or more Functions with one channel per DG inoperable. Additionally, ITS provides Actions for one or more DG-LOVS Functions with two channels per DG inoperable requiring one inoperable channel be restored to OPERABLE status within 1 hour (Unit 1 ACTION B and Unit 2 ACTION C). ITS also provides Actions if the Required Actions and Associated Completion Times are not met requiring the associated DG be declared inoperable immediately (Unit 1 ACTION C and Unit 2 ACTION D). This change is designated as less restrictive because the ITS Actions are less restrictive than the CTS Actions.

L02 **Unit 1 only:** *(Category 4 - Relaxation of Required Action)* CTS Table 3.3-3 Action 12 states, in part, that with the number of OPERABLE channels one less than the total number of channels, "operation may proceed until performance of the next required CHANNEL FUNCTIONAL TEST." This CTS Action applies to the Loss of Voltage and Degraded Voltage Functions of CTS Table 3.3-3. ITS 3.3.5 ACTION A is the applicable action for the Loss of Voltage and Degraded Voltage Functions when one channel is inoperable, and does not include the restoration time limit of "until performance of the next required CHANNEL FUNCTIONAL TEST." This changes the CTS by allowing operation with an inoperable channel for an unlimited amount of time provided the inoperable channel is in the tripped condition.

The purpose of CTS Table 3.3-3 Action 12 is to only allow operation until performance of the next required CHANNEL FUNCTIONAL TEST. This requirement is based upon the assumption that when it is time to test the other OPERABLE channels in the associated Function, the OPERABLE channels cannot be tested with the inoperable channel in trip. However, CTS 3.0.6 (ITS LCO 3.0.5) is a generic allowance that will allow the inoperable channel to be restored to service in order to perform Surveillances on the other OPERABLE

channels in the associated Function. Thus, using this generic allowance, it is possible to test the remaining OPERABLE channels in the associated Function, and there is no reason to restrict the generic allowance from applying to these specific channels. As such, the CTS Table 3.3-3 Action 12 statement is not necessary and has been deleted. The administrative controls required by ITS LCO 3.0.5 will ensure the time the channel is returned to service in conflict with the requirements of ITS 3.3.5 ACTION A is limited to the time absolutely necessary to perform the required testing to demonstrate OPERABILITY of the other channels. In addition, this specific example (taking an inoperable channel out of the tripped condition) is discussed in the Bases of ISTS SR 3.0.5. Therefore, this change is acceptable for the reasons described above. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.5, DIESEL GENERATOR (DG) – LOSS OF VOLTAGE START (LOVS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The heading for ISTS 3.3.6 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2). Therefore, ISTS 3.3.2 is not included in the PSL ITS. The successive Specifications are renumbered as necessary.

5

BASES

BACKGROUND

The DGs provide a source of emergency power when offsite power is either unavailable or insufficiently stable to allow safe plant operation. Undervoltage protection will generate a LOVS in the event a Loss of Voltage or Degraded Voltage condition occurs. There are two LOVS Functions for each 4.16 kV vital bus.

INSERT 1

~~Four undervoltage relays with inverse time characteristics are provided on each 4.16 kV Class 1E instrument bus for the purpose of detecting a sustained undervoltage condition or a loss of bus voltage. The relays are combined in a two-out-of-four logic to generate a LOVS if the voltage is below 75% for a short time or below 90% for a long time. The LOVS initiated actions are described in Reference 1.~~

1

Trip Setpoints and Allowable Values

The trip setpoints and Allowable Values are based on the analytical limits presented in Reference 2. The selection of these trip setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, and instrument drift, Allowable Values specified in SR 3.3.~~6~~.3 are conservatively adjusted with respect to the analytical limits. A detailed description of the methodology used to calculate the trip setpoints, including their explicit uncertainties, is provided in Reference 3. The actual nominal trip setpoint is normally still more conservative than that required by the plant specific setpoint calculations. If the measured setpoint does not exceed the documented surveillance trip acceptance criteria, the undervoltage relay is considered OPERABLE.

5

5

Setpoints in accordance with the Allowable Values will ensure that the consequences of accidents will be acceptable, providing the plant is operated from within the LCOs at the onset of the accident and the equipment functions as designed.

~~The undervoltage protection scheme has been designed to protect the plant from spurious trips caused by the offsite power source. This is made possible by the inverse voltage time characteristics of the relays used.~~ A complete loss of offsite power will result in approximately a 1 second delay in LOVS actuation. The DG starts and is available to

1

1

INSERT 1

The 4.16 kV LOVS Functions include Loss of Voltage and Degraded Voltage Functions. The allowable values are provided in SR 3.3.5.3.

Each Class 1E 4.16 kV Bus utilizes two undervoltage definite time delay relays, in a two-out-of-two coincident logic for loss of voltage detection. The function of these relays is to initiate source disconnection, load shedding, diesel generator starting, and load sequencing on the effected train (bus). The LOVS initiated actions are described in Reference 1. R1

Each Class 1E 4.16 kV Bus utilizes two sets of 2 undervoltage definite time delay relays in a two-out-of-two coincident logic for degraded voltage detection. The function of these relays is the same as described for the loss of voltage detection. R1

Each Class 1E 480V Bus utilizes two undervoltage definite time delay relays in a two-out-of-two coincident logic scheme for degraded voltage detection. R1

BASES

BACKGROUND (continued)

accept loads within a 10 second time interval on the Engineered Safety Features Actuation System (ESFAS) or LOVS. Emergency power is established within the maximum time delay assumed for each event analyzed in the accident analysis (Ref. 2).

INSERT 2 →

~~Since there are four protective channels in a two-out-of-four trip logic for each division of the 4.16 kV power supply, no single failure will cause or prevent protective system actuation. This arrangement meets IEEE Standard 279-1971 criteria (Ref. 4).~~

1

APPLICABLE SAFETY ANALYSES

The DG - LOVS is required for Engineered Safety Features (ESF) systems to function in any accident with a loss of offsite power. Its design basis is that of the ESFAS.

Accident analyses credit the loading of the DG based on a loss of offsite power during a loss of coolant accident. The actual DG start has historically been associated with the ESFAS actuation. The diesel loading has been included in the delay time associated with each safety system component requiring DG supplied power following a loss of offsite power. ~~The analysis assumes a nonmechanistic DG loading, which does not explicitly account for each individual component of the loss of power detection and subsequent actions.~~ This delay time includes contributions from the DG start, DG loading, and Safety Injection System component actuation. The response of the DG to a loss of power must be demonstrated to fall within this analysis response time when including the contributions of all portions of the delay.

1

The required channels of LOVS, in conjunction with the ESF systems powered from the DGs, provide plant protection in the event of any of the analyzed accidents discussed in Reference 2, in which a loss of offsite power is assumed. LOVS channels are required to meet the redundancy and testability requirements of GDC 21 in 10 CFR 50, Appendix A (Ref. ~~5~~).

6

The delay times assumed in the safety analysis for the ESF equipment include the ~~[~~10~~]~~ second DG start delay and the appropriate sequencing delay, if applicable. The response times for ESFAS actuated equipment include the appropriate DG loading and sequencing delay.

The DG - LOVS channels satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

two DG

The LCO for the LOVS requires that ~~four~~ channels per ~~bus~~ of each LOVS instrumentation Function be OPERABLE in MODES 1, 2, 3, and 4 and when the associated DG is required to be OPERABLE by LCO 3.8.2, "AC Sources - Shutdown." The LOVS supports safety systems associated

1

1

INSERT 2

The Class 1E 4.16 kV system and Class 1E 480 V system are designed to meet the single failure criteria as defined in IEEE 308 (Ref. 4) and IEEE 279 (Ref. 5). Specifically, any credible single failure shall not prevent the satisfactory performance of the minimum Class 1E 4.16 kV loads or Class 1E 480 V loads required to achieve and maintain safe shutdown or to monitor or mitigate the consequences of any design basis accident or event. The worst case single failure will disable only one train of the Class 1E 4.16 kV or Class 1E 480 V system. | R1

BASES

LCO (continued)

with the ESFAS. In MODES 5 and 6, the ~~four~~ two channels must be OPERABLE whenever the associated DG is required to be OPERABLE to ensure that the automatic start ovf the DG is available when needed.

~~Actions allow maintenance (trip channel) bypass of individual channels. Plants are restricted to 48 hours in a trip channel bypass condition before either restoring the Function to four channel operation (two-out-of-four logic) or placing the channel in trip (one-out-of-three logic). At plants where adequate channel to channel independence has been demonstrated, specific exceptions have been approved by the NRC staff to permit one of the two-out-of-four channels to be bypassed for an extended period of time.~~ 1

~~Loss of LOVS Function could result in the delay of safety system initiation when required. This could lead to unacceptable consequences during accidents. During the loss of offsite power, which is an anticipated operational occurrence, the DG powers the motor driven auxiliary feedwater pumps. Failure of these pumps to start would leave only the one turbine driven pump as well as an increased potential for a loss of decay heat removal through the secondary system.~~ 1

Only Allowable Values are specified for each Function in the LCO. Nominal trip setpoints are specified in the plant specific setpoint calculations. The nominal setpoints are selected to ensure that the setpoint measured by CHANNEL FUNCTIONAL TESTS does not exceed the Allowable Value if the bistable is performing as required. Operation with a trip setpoint less conservative than the nominal trip setpoint, but within the Allowable Value, is acceptable, provided that operation and testing are consistent with the assumptions of the plant specific setpoint calculation. A channel is inoperable if its actual trip setpoint is not within its required Allowable Value.

~~[For this unit, the Bases for the Allowable Values and trip setpoints are as follows:]~~ 1

APPLICABILITY

The DG - LOVS actuation Function is required in MODES 1, 2, 3, and 4 because ESF Functions are designed to provide protection in these MODES. Actuation in MODE 5 or 6 is required whenever the required DG must be OPERABLE, so that it can perform its function on a loss of power or degraded power to the vital bus.

ACTIONS

A LOVS channel is inoperable when it does not satisfy the OPERABILITY criteria for the channel's Function. The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the plant specific setpoint

BASES

ACTIONS (continued)

analysis. Typically, the drift is found to be small and results in a delay of actuation rather than a total loss of function. Determination of setpoint drift is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the instrument is set up for adjustment to bring it within specification. If the actual trip setpoint is not within the Allowable Value, the channel is inoperable and the appropriate Conditions must be entered.

In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value, or the channel is found inoperable, then all affected Functions provided by that channel must be declared inoperable and the LCO Condition entered. The required channels are specified on a per DG basis.

~~When the number of inoperable channels in a trip Function exceeds those specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be entered immediately if applicable in the current MODE of operation.~~

A Note has been added to the ACTIONS to clarify the application of Completion Time rules. The Conditions of this LCO may be entered independently for each Function. The Completion Time(s) of the inoperable channel(s)/train(s) of a Function will be tracked separately for each Function, starting from the time the Condition was entered for that Function.

A.1~~, A.2.1, and A.2.2~~

Condition A applies if one channel is inoperable for one or more Functions per DG bus.

If the channel cannot be restored to OPERABLE status, the affected channel should ~~either~~ be ~~bypassed or~~ tripped within 1 hour (Required Action A.1).

the this

Placing ~~this~~ channel in ~~either~~ Condition ensures that logic is in a known configuration. In trip, the LOVS Logic is one-out-of-~~three~~. ~~In bypass, the LOVS Logic is two-out-of-three.~~ The 1 hour Completion Time is sufficient to perform the~~se~~ Required Action~~s~~.

one

~~Once Required Action A.1 has been complied with, Required Action A.2.1 allows [48] hours to repair the inoperable channel for those plants that have not demonstrated sufficient channel to channel independence on this Function. [Alternatively, a Completion Time can be determined in~~

BASES

ACTIONS (continued)

~~accordance with the Risk Informed Completion Time Program.] If the channel cannot be restored to OPERABLE status, it must be tripped in accordance with Required Action A.2.2. The time allowed to repair or trip the channel is reasonable to repair the affected channel while ensuring that the risk involved in operating with the inoperable channel is acceptable. The [48] hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel is a rare event during any given [48] hour period. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 1

B.1~~, B.2.1, and B.2.2~~ 3

Condition B applies if two channels are inoperable for one or more Functions per DG.

either

Condition C is entered and the affected DG is declared inoperable.

If ~~the~~ channel cannot be restored to OPERABLE status within 1 hour, ~~the Conditions and Required Actions for the associated DG made inoperable by DG - LOVS instrumentation are required to be entered. Alternatively, one affected channel is required to be bypassed and the other is tripped, in accordance with Required Action B.2.1. This places the Function in one-out-of-two logic.~~ The 1 hour Completion Time is sufficient to perform the Required Actions. 1 1

~~Once Required Action B.2.1 has been complied with, Required Action B.2.2 allows [48] hours to repair the bypassed or inoperable channel. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 1

After one channel is restored to OPERABLE status, the provisions of Condition A still apply to the remaining inoperable channel. ~~Therefore, the channel that is still inoperable after completion of Required Action B.2.2 shall be placed in trip if more than [48] hours have elapsed since the initial channel failure. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 1

~~C.1~~

~~Condition C applies when more than two undervoltage or Degraded Voltage channels on a single bus are inoperable.~~ 1

BASES

ACTIONS (continued)

~~Required Action C.1 requires all but two channels to be restored to OPERABLE status within 1 hour [or in accordance with the Risk Informed Completion Time Program]. With more than two channels inoperable, the logic is not capable of providing a DG - LOVS signal for valid Loss of Voltage or Degraded Voltage conditions. The 1 hour Completion Time is reasonable to evaluate and take action to correct the degraded condition in an orderly manner and takes into account the low probability of an event requiring LOVS occurring during this interval.~~

C.1

Condition ~~D~~ applies if the Required Actions and associated Completion Times are not met.

Required Action ~~D~~.1 ~~ensures that Required Actions for~~ the affected DG inoperabi~~liti~~e~~s are initiated~~. Depending upon plant MODE, the actions specified in LCO 3.8.1, "AC Sources - Operating," or LCO 3.8.2 are required immediately.

SURVEILLANCE REQUIREMENTS

The following SRs apply to each DG - LOVS Function.

~~[~~ SR 3.3.~~6~~.1

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the indicated output of the potential transformers that feed the LOVS undervoltage relays. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two channels could be an indication of excessive drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff, based on a combination of the channel instrument uncertainties, including indication and readability. If the channels are within the criteria, it is an indication that the channels are OPERABLE. ~~]~~

~~[The Frequency, about once every shift, is based upon operating experience that demonstrates channel failure is rare. Since the probability of two random failures in redundant channels in any 12 hour period is extremely low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The~~

SURVEILLANCE REQUIREMENTS (continued)

~~CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of the displays associated with the LCO required channels.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 2

5
SR 3.3.~~6~~.2 3

A CHANNEL FUNCTIONAL TEST is performed to ensure that the entire channel will perform its intended function when needed. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

~~[The Frequency of [92] days is based on plant operating experience with regard to channel OPERABILITY and drift, which demonstrates that failure of more than one channel of a given function in any [92] day Frequency is a rare event. Any setpoint adjustment shall be consistent with the assumptions of the current plant specific setpoint analysis.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the surveillance interval extension analysis. ~~There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology.~~

SR 3.3.~~6~~.3

SR 3.3.~~6~~.3 is the performance of a CHANNEL CALIBRATION. The CHANNEL CALIBRATION verifies the accuracy of each component within the instrument channel. This includes calibration of the undervoltage relays and demonstrates that the equipment falls within the specified operating characteristics defined by the manufacturer.

The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. The~~re is a plant specific program which~~ verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

The setpoints, as well as the response to a Loss of Voltage and Degraded Voltage test, shall include a single point verification that the trip occurs within the required delay time as shown in Reference 1. ~~[The Frequency is based upon the assumption of an [18] month calibration interval for the determination of the magnitude of equipment drift in the setpoint analysis.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

5

BASES

BACKGROUND

The DGs provide a source of emergency power when offsite power is either unavailable or insufficiently stable to allow safe plant operation. Undervoltage protection will generate a LOVS in the event a Loss of Voltage or Degraded Voltage condition occurs. There are two LOVS Functions for each 4.16 kV vital bus.

INSERT 1

~~Four undervoltage relays with inverse time characteristics are provided on each 4.16 kV Class 1E instrument bus for the purpose of detecting a sustained undervoltage condition or a loss of bus voltage. The relays are combined in a two-out-of-four logic to generate a LOVS if the voltage is below 75% for a short time or below 90% for a long time. The LOVS initiated actions are described in Reference 1.~~

1

Trip Setpoints and Allowable Values

The trip setpoints and Allowable Values are based on the analytical limits presented in Reference 2. The selection of these trip setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, and instrument drift, Allowable Values specified in SR 3.3.~~6~~.3 are conservatively adjusted with respect to the analytical limits. A detailed description of the methodology used to calculate the trip setpoints, including their explicit uncertainties, is provided in Reference 3. The actual nominal trip setpoint is normally still more conservative than that required by the plant specific setpoint calculations. If the measured setpoint does not exceed the documented surveillance trip acceptance criteria, the undervoltage relay is considered OPERABLE.

5

5

Setpoints in accordance with the Allowable Values will ensure that the consequences of accidents will be acceptable, providing the plant is operated from within the LCOs at the onset of the accident and the equipment functions as designed.

~~The undervoltage protection scheme has been designed to protect the plant from spurious trips caused by the offsite power source. This is made possible by the inverse voltage time characteristics of the relays used.~~ A complete loss of offsite power will result in approximately a 1 second delay in LOVS actuation. The DG starts and is available to

1

1

INSERT 1

The 4.16 kV LOVS Functions include Loss of Voltage and Degraded Voltage Functions. The allowable values are provided in SR 3.3.5.3.

Each Class 1E 4.16 kV Bus utilizes two solid-state undervoltage relays, in a two-out-of-two coincident logic, for loss of voltage detection. The function of these relays is to initiate source disconnection, load shedding, diesel generator starting, and load sequencing on the effected train (bus). The LOVS initiated actions are described in Reference 1. | R1

Each Class 1E 4.16 kV Bus utilizes three solid state undervoltage relays in a two-out-of-three coincident logic for degraded voltage detection. The function of these relays is the same as described for the loss of voltage detection. | R1

Each Class 1E 480V Bus utilizes three solid state undervoltage relays in a two-out-of-three coincident logic scheme, for loss of voltage detection. | R1

Each Class 1E 480V Bus utilizes three solid state undervoltage relays in a two-out-of-three coincident logic scheme, for degraded voltage detection. | R1

BASES

BACKGROUND (continued)

accept loads within a 10 second time interval on the Engineered Safety Features Actuation System (ESFAS) or LOVS. Emergency power is established within the maximum time delay assumed for each event analyzed in the accident analysis (Ref. 2).

INSERT 2 →

~~Since there are four protective channels in a two-out-of-four trip logic for each division of the 4.16 kV power supply, no single failure will cause or prevent protective system actuation. This arrangement meets IEEE Standard 279-1971 criteria (Ref. 4).~~

1

APPLICABLE SAFETY ANALYSES

The DG - LOVS is required for Engineered Safety Features (ESF) systems to function in any accident with a loss of offsite power. Its design basis is that of the ESFAS.

Accident analyses credit the loading of the DG based on a loss of offsite power during a loss of coolant accident. The actual DG start has historically been associated with the ESFAS actuation. The diesel loading has been included in the delay time associated with each safety system component requiring DG supplied power following a loss of offsite power. ~~The analysis assumes a nonmechanistic DG loading, which does not explicitly account for each individual component of the loss of power detection and subsequent actions.~~ This delay time includes contributions from the DG start, DG loading, and Safety Injection System component actuation. The response of the DG to a loss of power must be demonstrated to fall within this analysis response time when including the contributions of all portions of the delay.

1

The required channels of LOVS, in conjunction with the ESF systems powered from the DGs, provide plant protection in the event of any of the analyzed accidents discussed in Reference 2, in which a loss of offsite power is assumed. LOVS channels are required to meet the redundancy and testability requirements of GDC 21 in 10 CFR 50, Appendix A (Ref. ~~5~~).

6

The delay times assumed in the safety analysis for the ESF equipment include the ~~[~~10~~]~~ second DG start delay and the appropriate sequencing delay, if applicable. The response times for ESFAS actuated equipment include the appropriate DG loading and sequencing delay.

The DG - LOVS channels satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

two channels per DG of the 4.16 kV Loss of Voltage Function; and three channels per DG of the 4.16 kV Degraded Voltage, 480 V Loss of Voltage, and 480 V Degraded Voltage Functions →

The LCO for the LOVS requires that ~~four channels per bus of each LOVS instrumentation Function~~ be OPERABLE in MODES 1, 2, 3, and 4 and when the associated DG is required to be OPERABLE by LCO 3.8.2, "AC Sources - Shutdown." The LOVS supports safety systems associated

1

1

INSERT 2

The Class 1E 4.16 kV system and Class 1E 480 V system are designed to meet the single failure criteria as defined in IEEE 308 (Ref. 4) and IEEE 279 (Ref. 5). Specifically, any credible single failure shall not prevent the satisfactory performance of the minimum Class 1E 4.16kV loads or Class 1E 480 V loads required to achieve and maintain safe shutdown or to monitor or mitigate the consequences of any design basis accident or event. The worst case single failure will disable only one train of the Class 1E 4.16 kV or Class 1E 480 V system. | R1

3

5

BASES

LCO (continued)

two channels per DG of the 4.16 kV Loss of Voltage Function; and three channels per DG of the 4.16 kV Degraded Voltage, 480 V Loss of Voltage, and 480 V Degraded Voltage Functions

with the ESFAS. In MODES 5 and 6, the ~~four channels~~ must be OPERABLE whenever the associated DG is required to be OPERABLE to ensure that the automatic start of the DG is available when needed.

~~Actions allow maintenance (trip channel) bypass of individual channels. Plants are restricted to 48 hours in a trip channel bypass condition before either restoring the Function to four channel operation (two-out-of-four logic) or placing the channel in trip (one-out-of-three logic). At plants where adequate channel to channel independence has been demonstrated, specific exceptions have been approved by the NRC staff to permit one of the two-out-of-four channels to be bypassed for an extended period of time.~~

1

~~Loss of LOVS Function could result in the delay of safety system initiation when required. This could lead to unacceptable consequences during accidents. During the loss of offsite power, which is an anticipated operational occurrence, the DG powers the motor driven auxiliary feedwater pumps. Failure of these pumps to start would leave only the one turbine driven pump as well as an increased potential for a loss of decay heat removal through the secondary system.~~

1

Only Allowable Values are specified for each Function in the LCO. Nominal trip setpoints are specified in the plant specific setpoint calculations. The nominal setpoints are selected to ensure that the setpoint measured by CHANNEL FUNCTIONAL TESTS does not exceed the Allowable Value if the bistable is performing as required. Operation with a trip setpoint less conservative than the nominal trip setpoint, but within the Allowable Value, is acceptable, provided that operation and testing are consistent with the assumptions of the plant specific setpoint calculation. A channel is inoperable if its actual trip setpoint is not within its required Allowable Value.

~~[For this unit, the Bases for the Allowable Values and trip setpoints are as follows:]~~

1

APPLICABILITY

The DG - LOVS actuation Function is required in MODES 1, 2, 3, and 4 because ESF Functions are designed to provide protection in these MODES. Actuation in MODE 5 or 6 is required whenever the required DG must be OPERABLE, so that it can perform its function on a loss of power or degraded power to the vital bus.

ACTIONS

A LOVS channel is inoperable when it does not satisfy the OPERABILITY criteria for the channel's Function. The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the plant specific setpoint

3

1

ACTIONS (continued)

analysis. Typically, the drift is found to be small and results in a delay of actuation rather than a total loss of function. Determination of setpoint drift is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the instrument is set up for adjustment to bring it within specification. If the actual trip setpoint is not within the Allowable Value, the channel is inoperable and the appropriate Conditions must be entered.

In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value, or the channel is found inoperable, then all affected Functions provided by that channel must be declared inoperable and the LCO Condition entered. The required channels are specified on a per DG basis.

~~When the number of inoperable channels in a trip Function exceeds those specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be entered immediately if applicable in the current MODE of operation.~~ 1

A Note has been added to the ACTIONS to clarify the application of Completion Time rules. The Conditions of this LCO may be entered independently for each Function. The Completion Time(s) of the inoperable channel(s)/train(s) of a Function will be tracked separately for each Function, starting from the time the Condition was entered for that Function.

A.1~~, A.2.1, and A.2.2~~ 4.16 kV Loss of Voltage Function channel per DG is inoperable. 1

Condition A applies if one ~~channel is inoperable for one or more Functions per DG bus~~.

within 48 hours

If the channel cannot be restored to OPERABLE status, the affected channel should ~~either~~ be ~~bypassed or~~ tripped within ~~1~~ hour (Required Action A.1). 1

48 s

the this

Placing ~~this~~ channel in ~~either~~ Condition ensures that logic is in a known configuration. In trip, the LOVS Logic is one-out-of-~~three~~. ~~In bypass, the LOVS Logic is two-out-of-three.~~ The ~~1~~ hour Completion Time is sufficient to perform the~~se~~ Required Action~~s~~. 1

48 one

INSERT 3

~~Once Required Action A.1 has been complied with, Required Action A.2.1 allows [48] hours to repair the inoperable channel for those plants that have not demonstrated sufficient channel to channel independence on this Function. [Alternatively, a Completion Time can be determined in~~ 1

1

INSERT 3

The Required Actions are modified by a Note that allows one channel to be bypassed for up to 2 hours for surveillance testing. This allowance is based on the average time required to perform the channel surveillance.

BASES

ACTIONS (continued)

~~accordance with the Risk Informed Completion Time Program.] If the channel cannot be restored to OPERABLE status, it must be tripped in accordance with Required Action A.2.2.~~ The time allowed to repair or trip the channel is reasonable to repair the affected channel while ensuring that the risk involved in operating with the inoperable channel is acceptable. The ~~[~~48~~]~~ hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel is a rare event during any given ~~[~~48~~]~~ hour period. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 1

INSERT 4

C → ~~B~~.1~~, B.2.1, and B.2.2~~ 3

C

Condition ~~B~~ applies if two channels or more are inoperable for one or more Functions per DG.

Condition D is entered and the affected DG is declared inoperable.

If the channel cannot be restored to OPERABLE status within 1 hour, ~~the Conditions and Required Actions for the associated DG made inoperable by DG - LOVS instrumentation are required to be entered. Alternatively, one affected channel is required to be bypassed and the other is tripped, in accordance with Required Action B.2.1. This places the Function in one-out-of-two logic.~~ The 1 hour Completion Time is sufficient to perform the Required Actions. 1 1

~~Once Required Action B.2.1 has been complied with, Required Action B.2.2 allows [48] hours to repair the bypassed or inoperable channel. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 1

or Condition B

After one channel is restored to OPERABLE status, the provisions of Condition A still apply to the remaining inoperable channel. ~~Therefore, the channel that is still inoperable after completion of Required Action B.2.2 shall be placed in trip if more than [48] hours have elapsed since the initial channel failure. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~ 1

~~C.1~~

~~Condition C applies when more than two undervoltage or Degraded Voltage channels on a single bus are inoperable.~~ 1

1

INSERT 4

B.1 and B.2

Table 3.3-3
Action 17B

Condition B applies if one or more Functions with one channel per DG inoperable (except 4.16 kV Loss of Voltage Function). The applicable Functions are the 4.16 kV Degraded Voltage Function, 480 V Loss of Voltage Function, and 480 V Degraded Voltage Function.

If the channel cannot be restored to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time (Required Action B.1), the affected channel is placed in trip (Required Action B.2). Placing the channel in this Condition ensures that logic is in a known configuration. In trip, the LOVS Logic is one-out-of-two. The 48 hour Completion Time is sufficient to perform these Required Actions.

The time allowed to repair or trip the channel is reasonable to repair the affected channel while ensuring that the risk involved in operating with the inoperable channel is acceptable. The 48 hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel is a rare event during any given 48 hour period. Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.

The Required Actions are modified by a Note that allows one channel to be bypassed for up to 2 hours for surveillance testing. This allowance is based on the average time required to perform the channel surveillance.

BASES

ACTIONS (continued)

~~Required Action C.1 requires all but two channels to be restored to OPERABLE status within 1 hour [or in accordance with the Risk Informed Completion Time Program]. With more than two channels inoperable, the logic is not capable of providing a DG - LOVS signal for valid Loss of Voltage or Degraded Voltage conditions. The 1 hour Completion Time is reasonable to evaluate and take action to correct the degraded condition in an orderly manner and takes into account the low probability of an event requiring LOVS occurring during this interval.~~ 1

D.1 3

Condition D applies if the Required Actions and associated Completion Times are not met. 3

requires declaring

Required Action D.1 ~~ensures that Required Actions for~~ the affected DG inoperabi~~li~~ti~~e~~s~~ are initiated~~. Depending upon plant MODE, the actions specified in LCO 3.8.1, "AC Sources - Operating," or LCO 3.8.2 are required immediately. 3 1

, "AC Sources - Shutdown", 1

SURVEILLANCE REQUIREMENTS

The following SRs apply to each DG - LOVS Function.

5

~~[~~ SR 3.3.~~6~~.1 2 3

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the indicated output of the potential transformers that feed the LOVS undervoltage relays. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two channels could be an indication of excessive drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff, based on a combination of the channel instrument uncertainties, including indication and readability. If the channels are within the criteria, it is an indication that the channels are OPERABLE. ~~]~~ 2

~~[The Frequency, about once every shift, is based upon operating experience that demonstrates channel failure is rare. Since the probability of two random failures in redundant channels in any 12 hour period is extremely low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The~~ 2

SURVEILLANCE REQUIREMENTS (continued)

~~CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of the displays associated with the LCO required channels.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~]~~

5
SR 3.3.~~6~~.2 3

A CHANNEL FUNCTIONAL TEST is performed to ensure that the entire channel will perform its intended function when needed. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

~~[The Frequency of [92] days is based on plant operating experience with regard to channel OPERABILITY and drift, which demonstrates that failure of more than one channel of a given function in any [92] day Frequency is a rare event. Any setpoint adjustment shall be consistent with the assumptions of the current plant specific setpoint analysis.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the surveillance interval extension analysis. ~~There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology.~~

SR 3.3.~~6~~.3

SR 3.3.~~6~~.3 is the performance of a CHANNEL CALIBRATION. The CHANNEL CALIBRATION verifies the accuracy of each component within the instrument channel. This includes calibration of the undervoltage relays and demonstrates that the equipment falls within the specified operating characteristics defined by the manufacturer.

The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. The~~re is a plant specific program which~~ verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

The setpoints, as well as the response to a Loss of Voltage and Degraded Voltage test, shall include a single point verification that the trip occurs within the required delay time as shown in Reference 1. ~~[The Frequency is based upon the assumption of an [18] month calibration interval for the determination of the magnitude of equipment drift in the setpoint analysis.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.5 BASES, DIESEL GENERATOR (DG) – LOSS OF VOLTAGE START (LOVS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The heading for ISTS 3.3.6 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2). Therefore, ISTS 3.3.2 is not included in the PSL ITS. The successive Specifications are renumbered as necessary.

DISCUSSION OF CHANGES
ITS 3.3.6, CONTAINMENT ISOLATION INSTRUMENTATION – REFUELING

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.3.3.1 specifies requirements for radiation monitoring instrumentation and list the requirements for each functional unit in CTS Table 3.3-6, including the containment radiation monitoring instrumentation. ITS 3.3.6 provides requirements for the containment isolation instrumentation - refueling instrumentation and provides the requirements in the LCO, Applicability, ACTIONS, and Surveillance Requirements. This changes the CTS by presenting the instrument requirements without use of an instrument table. This change is acceptable as it results solely from the change in the format and presentation of the CTS necessary to conform to the ISTS. As the proposed change is the result of changes in the format and presentation of the CTS requirements, it is designated administrative.

A03 CTS 3.3.3.1 Action c states that the provisions of Specification 3.0.3 are not applicable. CTS 3.0.3 (ITS LCO 3.0.3) does not apply in MODES 5 and 6, which encompasses the condition of during movement of recently irradiated fuel assemblies within the containment. This changes the CTS by eliminating an action requirement that is redundant to other Technical Specification requirements.

The purpose of CTS 3.3.3.1 Action c is to preclude action be taken per Specification 3.0.3 (ITS LCO 3.0.3) to shutdown the unit in the event there are no actions to perform or the actions cannot be performed within the required time when the containment radiation monitoring instrumentation is inoperable. CTS 3.0.3 (ITS LCO 3.0.3) is not applicable while in MODE 5 or 6. Recently irradiated fuel is defined as fuel that has occupied part of a critical reactor core within the previous 72 hours. To access the fuel to begin movement of recently irradiated fuel requires the unit to be in MODE 6. Therefore, the only time recently irradiated fuel can possibly be moved in the containment is following entry into MODE 6 and only up to 72 hours after reaching subcritical conditions. Since LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4, stating that the provisions of Specification 3.0.3 are not applicable is redundant and unnecessary. This change is designated as administrative and is acceptable because it does not result in a technical change to the CTS.

A04 CTS 3.3.3.1 Action b requires, when one or more radiation monitoring channels are inoperable, to take the Action shown in Table 3.3-6. Thus, when the minimum number of required containment radiation monitor channels are inoperable CTS Table 3.3-6, Action 16 (Unit 1) and Action 25 (Unit 2) require compliance with the Action requirements of Specification 3.9.9. ITS 3.3.6

provides explicit actions consistent with the actions of Specification 3.9.9; place and maintain containment purge and exhaust valves in the closed position or suspend movement of recently irradiated fuel assemblies within the containment (per the action of Specification 3.9.3, "Containment Penetrations."). This changes the action presentation of the CTS.

The purpose of the CTS action is to ensure the actions of the supported system, containment isolation valves, are performed consistent with the containment isolation system action requirements specified in CTS 3.9.9. CTS 3.9.9 action requires either suspending all operations involving movement of recently irradiated fuel assemblies within containment or close each of the containment penetrations providing direct access from the containment atmosphere to the outside atmosphere. ITS 3.3.6 Required Action A.1 requires immediately placing and maintaining at least one containment isolation valve in each penetration providing direct access from the containment atmosphere to outside atmosphere in the closed position. ITS 3.3.6 Required Action A.2 requires entering applicable ACTIONS for the affected valves of LCO 3.9.3, "Containment Penetrations," made inoperable by the isolation instrumentation. The applicable ACTIONS in Specification 3.9.3 require immediate suspension of movement of recently irradiated fuel assemblies within containment. This change is designated as administrative and is acceptable because it results in changes in the format and presentation of the CTS requirements.

MORE RESTRICTIVE CHANGES

M01 CTS 3.3.3.1 Action a allows the alarm/trip setpoint of Table 3.3-6 to exceed the setpoint for 4 hours and then to declare the channel inoperable. Upon declaring a required channel inoperable, CTS Table 3.3-6, Action 16 (Unit 1) and Action 25 (Unit 2) require compliance with the Action requirements of Specification 3.9.9. ITS 3.3.6 requires the required channels to be declared inoperable immediately when the actuation setting exceeds the setpoint specified in SR 3.3.6.2 and associated actions must be performed. This changes the CTS by deleting the 4 hour allowance to declare a channel inoperable and requiring the channel to be declared inoperable immediately upon discovery that the channel is outside the required setpoint value.

The purpose of CTS 3.3.3.1 Action a is to provide a short time period to restore an inoperable channel prior to requiring additional action. CTS 3.3.3.1 Action a allows the alarm/trip setpoint of Table 3.3-6 to exceed the setpoint for 4 hours and then to declare the channel inoperable. When LCO 3.3.6 is not met (e.g., SR 3.3.6.2 not met), LCO 3.0.2 requires the associated ACTIONS to be entered with no delay. Each radiation channel provides input to the associated containment high radiation instrument train which actuates the associated containment isolation valves. Therefore, the ITS action is considered appropriate. This change is designated as more restrictive because the Completion Time to declare the instrument channel inoperable following discovery of the channel exceeding it associated trip setpoint has been reduced.

M02 CTS 3.3.3.1 specifies requirements for radiation monitoring instrumentation and list the requirements for each functional unit in CTS Table 3.3-6, including the

containment radiation monitoring instrument channels. ITS 3.3.6 also includes requirements for the containment radiation monitoring instrument channels but also includes requirements for one automatic actuation logic train. LCO 3.3.6 requires, in part, one automatic Actuation Logic train to be OPERABLE and SR 3.3.6.3 requires performance of a CHANNEL FUNCTIONAL TEST on the required Actuation Logic train with a note specifying that testing of the Actuation Logic shall include verification of the proper operation of each initiation relay. The SR Frequency is proposed to be in accordance with the Surveillance Frequency Control Program (SFCP). The proposed actions for the automatic Actuation Logic train are the same as for the containment radiation monitor channels. This changes the CTS by adding requirements in the ITS associated with one train of containment isolation instrument logic.

The purpose of the containment radiation monitoring instrumentation requirements is to ensure isolation capability is maintained to penetrations providing direct access from the containment atmosphere to the outside atmosphere during movement of recently irradiated fuel assemblies within the containment. At least one automatic actuation logic train is required to ensure the applicable containment isolation valves receive an isolation signal from the containment radiation monitoring instrument channels. Therefore, these requirements are appropriate and necessary to ensure the containment radiation monitoring instrumentation can perform its intended safety function. This change is consistent with ISTS 3.3.7.

PSL controls periodic Frequencies for Surveillances in accordance with the SFCP per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, the initial periodic Frequency for ITS SR 3.3.6.3 in accordance with the SFCP will be 31 days consistent with the CHANNEL FUNCTIONAL TEST testing frequency for ISTS SR 3.3.7.3. The periodic Frequency is acceptable based on plant operating experience with regard to channel OPERABILITY, which demonstrates that failure of one automatic actuation logic channel in any 31 day interval is a rare event.

The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) "Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program" (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066)

DISCUSSION OF CHANGES
ITS 3.3.6, CONTAINMENT ISOLATION INSTRUMENTATION – REFUELING

REMOVED DETAIL CHANGES

LA01 *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* CTS Table 3.3-6 for radiation monitoring instrumentation has a column specifying the Measurement Range and a specific measurement range for the containment radiation instrumentation. ITS 3.3.6 does not retain the "MEASUREMENT RANGE" column or the specific measurement range of the containment radiation monitor channels. This changes the CTS by moving the instrument measurement range to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. The low end of the measurement range for the Unit 2 containment radiation monitoring instrumentation is changed from 1 mR/hr to 10 mR/hr to be consistent with the current radiation monitor instrument measurement range. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.6, CONTAINMENT ISOLATION INSTRUMENTATION – REFUELING

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS Specification number and title. Numbering is changed from 3.3.7 to 3.3.6, title is changed to “Containment Isolation Instrumentation – Refueling” and “(Analog)” is deleted from the title.

BASES

BACKGROUND

This LCO encompasses ~~CPIS actuation, which is a plant specific instrumentation system that performs an actuation Function required for plant protection but is not otherwise included in LCO 3.3.5, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual Trip," or LCO 3.3.6, "Diesel Generator (DG) - Loss of Voltage Start (LOVS)." This is a non-Nuclear Steam Supply System ESFAS Function that, because of differences in purpose, design, and operating requirements, is not included in LCOs 3.3.5 and 3.3.6. Details of this LCO are for illustration only. Individual plants shall include those Functions and LCO requirements applicable to them.~~

Insert 1

containment high radiation instrumentation

The ~~CPIS~~ provides protection from radioactive contamination in the containment in the event a~~n~~ irradiated fuel assembly should be severely damaged during handling.

recently

containment isolation

applicable containment isolation valves close to isolate the containment atmosphere from the outside atmosphere

The ~~CPIS~~ will detect any abnormal amounts of radioactive material in the containment and will initiate ~~purge~~ valve closure to limit the release of radioactivity to the environment. The ~~containment purge supply and exhaust valves are closed on a CPIS~~ when a high radiation level in containment is detected.

CIS logic

logic channels

Insert 2

The ~~CPIS~~ includes two independent, redundant actuation ~~subsystems~~. ~~Where two isolation control valves are provided for a single containment penetration, each valve is controlled by a separate actuation subsystem. Where one valve is available, a single actuation subsystem initiates valve closure. One train also isolates the containment air exhaust fan, whereas the other train actuates the containment air supply fan.~~ A list of actuated valves and an additional description of the ~~CPIS~~ are included in Reference 1. Both trains of ~~CPIS~~ are actuated on a two-out-of-four coincidence from the same four containment radiation sensor~~subsystems~~. ~~Containment purge isolation also occurs on a Containment Isolation Actuation Signal (CIAS). The CIAS is addressed by~~ LCO 3.3.4, "Engineered Safety Features Actuation System (ESFAS) ~~Instrumentation~~."

CIS

Insert 3

Logic and Manual Trip

1

Trip Setpoints and Allowable Values

~~Trip setpoints used in the bistables are based on the analytical limits stated in Reference 2.~~ The selection of ~~these~~ trip setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, and instrument drift, Allowable Value~~s~~

the

1 **INSERT 1**

containment radiation instrumentation which monitors radiation levels in the containment to automatically close at least one containment isolation valve in each penetration that provides direct access from the containment atmosphere to the outside atmosphere following a fuel handling accident (FHA). The containment isolation requirements during refueling are specified in LCO 3.9.3, “Containment Penetrations.”

1 **INSERT 2**

Four channels of containment high radiation instrumentation, with a sensing range of 10 mR/hr to 10^5 R/hr, are provided to the containment isolation signal (CIS) logic. R1

1 **INSERT 3**

Each containment isolation valve is actuated by its associated CIS channel. The instrumentation requirements associated with containment isolation actuation while the unit is operating are addressed in LCO 3.3.3, “Engineered Safety Features Actuation System (ESFAS) Instrumentation,” and

BASES

BACKGROUND (continued)

specified in SR 3.3.~~7~~6.2 ~~are~~ is conservatively adjusted with respect to the ~~analytical~~ design basis limit~~s~~. ~~A detailed description of the methodology used to calculate the trip setpoints, including their explicit uncertainties, is provided in "Plant Protection System Selection of Trip Setpoint Values" (Ref. 3).~~ The actual nominal trip setpoint entered into the bistable is normally ~~still~~ more conservative than that specified by the Allowable Value to account for changes in random measurement errors detectable by a CHANNEL FUNCTIONAL TEST. One example of such a change in measurement error is drift during the surveillance interval. If the measured setpoint does not exceed the Allowable Value, the bistable is considered OPERABLE.

~~Setpoints in accordance with the Allowable Value will ensure that Safety Limits are not violated during anticipated operational occurrences (AOOs) and the consequences of Design Basis Accidents will be acceptable, providing the plant is operated from within the LCOs at the onset of the AOO or accident and the equipment functions as designed.~~

Insert 4

APPLICABLE SAFETY ANALYSES

The ~~CPIS~~ satisfies the containment high radiation instrumentation requirements of Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Only the Allowable Value~~s are~~ is specified for ~~each~~ the trip Function in the LCO. Operation with a trip setpoint less conservative than the nominal trip setpoint, but within its Allowable Value, is acceptable, provided that the difference between the nominal trip setpoint and the Allowable Value is equal to or greater than the drift allowance ~~assumed for each trip in the transient and accident analyses~~.

~~Each~~ The Allowable Value specified is more conservative than the ~~analytical~~ design basis limit ~~assumed in the transient and accident analysis~~ in order to account for instrument uncertainties appropriate to the trip Function. ~~These uncertainties are defined in Reference 3.~~ A channel is inoperable if its actual trip setpoint is not within its required Allowable Value.

The Bases for the LCO on the ~~CPIS~~ containment high radiation instrumentation are discussed below for each Function:

~~a. Manual Trip~~

~~The LCO on Manual Trip backs up the automatic trips and ensures operators have the capability to rapidly initiate the CPIS Function if any parameter is trending toward its setpoint. At least one channel must be OPERABLE to be consistent with the requirements of LCO 3.9.3, "Containment Penetrations."~~

1

1

INSERT 4

The FHA is a postulated event that involves dropping a single irradiated fuel assembly resulting in damage to the assembly (Ref. 2). The FHA analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. Additionally, containment closure is not assumed for an FHA in the containment. The Technical Requirements Manual includes a decay time requirement that no fuel movement will commence until 72 hours after shutdown. This ensures that the FHA assumptions, including an open containment, are preserved. In the event an FHA in the containment occurs within 72 hours of a unit shutdown, actuation of the CIS when high radiation is indicated in the containment will isolate the containment from the outside environment to minimize the consequences of this improbable event.

BASES

LCO (continued)

a

~~b~~. Containment Radiation - High

Insert 5 → ~~The LCO on the radiation channels requires that all four be OPERABLE.~~

~~[For this unit, the basis for the Containment Radiation - High setpoint is as follows:]~~

2

b

~~c~~. Actuation Logic

Insert 6 → ~~One train of Actuation Logic must be OPERABLE to be consistent with the requirements of LCO 3.9.3. If one fails, it must be restored to OPERABLE status.~~

APPLICABILITY

In MODE 5 or 6, the ~~CPIS isolation of containment purge valves~~ containment high radiation instrumentation is not required to be OPERABLE. However, during movement of ~~[~~recently~~]~~ irradiated fuel ~~[~~(i.e., fuel that has occupied part of a critical reactor core within the previous ~~[X] days)~~]~~, there is the possibility of ~~a fuel handling accident~~ an FHA requiring the ~~CPIS~~ containment high radiation instrumentation on high radiation in containment. Accordingly, the ~~CPIS~~ containment high radiation instrumentation must be OPERABLE during movement of ~~[~~recently~~]~~ irradiated fuel in containment.

72 hours

isolation of penetrations providing direct access from the containment atmosphere to the outside atmosphere

2

2

1

In MODES 1, 2, 3, and 4, ~~the containment purge valves are sealed closed~~.

Insert 7

ACTIONS

A ~~CPIS~~ containment high radiation monitor channel is inoperable when it does not satisfy the OPERABILITY criteria for the channel's Function. The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the plant specific setpoint analysis. Typically, the drift is not large and would result in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the process instrument is set up for adjustment to bring it within specification. If the actual trip setpoint is not within the Allowable Value in SR 3.3.~~7~~.2, the channel is inoperable and the appropriate Conditions must be entered.

6

~~In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value, or the sensor, instrument loop, signal processing electronics, or bistable is found inoperable, then all affected Functions provided by that channel should be declared inoperable and the LCO Condition entered for the particular protective function affected.~~

1

INSERT 5

With one Containment Radiation – High channel inoperable, three OPERABLE channels remain available to actuate the CIS logic train concurrent with an additional single failure. Therefore, the LCO requires three of four channels to be OPERABLE.

During refueling conditions, closure of containment isolation valves associated with containment penetrations with direct access from the containment atmosphere to the outside atmosphere on high containment radiation is particularly important since other CIS input parameters are not available (i.e., low pressurizer pressure is bypassed and there is no mechanism for creating a containment pressure transient). With the reactor shutdown, the background radiation seen by the CIS detectors drops by a factor of 10 or more. For these reasons the Containment Radiation - High setpoint requires a much lower setpoint during refueling.

1

INSERT 6

Since LCO 3.9.3 requires, in part, an OPERABLE containment isolation valve for each penetration providing direct access from the containment atmosphere to the outside atmosphere, only one train of Actuation Logic associated with the required containment isolation valves is required to be OPERABLE.

1

INSERT 7

When movement of irradiated fuel assemblies within containment is not being conducted, the potential for an FHA within the containment does not exist. Therefore, due to radioactive decay, an FHA that involves handling non-recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core longer than 72 hours) will result in doses that are well within the guideline values specified in 10 CFR 50.67 even with the containment atmosphere having direct access to the outside atmosphere. Therefore, under these conditions, isolation of the containment penetrations providing direct access to the outside environment, including the associated containment area high radiation instrumentation, is not required to be OPERABLE.

In MODES 1, 2, 3, and 4, LCO 3.3.3 provide instrumentation requirements associated with containment isolation on high containment radiation.

BASES

ACTIONS (continued)

~~When the number of inoperable channels in a trip Function exceeds those specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered if applicable in the current MODE of operation.~~

~~A.1 and A.2~~

~~Condition A applies to the failure of one Containment Radiation - High CPIS channel. The Required Action is to place the affected channel in the trip condition within 4 hours. The Completion Time accounts for the fact that three redundant channels monitoring containment radiation are still available to provide a single trip input to the CPIS logic to provide the automatic mitigation of a radiation release. Alternately, action must be taken to place the unit in a condition where the LCO does not apply. This does not preclude the movement of fuel to a safe position.~~

A
A
~~B~~.1 and ~~B~~.2
A
or
at least one containment isolation valve in each penetration providing direct access from containment atmosphere to outside atmosphere
or more required
1
3

Condition ~~B~~ applies to the failure of the required ~~Manual Trip or~~ automatic Actuation Logic train, to the failure of ~~more than~~ one radiation monitoring channel~~, or if the Required Action and associated Completion Time of Condition A are not met~~. Required Action ~~B~~.1 is to place ~~the containment purge and exhaust isolation valves~~ in the closed position. The Required Action immediately performs the isolation Function of the ~~CPIS~~. Required Action ~~B~~.2 is to immediately enter the applicable Conditions and Required Actions for the affected isolation valves of LCO 3.9.3, "Containment Penetrations," that were made inoperable by the inoperable instrumentation ~~of the CPIS LCO~~. The Required Action directs the operator to take actions that are appropriate for the containment isolation Function ~~of the CPIS without initiating the containment air supply and exhaust fans~~. The Completion Time accounts for the fact that the automatic capability to isolate containment ~~and initiate supply and exhaust fans~~ on valid containment high radiation signal~~s~~ is degraded during conditions in which a fuel handling accident is possible ~~and CPIS provides the only automatic mitigation of radiation release~~.

s
A
A
a
CIS

BASES

SURVEILLANCE REQUIREMENTS

SR 3.3.~~7~~.1

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value.

Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff, based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the transmitter or the signal processing equipment has drifted outside its limits.

~~[The Frequency, about once every shift, is based on operating experience that demonstrates the rarity of channel failure. Since the probability of two random failures in redundant channels in any 12 hour period is low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of the displays associated with the LCO required channels.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

SURVEILLANCE REQUIREMENTS (continued)

6
SR 3.3.~~7~~.2 3

A CHANNEL FUNCTIONAL TEST is performed on each containment radiation monitoring channel to ensure the entire channel will perform its intended function. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. ~~This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.~~ There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology. Any setpoint adjustment shall be consistent with the assumptions of the current plant specific setpoint analysis. 1

~~[The Frequency of [92] days is based on plant operating experience with regard to channel OPERABILITY and drift, which demonstrates that failure of more than one channel of a given Function in any [92] day interval is a rare event.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~

6

SR 3.3.~~7~~.4 3

CHANNEL CALIBRATION is a complete check of the instrument channel including the sensor. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

~~[The Frequency is based upon the assumption of an [18] month calibration interval for the determination of the magnitude of equipment drift in the setpoint analysis.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~----------]~~

~~SR 3.3.7.5~~

~~A CHANNEL FUNCTIONAL TEST is performed on the manual CPIS actuation circuitry. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.~~ 1

~~This Surveillance verifies that the trip push buttons are capable of opening contacts in the Actuation Logic as designed, de-energizing the initiation relays and providing Manual Trip of the Function. [The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed at a Frequency of once every 18 months.~~ 1 2

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~ 2

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~----------]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~SR 3.3.7.6~~

~~This Surveillance ensures that the train actuation response times are less than or equal to the maximum times assumed in the analyses. [The 18 month Frequency is based upon plant operating experience, which shows random failures of instrumentation components causing serious response time degradation, but not channel failure, are infrequent occurrences.~~

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

~~Testing of the final actuating devices, which make up the bulk of the response time, is included. Testing of the final actuating device in one channel is included in the testing of each actuation logic channel.~~

BASES

BACKGROUND

This LCO encompasses ~~CPIS actuation, which is a plant specific instrumentation system that performs an actuation Function required for plant protection but is not otherwise included in LCO 3.3.5, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual Trip," or LCO 3.3.6, "Diesel Generator (DG) - Loss of Voltage Start (LOVS)." This is a non-Nuclear Steam Supply System ESFAS Function that, because of differences in purpose, design, and operating requirements, is not included in LCOs 3.3.5 and 3.3.6. Details of this LCO are for illustration only. Individual plants shall include those Functions and LCO requirements applicable to them.~~

Insert 1

containment high radiation instrumentation

The ~~CPIS~~ provides protection from radioactive contamination in the containment in the event a~~n~~ irradiated fuel assembly should be severely damaged during handling.

recently

containment isolation

applicable containment isolation valves close to isolate the containment atmosphere from the outside atmosphere

The ~~CPIS~~ will detect any abnormal amounts of radioactive material in the containment and will initiate ~~purge~~ valve closure to limit the release of radioactivity to the environment. The ~~containment purge supply and exhaust valves are closed on a CPIS~~ when a high radiation level in containment is detected.

CIAS logic

logic channels

Insert 2

The ~~CPIS~~ includes two independent, redundant actuation ~~subsystems~~. ~~Where two isolation control valves are provided for a single containment penetration, each valve is controlled by a separate actuation subsystem. Where one valve is available, a single actuation subsystem initiates valve closure. One train also isolates the containment air exhaust fan, whereas the other train actuates the containment air supply fan.~~ A list of actuated valves and an additional description of the ~~CPIS~~ are included in Reference 1. Both trains of ~~CPIS~~ are actuated on a two-out-of-four coincidence from the same four containment radiation sensor~~subsystems~~. ~~Containment purge isolation also occurs on a Containment Isolation Actuation Signal (CIAS). The CIAS is addressed by~~ LCO 3.3.4, "Engineered Safety Features Actuation System (ESFAS) ~~Instrumentation~~."

Logic and Manual Trip

1

Trip Setpoints and Allowable Values

~~Trip setpoints used in the bistables are based on the analytical limits stated in Reference 2.~~ The selection of ~~these~~ trip setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, and instrument drift, Allowable Value~~s~~

the

1 **INSERT 1**

containment radiation instrumentation which monitors radiation levels in the containment to automatically close at least one containment isolation valve in each penetration that provides direct access from the containment atmosphere to the outside atmosphere following a fuel handling accident (FHA). The containment isolation requirements during refueling are specified in LCO 3.9.3, "Containment Penetrations."

1 **INSERT 2**

Four channels of containment high radiation instrumentation, with a sensing range of 10 mR/hr to 10^7 R/hr, are provided to the containment isolation actuation signal (CIAS) logic. | R1

1 **INSERT 3**

Each containment isolation valve is actuated by its associated CIAS channel. The instrumentation requirements associated with containment isolation actuation while the unit is operating are addressed in LCO 3.3.3, "Engineered Safety Features Actuation System (ESFAS) Instrumentation," and | R1

BASES

BACKGROUND (continued)

6 is

specified in SR 3.3.~~7~~.2 ~~are~~ conservatively adjusted with respect to the ~~analytical~~ limit~~s~~. ~~A detailed description of the methodology used to calculate the trip setpoints, including their explicit uncertainties, is provided in "Plant Protection System Selection of Trip Setpoint Values" (Ref. 3).~~ The actual nominal trip setpoint entered into the bistable is normally ~~still~~ more conservative than that specified by the Allowable Value to account for changes in random measurement errors detectable by a CHANNEL FUNCTIONAL TEST. One example of such a change in measurement error is drift during the surveillance interval. If the measured setpoint does not exceed the Allowable Value, the bistable is considered OPERABLE.

design basis

~~Setpoints in accordance with the Allowable Value will ensure that Safety Limits are not violated during anticipated operational occurrences (AOOs) and the consequences of Design Basis Accidents will be acceptable, providing the plant is operated from within the LCOs at the onset of the AOO or accident and the equipment functions as designed.~~

Insert 4

APPLICABLE SAFETY ANALYSES

The ~~CPIS~~ satisfies the requirements of Criterion 3 of 10 CFR 50.36(c)(2)(ii).

containment high radiation instrumentation

LCO

is the

Only the Allowable Value~~s are~~ specified for ~~each~~ trip Function in the LCO. Operation with a trip setpoint less conservative than the nominal trip setpoint, but within its Allowable Value, is acceptable, provided that the difference between the nominal trip setpoint and the Allowable Value is equal to or greater than the drift allowance ~~assumed for each trip in the transient and accident analyses~~.

The

design basis

~~Each~~ Allowable Value specified is more conservative than the ~~analytical~~ limit ~~assumed in the transient and accident analysis~~ in order to account for instrument uncertainties appropriate to the trip Function. ~~These uncertainties are defined in Reference 3.~~ A channel is inoperable if its actual trip setpoint is not within its required Allowable Value.

containment high radiation instrumentation

The Bases for the LCO on the ~~CPIS~~ are discussed below for each Function:

~~a. Manual Trip~~

~~The LCO on Manual Trip backs up the automatic trips and ensures operators have the capability to rapidly initiate the CPIS Function if any parameter is trending toward its setpoint. At least one channel must be OPERABLE to be consistent with the requirements of LCO 3.9.3, "Containment Penetrations."~~

1

1

INSERT 4

The FHA is a postulated event that involves dropping a single irradiated fuel assembly resulting in damage to the assembly (Ref. 2). The FHA analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. Additionally, containment closure is not assumed for an FHA in the containment. The Technical Requirements Manual includes a decay time requirement that no fuel movement will commence until 72 hours after shutdown. This ensures that the FHA assumptions, including an open containment, are preserved. In the event an FHA in the containment occurs within 72 hours of a unit shutdown, actuation of the CIAS when high radiation is indicated in the containment will isolate the containment from the outside environment to minimize the consequences of this improbable event. | R1

BASES

LCO (continued)

a

~~b~~. Containment Radiation - High

Insert 5 → ~~The LCO on the radiation channels requires that all four be OPERABLE.~~

~~[For this unit, the basis for the Containment Radiation - High setpoint is as follows:]~~

2

b

~~c~~. Actuation Logic

Insert 6 → ~~One train of Actuation Logic must be OPERABLE to be consistent with the requirements of LCO 3.9.3. If one fails, it must be restored to OPERABLE status.~~

APPLICABILITY

containment high radiation instrumentation

In MODE 5 or 6, the ~~CPIS isolation of containment purge valves~~ is not required to be OPERABLE. However, during movement of ~~[~~recently~~]~~ irradiated fuel ~~[~~(i.e., fuel that has occupied part of a critical reactor core within the previous ~~[X] days)~~], there is the possibility of ~~a fuel handling accident~~ requiring the ~~CPIS~~ on high radiation in containment. Accordingly, the ~~CPIS~~ must be OPERABLE during movement of ~~[~~recently~~]~~ irradiated fuel in containment.

72 hours

isolation of penetrations providing direct access from the containment atmosphere to the outside atmosphere

an FHA

containment high radiation instrumentation

2

2

1

Insert 7 → In MODES 1, 2, 3, and 4, ~~the containment purge valves are sealed closed~~.

ACTIONS

containment high radiation monitor

A ~~CPIS~~ channel is inoperable when it does not satisfy the OPERABILITY criteria for the channel's Function. The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the plant specific setpoint analysis. Typically, the drift is not large and would result in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the process instrument is set up for adjustment to bring it within specification. If the actual trip setpoint is not within the Allowable Value in SR 3.3.~~7~~.2, the channel is inoperable and the appropriate Conditions must be entered.

6

~~In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value, or the sensor, instrument loop, signal processing electronics, or bistable is found inoperable, then all affected Functions provided by that channel should be declared inoperable and the LCO Condition entered for the particular protective function affected.~~

1

INSERT 5

With one Containment Radiation – High channel inoperable, three OPERABLE channels remain available to actuate the CIAS logic train concurrent with an additional single failure. Therefore, the LCO requires three of four channels to be OPERABLE. | R1

During refueling conditions, closure of containment isolation valves associated with containment penetrations with direct access from the containment atmosphere to the outside atmosphere on high containment radiation is particularly important since other CIAS input parameters are not available (i.e., low pressurizer pressure is bypassed and there is no mechanism for creating a containment pressure transient). With the reactor shutdown, the background radiation seen by the CIAS detectors drops by a factor of 10 or more. For these reasons the Containment Radiation - High setpoint requires a much lower setpoint during refueling. | R1 | R1

1

INSERT 6

Since LCO 3.9.3 requires, in part, an OPERABLE containment isolation valve for each penetration providing direct access from the containment atmosphere to the outside atmosphere, only one train of Actuation Logic associated with the required containment isolation valves is required to be OPERABLE.

1

INSERT 7

When movement of irradiated fuel assemblies within containment is not being conducted, the potential for an FHA within the containment does not exist. Therefore, due to radioactive decay, an FHA that involves handling non-recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core longer than 72 hours) will result in doses that are well within the guideline values specified in 10 CFR 50.67 even with the containment atmosphere having direct access to the outside atmosphere. Therefore, under these conditions, isolation of the containment penetrations providing direct access to the outside environment, including the associated containment area high radiation instrumentation, is not required to be OPERABLE.

In MODES 1, 2, 3, and 4, LCO 3.3.3 provide instrumentation requirements associated with containment isolation on high containment radiation.

BASES

ACTIONS (continued)

~~When the number of inoperable channels in a trip Function exceeds those specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered if applicable in the current MODE of operation.~~

~~A.1 and A.2~~

~~Condition A applies to the failure of one Containment Radiation - High CPIS channel. The Required Action is to place the affected channel in the trip condition within 4 hours. The Completion Time accounts for the fact that three redundant channels monitoring containment radiation are still available to provide a single trip input to the CPIS logic to provide the automatic mitigation of a radiation release. Alternately, action must be taken to place the unit in a condition where the LCO does not apply. This does not preclude the movement of fuel to a safe position.~~

A A at least one containment isolation valve in each penetration providing direct access from containment atmosphere to outside atmosphere

~~B~~.1 and ~~B~~.2

or

A or more required

Condition ~~B~~ applies to the failure of the required ~~Manual Trip or~~ automatic Actuation Logic train, to the failure of ~~more than~~ one radiation monitoring channel~~, or if the Required Action and associated Completion Time of Condition A are not met~~. Required Action ~~B~~.1 is to place ~~the containment purge and exhaust isolation valves~~ in the closed position. The Required Action immediately performs the isolation Function of the ~~CPIS~~. Required Action ~~B~~.2 is to immediately enter the applicable Conditions and Required Actions for the affected isolation valves of LCO 3.9.3, "Containment Penetrations," that were made inoperable by the inoperable instrumentation ~~of the CPIS LCO~~. The Required Action directs the operator to take actions that are appropriate for the containment isolation Function ~~of the CPIS without initiating the containment air supply and exhaust fans~~. The Completion Time accounts for the fact that the automatic capability to isolate containment ~~and initiate supply and exhaust fans~~ on valid containment high radiation signal~~s~~ is degraded during conditions in which a fuel handling accident is possible ~~and CPIS provides the only automatic mitigation of radiation release~~.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.3.~~7~~.1

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value.

Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff, based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the transmitter or the signal processing equipment has drifted outside its limits.

~~[The Frequency, about once every shift, is based on operating experience that demonstrates the rarity of channel failure. Since the probability of two random failures in redundant channels in any 12 hour period is low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of the displays associated with the LCO required channels.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~ACTION STATEMENTS~~

ACTION 22 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirement, perform area surveys of the monitored area with portable monitoring instrumentation at least once per 24 hours.

See ITS 3.3.8

ACTION 23 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirement, comply with the ACTION requirements of Specification 3.4.6.1.

See ITS 3.4.15

ACTION 24 - DELETED

ACTION 25 - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirement, comply with the ACTION requirements of Specification 3.9.9.

See ITS 3.3.6

ACTION A

~~ACTION 26~~ - With the number of channels OPERABLE less than required by the Minimum Channels OPERABLE requirements, within 1 hour initiate and maintain operation of the control room emergency ventilation system in the recirculation mode of operation. LCO 3.0.4.a is not applicable when entering HOT SHUTDOWN.

ACTION B Note

ACTION 27 - With the number of OPERABLE Channels less than required by the Minimum Channels OPERABLE requirement, either restore the inoperable Channel(s) to OPERABLE status within 72 hours, or:

1) Initiate the preplanned alternate method of monitoring the appropriate parameter(s), and

2) Prepare and submit a Special Report to the Commission pursuant to Specification 6.9.2 within 14 days following the event outlining the action taken, the cause of the inoperability and the plans and schedule for restoring the system to OPERABLE status.

DISCUSSION OF CHANGES
ITS 3.3.7, CONTROL ROOM ISOLATION SIGNAL (CRIS)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.3.3.1 specifies requirements for radiation monitoring instrumentation and list the requirements for each functional unit in CTS Table 3.3-6, including the control room isolation monitoring instrumentation. ITS 3.3.7 provides requirements for the control room isolation signal instrumentation and provides the requirements in the LCO, Applicability, ACTIONS, and Surveillance Requirements. This changes the CTS by presenting the instrument requirements without use of an instrument table. This change is acceptable as it results solely from the change in the format and presentation of the CTS necessary to conform to the ISTS. As the proposed change is the result of changes in the format and presentation of the CTS requirements, it is designated administrative.

MORE RESTRICTIVE CHANGES

M01 CTS 3.3.3.1 Action a allows the alarm/trip setpoint of Table 3.3-6 to exceed the setpoint for 4 hours and then to declare the channel inoperable. Upon declaring a required channel inoperable, CTS Table 3.3-6, Action 17 (Unit 1) and Action 26 (Unit 2) requires placing the CREVS in the recirculation mode of operation. ITS 3.3.6 requires the required channels to be declared inoperable immediately when the actuation setting exceeds the setpoint specified in SR 3.3.6.2 and associated actions must be performed. This changes the CTS by deleting the 4 hour allowance to declare a channel inoperable and requiring the channel to be declared inoperable immediately upon discovery that the channel is outside the required setpoint value.

The purpose of CTS 3.3.3.1 Action a is to provide a short time period to restore an inoperable channel prior to requiring additional action. CTS 3.3.3.1 Action a allows the alarm/trip setpoint of Table 3.3-6 to exceed the setpoint for 4 hours and then to declare the channel inoperable. When LCO 3.3.6 is not met (e.g., SR 3.3.6.2 not met), LCO 3.0.2 requires the associated ACTIONS to be entered with no delay. Each radiation channel provides input to the associated control room ventilation isolation dampers. Therefore, the ITS action is considered appropriate. This change is designated as more restrictive because the Completion Time to declare the instrument channel inoperable following discovery of the channel exceeding it associated trip setpoint has been reduced.

M02 CTS 3.3.3.1 specifies requirements for radiation monitoring instrumentation and list the requirements for each functional unit in CTS Table 3.3-6, including the Control Room outside air intake radiation monitoring instrument channels. ITS 3.3.7 also includes requirements for the control room isolation radiation

monitoring instrument channels but also includes requirements for one automatic actuation logic train. LCO 3.3.7 requires, in part, one automatic Actuation Logic train to be OPERABLE and SR 3.3.7.3 requires performance of a CHANNEL FUNCTIONAL TEST on the required Actuation Logic train with a note specifying that testing of the Actuation Logic shall include verification of the proper operation of each initiation relay. The SR Frequency is proposed to be in accordance with the Surveillance Frequency Control Program (SFCP). This changes the CTS by adding requirements in the ITS associated with one train of control room isolation instrument logic.

The purpose of the control room isolation radiation monitoring instrumentation requirements is to ensure isolation capability is maintained with the ability to isolate the control room atmosphere. At least one automatic actuation logic train is required to ensure the applicable control room ventilation dampers receive an isolation signal from the control room isolation radiation monitoring instrument channels. Therefore, these requirements are appropriate and necessary to ensure the radiation monitoring instrumentation can perform its intended safety function. This change is consistent with ISTS 3.3.8.

PSL controls periodic Frequencies for Surveillances in accordance with the SFCP per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, the initial periodic Frequency for ITS SR 3.3.7.3 in accordance with the SFCP will be 31 days consistent with the CHANNEL FUNCTIONAL TEST testing frequency for ISTS SR 3.3.8.3. The periodic Frequency is acceptable based on plant operating experience with regard to channel OPERABILITY, which demonstrates that failure of one automatic actuation logic channel in any 31 day interval is a rare event.

The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) "Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program" (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066).

M03 CTS 3.3.3.1 Action c states that the provisions of Specification 3.0.3 are not applicable. ITS 3.3.7 does not include exceptions to the applicability of LCO 3.0.3. CTS 3.0.3 (ITS LCO 3.0.3) does not apply in MODES 5 and 6, which encompasses the condition of during movement of recently irradiated fuel assemblies within the containment. This changes the CTS by adding the applicability of LCO 3.0.3 when in MODES 1, 2, 3, and 4.

The purpose of the control room isolation function is to ensure a habitable environment for the control room operators. This change is acceptable because LCO 3.0.3 is applicable in MODES 1, 2, 3, and 4 to implement actions when an LCO is not met and either an associated Required Action and Completion is not met with no Condition applicable; or the condition is not specifically addressed by the associated ACTIONS. This change is designated as more restrictive because it adds an additional requirement not in the CTS.

M04 CTS 3.3.3.1 does not explicitly require CRIS to be OPERABLE during movement of irradiated fuel assemblies and does not require the suspension of irradiated fuel assembly movement when control room isolation radiation monitoring channels or actuation logic is inoperable. ITS 3.3.7 Applicability includes the condition, “During movement of irradiated fuel assemblies,” consistent with the CTS 3.7.7.1 (Unit 1) and CTS 3.7.7 (Unit 2) Applicability for the Control Room Emergency Ventilation System. In addition, ITS 3.3.7, Required Action C.2 requires the suspension of movement of irradiated fuel assemblies when required actuation logic or radiation monitors are inoperable during movement of irradiated fuel assemblies if one CREVS train cannot be placed in the recirculation mode. This changes CTS by revising the applicability to include the condition of,” during movement of irradiated fuel assemblies,” and adding the requirement to suspend movement of irradiated fuel assemblies when the control room isolation radiation monitoring actuation logic or monitoring becomes inoperable while in MODES 5 or 6; or, moving irradiated fuel assemblies.

The purpose of the Applicability and action to suspend movement of irradiated fuel assemblies recognizes the fact that the radiation signals are the only Functions available to initiate control room isolation in the event of a fuel handling accident. This change is designated as more restrictive because the change expands the Applicability to include a specified condition and adds a required action that CTS does not have.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* CTS Table 3.3-6 for radiation monitoring instrumentation has a column specifying the Measurement Range and a specific measurement range for the control room isolation radiation instrumentation. ITS 3.3.7 does not retain the "MEASUREMENT RANGE" column or the specific measurement range of the radiation monitor channels. This changes the CTS by moving the instrument measurement range to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of

detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 - Relaxation of Required Action)* CTS Action b requires when one or more radiation monitoring channels are inoperable to take the ACTION shown in Table 3.3-6. When the minimum number of required control room isolation radiation monitoring channels are inoperable Table 3.3-6 ACTION 17 (Unit 1) and ACTION 26 (Unit 2) require that the control room ventilation system be placed in the recirculation mode of operation within 1 hour. CTS 3.3.3.1 does not specifically address additional required actions if ACTION 17 (Unit 1) and ACTION 26 (Unit 2) cannot meet the required actions. Under similar conditions, ITS 3.3.7 Condition B requires the unit to be in MODE 3 within 6 hours and MODE 4 within 12 hours. Consistent with the ISTS and the CREV Specification ACTIONS, proposed Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. This changes the CTS by allowing a unit shutdown to MODE 4 in lieu of an LCO 3.0.3 shutdown to cold shutdown conditions (MODE 5).

If the required CRIS channel cannot be restored to OPERABLE status, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours (Required Action B.1) and to MODE 4 within 12 hours (Required Action B.2). Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5. In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

This change is acceptable since it provides for an orderly shutdown to hot shutdown condition (MODE 4) if the train is not placed in the recirculation mode within 1 hour and the modification of the end state is consistent with CE-NPSD-1186-A, Revision 00, “Technical Justification for the Risk-Informed Modification to Selected Required Action End States for CEOG Member PWRs,” dated October 2001 (ADAMS Accession No. 110410539). In addition, this allowance is consistent with that provided in the CREVS Specification, when an actual train is inoperable. Once the unit is in MODE 4, the probability of an event requiring the CREVS is minimized. This change is designated as less restrictive because the ITS provides an alternate action than is not currently allowed in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.7, CONTROL ROOM ISOLATION SIGNAL (CRIS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. Changes are made to reflect the ITS Specification number and title. Numbering is changed from 3.3.8 to 3.3.7 and "(Analog)" is deleted from the title.

3. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

4. Required Action C.2.2 and associated Note are not included in the ITS consistent with the PSL current licensing basis. The boron dilution event analysis for MODES 5 and 6 does not assume operation of the Control Room Emergency Ventilation System or the associated control room isolation signal actuation instrumentation. Therefore, the ISTS Required Action to suspend positive reactivity additions with one CRIS automatic actuation logic or radiation monitor channel inoperable in MODE 5 or 6 is unnecessary. As a result, Required Action C.2.1 is renumbered to C.2.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.3 INSTRUMENTATION ~~(Analog)~~ 2

B 3.3.~~8~~ 7 Control Room Isolation Signal (CRIS) ~~(Analog)~~ 2

BASES

BACKGROUND

This LCO encompasses CRIS actuation, which is a plant specific instrumentation channel that performs an actuation Function required for plant protection but is not otherwise included in LCO 3.3.~~5~~ 4, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual ~~Trip," or LCO 3.3.6, "Diesel Generator (DG) - Loss of Voltage Start (LOVS)~~." This is a non-Nuclear Steam Supply System ESFAS Function that, because of differences in purpose, design, and operating requirements~~,~~ is not included in LCO 3.3.~~5 and LCO 3.3.6~~. ~~Details of this LCO are for illustration only. Individual plants shall include those Functions and LCO requirements that are applicable to them.~~

Actuation

4

6

6

Control Room Emergency Ventilation

The CRIS terminates the normal supply of outside air to the control room and initiates actuation of the ~~Emergency Radiation Protection~~ System to minimize operator radiation exposure. The CRIS includes two independent, redundant subsystems, including actuation trains. Each train employs two separate sensors~~.~~ ~~One sensor detects gaseous activity. The other detects particulate and iodine activity. Since the two sensors detect different types of activity, they are not considered redundant to each other. However, since there are separate sensors in each train, the trains are redundant.~~ If the bistable monitoring either sensor indicates an unsafe condition, that train will be actuated (one-out-of-two logic). The two trains actuate separate equipment. Actuating either train will perform the intended function. Control room isolation also occurs on a ~~Safety Injection Actuation Signal (SIAS)~~.

with a measurement range of 10 to 10^7 cpm

R1

1

Containment Isolation Signal (CIS)

Trip Setpoints and Allowable Values

selection of a setpoint as low as possible without causing spurious alarms or actuations

Trip setpoints used in the bistables are based on the ~~analytical limits~~ (Ref. 1). The selection of these trip setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, and instrument drift, Allowable Values specified in LCO 3.3.~~8~~ 7 are conservatively adjusted with respect to the ~~analytical limits~~ setpoint. ~~A detailed description of the methodology used to calculate the trip setpoints, including their explicit uncertainties, is provided in "Plant Protection System Selection of Trip Setpoint Values" (Ref. 2).~~ The actual nominal trip setpoint entered into the bistable is ~~normally~~ still more conservative than that specified by the Allowable Value to account for changes in random measurement errors detectable by a CHANNEL FUNCTIONAL TEST. One example of such a change in measurement error is drift during the surveillance interval. ~~If the measured setpoint does not exceed the Allowable Value, the bistable is considered OPERABLE.~~

2

BASES

BACKGROUND (continued)

Setpoints in accordance with the Allowable Value will ensure that Safety Limits are not violated during anticipated operational occurrences (AOOs) and the consequences of Design Basis Accidents will be acceptable, providing the plant is operated from within the LCOs at the onset of the AOO or accident and the equipment functions as designed.

APPLICABLE SAFETY ANALYSES

V The CRIS, in conjunction with the Control Room Emergency Ventilation ~~Air Cleanup~~ System (CRE~~AC~~S), maintains the control room atmosphere within conditions suitable for prolonged occupancy throughout the duration of any one of the accidents discussed in Reference ~~1~~. The radiation exposure of control room personnel, through the duration of any one of the postulated accidents discussed in "Accident Analysis," U FSAR, Chapter ~~[~~15~~]~~ (Ref. ~~1~~), does not exceed the limits set by 10 CFR 50, Appendix A, GDC 19 (Ref. 3). 1 3 R1

Loss of Coolant Accident (LOCA) is not a limiting event because the CIS is credited for isolation of the Control Room, no credit is taken for isolation on high radiation in the accident analysis.

The CRIS satisfies the requirements of Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

LCO 3. 3.~~8~~ requires one channel of CRIS to be OPERABLE. The required channel consists of Actuation Logic, ~~Manual Trip,~~ and ~~particulate/iodine and gaseous~~ radiation monitors. The specific Allowable Value~~s~~ for the setpoint~~s~~ of the CRIS ~~are~~ is listed in the SRs.

Only the Allowable Value~~s~~ ~~are~~ is specified for ~~each~~ the trip Function in the LCO. Operation with a trip setpoint less conservative ~~than the nominal trip setpoint,~~ but within its Allowable Value, is acceptable, provided that the difference between the ~~nominal~~ trip setpoint and the Allowable Value is equal to or greater than the drift allowance assumed ~~for each trip~~ in the ~~transient and accident~~ analyses. 1 2

~~Each~~ The Allowable Value specified is more conservative than the ~~analytical limit assumed in the transient and accident analysis~~ setpoint in order to account for instrument uncertainties appropriate to the trip Function. These uncertainties are defined in Reference ~~2~~. A channel is inoperable if its actual trip setpoint is not within its required Allowable Value.

The Bases for the LCO on the CRIS are discussed below for each Function:

BASES

LCO (continued)

a. ~~Manual Trip~~

~~The LCO on Manual Trip backs up the automatic trips and ensures operators have the capability to rapidly initiate the CRIS Function if any parameter is trending toward its setpoint. One channel must be OPERABLE. This considers that the Manual Trip capability is a backup and that other means are available to actuate the redundant train if required, including manual SIAS.~~

~~b.~~ ~~Airborne~~ Radiation

One ~~Both~~ channel~~s~~ of ~~Airborne~~ Radiation detection in each ~~the~~ required train is ~~are~~ required to be OPERABLE to ensure the control room isolates ~~on either high iodine and high particulate or gaseous concentration~~.

~~[~~For this unit, the basis for the Allowable Value is as follows:~~]~~

b. ~~c.~~ Actuation Logic

A background reading of approximately 40 cpm is typical for the air intake radiation monitors. An actuation setpoint of ≤ 320 cpm is consistent with the EPRI TR-102644 setpoint value recommendation of 8 times background.

One train of Actuation Logic must be OPERABLE, since there are alternate means available to actuate the redundant train, including CIS ~~SIAS~~.

APPLICABILITY

The CRIS Functions must be OPERABLE in MODES 1, 2, 3, 4, ~~[~~5, and 6~~]~~ and during movement of ~~[recently]~~ irradiated fuel assemblies ~~[(i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~ to ensure a habitable environment for the control room operators.

~~REVIEWER'S NOTE~~

~~For those plants that credit gas decay tank rupture accidents, the CRIS must also be OPERABLE in MODES 5 and 6.~~

ACTIONS

A CRIS channel is inoperable when it does not satisfy the OPERABILITY criteria for the channel's function. The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the ~~plant~~ specific setpoint ~~analysis~~. Typically, the drift is not large and would result in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the process instrument is set up for adjustment to bring it within specification. If the trip setpoint is not within the Allowable Value, the channel is inoperable and the appropriate Conditions must be entered.

BASES

ACTIONS (continued)

A.1, B.1, B.2, C.1, C.2~~.1,~~ and ~~C.2.2~~ 5

~~Conditions A and C have been modified by a Note, which specifies that CREACS be placed manually in the toxic gas protection mode if the automatic transfer to the toxic gas protection mode is inoperable. [At this unit, the basis for this Note is as follows:]~~

Conditions A, B, and C are applicable to ~~manual and~~ automatic actuation of the CRE~~AC~~S by CRIS. Condition A applies to the failure of the CRIS ~~Manual Trip,~~ Actuation Logic~~, and required particulate/iodine~~ and required ~~gaseous~~ radiation monitor channels in MODE 1, 2, 3, or 4. Entry into this Condition requires action to either restore the failed channel(s) or manually perform the CRIS safety function (Required Action A.1). The Completion Time of 1 hour is sufficient to complete the Required Actions and accounts for the fact that CRIS supplements control room isolation by other Functions (e.g., ~~S~~IAS~~S~~) in MODES 1, 2, 3, and 4. If the channel cannot be restored to OPERABLE status, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours (Required Action B.1) and to MODE 4 within 12 hours (Required Action B.2). 1

CIS

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~4~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 5 1

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

BASES

ACTIONS (continued)

The Completion Times of 6 hours and 12 hours for reaching MODES 3 and 4 from MODE 1 are reasonable, based on operating experience and normal cooldown rates, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant safety systems or operators.

Condition C applies to the failure of CRIS ~~Manual Trip,~~ Actuation Logic~~,~~ and required ~~particulate/iodine and required gaseous~~ radiation monitor ~~channels~~ ~~[~~in MODE 5 or 6~~]~~ or when moving ~~[recently]~~ irradiated assemblies. The Required Actions are immediately taken to place one OPERABLE CRE~~A~~CS train in the ~~emergency radiation protection~~ mode or to suspend ~~positive reactivity additions and~~ movement of ~~[recently]~~ irradiated fuel assemblies. The Completion Time recognizes the fact that the radiation signals are the only Functions available to initiate control room isolation in the event of a fuel handling accident requiring control room isolation. 3 recirculation V 3 1

~~Required Action [C.2.2] is modified by a Note to indicate that normal plant control operations that individually add limited positive reactivity (e.g., temperature or boron fluctuations associated with RCS inventory management or temperature control) are not precluded by this Action, provided they are accounted for in the calculated SDM.~~ 5

SURVEILLANCE REQUIREMENTS

SR 3.3.~~8~~.1 7 2

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value.

Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the transmitter or the signal processing equipment has drifted outside its limit.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[The Frequency, about once every shift, is based on operating experience that demonstrates the rarity of channel failure. Since the probability of two random failures in redundant channels in any 12 hour period is low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of the displays associated with the LCO required channels.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4 3

~~At this unit, the following administrative controls and design features (e.g., downscale alarms) immediately alert operations to loss of function in the nonredundant channels.~~ 1

~~[At this unit, verification of sample system alignment and operation for gaseous, particulate, and iodine monitors is required as follows:]~~ 3

SR 3.3.~~8~~.2 7 2

A CHANNEL FUNCTIONAL TEST is performed on the required control room radiation monitoring channel to ensure the entire channel will perform its intended function. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology. Any setpoint adjustment shall be consistent with the assumptions of the current plant specific setpoint analysis.

SURVEILLANCE REQUIREMENTS (continued)

~~[The Frequency of [92] days is based on plant operating experience with regard to channel OPERABILITY and drift, which demonstrates that failure of more than one channel of a given Function in any [92] day interval is a rare event.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. 3

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4 3

SR 3.3.~~8~~.3 7 2

Proper operation of the individual initiation relays is verified by de-energizing these relays during the CHANNEL FUNCTIONAL TEST of the Actuation Logic. This will actuate the Function, operating all associated equipment. Proper operation of the equipment actuated by each train is thus verified. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

~~[The Frequency of [31] days is based on plant operating experience with regard to channel OPERABILITY, which demonstrates that failure of more than one channel of a given Function in any [31] days interval is a rare event.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. 3

B 3.3 INSTRUMENTATION ~~(Analog)~~ 2

B 3.3.~~8~~ 7 Control Room Isolation Signal (CRIS) ~~(Analog)~~ 2

BASES

BACKGROUND

This LCO encompasses CRIS actuation, which is a plant specific instrumentation channel that performs an actuation Function required for plant protection but is not otherwise included in LCO 3.3.~~5~~ 4, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual ~~Trip," or LCO 3.3.6, "Diesel Generator (DG) - Loss of Voltage Start (LOVS)~~." This is a non-Nuclear Steam Supply System ESFAS Function that, because of differences in purpose, design, and operating requirements~~,~~ is not included in LCO 3.3.~~5 and LCO 3.3.6~~. ~~Details of this LCO are for illustration only. Individual plants shall include those Functions and LCO requirements that are applicable to them.~~

The CRIS terminates the normal supply of outside air to the control room and initiates actuation of the ~~Emergency Radiation Protection~~ System to minimize operator radiation exposure. The CRIS includes two independent, redundant subsystems, including actuation trains. Each train employs two separate sensors. ~~One sensor detects gaseous activity. The other detects particulate and iodine activity. Since the two sensors detect different types of activity, they are not considered redundant to each other. However, since there are separate sensors in each train, the trains are redundant.~~ If the bistable monitoring either sensor indicates an unsafe condition, that train will be actuated (one-out-of-two logic). The two trains actuate separate equipment. Actuating either train will perform the intended function. Control room isolation also occurs on a ~~Safety Injection Actuation Signal (SIAS)~~.

Trip Setpoints and Allowable Values

Trip setpoints used in the bistables are based on the ~~analytical limits~~ (Ref. 1). The selection of these trip setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, and instrument drift, Allowable Values specified in LCO 3.3.~~8~~ 7 are conservatively adjusted with respect to the ~~analytical limits~~ setpoint. ~~A detailed description of the methodology used to calculate the trip setpoints, including their explicit uncertainties, is provided in "Plant Protection System Selection of Trip Setpoint Values" (Ref. 2).~~ The actual nominal trip setpoint entered into the bistable is ~~normally~~ still more conservative than that specified by the Allowable Value to account for changes in random measurement errors detectable by a CHANNEL FUNCTIONAL TEST. One example of such a change in measurement error is drift during the surveillance interval. ~~If the measured setpoint does not exceed the Allowable Value, the bistable is considered OPERABLE.~~

BASES

BACKGROUND (continued)

Setpoints in accordance with the Allowable Value will ensure that Safety Limits are not violated during anticipated operational occurrences (AOOs) and the consequences of Design Basis Accidents will be acceptable, providing the plant is operated from within the LCOs at the onset of the AOO or accident and the equipment functions as designed.

APPLICABLE SAFETY ANALYSES

The CRIS, in conjunction with the Control Room Emergency ~~Air Cleanup~~ System (CRE~~AC~~S), maintains the control room atmosphere within conditions suitable for prolonged occupancy throughout the duration of any one of the accidents discussed in Reference ~~1~~. The radiation exposure of control room personnel, through the duration of any one of the postulated accidents discussed in "Accident Analysis," FSAR, Chapter ~~[~~15~~]~~ (Ref. ~~1~~), does not exceed the limits set by 10 CFR 50, Appendix A, GDC 19 (Ref. 3).

Loss of Coolant Accident (LOCA) is not a limiting event because the CIAS is credited for isolation of the Control Room, no credit is taken for isolation on high radiation in the accident analysis.

The CRIS satisfies the requirements of Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

LCO 3. 3.~~8~~ requires one channel of CRIS to be OPERABLE. The required channel consists of Actuation Logic, ~~Manual Trip,~~ and ~~particulate/iodine and gaseous~~ radiation monitors. The specific Allowable Value~~s~~ for the setpoint~~s~~ of the CRIS ~~are~~ listed in the SRs.

Only the Allowable Value~~s~~ ~~are~~ specified for ~~each~~ trip Function in the LCO. Operation with a trip setpoint less conservative ~~than the nominal trip setpoint,~~ but within its Allowable Value, is acceptable, provided that the difference between the ~~nominal~~ trip setpoint and the Allowable Value is equal to or greater than the drift allowance assumed ~~for each trip~~ in the ~~transient and accident~~ analyses.

~~E~~ach Allowable Value specified is more conservative than the ~~analytical limit assumed in the transient and accident analysis~~ in order to account for instrument uncertainties appropriate to the trip Function. These uncertainties are defined in Reference ~~2~~. A channel is inoperable if its actual trip setpoint is not within its required Allowable Value.

The Bases for the LCO on the CRIS are discussed below for each Function:

BASES

LCO (continued)

a. ~~Manual Trip~~

~~The LCO on Manual Trip backs up the automatic trips and ensures operators have the capability to rapidly initiate the CRIS Function if any parameter is trending toward its setpoint. One channel must be OPERABLE. This considers that the Manual Trip capability is a backup and that other means are available to actuate the redundant train if required, including manual SIAS.~~ 1

b. ~~Airborne~~ Radiation

One ~~Both~~ channel~~s~~ of ~~Airborne~~ Radiation detection in each ~~the~~ required train is ~~are~~ required to be OPERABLE to ensure the control room isolates ~~on either high iodine and high particulate or gaseous concentration~~.

~~[~~For this unit, the basis for the Allowable Value is as follows:~~]~~ 3

b. ~~c.~~ Actuation Logic 1

A background reading of approximately 40 cpm is typical for the air intake radiation monitors. An actuation setpoint of ≤ 320 cpm is consistent with the EPRI TR-102644 setpoint value recommendation of 8 times background.

One train of Actuation Logic must be OPERABLE, since there are alternate means available to actuate the redundant train, including CIAS ~~SIAS~~. 1 | R1

APPLICABILITY

The CRIS Functions must be OPERABLE in MODES 1, 2, 3, 4, ~~[~~5, and 6~~]~~ and during movement of ~~[recently]~~ irradiated fuel assemblies ~~[(i.e., fuel that has occupied part of a critical reactor core within the previous [X] days)]~~ to ensure a habitable environment for the control room operators. 3

~~REVIEWER'S NOTE~~

~~For those plants that credit gas decay tank rupture accidents, the CRIS must also be OPERABLE in MODES 5 and 6.~~ 4

ACTIONS

A CRIS channel is inoperable when it does not satisfy the OPERABILITY criteria for the channel's function. The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the ~~plant~~ specific setpoint ~~analysis~~. Typically, the drift is not large and would result in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the process instrument is set up for adjustment to bring it within specification. If the trip setpoint is not within the Allowable Value, the channel is inoperable and the appropriate Conditions must be entered. 1

BASES

ACTIONS (continued)

A.1, B.1, B.2, C.1, C.2~~.1,~~ and ~~C.2.2~~ 5

~~Conditions A and C have been modified by a Note, which specifies that CREACS be placed manually in the toxic gas protection mode if the automatic transfer to the toxic gas protection mode is inoperable. [At this unit, the basis for this Note is as follows:]~~

Conditions A, B, and C are applicable to ~~manual and~~ automatic actuation of the CRE~~AC~~S by CRIS. Condition A applies to the failure of the CRIS ~~Manual Trip,~~ Actuation Logic~~, and required particulate/iodine~~ and required ~~gaseous~~ radiation monitor channels in MODE 1, 2, 3, or 4. Entry into this Condition requires action to either restore the failed channel(s) or manually perform the CRIS safety function (Required Action A.1). The Completion Time of 1 hour is sufficient to complete the Required Actions and accounts for the fact that CRIS supplements control room isolation by other Functions (e.g., ~~S~~IAS) in MODES 1, 2, 3, and 4. If the channel cannot be restored to OPERABLE status, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours (Required Action B.1) and to MODE 4 within 12 hours (Required Action B.2). 1 R1

CIAS

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. ~~4~~). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 5 1

Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

BASES

ACTIONS (continued)

The Completion Times of 6 hours and 12 hours for reaching MODES 3 and 4 from MODE 1 are reasonable, based on operating experience and normal cooldown rates, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant safety systems or operators.

Condition C applies to the failure of CRIS ~~Manual Trip,~~ Actuation Logic~~,~~ and required ~~particulate/iodine and required gaseous~~ radiation monitor ~~channels~~ ~~[~~in MODE 5 or 6~~]~~ or when moving ~~[recently]~~ irradiated assemblies. The Required Actions are immediately taken to place one OPERABLE CRE~~A~~CS train in the ~~emergency radiation protection~~ mode or to suspend ~~positive reactivity additions and~~ movement of ~~[recently]~~ irradiated fuel assemblies. The Completion Time recognizes the fact that the radiation signals are the only Functions available to initiate control room isolation in the event of a fuel handling accident requiring control room isolation.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.7 BASES, CONTROL ROOM ISOLATION SIGNAL (CRIS)

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. Changes are made to reflect the ITS Specification number and title. Numbering is changed from 3.3.7 to 3.3.6, title is changed to “Containment Isolation Instrumentation – Refueling” and “(Analog)” is deleted from the title.

3. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. Changes have been made to reflect changes made to the Specification.

6. Changes have been made to reflect a change to the numbering of ISTS Specification 3.3.5.

DISCUSSION OF CHANGES
ITS 3.3.8, FUEL POOL AREA HIGH RADIATION INSTRUMENTATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.3.3.1 specify requirements for radiation monitoring instrumentation and list the requirements for each functional unit in CTS Table 3.3-6, including the Fuel Pool Storage Area Monitor instrumentation. ITS 3.3.8 provides requirements for the fuel pool area radiation instrumentation and provides the requirements in the LCO, Applicability, ACTIONS, and Surveillance Requirements. This changes the CTS by presenting the instrument requirements without use of an instrument table. This change is acceptable as it results solely from the change in the format and presentation of the CTS necessary to conform to the ISTS. This change is designated as administrative and is acceptable because it is the result of changes in the format and presentation of the CTS requirements and does not result in a technical change to the CTS.

A03 CTS 3.3.3.1 Action c states that the provisions of Specification 3.0.3 are not applicable. CTS 3.0.3 (ITS LCO 3.0.3) does not apply in MODES 5 and 6, which encompasses the condition of during movement of recently irradiated fuel assemblies. This changes the CTS by eliminating an action requirement that is redundant to other Technical Specification requirements.

The purpose of CTS 3.3.3.1 Action c is to preclude action be taken per Specification 3.0.3 (ITS LCO 3.0.3) to shutdown the unit in the event there are no actions to perform or the actions cannot be performed within the required time when the fuel pool area radiation monitoring instrumentation is inoperable. The ITS Applicability is changed to “During movement of recently irradiated fuel assemblies in the spent fuel storage pool (Refer to Discussion of Change L01). CTS 3.0.3 (ITS LCO 3.0.3) is not applicable while in MODE 5 or 6. Recently irradiated fuel is defined as fuel that has occupied part of a critical reactor core within the previous 72 hours. To access the fuel to begin movement of recently irradiated fuel requires the unit to be in MODE 6. Therefore, the only time recently irradiated fuel can possibly be moved in the spent fuel storage pool is following entry into MODE 6 and only up to 72 hours after reaching subcritical conditions. Since LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4, stating that the provisions of Specification 3.0.3 are not applicable is redundant and unnecessary. This change is designated as administrative and is acceptable because it does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.3.3.1 Action a allows the alarm/trip setpoint of Table 3.3-6 to exceed the setpoint for 4 hours and then to declare the channel inoperable. Upon declaring the channel inoperable, CTS Table 3.3-6, Action 13 (Unit 1) and Action 22 (Unit 2) require area surveys of the monitored area to be performed with portable monitoring instrumentation at least one every 24 hours. ITS 3.3.8 requires the channel to be declared inoperable immediately when the alarm (Unit 1) / actuation (Unit 2) setting exceeds the setpoint specified in SR 3.3.8.3 and associated actions must be performed. This changes the CTS by deleting the 4 hour allowance to declare a channel inoperable and requiring the channel to be declared inoperable immediately upon discovery that the channel is outside the required trip/alarm setpoint value.

The purpose of CTS 3.3.3.1 Action a is to provide a short time period to restore an inoperable channel prior to requiring additional action. CTS 3.3.3.1 Action a allows the alarm/trip setpoint of Table 3.3-6 to exceed the setpoint for 4 hours and then to declare the channel inoperable. When LCO 3.3.8 is not met (i.e., SR 3.3.8.3 not met), LCO 3.0.2 requires the associated ACTIONS to be entered with no delay. For Unit 2, each radiation channel provides input to the associated fuel pool area high radiation instrument train which actuates the associated Shield Building Ventilation System (SBVS) train. Therefore, the ITS action is considered appropriate. This change is designated as more restrictive because the Completion Time to declare the required fuel pool area radiation instrument channels inoperable following discovery of an associated channel exceeding it associated trip setpoint has been reduced.

M02 CTS 3.3.3.1 Action b requires, when one or more radiation monitoring channels are inoperable, to take the ACTION shown in Table 3.3-6. Thus, when the Unit 1 Fuel Storage Pool Area monitor channel is inoperable CTS Table 3.3-6, Action 13 requires area surveys of the monitored area to be performed with portable monitoring instrumentation at least once every 24 hours. When one or more Unit 2 Fuel Storage Pool Area Criticality and Ventilation System Isolation Monitor channels are inoperable CTS Table 3.3-6, Action 22 also requires area surveys of the monitored area to be performed with portable monitoring instrumentation at least once every 24 hours. Unit 1 ITS 3.3.8 ACTIONS require, when the required fuel pool area high radiation monitoring channel is inoperable, immediate suspension of movement of recently irradiated fuel assemblies within the spent fuel storage pool. Unit 2 ITS 3.3.8 ACTION A requires, with one fuel pool area high radiation instrument train inoperable, the associated fuel pool area high radiation instrument train to be restored to OPERABLE status within 7 days. With two fuel pool area high radiation instrument trains inoperable or if one inoperable instrument train cannot be restored within 7 days, Unit 2 ITS 3.3.8 ACTION B requires immediate suspension of recently irradiated fuel assemblies within the spent fuel storage pool (i.e., exit the Applicability). This changes the CTS actions by replacing the requirement to perform radiation surveys every 24 hours with portable monitoring instrumentation with actions to restore the instrumentation to OPERABLE status (Unit 2) or exit the Applicability (Unit 1 and Unit 2).

DISCUSSION OF CHANGES
ITS 3.3.8, FUEL POOL AREA HIGH RADIATION INSTRUMENTATION

The purpose of the CTS 3.3.3.1 requirements is to ensure radiation instrumentation required to actuate safety related systems are OPERABLE. The fuel storage pool area monitoring instrumentation for Unit 1 is provided to monitor radiation levels in the fuel pool area to alert the operator of the need to filter airborne radioactive particulate following a fuel handling accident (FHA). On a Unit 1 high fuel pool area radiation signal, the Fuel Pool Area Ventilation System is manually started and aligned to exhaust the spent fuel storage pool area through the Fuel Pool Area Ventilation System filtration unit, if the alarm is due to an FHA. The fuel storage pool area monitoring instrumentation for Unit 2 is provided to actuate the SBVS and aligns the system to the area of the spent fuel storage pool to filter airborne radioactive particulate following an FHA. On a Unit 2 high fuel pool area radiation signal, the SBVS automatically starts and aligns to exhaust the spent fuel storage pool area through the SBVS filtration units.

10 CFR 50.36(c)(2)(i) requires, in part, when LCO is not met, the licensee to shut down the reactor or follow any remedial action permitted by the Technical Specifications until the condition can be met. Although the CTS action to perform area surveys of the monitored area with portable monitoring instrumentation at least once every 24 hours does provide compensatory actions for monitoring radiation levels during normal operation, the action requirement does not provide an appropriate remedial action necessary to place the plant in a safe condition with required monitoring instrumentation inoperable that is necessary to support the mitigation of an FHA in the spent fuel storage pool. Unit 1 ITS 3.3.8 ACTION A is acceptable because the action places the unit in a condition in which the LCO does not apply (i.e., immediately suspend movement of recently irradiated fuel assemblies in the spent fuel storage pool). This does not preclude the movement of fuel to a safe position. Unit 2 ITS 3.3.8 ACTION A is acceptable because when one fuel pool area high radiation instrument train is inoperable (e.g., one or two required fuel pool area high radiation channels are inoperable or an actuation logic relay is inoperable), the inoperable instrument train must be restored to OPERABLE status within 7 days. The remaining OPERABLE instrument train in this degraded condition is capable of actuating one SBVS train following an FHA. The Completion Time is consistent with the Completion Time to restore one inoperable SBVS train to OPERABLE status in the ACTIONS of Specification 3.6.9, “Shield Building Ventilation System (SBVS),” and is based on consideration of such factors as the availability of the OPERABLE redundant instrument train and the low probability of an FHA occurring during this period. Unit 2 ITS 3.3.8 ACTION B is acceptable because, when one fuel pool area high radiation instrument train cannot be restored to OPERABLE status within 7 days or when two fuel pool area high radiation instrument trains are inoperable during movement of recently irradiated fuel assemblies, the action places the unit in a condition in which the LCO does not apply (i.e., immediately suspend movement of recently irradiated fuel assemblies in the spent fuel storage pool). This does not preclude the movement of fuel to a safe position. This change is designated as more restrictive because the current actions that allow operation to continue for an unlimited period of time with the inoperable radiation monitoring instrumentation have been replaced with actions that limit the time operation in the specified condition can continue with the inoperable instrumentation.

DISCUSSION OF CHANGES
ITS 3.3.8, FUEL POOL AREA HIGH RADIATION INSTRUMENTATION

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* CTS Table 3.3-6 for radiation monitoring instrumentation has a column specifying the Measurement Range and a specific measurement range for the fuel storage pool area instrumentation. ITS 3.3.8 does not retain the "MEASUREMENT RANGE" column or the specific measurement range of the fuel pool area high radiation instrumentation. This changes the CTS by moving the instrument measurement range to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 (*Category 2 – Relaxation of Applicability*) CTS 3.3.3.1 requires the radiation monitoring instrumentation channels shown in Table 3.3-6 to be OPERABLE, which includes the Unit 1 Fuel Storage Pool Area Monitors (Instrument 1.a) and the Unit 2 Fuel Storage Pool Area Criticality and Ventilation System Isolation Monitors (Instrument 1.a.i). Footnote * specifies the Applicability for Unit 1 Instrument 1.a and Unit 2 Instrument 1.a.i and states," With fuel in the storage pool or building." The ITS 3.3.8 Applicability requires the instrumentation to be OPERABLE, "During movement of recently irradiated fuel assemblies in the spent fuel storage pool." This changes the CTS by relaxing the Applicability of the Fuel Storage Pool Area Monitors to only when there is a potential for a fuel handling accident (FHA) involving recently irradiated fuel, that is, during the movement of recently irradiated fuel assemblies in the spent fuel storage pool. | R1

The purpose of the area radiation monitoring instrumentation is to ensure that the Fuel Pool Ventilation System (Unit 1) or SBVS (Unit 2) can provide filtration to minimize the consequences of an FHA involving recently irradiated fuel (i.e., an irradiated fuel assembly that has occupied part of a critical reactor core within the previous 72 hours). This change is acceptable because the requirements continue to ensure that the structures, systems, and components are maintained in the specified conditions needed to minimize event consequences during an

FHA involving recently irradiated fuel. The FHA analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. It is improbable to move irradiated fuel within 72 hours of a plant shutdown (i.e., keff < 0.99) because of the physical time required to perform a controlled plant shutdown, cooldown and depressurize the Reactor Coolant System (RCS), and disassemble the reactor vessel to access irradiated fuel to begin fuel movement. Additionally, filtration of the fuel handling building is not assumed for an FHA in the spent fuel storage pool. The ITS requires OPERABLE fuel pool area high radiation instrumentation to ensure that, in the unlikely event an FHA in the spent fuel storage pool occurs within 72 hours of a unit shutdown, fuel pool area ventilation and filtration are provided to minimize the consequences of this improbable event. This change is designated as less restrictive because the LCO requirements are applicable in fewer conditions than in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.8, FUEL POOL AREA RADIATION INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS Specification number and title. Numbering is changed from 3.3.10 to 3.3.8 and “(Analog)” is deleted from the title.

BASES

BACKGROUND

This LCO encompasses the SBFAS, which is a plant specific instrumentation system that performs an actuation Function required for plant protection but is not otherwise included in LCO 3.3.5, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual Trip," or LCO 3.3.6, "Diesel Generator (DG) - Loss of Voltage Start (LOVS)." This is a non-Nuclear Steam Supply System ESFAS Function that, because of differences in purpose, design, and operating requirements, is not included in LCOs 3.3.5 and 3.3.6. Details of this LCO are for illustration only. Individual plants shall include those Functions and LCO requirements that are applicable to them.

Insert 1

1

APPLICABLE SAFETY ANALYSES

monitor

The SBFAS is required to filter the air space between the containment and shield building during a loss of coolant accident (LOCA), as discussed in FSAR, Chapter 15 (Ref. 1).

Insert 2

1

fuel pool area radiation instrumentation

The SBFAS satisfies the requirements of Criterion 3 of 10 CFR 50.36(c)(2)(ii).

1

LCO

The LCO on equipment OPERABILITY ensures that the SBFAS will perform as required when called upon.

fuel pool area radiation instrumentation

1

one fuel pool area high radiation monitoring channel

The LCO requires two channels of SBFAS automatic and Manual Trip to be OPERABLE. Two channels are necessary to ensure the required redundancy should one channel become inoperable.

Insert 3

1

APPLICABILITY

The SBFAS must be OPERABLE in MODES 1, 2, 3, and 4, since the possibility of a LOCA is greatest in these MODES. In MODE 5 or 6 the probability of a LOCA is greatly diminished, and there is ample time to respond manually to a LOCA event.

Insert 4

1

ACTIONS

When the number of inoperable channels in a trip Function exceeds those specified in the Conditions associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered if applicable in the current MODE of operation.

1

1 **INSERT 1**

fuel pool area radiation instrumentation which monitors radiation levels in the fuel pool area to alert the operator of the need to filter airborne radioactive particulate following a fuel handling accident (FHA). The Fuel Pool Area Ventilation System requirements are specified in LCO 3.7.17, "Fuel Pool Area Ventilation System." On a high fuel pool area radiation signal, the Fuel Pool Area Ventilation System is manually started and aligned to exhaust the spent fuel storage pool area through the Fuel Pool Area Ventilation System filtration unit if the alarm is due to an FHA. In this alignment, the system achieves and maintains a negative air pressure in the fuel handling building. Two channels of fuel pool area high radiation instrumentation, with a sensing range of 1 to 10E4 mR/hr, are provided to monitor the fuel pool area. | R1

1 **INSERT 2**

spent fuel storage pool area during an FHA involving recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous 72 hours). The analysis of the FHA is given in Reference 1

The FHA analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. Additionally, filtration of the fuel handling building is not assumed for an FHA in the spent fuel storage pool. The Technical Requirements Manual includes a decay time requirement that no fuel movement will commence until 72 hours after shutdown. This ensures that the FHA assumptions, including no filtration of the fuel handling building, are preserved. In the event an FHA in the spent fuel storage pool occurs within 72 hours of a unit shutdown, actuation of the Fuel Pool Area Ventilation System when high radiation is indicated in the fuel pool area high will provide filtration to minimize the consequences of this improbable event.

1 **INSERT 3**

Since the Fuel Pool Area Ventilation System consists of a common filtration unit and is a manually actuated system, only one channel of the fuel pool area radiation monitoring instrumentation is required to be OPERABLE.

1

INSERT 4

During movement of recently irradiated fuel assemblies in the spent fuel storage pool, the fuel pool area ventilation high radiation instrumentation is required to be OPERABLE to support the Fuel Pool Area Ventilation System. Due to radioactive decay associated with irradiated fuel assemblies in the spent fuel storage pool, the Fuel Pool Area Ventilation System is only required to mitigate FHAs that involve handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous 72 hours).

When movement of irradiated fuel assemblies within the spent fuel storage pool is not being conducted, the potential for an FHA within the fuel pool area does not exist. Additionally, due to radioactive decay, an FHA that involves handling non-recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core longer than 72 hours) will result in doses that are well within the guideline values specified in 10 CFR 50.67 even without fuel pool area ventilation filtration capability. Therefore, under these conditions the Fuel Pool Area Ventilation System, including the associated high radiation monitoring instrumentation, is not required to be OPERABLE.

BASES

ACTIONS (continued)

A.1

Insert 5

Condition A applies to the failure of one SBFAS Manual Trip channel or of one Actuation Logic associated with the Chemical and Volume Control System Isolation Signal or SBFAS. Required Action A.1 requires restoration of the inoperable channel to restore redundancy of the affected Function. The Completion Time of 48 hours is consistent with the Completion Time of other ESFAS Functions employing similar logic and should be adequate for most repairs while minimizing the risk of operating with an inoperable channel for a manually actuated Function. 1

B.1 and B.2

REVIEWER'S NOTE

Adoption of a MODE 4 end state requires the licensee to make the following commitments:

1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F]. 2

2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010. 2

Condition B specifies the shutdown track to be followed if the Required Action and associated Completion Time of Condition A are not met. If Required Action A.1 cannot be met within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. Inoperability of the SBFAS has no effect on plant core damage frequency in any operational MODE. 1

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 2). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 1

1

INSERT 5

When the required fuel pool area ventilation high radiation monitoring channel is inoperable during movement of recently irradiated fuel assemblies, action must be taken to place the unit in a condition in which the LCO does not apply. This involves immediately suspending movement of recently irradiated fuel assemblies in the spent fuel storage pool. This does not preclude the movement of fuel to a safe position.

BASES

ACTIONS (continued)

~~Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.~~

1

~~The Completion Times are reasonable, based on operating experience, to reach the required MODE from full power conditions in an orderly manner and without challenging plant systems.~~

~~- - - - - - - - - - - - - - - - -

1

INSERT 6

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit. If the channels are within the criteria, it is an indication that the channels are OPERABLE. If the channels are normally off scale during times when Surveillance is required, the CHANNEL CHECK will only verify that they are off scale in the same direction. Offscale low current loop channels are verified to be reading at the bottom of the range and not failed downscale.

INSERT 7

The CHANNEL FUNCTIONAL TEST tests the individual sensor subsystems using an analog test input to each bistable. A test signal is superimposed on the input in one channel at a time to verify that the bistable trips within the specified tolerance around the setpoint. Any setpoint adjustment shall be consistent with the assumptions of the plant specific setpoint analysis.

1

INSERT 8

SR 3.3.8.3 CHANNEL CALIBRATION is a complete check of the instrument channel, including the sensor. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive surveillances. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the extension analysis. The requirements for this review are outlined in Reference 2.

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.~~10~~ ~~Shield Building Filtration Actuation Signal (SBFAS) (Analog)~~

8

Fuel Pool Area Radiation Instrumentation

BASES

BACKGROUND

This LCO encompasses the ~~SBFAS, which is a plant specific instrumentation system that performs an actuation Function required for plant protection but is not otherwise included in LCO 3.3.5, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual Trip," or LCO 3.3.6, "Diesel Generator (DG) - Loss of Voltage Start (LOVS)." This is a non-Nuclear Steam Supply System ESFAS Function that, because of differences in purpose, design, and operating requirements, is not included in LCOs 3.3.5 and 3.3.6. Details of this LCO are for illustration only. Individual plants shall include those Functions and LCO requirements that are applicable to them.~~

Insert 1

1

APPLICABLE SAFETY ANALYSES

monitor

The ~~SBFAS~~ is required to ~~filter~~ the ~~air space between the containment and shield building during a loss of coolant accident (LOCA), as discussed in FSAR, Chapter 15 (Ref. 1)~~.

Insert 2

1

fuel pool area radiation instrumentation

The ~~SBFAS~~ satisfies the requirements of Criterion 3 of 10 CFR 50.36(c)(2)(ii).

1

LCO

The LCO on equipment OPERABILITY ensures that the ~~SBFAS~~ will perform as required when called upon.

fuel pool area radiation instrumentation

1

fuel pool area high radiation instrument logic trains

The LCO requires two ~~channels of SBFAS automatic and Manual Trip~~ to be OPERABLE. ~~Two channels are necessary to ensure the required redundancy should one channel become inoperable~~.

Insert 3

1

APPLICABILITY

~~The SBFAS must be OPERABLE in MODES 1, 2, 3, and 4, since the possibility of a LOCA is greatest in these MODES. In MODE 5 or 6 the probability of a LOCA is greatly diminished, and there is ample time to respond manually to a LOCA event.~~

Insert 4

1

ACTIONS

~~When the number of inoperable channels in a trip Function exceeds those specified in the Conditions associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered if applicable in the current MODE of operation.~~

1

1

INSERT 1

fuel pool area radiation instrumentation which actuates the Shield Building Ventilation System (SBVS) and aligns the system to the area of the spent fuel storage pool to filter airborne radioactive particulate following a fuel handling accident (FHA). The SBVS requirements are specified in LCO 3.6.9, "Shield Building Ventilation System (SBVS)." On a high fuel pool area radiation signal, the SBVS starts and aligns to exhaust the spent fuel storage pool area through the SBVS filtration units. In this alignment, the system achieves and maintains a negative air pressure in the fuel handling building. Six channels of fuel pool area high radiation instrumentation, with a sensing range of 1 to 10E4 mR/hr, are provided to the fuel pool area instrument logic. The fuel pool area instrument logic includes two independent, redundant actuation logic trains arranged in a two-out-of-three coincidence with input from the fuel pool area high radiation channels; three channels per train. Each SBVS train is actuated by its associated fuel pool area instrument logic train. The instrumentation requirements associated with other SBVS actuations are included in LCO 3.3.3, "Engineered Safety Features Actuation System (ESFAS) Instrumentation," and LCO 3.3.4, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual Trip." | R1

1

INSERT 2

spent fuel storage pool area during an FHA involving recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous 72 hours). The analysis of the FHA is given in Reference 1

The FHA analysis assumes movement of an irradiated fuel assembly that has not occupied part of a critical reactor core within the previous 72 hours. Additionally, filtration of the fuel handling building is not assumed for an FHA in the spent fuel storage pool. The Technical Requirements Manual includes a decay time requirement that no fuel movement will commence until 72 hours after shutdown. This ensures that the FHA assumptions, including no filtration of the fuel handling building, are preserved. In the event an FHA in the spent fuel storage pool occurs within 72 hours of a unit shutdown, automatic actuation of the SBVS on fuel pool area high radiation will provide filtration to minimize the consequences of this improbable event.

1

INSERT 3

For the purpose of this LCO, each instrument logic train consists of at least two fuel pool area high radiation channels, associated actuation logic and relays necessary to actuate the associated SBVS train and valves.

1

INSERT 4

During movement of recently irradiated fuel assemblies in the spent fuel storage pool, the fuel pool area ventilation high radiation instrumentation is required to be OPERABLE to support the fuel pool area ventilation mode of the SBVS. Due to radioactive decay associated with irradiated fuel assemblies in the spent fuel storage pool, the SBVS is only required to mitigate FHAs that involve handling recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core within the previous 72 hours).

When movement of irradiated fuel assemblies within the spent fuel storage pool is not being conducted, the potential for an FHA within the fuel pool area does not exist. Additionally, due to radioactive decay, an FHA that involves handling non-recently irradiated fuel (i.e., fuel that has occupied part of a critical reactor core longer than 72 hours) will result in doses that are well within the guideline values specified in 10 CFR 50.67 even without fuel pool area ventilation filtration capability. Therefore, under these conditions the fuel pool area ventilation mode of the SBVS, including the associated high radiation instrumentation, is not required to be OPERABLE.

BASES

ACTIONS (continued)

A.1

Insert 5

Condition A applies to the failure of one SBFAS Manual Trip channel or of one Actuation Logic associated with the Chemical and Volume Control System Isolation Signal or SBFAS. Required Action A.1 requires restoration of the inoperable channel to restore redundancy of the affected Function. The Completion Time of 48 hours is consistent with the Completion Time of other ESFAS Functions employing similar logic and should be adequate for most repairs while minimizing the risk of operating with an inoperable channel for a manually actuated Function. 1

B.1 and B.2

---------- REVIEWER'S NOTE ----------
Adoption of a MODE 4 end state requires the licensee to make the following commitments:

1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F]. 2

2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010. 2

Condition B specifies the shutdown track to be followed if the Required Action and associated Completion Time of Condition A are not met. If Required Action A.1 cannot be met within the required Completion Time, the plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. Inoperability of the SBFAS has no effect on plant core damage frequency in any operational MODE. 1

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 2). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. 1

1

INSERT 5

When one fuel pool area high radiation instrument train is inoperable (e.g., one or two required fuel pool area high radiation channels are inoperable or an actuation logic relay is inoperable), the inoperable instrument train must be restored to OPERABLE status within 7 days. The remaining OPERABLE instrument train in this degraded condition is capable of actuating one SBVS train following an FHA. The Completion Time is consistent with the Completion Time to restore one inoperable SBVS train to OPERABLE status in the ACTIONS of Specification 3.6.9 and is based on consideration of such factors as the availability of the OPERABLE redundant instrument train and the low probability of an FHA occurring during this period.

B.1

When Required Action A.1 is not met within the required Completion Time or when two fuel pool area high radiation instrument trains are inoperable during movement of recently irradiated fuel assemblies, action must be taken to place the unit in a condition in which the LCO does not apply. This involves immediately suspending movement of recently irradiated fuel assemblies in the spent fuel storage pool. This does not preclude the movement of fuel to a safe position.

BASES

ACTIONS (continued)

~~Required Action B.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.~~

See ITS 5.6

DISCUSSION OF CHANGES
ITS 3.3.9, POST ACCIDENT MONITORING (PAM) INSTRUMENTATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.3.3.8 and Unit 2 CTS 3.3.3.6 Actions provide the compensatory actions to take when PAM instrumentation is inoperable. ITS 3.3.9 ACTIONS provide the compensatory actions for inoperable PAM instrumentation. The ITS 3.3.9 ACTIONS include a Note that allows separate Condition entry for each Function. This changes CTS by providing a specific allowance to enter the Action for each inoperable PAM instrumentation Function.

This change is acceptable because it clearly states the current requirement. The CTS considers each PAM instrumentation Function to be separate and independent from the others. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 Unit 1 CTS 3.3.3.8 and Unit 2 CTS 3.3.3.6 Surveillance Requirements consist of a single surveillance (4.3.3.8 and 4.3.3.6, respectively). CTS Surveillances 4.3.3.8 and 4.3.3.6 state the defined test requirements (Channel Check and Channel Calibration) in accordance with the Surveillance Frequency Control Program. ITS 3.3.9 Surveillance Requirements consist of two separate surveillances SR 3.3.9.1 (Channel Check) and SR 3.3.9.2 (Channel Calibration). A note precedes the ITS surveillances and specifies the applicability of the surveillances to each PAM Function. In addition, ITS SR 3.3.9.2 contains a Note that excludes neutron detectors from the Channel Calibration requirement. Each ITS surveillance is applicable to the PAM Functions (including the newly added Functions) specified in ITS Table 3.3.9-1. This changes CTS by presenting the surveillance requirements in two distinct surveillance requirements and including an exception to the channel calibration requirement for neutron detectors. This change is acceptable as it results solely from the change in the format and presentation of the CTS surveillance requirements necessary to conform to the ITS. Separate change discussions address additional changes where applicable (e.g., addition of functions).

A04 Unit 1 CTS Table 3.3-11 and Unit 1 and 2 Tables 3.3-6 contain a column that specifies the applicable Action(s) for each instrument listed on the Table. The corresponding column in ITS Table 3.3.9-1 specifies the applicable Action Condition referenced from Required Action D.1. Unit 2 CTS 3.3.3.6 addresses Actions within the ACTION section and does not specify Actions for each Instrument (Function) individually in Unit 2 CTS Table 3.3-10. This changes the Unit 1 CTS by replacing the CTS table column specifying the applicable Actions for each PAM instrument with the ITS Table column specifying only the Action referenced from Required Action D.1 for each PAM Function. This changes the

Unit 2 CTS by replacing a table column and adding a table column specifying only the Action referenced from Required Action D.1 for each PAM instrument (Function).

In the ITS, ACTIONS except ACTIONS E and F are common to the PAM Functions listed on Table 3.3.9-1. Therefore, in the ITS, only ACTIONS E and F must be referenced from the Table as applicable for each PAM Function.

The proposed change to the Actions column in the PAM Table is acceptable because it is necessary to conform to the format and presentation of the PAM requirements in the ITS. Technical changes to the CTS Actions are identified and discussed in separate DOCs. The revision of the PAM table Action column does not introduce any additional technical changes and represents a necessary reformat to conform to the ITS. As the proposed change is the result of changes in the format and presentation of the PAM requirements, it is designated administrative.

A05 The title of Unit 1 CTS 3.3.3.8 and Unit 2 CTS 3.3.3.6, “Accident Monitoring Instrumentation” and CTS 3.3.3.1, “Radiation Monitoring Instrumentation” is revised to “Post Accident Monitoring (PAM) Instrumentation.” The CTS LCO operability requirement and Actions are revised from referencing instrument “channels” to referencing instrument “Functions.” The requirements for each PAM instrument (Function) listed in CTS Table 3.3-11 (Unit 1), CTS Table 3.3-10 (Unit 2) and CTS Table 3.3-6 are further revised to specify the "Required Channels" for each instrument Function. In addition, the CTS reference to "Minimum Channels Operable" on Table 3.3-11 (Unit 1), Table 3.3-10 (Unit 2) and CTS 3.3-6 is deleted. The proposed changes are consistent with the presentation of this information in the corresponding ITS 3.3.9, “Post Accident Monitoring (PAM) Instrumentation.” R1

The proposed changes are acceptable because they result in a uniform presentation of the PAM requirements without introducing a technical change to the requirements. The use of the term "Function" in the LCO and on ITS Tables 3.3.9-1 merely replaces the term "channel" in the LCO and "Instrument" in CTS Table 3.3-11 (Unit 1), CTS Table 3.3-10 (Unit 2) and CTS Table 3.3-6 to provide a uniform reference in the ITS. The corresponding proposed ITS Actions reference one or two inoperable channels associated with a PAM Function. As such, the proposed Actions are consistent with the use of the term Function and "Required Channels" used in the ITS to specify the instrument requirements. In addition, the proposed Actions, by addressing two or more inoperable channels (i.e., ITS Action C) effectively replace the CTS need to reference less than the "Minimum Operable Channels" in the Actions. Thus, the CTS "Minimum Operable Channels" column on Table 3.3-11, Table 3.3-10 and Table 3.3-6 is not needed and is deleted. The proposed changes are designated administrative because they represent a change in the format and presentation of the requirements and do not result in a technical change. R1 R1

A06 The CTS PAM requirement for Core Exit Temperature consists of specifying 4 incore thermocouples per core quadrant. The ITS presents this requirement differently. The corresponding ITS requirement for Core Exit Temperature specifies (2) Required Channels for each core quadrant and lists each quadrant R1

separately. In addition, the ITS requirement for two channels is modified by footnote (c) that requires each channel to contain two or more core exit thermocouples (CETs). The CTS is revised to conform to the ITS. This changes the CTS by revising the presentation of the Core Exit Temperature Function to be stated in terms of "Required Channels" per quadrant. | R1 | R1

The purpose of the PAM TS requirement is to ensure sufficient indication instrumentation is maintained operable to provide the necessary indication in post-accident conditions. The CTS requires (4) CETs per core quadrant. The ITS, by specifying (2) channels per quadrant with each channel consisting of (2) CETs, effectively requires the same number of CETs operable as the CTS. As such, the proposed change is acceptable because it continues to require an adequate number of operable CETs to assure the Core Exit Temperature indication continues to be available for PAM purposes. The proposed change only revises the presentation of this information to be consistent with the ITS. This change in format does not introduce a technical change to the CTS requirements. The proposed change is designated administrative because it does not introduce a technical change to the CTS.

A07 Unit 1 CTS Table 3.3-11 Actions 4 and 5, Unit 2 CTS 3.3.3.6 Actions c and d, and CTS Table 3.3-6 Unit 1 Action 15 and Unit 2 Action 27 require, in part, to prepare and submit a Special Report to the Commission pursuant to Specification 6.9.2 and includes detail on what to include in the report and the timing to submit the report. ITS 3.3.9 ACTIONS B and F require a similar action by stating “Initiate action in accordance with Specification 5.6.4,” but does not include the detail of what to include in the report or the timing to submit the report. These details are provided in Specification 5.6.4, “Post Accident Monitoring Report.” This changes the CTS by moving report detail to another Specification in the ITS.

The purpose of the CTS action is to ensure appropriate level of information is provided to the NRC when submitting a special PAM report. Moving these administrative details to another Specification is acceptable equivalent information in retained in the ITS. Any changes related to the CTS actions moved to ITS Section 5.6 are discussed in the ITS 5.6 Discussion of Changes. This change is a presentation preference and is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS Table 3.3-11, Instrument 9 (Containment Sump Water Level (Wide Range)) specifies Action 5 when less than the Minimum Operable Channels is not met (i.e., both required channels are inoperable). Unit 2 CTS 3.3.3.6, Action d applies to Table 3.3-10, Instrument 16 (Containment Water Level (Wide Range) when the number of OPERABLE channels is less than the Minimum Channels Operable requirements (i.e., both required channels are inoperable). These actions require, in part, to prepare and submit a Special Report to the Commission within 30 days if the instrument cannot be restored to OPERABLE status within 48 hours. For the same Function (ITS Table 3.3.9-1, Function 6), ITS 3.3.9 ACTION E requires the unit to be placed in MODE 3 within 6 hours and | R1

MODE 4 within 12 hours if one channel cannot be restored to OPERABLE status within 7 days. This changes the CTS by requiring a plant shutdown instead of preparing and submitting a report to the NRC.

The purpose of the action requirement when at least one channel of Containment Water Level (wide range) cannot be restored to OPERABLE status within the required time is to ensure remedial actions are provided that are acceptable for continued operation or a plant shutdown is required. ISTS 3.3.11 (ITS 3.3.9), ACTION F, which requires initiation of action to prepare and submit a PAM report to the NRC, is applicable to PAM instrument Functions that have alternate means of monitoring developed and tested. This change is necessary because the Containment Water Level (wide range) PAM instrument does not currently have an established alternate means developed and tested to monitor containment level during worst case post-accident conditions. Therefore, if at least one Containment Water Level (wide range) channel cannot be restored to OPERABLE status within the required Completion Time when two required channels are inoperable, ACTION E will require placing the unit in MODE 3 in 6 hours and MODE 4 in 12 hours. This change is designated as more restrictive because a plant shutdown is required in ITS that is not required in CTS for a similar condition. | R1

M02 Unit 1 CTS Table 3.3-11 does not require OPERABLE indication channels for Excore Neutron Flux, Reactor Coolant System Hot Leg Temperature, Reactor Coolant System Cold Leg Temperature, Pressurizer Pressure, Penetration Flow Path Containment Isolation Valve Position, Condensate Storage Tank Level and Containment Hydrogen Concentration. These are added to the Unit 1 CTS and shown in ITS Table 3.3.9-1, Functions 1, 2, 3, 4, 8, 11,12, and 17. Unit 2 CTS Table 3.3-10 does not require OPERABLE indication channels for Excore Neutron Flux, Penetration Flow Path Containment Isolation Valve Position, Steam Generator Water Level (Wide Range), Condensate Storage Tank Level and Containment Hydrogen Concentration. These are added to the Unit 2 CTS and shown in ITS Table 3.3.9-1, Functions 1, 8, 12, and 17. Two channels are provided for Excore Neutron Flux (Function 1). Two channels per loop are provided for Reactor Coolant System Hot and Cold Leg Temperature (Functions 2 and 3, respectively). Two channels are provided for Pressurizer Pressure (Function 4). Two channels per penetration flow path are provided for Penetration Flow Path Containment Isolation Valve Position (Function 8). This requirement is modified by two footnotes, footnotes (a) and (b). Footnote (a) does not require position indication for isolation valves whose penetration is isolated by at least one closed and deactivated automatic valve, closed manual valve, blind flange or check valve with flow through the valve secured. Footnote (b) requires only one position indication channel per penetration flow path with one installed channel located in the control room. One channel per steam generator is provided for Steam Generator Water Level (Wide Range) (Function 11). One channel is provided for Condensate Storage Tank Level (Function 12). Two channels are provided for Containment Hydrogen Concentration (Function 17). ITS 3.3.9 ACTION A has been added to cover the Condition when one or more Functions have one required channel inoperable. ITS 3.3.9 Required Action A.1 allows 30 days to restore the required channel to OPERABLE status. If this Required Action and associated Completion Time of Condition A is not met, then ITS Required Action B.1 requires the immediate initiation of the actions specified

in Specification 5.6.4. ITS 3.3.9 ACTION C has been added to cover the Condition when one or more Functions have two required channels inoperable. ITS 3.3.9 Required Action C.1 requires restoration of one channel to OPERABLE status within 7 days. If this cannot be met, then ITS 3.3.9 Condition D must be entered, which will then require entry into Condition E where ITS 3.3.9 Required Actions E.1 and E.2 require the unit to be in MODE 3 within 6 hours and MODE 4 within 12 hours. A Note has been added to the ACTIONS to allow Separate Condition entry for each Function. In addition, separate Condition entry is allowed within a Function as follows: (a) for Function 8 on a penetration flow path basis and b) for Function 11 on a steam generator basis. In addition, SRs are added for each Function. These SRs are a CHANNEL CHECK for each required instrumentation channel that is normally energized (SR 3.3.9.1) and a CHANNEL CALIBRATION (SR 3.3.9.2). For the CHANNEL CALIBRATION of the Excore Neutron Flux Function channels, SR 3.3.9.2 is modified by a note that states "Neutron detectors are excluded from CHANNEL CALIBRATION." This changes the CTS by adding new Functions, Footnotes, a Note, applicable ACTIONS, and SRs. R1

This change is acceptable because a plant specific evaluation has concluded that these instrumentation channels are required to provide the primary, unambiguous information to the operator necessary to perform manual actions for which no automatic controls exist and that are required for safety systems to accomplish their safety functions for design basis accident (DBA) events. The change is designated as more restrictive because 8 new instrumentation functions are added to the Unit 1 Technical Specifications and 4 new instrumentation functions are added to the Unit 2 Technical Specifications.

M03 CTS 3.3.3.1 Action c states that the provisions of Specification 3.0.3 are not applicable. ITS 3.3.9 does not include an LCO 3.0.3 exception. This changes the CTS by eliminating the CTS 3.0.3 exception. CTS 3.0.3 requires the unit to be shutdown when the requirements of LCOs and associated Actions are not satisfied. In CTS or ITS, an exception to CTS 3.0.3 (ITS LCO 3.0.3) is not provided to the PAM instrumentation Specification. The containment radiation high range instrumentation is a PAM instrument and is being appropriately moved to the PAM Instrumentation Specification. Eliminating the CTS 3.0.3 exception ensures that the operators are provided guidance regarding actions to take in the event the required PAM instrumentation is inoperable and associated ACTIONS are not satisfied within the required time periods. This change is designated as more restrictive because an explicit exception provided in the CTS is eliminated.

M04 CTS Table 3.3-6 Instrument 1.c (Containment Area – Hi Range), in part, requires one channel to be OPERABLE. ITS Table 3.3.9-1 Function 9 (Containment Radiation (high range)) requires two channels to be OPERABLE. ITS 3.3.9 also includes actions when one of the two Containment Radiation (high range) channels is inoperable. ACTION A requires the inoperable channel to be restored to OPERABLE status within 30 days and ACTION B requires immediately initiating action in accordance with Specification 5.6.4 (i.e., prepare and submit a report to the NRC) if the channel cannot be restored to OPERABLE status within 30 days. This changes the CTS by changing the number of

OPERABLE containment radiation high range monitoring channels from one to two and provides ACTIONS when one of two channels is inoperable.

The availability of PAM instrumentation is important so that responses to corrective actions can be observed and the need for, and magnitude of, further actions can be determined. The containment radiation high range instruments are essential PSL identified instruments addressing the recommendations of Regulatory Guide 1.97, as required by Supplement 1 to NUREG-0737, "Clarification of TMI Action Plan Requirements." This change is acceptable because the ITS reflects the requirements for diversity and redundancy stated in Regulatory Guide 1.97 and NRC Generic Letter 82-33. This provides the operator an unambiguous source of information for decisions needed following design basis events. The change is designated as a more restrictive because the number of required channels for the containment radiation high range Function is increased from one to two. Remedial actions are provided consistent with actions in the ISTS associated with the inoperability of a redundant channel of other PAM instruments.

RELOCATED SPECIFICATIONS

R01 Unit 1 CTS Table 3.3-11 and Unit 2 CTS Table 3.3-10 provide requirements for Post-Accident Monitoring Instrumentation channels. Each individual post accident monitoring parameter has a specific purpose, however, the general purpose for all accident monitoring instrumentation is to ensure sufficient information is available following an accident to allow an operator to verify the response of automatic safety systems, and to take preplanned manual actions to accomplish a safe shutdown of the plant.

The NRC position on application of the screening criteria to post-accident monitoring instrumentation is documented in a letter dated May 9, 1988 from T.E. Murley (NRC) to the Owners Groups. Regulatory Guide (RG) 1.97, Type A variables provide primary information; i.e., information that is essential for the direct accomplishment of the specified manual actions (including long term recovery actions) for which no automatic control is provided and that are required for safety systems to accomplish their safety functions for DBAs or transients. Additionally, it could not be confirmed that RG 1.97, non-Type A Category 1 variables are not of prime importance in limiting risk. Therefore, the NRC position is that the post-accident monitoring instrumentation list should contain Type A instruments and non-Type A Category 1 instruments specified in the plant's safety evaluation report (SER) on RG 1.97. Accordingly, this position has been applied to the PSL Units 1 and 2 RG 1.97 instruments. Those instruments meeting these criteria are retained in the Technical Specifications. The instruments not meeting these criteria will be relocated from the Technical Specifications to the Technical Requirements Manual (TRM). | R1

A review of the PSL Units 1 and 2 UFSAR and the NRC Regulatory Guide 1.97 Safety Evaluation for PSL Units 1 and 2 shows that the following Unit 1 CTS Table 3.3-11 and Unit 2 CTS Table 3.3.10 Instruments do not meet Category 1 or Type A requirements.

Unit 1 CTS Table 3.3-11

Instrument 2	Auxiliary Feedwater Flow Rate
Instrument 3	RCS Subcooling Margin Monitor
Instrument 4	PORV Position Indicator – Acoustic Flow Monitor
Instrument 5	PORV Block Valve Position Indicator
Instrument 6	Safety Valve Position Indicator
Instrument 8	Containment Sump Level

Unit 2 CTS Table 3.3-10

Instrument 6	Steam Generator Pressure
Instrument 7	Steam Generator Water Level – Narrow Range
Instrument 9	Refueling Water Tank Water Level
Instrument 10	Auxiliary Feedwater Flow Rate
Instrument 11	RCS Subcooling Margin Monitor
Instrument 12	PORV Position/Flow Indicator
Instrument 13	PORV Block Valve Position Indicator
Instrument 14	Safety Valve Position/Flow Indicator
Instrument 15	Containment Sump Water Level (Narrow Range)

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. These instruments are not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. The monitored parameters are not process variables, design features, or operating restrictions that are initial conditions of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier.

3. These instruments are not structures, systems, or components that are part of the primary success path or which function or actuate to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. These post-accident monitoring instrument functions are not addressed in the PSL PRA and do not represent a structure, system, or component which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

Since the 10 CFR 50.36(c)(2)(ii) criteria have not been satisfied for instruments which do not meet Regulatory Guide 1.97 Type A or non-Type A, Category 1 variable requirements, the requirements for these instruments may be relocated outside the Technical Specifications. The Technical Specification requirements for these instruments will be relocated to the TRM. Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as a relocation because the requirements for these instruments do not meet the criteria in 10 CFR 50.36(c)(2)(ii) and have been relocated to the TRM.

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS Table 3.3-11, Instrument 10 and Unit 2 CTS Table 3.3-10, Instrument 18, Reactor Vessel Level Monitoring channel OPERABILITY requirements are modified by Unit 1 footnote ** and Unit 2 footnote ***** that states "Definition of OPERABLE: A channel is composed of eight (8) sensors in a probe, of which four (4) sensors must be OPERABLE." ITS Table 3.3.9-1 Function 5 requires two channels to be OPERABLE but the details of what constitutes an OPERABLE channel are moved to the Bases. This changes the CTS by moving the details of what constitutes an OPERABLE channel to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for two channels of Reactor Vessel Level Indication to be OPERABLE and to perform CHANNEL CHECKS and CHANNEL CALIBRATIONS of the channels and ITS retains the definition of OPERABLE – OPERABILITY in ITS Section 1.1. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5 of the ITS. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 - Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS 3.3.3.8 Actions 4 and 5 and Unit 2 CTS 3.3.3.6 Actions c and d require restoring the channel to OPERABLE status within 7 days and 48 hours, respectively, “if repairs are feasible without shutting down.” In addition, Unit 1 CTS Action 5 and Unit 2 CTS Action d include the requirement to “Restore the Channel to OPERABLE status at the next scheduled refueling.” ITS SR 3.3.9 ACTIONS do not contain these details. This changes the CTS by removing the unnecessary detail in meeting the Action requirement. (See DOC L02 for additional discussion.)

The removal of these details from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the shutdown requirement as applicable. This change is designated as a less restrictive removal of detail change because operational details for meeting Technical Specifications requirements are being removed from the Technical Specification.

LA03 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS Table 3.3-6 for radiation monitoring instrumentation has a column specifying the Measurement Range and a specific measurement range for the containment radiation instrumentation. ITS 3.3.6 does not retain the "MEASUREMENT RANGE" column or the specific measurement range of the R1

containment radiation monitor channels. This changes the CTS by moving the instrument measurement range to the Bases. R1

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. The upper end of the measurement range for the containment radiation monitoring instrumentation is changed from 10^7 to 10^8 R/hr to be consistent with the current radiation monitor instrument measurement range. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 (*Category 3 - Relaxation of Completion Time*) Unit 1 CTS 3.3.3.8 Actions 1 and 4 and Unit 2 CTS 3.3.3.6 Actions a and c address a single inoperable channel in one or more PAM Functions. Unit 1 CTS Action 4 and Unit 2 CTS Action a and c are revised to extend the allowed restoration time of 7 days to 30 days. In addition, the Unit 1 CTS Action 1 and Unit 2 Action a requirement to place the plant in HOT SHUTDOWN (Mode 4) if the affected channel is not restored to operable status is replaced with ITS ACTION B. ITS ACTION B requires that action be “initiated immediately in accordance with Specification 5.6.4.” Specification 5.6.4 requires a report to be submitted to the NRC outlining the preplanned alternate method of monitoring, the cause of the inoperability, and the plans and schedule for restoring the instrumentation channels of the Function to OPERABLE status. This changes the CTS by removing the shutdown requirement and allowing continued operation with one inoperable channel provided the reporting requirement is initiated immediately.

The proposed changes are acceptable due to the passive function of the PAM instrumentation (indication only) and the ability to adequately respond to an accident or event using redundant or alternate indications. In addition, the Completion Time extension is justified based on the low likelihood of an event occurring within the allowed Completion Time that would require the affected PAM Function to be Operable. If the channel cannot be restored to Operable status within 30 days, ITS ACTION B requires initiation of action to submit a report to the NRC describing the plan to restore the function to operable status and the alternate method of monitoring during post-accident conditions. The change to submit a report to the NRC in lieu of a plant shutdown is acceptable, because it takes into account the adequacy of indication(s) available to monitor the required parameter. In addition, the proposed ITS Action Condition B requires a report to be issued to advise the NRC of the circumstances and expected duration of the inoperability. The proposed changes are designated less

restrictive as they result in additional time being allowed to restore the inoperable PAM instrumentation to operable status.

L02 (*Category 3 - Relaxation of Completion Time*) Unit 1 CTS Table 3.3-11 Actions 5 and 6 and Unit 2 CTS 3.3.3.6 Actions b and d address the condition of instruments with less than the minimum channels operable and requires the inoperable channel(s) to be restored to operable status in 48 hours. Unit 1 CTS Table 3.3-6 Action 15 and Unit 2 CTS Table 3.3-6 Action 27 address, in part, the condition of containment area hi range instrument with less than the minimum channels operable and requires the inoperable channel(s) to be restored to OPERABLE status in 72 hours. The corresponding ITS 3.3.9 Conditions C, D, E and F address one or more Functions with two or more inoperable channels. Required Action C.1 allows 7 days to restore all but one of the inoperable channels (which effectively leaves the inoperability within ITS Action Condition A for a single inoperable channel). Failure to meet Required Action C.1 results in entry into ITS Action Condition D. Required Action D.1 requires entry into the Action Condition referenced on Table 3.3.9-1 for the affected Function.

The significant changes introduced by the new ITS Actions used in place of Unit 1 CTS Table 3.3-11 Actions 5 and 6, Unit 2 CTS 3.3.3.6 Actions b and d, and CTS Table 3.3-6 Unit 1 Action 15 and Unit 2 Action 27 include:

- The extension of the 48 hour restoration time to 7 days (by ITS Action Condition C), and
- The extension of the 72 hour CTS restoration time to 7 days (by ITS Action Condition C).

The proposed change extends the existing limit on operation from 48 hours and 72 hours to 7 days for all instrument Functions. The proposed change is consistent with the industry standard operating limits in the ISTS (i.e., NUREG-1432) for this equipment. The changes are acceptable because they take into consideration the relatively low likelihood of an event that would require the use of the affected PAM Function, the availability of alternate means to obtain the information, and the fact that the indication is passive and does not provide any automatic protective actions. In addition, the proposed change provides additional restoration time that reduces the potential for a unit transient (i.e., reduces risk) introduced by a plant shutdown and restart due solely to inoperable indicating instruments that provide no automatic protective features. These changes are designated less restrictive because additional time is allowed in the ITS to restore channels to OPERABLE status than was allowed in the CTS.

L03 (*Category 1 – Relaxation of LCO Requirements*) CTS 3.3.3.1 and CTS Table 3.3-6, Instrument 1.c provide alarm setpoint requirements for the Containment Area Hi Range instrument. CTS 3.3.3.1 Action a provides actions to take when the Containment Area Hi Range instrument alarm setpoint exceeds the specified value. ITS 3.3.9 does not include alarm setpoint for the Containment Radiation (high range) instrumentation. This changes the CTS by eliminating the alarm setpoint requirements for the Containment Area Hi Range instrument, including the associated actions and alarm setpoint value.

The purpose of the Containment Area Hi Range PAM instrumentation is to provide the control room operator with indication of radiation in the containment

to monitor for the potential of significant radiation releases and to provide indication for release assessment used by operators in determining the need to invoke site emergency plans. This change is acceptable because the alarm setpoint is not assumed to acuate in any design basis accident or transient nor required to mitigate any design basis accident or transient. Additionally, the alarm setpoint is not necessary for the Containment Area Hi Range PAM instrumentation to perform its specified function of providing indication to the control room operators. ITS 3.3.9 requires the Containment Radiation (high range) instrumentation to be OPERABLE. The ITS 3.3.9 requirement and the definition of OPERABLE-OPERABILITY are adequate to ensure that the Containment Radiation (high Range) PAM instrumentation remains capable of providing indication to the control room operators. Additionally, this change does not preclude the plant from maintaining an active alarm setpoint to notify operators of high radiation conditions within the containment. This change is consistent with the ISTS and is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than were applied in the CTS.

L04 *(Category 2 – Relaxation of Applicability)* CTS Table 3.3-6 requires the Containment Area Hi Range instrument to be OPERABLE in MODES 1, 2, 3, and 4. ITS 3.3.9 requires the Containment Radiation (high range) PAM Function to be OPERABLE in MODES 1, 2, and 3. This changes the CTS by deleting the requirements for the Function in MODE 4.

The purpose of the Containment Area Hi Range PAM instrumentation is to provide the control room operator with indication of radiation in the containment to monitor for the potential of significant radiation releases and to provide indication for release assessment used by operators in determining the need to invoke site emergency plans. This change is acceptable because the requirements continue to ensure that the instruments are maintained in the MODES and other specified conditions assumed in the safety analyses and licensing basis. The Containment Radiation (high range) PAM instrumentation is required to be OPERABLE in MODES 1, 2, and 3. This is acceptable because in MODES 4, 5, and 6, accidents of the type that would require these instruments are less likely to occur because of reduced temperature and pressure in the RCS and secondary system. This change is consistent with the ISTS and is designated as less restrictive because the LCO requirements are applicable in fewer operating conditions than in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.9, POST ACCIDENT MONITORING (PAM) INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The heading for ISTS 3.3.11 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2) and Chemical and Volume Control System (CVCS) Isolation Signal (ISTS 3.3.9). Therefore, ISTS 3.3.2 and ISTS 3.3.9 are not included in the PSL ITS. The successive Specifications are renumbered as necessary.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. Changes have been made to reflect change to numbering in ISTS Specification 5.6.5.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.~~11~~ 9 Post Accident Monitoring (PAM) Instrumentation ~~(Analog)~~ 2

BASES

BACKGROUND

The primary purpose of the post accident monitoring (PAM) instrumentation is to display plant variables that provide information required by the control room operators during accident situations. This information provides the necessary support for the operator to take the manual actions, for which no automatic control is provided, that are required for safety systems to accomplish their safety Functions for Design Basis Events.

The OPERABILITY of the PAM instrumentation ensures that there is sufficient information available on selected plant parameters to monitor and assess plant status and behavior following an accident.

The availability of PAM instrumentation is important so that responses to corrective actions can be observed and the need for, and magnitude of, further actions can be determined. These essential instruments are identified by ~~plant specific documents (Ref. 1)~~ in Reference 1 addressing the recommendations of Regulatory Guide 1.97 (Ref. 2), as required by Supplement 1 to NUREG-0737, "TMI Action Items" (Ref. 3). 1

Type A variables are included in this LCO because they provide the primary information required to permit the control room operator to take specific manually controlled actions, for which no automatic control is provided, that are required for safety systems to accomplish their safety functions for Design Basis Accidents (DBAs). ~~Because the list of Type A variables differs widely between plants, Table 3.3.11-1, in the accompanying LCO, contains no examples of Type A variables, except for those that may also be Category I.~~ 1

Category I variables are the key variables deemed risk significant because they are needed to:

- Determine whether other systems important to safety are performing their intended functions,
- Provide information to the operators that will enable them to determine the potential for causing a gross breach of the barriers to radioactivity release, and
- Provide information regarding the release of radioactive materials to allow for early indication of the need to initiate action necessary to protect the public and for an estimate of the magnitude of any impending threat.

BASES

BACKGROUND (continued)

These key variables are identified by plant specific Regulatory Guide 1.97 analyses (Ref. 1). These analyses identified the plant specific Type A and Category I variables and provided justification for deviating from the NRC proposed list of Category I variables.

~~REVIEWER'S NOTE~~

~~Table 3.3.11-1, in the accompanying LCO, provides a list of variables typical of those identified by plant specific Regulatory Guide 1.97 analyses. Table 3.3.11-1 in the plant specific Technical Specifications shall list all Type A and Category I variables identified by plant specific Regulatory Guide 1.97 analyses, as amended by NRC's Safety Evaluation Report (SER) (Ref. 4). The specific instrument Functions listed in Table 3.3.11-1 are discussed in the LCO Bases.~~ 4

APPLICABLE SAFETY ANALYSES

The PAM instrumentation ensures the OPERABILITY of Regulatory Guide 1.97 Type A variables, so that the control room operating staff can:

- Perform the diagnosis specified in the emergency operating procedures. These variables are restricted to preplanned actions for the primary success path of DBAs and
- Take the specified, preplanned, manually controlled actions, for which no automatic control is provided, that are required for safety systems to accomplish their safety functions.

The PAM instrumentation also ensures OPERABILITY of Category I, non-Type A variables. This ensures the control room operating staff can:

- Determine whether systems important to safety are performing their intended functions,
- Determine the potential for causing a gross breach of the barriers to radioactivity release,
- Determine if a gross breach of a barrier has occurred, and
- Initiate action necessary to protect the public as well as to obtain an estimate of the magnitude of any impending threat.

BASES

APPLICABLE SAFETY ANALYSES (continued)

PAM instrumentation that satisfies the definition of Type A in Regulatory Guide 1.97 meets Criterion 3 of 10 CFR 50.36(c)(2)(ii).

Category I, non-Type A PAM instruments are retained in the Specification because they are intended to assist operators in minimizing the consequences of accidents. Therefore, these Category I variables are important in reducing public risk.

LCO

LCO 3.3.~~11~~ (9) requires two OPERABLE channels for all but one Function to ensure no single failure prevents the operators from being presented with the information necessary to determine the status of the plant and to bring the plant to, and maintain it in, a safe condition following that accident. (2)

Furthermore, provision of two channels allows a CHANNEL CHECK during the post accident phase to confirm the validity of displayed information.

~~[More than two channels may be required at some units if the Regulatory Guide 1.97 analysis determined that failure of one PAM channel results in information ambiguity (that is, the redundant displays disagree) that could lead operators to defeat or to fail to accomplish a required safety function.]~~ (3)

The exception to the two channel requirement is Penetration Flow Path Containment Isolation Valve Position. In this case, the important information is the status of the containment penetrations. The LCO requires one position indicator for each active containment isolation valve. This is sufficient to redundantly verify the isolation status of each isolable penetration either via indicated status of the active valve and prior knowledge of the passive valve or via system boundary status. If a normally active containment isolation valve is known to be closed and deactivated, position indication is not needed to determine status. Therefore, the position indication for valves in this state is not required to be OPERABLE. (1)

The applicable CIVs are identified in UFSAR Table 6.2-16.

Listed below are discussions of the specified instrument Functions listed in Table 3.3.~~11~~-1. ~~These discussions are intended as examples of what should be provided for each Function when the plant specific list is prepared.~~ (9) (2) (1)

BASES

LCO (continued)

1. ~~[Logarithmic]~~ Excore (wide range) Neutron Flux

~~[Logarithmic]~~ Neutron Flux ~~indication~~ is a Type A and Category 1 variable provided to verify reactor shutdown. 1 3

Excore

~~[At this unit, the [Logarithmic]~~ Neutron Flux PAM channels consist of ~~the following:]~~

Insert 1

2, 3. Reactor Coolant System (RCS) Hot and Cold Leg Temperature

Type A and

RCS Hot and Cold Leg Temperatures are Category I variables provided for verification of core cooling and long term surveillance.

coolant loop consists of two channels per reactor coolant loop.

Reactor outlet temperature ~~inputs to the PAM are provided by two fast response resistance elements~~ and associated transmitters ~~s~~ in each loop. The channels provide indication over a range of ~~32~~ 212 °F to 70~~0~~ °F.

Each channel consists of a resistance temperature detector

5 Insert 2

4. ~~Reactor Coolant System~~ Pressurizer Pressure ~~(wide range)~~ R1

Type A and

Pressurizer ~~RCS wide range~~ pressure is a Category I variable provided for verification of core cooling and RCS integrity long term surveillance.

Pressurizer

~~Wide range RCS loop~~ pressure is measured by pressure transmitters with a span of 0 ~~psig~~ to 3000 psi~~g~~. The pressure transmitters are located ~~o~~utside the containment. Redundant monitoring capability is provided by two trains of instrumentation. Control room indications are provided through the ~~inadequate core cooling (ICC) plasma~~ QSPDS display. The ~~ICC plasma~~ display is the primary indication used by the operator during an accident. Therefore, the PAM instrumentation LCO deals specifically with this portion of the instrument channel. R1 1

a

in

Pressurizer

~~In some plants, RCS~~ pressure is a Type A variable because the operator uses this indication to monitor the cooldown of the RCS following a steam generator tube rupture or small break loss of coolant accident (LOCA). Operator actions to maintain a controlled cooldown, such as adjusting steam generator pressure or level, would use this indication. Furthermore, ~~RCS~~ pressure is one factor that may be used in decisions to terminate reactor coolant pump operation.

Pressurizer

1

Insert 1

two channels; each consisting of a fission chamber detector assembly providing continuous independent indication in the control room and on the hot shutdown panel. This signal is processed for a wide range of 2 x 10^{-8} to 200% power. | R1

1

Insert 2

Channel output is provided to the Qualified Safety Parameter Display System (QSPDS) which provides control room indication. Although the temperature range of 212°F to 705°F deviates from RG 1.97 Rev. 3 criteria. For temperatures where RCS temperature is below 350°F the shutdown cooling system would be in operation and hot leg temperatures would be closely represented by the core exit thermocouples which have a range of 32°F to 2300°F and cold leg temperature would be closely represented by the shutdown cooling system temperature element that has a range of 0°F to 400°F, therefore the range of 212°F to 705°F is acceptable (Ref. 4).

BASES

LCO (continued)

5. Reactor Vessel Water Level

Reactor Vessel Water Level is provided for verification and long term surveillance of core cooling. (a Category 1 variable) 1

The Reactor Vessel Water Level monitoring system provides a direct measurement of the collapsed liquid level above the fuel alignment plate. The collapsed level represents the amount of liquid mass that is in the reactor vessel above the core. Measurement of the collapsed water level is selected because it is a direct indication of the water inventory. The collapsed level is obtained over the same temperature and pressure range as the saturation measurements, thereby encompassing all operating and accident conditions where it must function. Also, it functions during the recovery interval. Therefore, it is designed to survive the high steam temperature that may occur during the preceding core recovery interval.

The level range extends from the top of the vessel down to the top of the fuel alignment plate. The response time is short enough to track the level during small break LOCA events. The resolution is sufficient to show the initial level drop, the key locations near the hot leg elevation, and the lowest levels just above the alignment plate. This provides the operator with adequate indication to track the progression of the accident and to detect the consequences of its mitigating actions or the functionality of automatic equipment.

Each channel consists of eight sensors in a probe. A channel is OPERABLE if four sensors, with one sensor in the upper head and three sensors in the upper plenum, are OPERABLE.

6. Containment ~~Sump~~ Water Level (wide range) 1

Containment ~~Sump~~ Water Level is provided for verification and long term surveillance of RCS integrity. (a Category 1 variable)

~~[~~ ~~For this unit,~~ Containment ~~Sump~~ Water Level instrumentation consists of ~~the following:~~ ~~]~~ 3
Insert 3

7. Containment Pressure (wide range)

Containment Pressure is provided for verification of RCS and containment OPERABILITY. (a Category 1 variable) 1

~~[~~ ~~For this unit,~~ Containment Pressure instrumentation consists of ~~the following:~~ ~~]~~ 3
Insert 4

1 3

Insert 3

two channels. Each channel consists of a level transmitter with output to an indicator in the control room. One channel is recorded. The wide range containment level transmitters are located inside containment. The wide range containment water level monitors have a range of -1 ft (bottom of the containment) to elevation 26 feet 1 inch of the containment.

Insert 4 1 3

two channels. Each channel consists of a pressure transmitter mounted outside containment with output to an indicator in the control room. One channel is recorded. The containment wide range pressure monitors have a range of -5 to 175 psig.

BASES

LCO (continued)

8. Penetration Flow Path Containment Isolation Valve Position

Penetration Flow Path Containment Isolation Valve (CIV) Position is provided for verification of containment OPERABILITY.

a Category 1 variable

CIV position is provided for verification of containment integrity. In the case of CIV position, the important information is the isolation status of the containment penetration. The LCO requires one channel of valve position indication in the control room to be OPERABLE for each active CIV in a containment penetration flow path, i.e., two total channels of CIV position indication for a penetration flow path with two active valves. For containment penetrations with only one active CIV having control room indication, Note (b) requires a single channel of valve position indication to be OPERABLE. This is sufficient to redundantly verify the isolation status of each isolable penetration via indicated status of the active valve, as applicable, and prior knowledge of passive valve or system boundary status. If a penetration flow path is isolated, position indication for the CIV(s) in the associated penetration flow path is not needed to determine status. Therefore, the position indication for valves in an isolated penetration flow path is not required to be OPERABLE. Each penetration is treated separately and each penetration flow path is considered a separate function. Therefore, separate Condition entry is allowed for each inoperable penetration flow path.

~~[For this unit, the CIV position PAM instrumentation consists of the following:]~~

9. Containment ~~Area~~ Radiation (high range)

a Category 1 variable

Containment ~~Area~~ Radiation is provided to monitor for the potential of significant radiation releases and to provide release assessment for use by operators in determining the need to invoke site emergency plans.

~~[For this unit,~~ Containment ~~Area~~ Radiation instrumentation consists of ~~the following:]~~

Insert 5

Insert 5 1 3

two channels. Each channel consists of an ambient radiation detector mounted inside containment transmitting to an indicator in the control room. One channel is recorded. The containment high range radiation monitors have a range of 1 r/hr to 10^8 r/hr. |R1

as 0 – 100% level.

1

converted and

O

~~At some plants,~~ operator action is based on the control room indication of Steam Generator Water Level. The RCS response during a design basis small break LOCA is dependent on the break size. ~~For a certain range of break sizes, the boiler condenser mode of heat transfer is necessary to remove decay heat. At these plants,~~ Steam Generator Water L ~~extended startup range~~ level is a Type A variable because the operator must manually raise and control the steam generator level to establish ~~boiler condenser heat transfer~~. Operator action is initiated on a loss of subcooled margin. Feedwater flow is increased until the indicated ~~extended startup range~~ level reaches the ~~boiler condenser setpoint~~.

two channels. Each channel consists of a differential pressure instrument transmitting to an indicator in the control room. One channel is recorded. The pressurizer water level instrument has a calibration range of 175 inches to 349 inches (0 – 100% indicated level). |R1

BASES

LCO (continued)

12. Condensate Storage Tank (CST) Level

a Category 1 variable

CST Level is provided to ensure water supply for ~~[~~AFW~~]~~. The CST provides the ensured safety grade water supply for the ~~[~~AFW~~]~~ System. ~~The CST consists of two identical tanks connected by a common outlet header.~~ Inventory is monitored by a 0 to ~~144 inch~~ 40 foot level indication ~~for each tank~~. CST Level is displayed on a control room indicator~~, strip chart recorder, and plant computer~~. In addition, a control room annunciator alarms on low level. 1 3 1

~~At some plants, CST Level is considered a Type A variable because the control room meter and annunciator are considered the primary indication used by the operator. The DBAs that require [AFW] are the loss of electric power, steam line break (SLB), and small break LOCA~~. The CST is the initial source of water for the ~~[~~AFW~~]~~ System. However, as the CST is depleted, manual operator action is necessary to replenish the CST or align suction to the ~~[AFW] pumps from the hotwell~~. 3 3 1

Unit 2 CST

13, 14, 15, 16. Core Exit Temperature

a Category 1 variable

Core Exit Temperature is provided for verification and long term surveillance of core cooling. 1

An evaluation was made of the minimum number of valid core exit thermocouples necessary for inadequate core cooling detection. The evaluation determined the reduced complement of core exit thermocouples necessary to detect initial core uncovery and trend the ensuing core heatup. The evaluations account for core nonuniformities including incore effects of the radial decay power distribution and excore effects of condensate runback in the hot legs and nonuniform inlet temperatures. Based on these evaluations, adequate or inadequate core cooling detection is ensured with two valid core exit thermocouples per quadrant.

The design of the Incore Instrumentation System includes a Type K (chromel alumel) thermocouple within each of the 56 incore instrument detector assemblies.

LCO (continued)

The junction of each thermocouple is located a few inches above the fuel assembly, inside a structure that supports and shields the incore instrument detector assembly string from flow forces in the outlet plenum region. These core exit thermocouples monitor the temperature of the reactor coolant as it exits the fuel assemblies.

The core exit thermocouples have a usable temperature range from 32°F to 2300°F, although accuracy is reduced at temperatures above 1800°F.

17. ~~[Auxiliary Feedwater (AFW)] Flow~~ Insert 7 3

~~[AFW] Flow is provided to monitor operation of decay heat removal via the steam generators.~~

~~The [AFW] Flow to each steam generator is determined from a differential pressure measurement calibrated to a span of 0 gpm to 1200 gpm. Redundant monitoring capability is provided by two independent trains of instrumentation for each steam generator. Each differential pressure transmitter provides an input to a control room indicator and the plant computer. Since the primary indication used by the operator during an accident is the control room indicator, the PAM instrumentation Specification deals specifically with this portion of the instrument channel.~~

~~At some plants [AFW] Flow is a Type A variable because operator action is required to throttle flow during an SLB accident in order to prevent the [AFW] pumps from operating in runout conditions. [AFW] Flow is also used by the operator to verify that the [AFW] System is delivering the correct flow to each steam generator. However, the primary indication used by the operator to ensure an adequate inventory is steam generator level.~~ 1

Two channels are required to be OPERABLE for all but one Function. Two OPERABLE channels ensure that no single failure, within either the PAM instrumentation or its auxiliary supporting features or power sources (concurrent with the failures that are a condition of or result from a specific accident), prevents the operators from being presented the information necessary for them to determine the safety status of the plant and to bring the plant to and maintain it in a safe condition following that accident.

1

Insert 7

Containment Hydrogen Concentration

Containment Hydrogen Concentration is a Type A and Category 1 variable provided to allow an ability to measure containment hydrogen concentration without laboratory analysis. The channels provide indication over a range of 0 – 10%.

BASES

LCO (continued)

In Table 3.3.~~11~~-1 the exception to the two channel requirement is Containment Isolation Valve Position.

Two OPERABLE channels of core exit thermocouples are required for each channel in each quadrant to provide indication of radial distribution of the coolant temperature rise across representative regions of the core. Power distribution symmetry was considered in determining the specific number ~~and locations~~ provided for diagnosis of local core problems. ~~Therefore, two randomly selected thermocouples may not be sufficient to meet the two thermocouples per channel requirement in any quadrant. The two thermocouples in each channel must meet the additional requirement that one be located near the center of the core and the other near the core perimeter, such that the pair of core exit thermocouples indicate the radial temperature gradient across their core quadrant. Plant specific evaluations in response to Item II.F.2 of NUREG-0737 should have identified the thermocouple pairings that satisfy these requirements.~~ Two sets of two thermocouples in each quadrant ensure a single failure will not disable the ability to determine the radial temperature gradient.

Core uniformities including in-core effects of the radial decay power distribution, ex-core effects of condensate runback in the hot legs and non-uniform inlet temperatures were accounted for in the evaluation.

For loop and steam generator related variables, the required information is individual loop temperature and individual steam generator level. In these cases two channels are required to be OPERABLE for each loop of steam generator to redundantly provide the necessary information.

In the case of Containment Isolation Valve Position, the important information is the status of the containment penetrations. The LCO requires one position indicator for each active containment isolation valve. This is sufficient to redundantly verify the isolation status of each isolable penetration either via indicated status of the active valve and prior knowledge of the passive valve or via system boundary status. If a normally active containment isolation valve is known to be closed and deactivated, position indication is not needed to determine status. Therefore, the position indication for valves in this state is not required to be OPERABLE.

APPLICABILITY

The PAM instrumentation LCO is applicable in MODES 1, 2, and 3. These variables are related to the diagnosis and preplanned actions required to mitigate DBAs. The applicable DBAs are assumed to occur in MODES 1, 2, and 3. In MODES 4, 5, and 6, plant conditions are such that the likelihood of an event occurring that would require PAM instrumentation is low; therefore, PAM instrumentation is not required to be OPERABLE in these MODES.

BASES

ACTIONS

A Note has been added in the ACTIONS to clarify the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function listed in Table 3.3.~~11~~-1. The Completion Time(s) of the inoperable channel(s) of a Function will be tracked separately for each Function, starting from the time the Condition was entered for that Function. When the Required Channels in Table 3.3.~~11~~-1 are specified (e.g., on a ~~per steam line,~~ per loop, per SG, etc., basis) then Condition may be entered separately for each steam line, loop, SG, etc., as appropriate.

A.1

When one or more Functions have one required channel that is inoperable, the required inoperable channel must be restored to OPERABLE status within 30 days. The 30 day Completion Time is based on operating experience and takes into account the remaining OPERABLE channel (or in the case of a Function that has only one required channel, other non-Regulatory Guide 1.97 instrument channels to monitor the Function), the passive nature of the instrument (no critical automatic action is assumed to occur from these instruments), and the low probability of an event requiring PAM instrumentation during this interval.

B.1

This Required Action specifies initiation of actions in accordance with Specification 5.6.~~5~~, which requires a written report to be submitted to the Nuclear Regulatory Commission. This report discusses the cause of the inoperability and identifies proposed restorative Required Actions. This Required Action is appropriate in lieu of a shutdown requirement, given the likelihood of plant conditions that would require information provided by this instrumentation. Also, alternative Required Actions are identified before a loss of functional capability condition occurs.

C.1

When one or more Functions have two required channels inoperable (i.e., two channels inoperable in the same Function), one channel in the Function should be restored to OPERABLE status within 7 days. The Completion Time of 7 days is based on the relatively low probability of an event requiring PAM instrumentation operation and the availability of alternate means to obtain the required information. Continuous operation with two required channels inoperable in a Function is not acceptable

BASES

ACTIONS (continued)

because the alternate indications may not fully meet all performance qualification requirements applied to the PAM instrumentation. Therefore, requiring restoration of one inoperable channel of the Function limits the risk that the PAM Function will be in a degraded condition should an accident occur.

D.1

This Required Action directs entry into the appropriate Condition referenced in Table 3.3.~~11~~-1. The applicable Condition referenced in the Table is Function dependent. Each time Required Action C.1 is not met, and the associated Completion Time has expired, Condition D is entered for that channel and provides for transfer to the appropriate subsequent Condition. 9 2

E.1 and E.2

If the Required Action and associated Completion Time of Condition D is not met, and Table 3.3.~~11~~-1 directs entry into Condition E, the plant must be brought to a MODE in which the requirements of this LCO do not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. 9 2

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

F.1

~~[At this plant,~~ alternate means of monitoring Reactor Vessel Water Level and Containment Area Radiation have been developed and tested. These alternate means may be temporarily installed if the normal PAM channel cannot be restored to OPERABLE status within the allotted time. If these alternate means are used, the Required Action is not to shut down the plant, but rather to follow the directions of Specification 5.6.~~5~~. 4 3 5 The report provided to the NRC should discuss the alternate means used, describe the degree to which the alternate means are equivalent to the installed PAM channels, justify the areas in which they are not equivalent, and provide a schedule for restoring the normal PAM channels.~~]~~

BASES

SURVEILLANCE REQUIREMENTS

A Note at the beginning of the Surveillance Requirements specifies that the following SRs apply to each PAM instrumentation Function in Table 3.3.~~11~~-1. 9 2

SR 3.3.~~11~~.1

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit. If the channels are within the criteria, it is an indication that the channels are OPERABLE. If the channels are normally off scale during times when surveillance is required, the CHANNEL CHECK will only verify that they are off scale in the same direction. Off scale low current loop channels are verified to be reading at the bottom of the range and not failed downscale.

~~[The Frequency of 31 days is based upon plant operating experience with regard to channel OPERABILITY and drift, which demonstrates that failure of more than one channel of a given Function in any 31 day interval is a rare event. The CHANNEL CHECK supplements less formal, but more frequent, checks of channel during normal operational use of the displays associated with this LCO's required channels.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

SR 3.3.~~11~~.2

A CHANNEL CALIBRATION is a complete check of the instrument channel including the sensor. The Surveillance verifies the channel responds to the measured parameter within the necessary range and accuracy. A Note allows exclusion of neutron detectors from the CHANNEL CALIBRATION.

[~~At this unit,~~ CHANNEL CALIBRATION shall find measurement errors are within the following acceptance criteria: ~~]~~

For the Containment ~~Area~~ Radiation instrumentation, a CHANNEL CALIBRATION may consist of an electronic calibration of the channel, not including the detector, for range decades above 10 R/hr, and a one point calibration check of the detector below 10 R/hr with a gamma source. | R1

Whenever a sensing element is replaced, the next required CHANNEL CALIBRATION of the resistance temperature detectors (RTD) sensors is accomplished by an inplace cross calibration that compares the other sensing elements with the recently installed sensing element.

Whenever a sensing element is replaced, the next required CHANNEL CALIBRATION of the Core Exit thermocouple sensors is accomplished by an inplace cross calibration that compares the other sensing elements with the recently installed sensing element.

[~~The Frequency is based upon operating experience and consistency with the typical industry refueling cycle and is justified by an [18] month calibration interval for the determination of the magnitude of equipment drift.~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~ 3

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.~~11~~ 9 Post Accident Monitoring (PAM) Instrumentation ~~(Analog)~~ 2

BASES

BACKGROUND

The primary purpose of the post accident monitoring (PAM) instrumentation is to display plant variables that provide information required by the control room operators during accident situations. This information provides the necessary support for the operator to take the manual actions, for which no automatic control is provided, that are required for safety systems to accomplish their safety Functions for Design Basis Events.

The OPERABILITY of the PAM instrumentation ensures that there is sufficient information available on selected plant parameters to monitor and assess plant status and behavior following an accident.

The availability of PAM instrumentation is important so that responses to corrective actions can be observed and the need for, and magnitude of, further actions can be determined. These essential instruments are identified by ~~plant specific documents (Ref. 1)~~ in Reference 1 addressing the recommendations of Regulatory Guide 1.97 (Ref. 2), as required by Supplement 1 to NUREG-0737, "TMI Action Items" (Ref. 3). 1

Type A variables are included in this LCO because they provide the primary information required to permit the control room operator to take specific manually controlled actions, for which no automatic control is provided, that are required for safety systems to accomplish their safety functions for Design Basis Accidents (DBAs). ~~Because the list of Type A variables differs widely between plants, Table 3.3.11-1, in the accompanying LCO, contains no examples of Type A variables, except for those that may also be Category I.~~ 1

Category I variables are the key variables deemed risk significant because they are needed to:

- Determine whether other systems important to safety are performing their intended functions,
- Provide information to the operators that will enable them to determine the potential for causing a gross breach of the barriers to radioactivity release, and
- Provide information regarding the release of radioactive materials to allow for early indication of the need to initiate action necessary to protect the public and for an estimate of the magnitude of any impending threat.

BASES

BACKGROUND (continued)

These key variables are identified by plant specific Regulatory Guide 1.97 analyses (Ref. 1). These analyses identified the plant specific Type A and Category I variables and provided justification for deviating from the NRC proposed list of Category I variables.

~~REVIEWER'S NOTE~~

~~Table 3.3.11-1, in the accompanying LCO, provides a list of variables typical of those identified by plant specific Regulatory Guide 1.97 analyses. Table 3.3.11-1 in the plant specific Technical Specifications shall list all Type A and Category I variables identified by plant specific Regulatory Guide 1.97 analyses, as amended by NRC's Safety Evaluation Report (SER) (Ref. 4). The specific instrument Functions listed in Table 3.3.11-1 are discussed in the LCO Bases.~~ 4

APPLICABLE SAFETY ANALYSES

The PAM instrumentation ensures the OPERABILITY of Regulatory Guide 1.97 Type A variables, so that the control room operating staff can:

- Perform the diagnosis specified in the emergency operating procedures. These variables are restricted to preplanned actions for the primary success path of DBAs and
- Take the specified, preplanned, manually controlled actions, for which no automatic control is provided, that are required for safety systems to accomplish their safety functions.

The PAM instrumentation also ensures OPERABILITY of Category I, non-Type A variables. This ensures the control room operating staff can:

- Determine whether systems important to safety are performing their intended functions,
- Determine the potential for causing a gross breach of the barriers to radioactivity release,
- Determine if a gross breach of a barrier has occurred, and
- Initiate action necessary to protect the public as well as to obtain an estimate of the magnitude of any impending threat.

BASES

APPLICABLE SAFETY ANALYSES (continued)

PAM instrumentation that satisfies the definition of Type A in Regulatory Guide 1.97 meets Criterion 3 of 10 CFR 50.36(c)(2)(ii).

Category I, non-Type A PAM instruments are retained in the Specification because they are intended to assist operators in minimizing the consequences of accidents. Therefore, these Category I variables are important in reducing public risk.

LCO

LCO 3.3.~~11~~ (9) requires two OPERABLE channels for all but one Function to ensure no single failure prevents the operators from being presented with the information necessary to determine the status of the plant and to bring the plant to, and maintain it in, a safe condition following that accident. (2)

Furthermore, provision of two channels allows a CHANNEL CHECK during the post accident phase to confirm the validity of displayed information.

~~[More than two channels may be required at some units if the Regulatory Guide 1.97 analysis determined that failure of one PAM channel results in information ambiguity (that is, the redundant displays disagree) that could lead operators to defeat or to fail to accomplish a required safety function.]~~ (3)

The exception to the two channel requirement is Penetration Flow Path Containment Isolation Valve Position. In this case, the important information is the status of the containment penetrations. The LCO requires one position indicator for each active containment isolation valve. This is sufficient to redundantly verify the isolation status of each isolable penetration either via indicated status of the active valve and prior knowledge of the passive valve or via system boundary status. If a normally active containment isolation valve is known to be closed and deactivated, position indication is not needed to determine status. Therefore, the position indication for valves in this state is not required to be OPERABLE. (1)

The applicable CIVs are identified in UFSAR Table 6.2-52.

Listed below are discussions of the specified instrument Functions listed in Table 3.3.~~11~~-1. ~~These discussions are intended as examples of what should be provided for each Function when the plant specific list is prepared.~~ (9) (2) (1)

Insert 2

4. ~~Reactor Coolant System~~ Pressurizer Pressure ~~(wide range)~~

Pressurizer

Type A and

~~RCS~~ ~~wide range~~ pressure is a Category I variable provided for verification of core cooling and RCS integrity long term surveillance.

Pressurizer

~~Wide range RCS loop~~ pressure is measured by pressure transmitters with a span of 0 ~~psig~~ to 3000 psi~~g~~. The pressure transmitters are located ~~o~~utside the containment. Redundant monitoring capability is provided by two trains of instrumentation. Control room indications are provided through the ~~inadequate core cooling (ICC) plasma~~ display. The ~~ICC plasma~~ display is the primary indication used by the operator during an accident. Therefore, the PAM instrumentation LCO deals specifically with this portion of the instrument channel.

a

in

QSPDS

Pressurizer

~~In some plants, RCS~~ pressure is a Type A variable because the operator uses this indication to monitor the cooldown of the RCS following a steam generator tube rupture or small break loss of coolant accident (LOCA). Operator actions to maintain a controlled cooldown, such as adjusting steam generator pressure or level, would use this indication. Furthermore, ~~RCS~~ pressure is one factor that may be used in decisions to terminate reactor coolant pump operation.

Insert 2

Channel output is provided to the Qualified Safety Parameter Display System (QSPDS) which provides control room indication.

BASES

LCO (continued)

5. Reactor Vessel Water Level

Reactor Vessel Water Level is provided for verification and long term surveillance of core cooling. (a Category 1 variable) 1

The Reactor Vessel Water Level monitoring system provides a direct measurement of the collapsed liquid level above the fuel alignment plate. The collapsed level represents the amount of liquid mass that is in the reactor vessel above the core. Measurement of the collapsed water level is selected because it is a direct indication of the water inventory. The collapsed level is obtained over the same temperature and pressure range as the saturation measurements, thereby encompassing all operating and accident conditions where it must function. Also, it functions during the recovery interval. Therefore, it is designed to survive the high steam temperature that may occur during the preceding core recovery interval.

The level range extends from the top of the vessel down to the top of the fuel alignment plate. The response time is short enough to track the level during small break LOCA events. The resolution is sufficient to show the initial level drop, the key locations near the hot leg elevation, and the lowest levels just above the alignment plate. This provides the operator with adequate indication to track the progression of the accident and to detect the consequences of its mitigating actions or the functionality of automatic equipment.

Each channel consists of eight sensors in a probe. A channel is OPERABLE if four sensors, with one sensor in the upper head and three sensors in the upper plenum, are OPERABLE.

6. Containment ~~Sump~~ Water Level (wide range) 1

Containment ~~Sump~~ Water Level is provided for verification and long term surveillance of RCS integrity. (a Category 1 variable)

~~[~~ ~~For this unit,~~ Containment ~~Sump~~ Water Level instrumentation consists of ~~the following:~~ ~~]~~ 3
Insert 3

7. Containment Pressure (wide range)

Containment Pressure is provided for verification of RCS and containment OPERABILITY. (a Category 1 variable) 1

~~[~~ ~~For this unit,~~ Containment Pressure instrumentation consists of ~~the following:~~ ~~]~~ 3
Insert 4

Insert 3 (1) (3)

two channels. Each channel consists of a level transmitter with output to an indicator in the control room. Both channels are recorded. The wide range containment level transmitters are located outside containment. The wide range containment water level monitors have a range of -1 foot (bottom of the containment) to elevation 26 feet of the containment.

Insert 4 (1) (3)

two channels. Each channel consists of a pressure transmitter mounted outside containment with output to an indicator in the control room. One channel is recorded. The containment wide range pressure monitors have a range of -5 to 175 psig.

BASES

LCO (continued)

8. Penetration Flow Path Containment Isolation Valve Position

a Category 1 variable

Penetration Flow Path Containment Isolation Valve (CIV) Position is provided for verification of containment OPERABILITY. 1

CIV position is provided for verification of containment integrity. In the case of CIV position, the important information is the isolation status of the containment penetration. The LCO requires one channel of valve position indication in the control room to be OPERABLE for each active CIV in a containment penetration flow path, i.e., two total channels of CIV position indication for a penetration flow path with two active valves. For containment penetrations with only one active CIV having control room indication, Note (b) requires a single channel of valve position indication to be OPERABLE. This is sufficient to redundantly verify the isolation status of each isolable penetration via indicated status of the active valve, as applicable, and prior knowledge of passive valve or system boundary status. If a penetration flow path is isolated, position indication for the CIV(s) in the associated penetration flow path is not needed to determine status. Therefore, the position indication for valves in an isolated penetration flow path is not required to be OPERABLE. Each penetration is treated separately and each penetration flow path is considered a separate function. Therefore, separate Condition entry is allowed for each inoperable penetration flow path.

~~[For this unit, the CIV position PAM instrumentation consists of the following:]~~ 3

9. Containment ~~Area~~ Radiation (high range) R1

a Category 1 variable

Containment ~~Area~~ Radiation is provided to monitor for the potential of significant radiation releases and to provide release assessment for use by operators in determining the need to invoke site emergency plans. 1

~~[For this unit,~~ Containment ~~Area~~ Radiation instrumentation consists of ~~the following:]~~ 3

Insert 5

Insert 5 1 3

two channels. Each channel consists of an ambient radiation detector mounted inside containment transmitting to an indicator in the control room. Both channels are recorded. The containment high range radiation monitors have a range of 1 r/hr to 10^8 r/hr. |R1

BASES

LCO (continued)

10. Pressurizer Level

Water

a Category 1 variable

Pressurizer Level is used to determine whether to terminate safety injection (SI), if still in progress, or to reinitiate SI if it has been stopped. Knowledge of pressurizer water level is also used to verify the plant conditions necessary to establish natural circulation in the RCS and to verify that the plant is maintained in a safe shutdown condition. 1 R1

Water

~~[For this unit,~~ Pressurizer Level instrumentation consists of ~~the following:]~~ 3 R1

Insert 6

11. Steam Generator Water Level

a Type A and Category 1 variable

Steam Generator Water Level is provided to monitor operation of decay heat removal via the steam generators. The Category I indication of steam generator level ~~is the extended startup range level instrumentation. The extended startup range level~~ covers a span of ~~6~~ inches to ~~394~~ inches ~~above the lower tubesheet~~. The measured differential pressure is displayed ~~in inches of water at 68°F~~. ~~Temperature compensation of this indication is performed manually by the operator.~~ Redundant monitoring capability is provided by two trains of instrumentation. ~~The uncompensated level signal is input to the plant computer, a control room indicator, and the [Auxiliary Feedwater (AFW)] Control System~~. 1

0

183

as 0 – 100% level. 1

converted and

O

~~At some plants,~~ operator action is based on the control room indication of Steam Generator Water Level. The RCS response during a design basis small break LOCA is dependent on the break size. ~~For a certain range of break sizes, the boiler condenser mode of heat transfer is necessary to remove decay heat. At these plants,~~ ~~extended~~ ~~startup range~~ level is a Type A variable because the operator must manually raise and control the steam generator level to establish ~~boiler condenser heat transfer~~. Operator action is initiated on a loss of subcooled margin. Feedwater flow is increased until the indicated ~~extended startup range~~ level reaches the ~~boiler condenser setpoint~~. 1

Steam Generator Water L

two channels. Each channel consists of a differential pressure instrument transmitting to an indicator in the control room. One channel is recorded. The pressurizer water level instrument has a calibration range of 145.6 inches to 331.8 inches (0 – 100% indicated level). |R1

BASES

LCO (continued)

12. Condensate Storage Tank (CST) Level

a Category 1 variable

CST Level is provided to ensure water supply for ~~[~~AFW~~]~~. The CST provides the ensured safety grade water supply for the ~~[~~AFW~~]~~ System. ~~The CST consists of two identical tanks connected by a common outlet header.~~ Inventory is monitored by a 0 to ~~144 inch~~ 50 foot level indication ~~for each tank~~. CST Level is displayed on a control room indicator~~, strip chart recorder, and plant computer~~. In addition, a control room annunciator alarms on low level. 1 3 1

~~At some plants, CST Level is considered a Type A variable because the control room meter and annunciator are considered the primary indication used by the operator. The DBAs that require [AFW] are the loss of electric power, steam line break (SLB), and small break LOCA~~. The CST is the initial source of water for the ~~[~~AFW~~]~~ System. However, as the CST is depleted, manual operator action is necessary to replenish the CST ~~or align suction to the [AFW] pumps from the hotwell~~. 3 3 1

13, 14, 15, 16. Core Exit Temperature

a Category 1 variable

Core Exit Temperature is provided for verification and long term surveillance of core cooling. 1

An evaluation was made of the minimum number of valid core exit thermocouples necessary for inadequate core cooling detection. The evaluation determined the reduced complement of core exit thermocouples necessary to detect initial core uncovery and trend the ensuing core heatup. The evaluations account for core nonuniformities including incore effects of the radial decay power distribution and excore effects of condensate runback in the hot legs and nonuniform inlet temperatures. Based on these evaluations, adequate or inadequate core cooling detection is ensured with two valid core exit thermocouples per quadrant.

The design of the Incore Instrumentation System includes a Type K (chromel alumel) thermocouple within each of the 56 incore instrument detector assemblies.

LCO (continued)

The junction of each thermocouple is located a few inches above the fuel assembly, inside a structure that supports and shields the incore instrument detector assembly string from flow forces in the outlet plenum region. These core exit thermocouples monitor the temperature of the reactor coolant as it exits the fuel assemblies.

The core exit thermocouples have a usable temperature range from 32°F to 2300°F, although accuracy is reduced at temperatures above 1800°F.

17. ~~[Auxiliary Feedwater (AFW)] Flow~~ Insert 7 3

~~[AFW] Flow is provided to monitor operation of decay heat removal via the steam generators.~~

~~The [AFW] Flow to each steam generator is determined from a differential pressure measurement calibrated to a span of 0 gpm to 1200 gpm. Redundant monitoring capability is provided by two independent trains of instrumentation for each steam generator. Each differential pressure transmitter provides an input to a control room indicator and the plant computer. Since the primary indication used by the operator during an accident is the control room indicator, the PAM instrumentation Specification deals specifically with this portion of the instrument channel.~~

~~At some plants [AFW] Flow is a Type A variable because operator action is required to throttle flow during an SLB accident in order to prevent the [AFW] pumps from operating in runout conditions. [AFW] Flow is also used by the operator to verify that the [AFW] System is delivering the correct flow to each steam generator. However, the primary indication used by the operator to ensure an adequate inventory is steam generator level.~~ 1

Two channels are required to be OPERABLE for all but one Function. Two OPERABLE channels ensure that no single failure, within either the PAM instrumentation or its auxiliary supporting features or power sources (concurrent with the failures that are a condition of or result from a specific accident), prevents the operators from being presented the information necessary for them to determine the safety status of the plant and to bring the plant to and maintain it in a safe condition following that accident.

1

Insert 7

Containment Hydrogen Concentration

Containment Hydrogen Concentration is a Type A and Category 1 variable provided to allow an ability to measure containment hydrogen concentration without laboratory analysis. The channels provide indication over a range of 0 – 10%.

BASES

LCO (continued)

9 In Table 3.3.~~11~~-1 the exception to the two channel requirement is Containment Isolation Valve Position. 2

Two OPERABLE channels of core exit thermocouples are required for each channel in each quadrant to provide indication of radial distribution of the coolant temperature rise across representative regions of the core. Power distribution symmetry was considered in determining the specific number ~~and locations~~ provided for diagnosis of local core problems. ~~Therefore, two randomly selected thermocouples may not be sufficient to meet the two thermocouples per channel requirement in any quadrant. The two thermocouples in each channel must meet the additional requirement that one be located near the center of the core and the other near the core perimeter, such that the pair of core exit thermocouples indicate the radial temperature gradient across their core quadrant. Plant specific evaluations in response to Item II.F.2 of NUREG-0737 should have identified the thermocouple pairings that satisfy these requirements.~~ 1
Two sets of two thermocouples in each quadrant ensure a single failure will not disable the ability to determine the radial temperature gradient.

Core uniformities including in-core effects of the radial decay power distribution, ex-core effects of condensate runback in the hot legs and non-uniform inlet temperatures were accounted for in the evaluation.

For loop and steam generator related variables, the required information is individual loop temperature and individual steam generator level. In these cases two channels are required to be OPERABLE for each loop of steam generator to redundantly provide the necessary information.

In the case of Containment Isolation Valve Position, the important information is the status of the containment penetrations. The LCO requires one position indicator for each active containment isolation valve. This is sufficient to redundantly verify the isolation status of each isolable penetration either via indicated status of the active valve and prior knowledge of the passive valve or via system boundary status. If a normally active containment isolation valve is known to be closed and deactivated, position indication is not needed to determine status. Therefore, the position indication for valves in this state is not required to be OPERABLE.

APPLICABILITY

The PAM instrumentation LCO is applicable in MODES 1, 2, and 3. These variables are related to the diagnosis and preplanned actions required to mitigate DBAs. The applicable DBAs are assumed to occur in MODES 1, 2, and 3. In MODES 4, 5, and 6, plant conditions are such that the likelihood of an event occurring that would require PAM instrumentation is low; therefore, PAM instrumentation is not required to be OPERABLE in these MODES.

BASES

ACTIONS

A Note has been added in the ACTIONS to clarify the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function listed in Table 3.3.~~11~~-1. The Completion Time(s) of the inoperable channel(s) of a Function will be tracked separately for each Function, starting from the time the Condition was entered for that Function. When the Required Channels in Table 3.3.~~11~~-1 are specified (e.g., on a ~~per steam line,~~ per loop, per SG, etc., basis) then Condition may be entered separately for each steam line, loop, SG, etc., as appropriate.

A.1

When one or more Functions have one required channel that is inoperable, the required inoperable channel must be restored to OPERABLE status within 30 days. The 30 day Completion Time is based on operating experience and takes into account the remaining OPERABLE channel (or in the case of a Function that has only one required channel, other non-Regulatory Guide 1.97 instrument channels to monitor the Function), the passive nature of the instrument (no critical automatic action is assumed to occur from these instruments), and the low probability of an event requiring PAM instrumentation during this interval.

B.1

This Required Action specifies initiation of actions in accordance with Specification 5.6.~~5~~, which requires a written report to be submitted to the Nuclear Regulatory Commission. This report discusses the cause of the inoperability and identifies proposed restorative Required Actions. This Required Action is appropriate in lieu of a shutdown requirement, given the likelihood of plant conditions that would require information provided by this instrumentation. Also, alternative Required Actions are identified before a loss of functional capability condition occurs.

C.1

When one or more Functions have two required channels inoperable (i.e., two channels inoperable in the same Function), one channel in the Function should be restored to OPERABLE status within 7 days. The Completion Time of 7 days is based on the relatively low probability of an event requiring PAM instrumentation operation and the availability of alternate means to obtain the required information. Continuous operation with two required channels inoperable in a Function is not acceptable

BASES

ACTIONS (continued)

because the alternate indications may not fully meet all performance qualification requirements applied to the PAM instrumentation. Therefore, requiring restoration of one inoperable channel of the Function limits the risk that the PAM Function will be in a degraded condition should an accident occur.

D.1

This Required Action directs entry into the appropriate Condition referenced in Table 3.3.~~11~~-1. The applicable Condition referenced in the Table is Function dependent. Each time Required Action C.1 is not met, and the associated Completion Time has expired, Condition D is entered for that channel and provides for transfer to the appropriate subsequent Condition. 9 2

E.1 and E.2

If the Required Action and associated Completion Time of Condition D is not met, and Table 3.3.~~11~~-1 directs entry into Condition E, the plant must be brought to a MODE in which the requirements of this LCO do not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. 9 2

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

F.1

~~[At this plant,~~ alternate means of monitoring Reactor Vessel Water Level and Containment Area Radiation have been developed and tested. These alternate means may be temporarily installed if the normal PAM channel cannot be restored to OPERABLE status within the allotted time. If these alternate means are used, the Required Action is not to shut down the plant, but rather to follow the directions of Specification 5.6.~~5~~. 4 The report provided to the NRC should discuss the alternate means used, describe the degree to which the alternate means are equivalent to the installed PAM channels, justify the areas in which they are not equivalent, and provide a schedule for restoring the normal PAM channels.~~]~~ 3 5

BASES

SURVEILLANCE REQUIREMENTS

A Note at the beginning of the Surveillance Requirements specifies that the following SRs apply to each PAM instrumentation Function in Table 3.3.~~11~~-1. 9 2

SR 3.3.~~11~~.1

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit. If the channels are within the criteria, it is an indication that the channels are OPERABLE. If the channels are normally off scale during times when surveillance is required, the CHANNEL CHECK will only verify that they are off scale in the same direction. Off scale low current loop channels are verified to be reading at the bottom of the range and not failed downscale.

~~[The Frequency of 31 days is based upon plant operating experience with regard to channel OPERABILITY and drift, which demonstrates that failure of more than one channel of a given Function in any 31 day interval is a rare event. The CHANNEL CHECK supplements less formal, but more frequent, checks of channel during normal operational use of the displays associated with this LCO's required channels.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

SR 3.3.~~11~~.2

A CHANNEL CALIBRATION is a complete check of the instrument channel including the sensor. The Surveillance verifies the channel responds to the measured parameter within the necessary range and accuracy. A Note allows exclusion of neutron detectors from the CHANNEL CALIBRATION.

[~~At this unit,~~ CHANNEL CALIBRATION shall find measurement errors are within the following acceptance criteria: ~~]~~

For the Containment ~~Area~~ Radiation instrumentation, a CHANNEL CALIBRATION may consist of an electronic calibration of the channel, not including the detector, for range decades above 10 R/hr, and a one point calibration check of the detector below 10 R/hr with a gamma source. | R1

Whenever a sensing element is replaced, the next required CHANNEL CALIBRATION of the resistance temperature detectors (RTD) sensors is accomplished by an inplace cross calibration that compares the other sensing elements with the recently installed sensing element.

Whenever a sensing element is replaced, the next required CHANNEL CALIBRATION of the Core Exit thermocouple sensors is accomplished by an inplace cross calibration that compares the other sensing elements with the recently installed sensing element.

[~~The Frequency is based upon operating experience and consistency with the typical industry refueling cycle and is justified by an [18] month calibration interval for the determination of the magnitude of equipment drift.~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~ 3

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.9 BASES, POST ACCIDENT MONITORING (PAM) INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The heading for ISTS 3.3.11 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2) and Chemical and Volume Control System (CVCS) Isolation Signal (ISTS 3.3.9). Therefore, ISTS 3.3.2 and ISTS 3.3.9 are not included in the PSL ITS. The successive Specifications are renumbered as necessary.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. Changes have been made to reflect the change to numbering in ISTS Specification 5.6.5.

DISCUSSION OF CHANGES
ITS 3.3.10, REMOTE SHUTDOWN SYSTEM

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.3.3.5 Action a , and Unit 2 CTS 3.3.3.5 Actions a and b, provide the compensatory actions to take when remote shutdown monitoring instrumentation is inoperable. ITS 3.3.10 ACTIONS provide the compensatory actions for inoperable remote shutdown monitoring instrumentation. The ITS 3.3.10 ACTIONS include a Note that allows separate Condition entry for each Function. This modifies the CTS by providing a specific allowance to enter the Action for each inoperable remote shutdown monitoring instrumentation Function. This change is acceptable because it clearly states the current requirement. The CTS considers each remote shutdown monitoring instrumentation Function to be separate and independent from the others. This change is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.3.3.5 Action a requires that if an inoperable channel cannot be restored to OPERABLE status within the allowed completion time, then the unit shall be placed in HOT SHUTDOWN within the next 12 hours. ITS 3.3.10 ACTION B requires, if a required channel cannot be returned to OPERABLE status within the associated Completion Time, then the unit shall be in MODE 3 (HOT STANDBY) within 6 hours and MODE 4 (HOT SHUTDOWN) within 12 hours. This changes the CTS requirements by specifying that MODE 3 must be achieved within 6 hours. The purpose of ITS 3.3.10 Required Action B.1 is to specify consistent Completion Times to shutdown the unit from full power to MODE 3. This change is acceptable because the proposed Completion Time is sufficient to allow an operator to reduce power from full power to MODE 3 in a controlled manner without challenging unit safety systems. The 6 hour time provided to reach MODE 3 is also consistent with the time provided in similar actions in both the CTS and ITS. The change has been designated as more restrictive because it specifies the amount of time within which the unit must be placed in MODE 3.

M02 ITS SR 3.10.3.3 states "Perform CHANNEL FUNCTIONAL TEST of the reactor trip circuit breaker open/closed indication." CTS does not require this Surveillance. This changes CTS by adding a requirement to verify the OPERABILITY of the reactor trip circuit breaker (RTCB) open/closed indication by actuating the RTCBs at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months.

The purpose of ITS SR 3.3.10.3 is to provide assurance that the reactor trip circuit breaker (RTCB) open/closed indication represents the correct position of the RTCBs when open and closed. This change is necessary to ensure sufficient testing is conducted at a frequency to assure that the correct open/closed position of the RTCBs is indicated and that the LCO will be met. This SR verifies the RCTB open/closed indication represents the correct position of the RTCBs when open and closed.

PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). The performance Frequency of ITS SR 3.3.10.3 is in accordance with the SFCP. The initial periodic Frequency established in accordance with the SFCP will be 18 months consistent with the ISTS SR 3.3.12.4 and necessary because the RTCBs cannot be exercised while the unit is at power. Industry operating experience has shown that these components usually pass the Surveillance when performed at a Frequency of once every 18 months. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint. See FPL (PSL Unit 1 and Unit 2) "Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program" (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066), which approved the adoption of a SFCP at PSL.

This change is designated as more restrictive because a Surveillance Requirement is added to the Technical Specifications.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.3.3.5 requires the remote shutdown monitoring instrumentation in Table 3.3-9 to be OPERABLE. CTS Table 3.3-9 lists each of the required remote shutdown monitoring instruments, the location of each instrument readout, the measurement range of each instrument, the minimum number of channels required for each instrument, and the minimum channels OPERABLE for each instrument (Unit 2). ITS LCO 3.3.10 states that the remote shutdown monitoring instrumentation Functions shall be OPERABLE. This changes the CTS by moving the details in Tables 3.3-9 from the Technical Specifications to the ITS Bases. Note that Discussion of Change L02 (Unit 2) describes deleting the minimum channels OPERABLE column in Unit 2 Table 3.3-9, while retaining the minimum number of channels required for each instrument requirement.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the remote shutdown monitoring instrumentation to be OPERABLE. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 **Unit 1 only:** *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.3.3.5 states that the remote shutdown monitoring instrumentation channels shown in Table 3.3-9 shall be OPERABLE "with readouts displayed external to the control room." ITS LCO 3.3.10 states that the remote shutdown monitoring instrumentation Functions shall be OPERABLE. This changes the CTS by moving the requirement for readouts displayed external to the control room from the Technical Specifications to the ITS Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the remote shutdown monitoring instrumentation to be OPERABLE. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 5 – Deletion of Surveillance Requirement)* Unit 1 CTS 4.3.3.5 and Unit 2 CTS 4.3.3.5.1 include a Surveillance Requirements Note that states the CHANNEL CALIBRATION is not applicable to reactor trip breaker indication. ITS 3.3.10 Surveillance Requirements do not provide this note. Rather than a Note, ITS 3.3.10 provides Surveillance SR 3.3.10.3 which requires performing a CHANNEL FUNCTIONAL TEST of the reactor trip circuit breaker (RTCB) open/closed indication. This changes the CTS by deleting the Surveillance Requirements Note and adding ITS SR 3.3.10.3 to perform a CHANNEL FUNCTIONAL TEST of the reactor trip circuit breaker open/closed indication.

The purpose of Unit 1 CTS 4.3.3.5 and Unit 2 CTS 4.3.3.5.1 Surveillance Requirements Note is to clarify that CHANNEL CALIBRATION is not applicable to the reactor trip breaker indication. The purpose of ITS SR 3.3.10.3 is to

perform a CHANNEL FUNCTIONAL TEST. This Surveillance verifies the OPERABILITY of the RTCB open/closed indication by actuating the RTCBs.

This change is acceptable because the deleted Surveillance Requirement Note is not necessary to verify that the remote shutdown reactor trip breaker indication used to meet the LCO can perform its required function. The addition of ITS SR 3.3.10.3 to perform a CHANNEL FUNCTIONAL TEST is appropriate to assure the remote shutdown reactor trip breaker indication continues to be tested in a manner and at a frequency necessary to give confidence that the equipment can perform its assumed safety function. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

L02 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* CTS LCO 3.3.3.5 requires the remote shutdown system instrumentation channels shown in Table 3.3.9 to be OPERABLE. CTS Action a requires that with the number of OPERABLE remote shutdown channels less than the required number of channels shown in Table 3.3-9, restore the inoperable channel to OPERABLE status within 30 days, or be in HOT SHUTDOWN within the next 12 hours. CTS Action b requires that with the number of OPERABLE remote shutdown channels less than the Minimum Channels OPERABLE shown in Table 3.3-9, restore the inoperable channel to OPERABLE status within 7 days, or be in HOT SHUTDOWN within the next 12 hours." ITS LCO 3.3.10 states that the Remote Shutdown System Functions shall be OPERABLE. ITS 3.3.10 Required Action A.1 states that with one or more required Functions inoperable, restore the required Functions to OPERABLE status within 30 days. If Required Action A.1 is not completed within the associated Completion Time, ACTION B is entered, and the unit must be in MODE 3 in 6 hours and MODE 4 in 12 hours. ITS 3.3.10 does not contain an Action to restore the inoperable channel to OPERABLE status within 7 days with the number of OPERABLE remote shutdown channels less than the Minimum Channels OPERABLE shown in Table 3.3-9. This changes the Unit 2 CTS by allowing 30 days instead of 7 days for a remote shutdown Function to be inoperable when the number of OPERABLE remote shutdown channels is less than the minimum channels OPERABLE shown in CTS Table 3.3-9 before requiring the unit to shutdown. This changes the CTS by retaining the required number of channels requirement and deleting the minimum channels OPERABLE requirement for each Function in Table 3.3-9. With the change from the 7-day to 30-day Completion Time when a Function does not meet the minimum channel OPERABLE requirement, deleting the minimum channels OPERABLE requirement for each Function in Table 3.3-9 is bounded by the fact that is most cases the required number of channels, which are retained in the CTS, is greater than the minimum required channels. In some cases the required number of channels is the same as the minimum channels OPERABLE. It should be noted that the PSL Unit 1 CTS 3.3.3.5 provides a 30 day allowed outage time when the number of OPERABLE remote shutdown channels is less than the Minimum Channels OPERABLE shown in CTS Table 3.3-9, so this change does not apply to Unit 1.

The proposed change is acceptable considering that the operability of the Remote Shutdown System instrumentation is not a specific assumption of a design basis accident analysis and the proposed 30-day Completion Time

continues to provide a sufficient limit on plant operation if a Remote Shutdown Function is not restored to operable status. As such, the 30-day Completion is acceptable due to the lower safety significance of the Remote Shutdown System instrumentation relative to systems and components necessary to mitigate design basis accidents and considering the low probability of an event occurring within this time that would require the use of the Remote Shutdown System (i.e., control room evacuation). The proposed change provides additional operational flexibility for equipment restoration without significantly affecting the safe operation of the plant. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.10, REMOTE SHUTDOWN SYSTEM

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS Specification number.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.~~12~~ Remote Shutdown System ~~(Analog)~~

BASES

BACKGROUND

The Remote Shutdown System provides the control room operator with sufficient instrumentation and controls to place and maintain the unit in a safe shutdown condition from a location other than the control room. This capability is necessary to protect against the possibility that the control room becomes inaccessible. A safe shutdown condition is defined as MODE 3. With the unit in MODE 3, the ~~[~~Auxiliary Feedwater (AFW) System~~]~~ and ~~the steam generator safety valves or~~ the steam generator atmospheric dump valves can be used to remove core decay heat and meet all safety requirements. The long term supply of water for the ~~[~~AFW System~~]~~ and the ability to borate the Reactor Coolant System (RCS) from outside the control room allow extended operation in MODE 3.

In the event that the control room becomes inaccessible, the operators can establish control at the ~~remote~~ shutdown panel and place and maintain the unit in MODE 3. ~~Not all controls and necessary transfer switches are located at the remote shutdown panel. Some controls and transfer switches will be operated locally at the switchgear, motor control panels, or other local stations.~~ The unit automatically reaches MODE 3 following a unit shutdown and can be maintained safely in MODE 3 for an extended period of time.

The OPERABILITY of the Remote Shutdown System control and instrumentation Functions ensures that there is sufficient information available on selected plant parameters to place and maintain the plant in MODE 3, should the control room become inaccessible.

APPLICABLE SAFETY ANALYSES

The Remote Shutdown System is required to provide equipment at appropriate locations outside the control room with a capability to promptly shut down and maintain the plant in a safe condition in MODE 3.

The criteria governing the design and the specific system requirements of the Remote Shutdown System are located in 10 CFR 50, Appendix A, GDC 19 (Ref. 1).

The Remote Shutdown System satisfies Criterion 4 of 10 CFR 50.36(c)(2)(ii).

LCO

The Remote Shutdown System LCO provides the requirements for the OPERABILITY of the instrumentation ~~and controls~~ necessary to place and maintain the unit in MODE 3 from a location other than the control room. The instrumentation ~~and controls~~ required are listed in Table B 3.3.~~12~~-1.

BASES

LCO (continued)

~~The controls, instrumentation, and transfer switches are those required for:~~

- ~~Core Reactivity Control (initial and long term),~~
- ~~RCS Pressure Control,~~
- ~~Decay Heat Removal via the [AFW System] and the safety valves or steam generator ADVs,~~
- ~~RCS Inventory Control via charging flow, and~~
- ~~Safety support systems for the above Functions, as well as service water, component cooling water, and onsite power including the diesel generators.~~

1

A Function of a Remote Shutdown System is OPERABLE if all instrument ~~and control~~ channels needed to support the remote shutdown Functions are OPERABLE. ~~In some cases, Table B 3.3.12-1 may indicate that the required information or control capability is available from several alternate sources. In these cases, the Function is OPERABLE as long as one channel of any of the alternate information or control sources for each Function is OPERABLE.~~

1

1

The Remote Shutdown System instrumentation ~~and control circuits~~ covered by this LCO do not need to be energized to be considered OPERABLE. This LCO is intended to ensure that the instrument ~~and control circuits~~ will be OPERABLE if plant conditions require that the Remote Shutdown System be placed in operation.

1

1

s

APPLICABILITY

The Remote Shutdown System LCO is applicable in MODES 1, 2, and 3. This is required so that the unit can be placed and maintained in MODE 3 for an extended period of time from a location other than the control room.

This LCO is not applicable in MODE 4, 5, or 6. In these MODES, the unit is already subcritical and in the condition of reduced RCS energy. Under these conditions, considerable time is available to restore necessary instrument ~~control~~ Functions if control room instruments ~~or control~~ become unavailable.

1

BASES

ACTIONS

A Remote Shutdown System ~~division~~ is inoperable when ~~each~~ Function ~~is not accomplished by at least one designated Remote Shutdown System channel that satisfies the~~ OPERABILITY criteria for the channel's Function. These criteria are outlined in the LCO section of the Bases.

channel
a
1
does not satisfy the minimum channels

A Note has been added in the ACTIONS to clarify the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function. The Completion Time(s) of the inoperable channel(s)/train(s) of a Function will be tracked separately for each Function, starting from the time the Condition was entered for that Function.

A.1

required Functions
1

Condition A addresses the situation where one or more ~~channels~~ of the Remote Shutdown System are inoperable. ~~This includes the control and transfer switches for any required Function.~~
1

required Functions

The Required Action is to restore the ~~divisions~~ to OPERABLE status within 30 days. The Completion Time is based on operating experience and the low probability of an event that would require evacuation of the control room.
1

B.1 and B.2

If the Required Action and associated Completion Time of Condition A are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required MODE from full power conditions in an orderly manner and without challenging plant systems.
2

SURVEILLANCE REQUIREMENTS

~~[~~ SR 3.3.~~12~~.1
10
2
3

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that

BASES

SURVEILLANCE REQUIREMENTS (continued)

the instrumentation continues to operate properly between each CHANNEL CALIBRATION. Agreement criteria are determined by the plant staff, based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit. As specified in the Surveillance, a CHANNEL CHECK is only required for those channels that are normally energized. If the channels are within the criteria, it is an indication that the channels are OPERABLE. If the channels are normally off scale during times when surveillance is required, the CHANNEL CHECK will only verify that they are off scale in the same direction. Off scale low current loop channels are verified to be reading at the bottom of the range and not failed downscale.

~~[The Frequency of 31 days is based on plant operating experience that demonstrates channel failure is rare.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 4

~~]~~

~~SR 3.3.12.2~~ 1

~~SR 3.3.12.2 verifies that each required Remote Shutdown System transfer switch and control circuit performs its intended function. This verification is performed from the reactor shutdown panel and locally, as appropriate. Operation of the equipment from the remote shutdown panel is not necessary. The Surveillance can be satisfied by performance of a continuity check. This will ensure that if the control room becomes inaccessible, the plant can be placed and maintained in MODE 3 from the reactor shutdown panel and the local control stations. [The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an~~ 1

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~unplanned transient if the Surveillance were performed with the reactor at power. Operating experience demonstrates that Remote Shutdown System control channels seldom fail to pass the Surveillance when performed at a Frequency of once every [18] months.~~ 1

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~ 1

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4

SR 3.3.~~12~~.3 3

10.2

CHANNEL CALIBRATION is a complete check of the instrument channel including the sensor. The Surveillance verifies that the channel responds to the measured parameter within the necessary range and accuracy. Whenever a sensing element is replaced, the next required CHANNEL CALIBRATION of the resistance temperature detectors (RTD) sensors is accomplished by an inplace cross calibration that compares the other sensing elements with the recently installed sensing element.

~~[The 18 month Frequency is based upon the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

REVIEWER'S NOTE
The number of channels that fulfill GDC 19 requirements for the number of OPERABLE channels required depends upon the plant's licensing basis as described in the NRC plant specific Safety Evaluation Report (SER) (Ref. 2). Generally, two divisions are required to be OPERABLE. However, only one channel is required if the plant has justified such a design and the NRC's SER accepted the justification.

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.~~12~~ Remote Shutdown System ~~(Analog)~~

BASES

BACKGROUND

The Remote Shutdown System provides the control room operator with sufficient instrumentation and controls to place and maintain the unit in a safe shutdown condition from a location other than the control room. This capability is necessary to protect against the possibility that the control room becomes inaccessible. A safe shutdown condition is defined as MODE 3. With the unit in MODE 3, the ~~[~~Auxiliary Feedwater (AFW) System~~]~~ and ~~the steam generator safety valves or~~ the steam generator atmospheric dump valves can be used to remove core decay heat and meet all safety requirements. The long term supply of water for the ~~[~~AFW System~~]~~ and the ability to borate the Reactor Coolant System (RCS) from outside the control room allow extended operation in MODE 3.

In the event that the control room becomes inaccessible, the operators can establish control at the ~~remote~~ shutdown panel and place and maintain the unit in MODE 3. Not all controls and necessary transfer switches are located at the ~~remote~~ shutdown panel. Some controls and transfer switches will be operated locally at the switchgear, motor control panels, or other local stations. The unit automatically reaches MODE 3 following a unit shutdown and can be maintained safely in MODE 3 for an extended period of time.

The OPERABILITY of the Remote Shutdown System control and instrumentation Functions ensures that there is sufficient information available on selected plant parameters to place and maintain the plant in MODE 3, should the control room become inaccessible.

APPLICABLE SAFETY ANALYSES

The Remote Shutdown System is required to provide equipment at appropriate locations outside the control room with a capability to promptly shut down and maintain the plant in a safe condition in MODE 3.

The criteria governing the design and the specific system requirements of the Remote Shutdown System are located in 10 CFR 50, Appendix A, GDC 19 (Ref. 1).

The Remote Shutdown System satisfies Criterion 4 of 10 CFR 50.36(c)(2)(ii).

LCO

The Remote Shutdown System LCO provides the requirements for the OPERABILITY of the instrumentation and controls necessary to place and maintain the unit in MODE 3 from a location other than the control room. The instrumentation and controls required are listed in Table B 3.3.~~12~~-1.

BASES

LCO (continued)

~~The controls, instrumentation, and transfer switches are those required for:~~

- ~~Core Reactivity Control (initial and long term),~~
- ~~RCS Pressure Control,~~
- ~~Decay Heat Removal via the [AFW System] and the safety valves or steam generator ADVs,~~
- ~~RCS Inventory Control via charging flow, and~~
- ~~Safety support systems for the above Functions, as well as service water, component cooling water, and onsite power including the diesel generators.~~

1

A Function of a Remote Shutdown System is OPERABLE if all instrument and control channels needed to support the remote shutdown Functions are OPERABLE. ~~In some cases, Table B 3.3.12-1 may indicate that the required information or control capability is available from several alternate sources. In these cases, the Function is OPERABLE as long as one channel of any of the alternate information or control sources for each Function is OPERABLE.~~

1

The Remote Shutdown System instrumentation and control circuits covered by this LCO do not need to be energized to be considered OPERABLE. This LCO is intended to ensure that the instrument and control circuits will be OPERABLE if plant conditions require that the Remote Shutdown System be placed in operation.

s

1

APPLICABILITY

The Remote Shutdown System LCO is applicable in MODES 1, 2, and 3. This is required so that the unit can be placed and maintained in MODE 3 for an extended period of time from a location other than the control room.

This LCO is not applicable in MODE 4, 5, or 6. In these MODES, the unit is already subcritical and in the condition of reduced RCS energy. Under these conditions, considerable time is available to restore necessary instrument control Functions if control room instruments or control become unavailable.

BASES

ACTIONS

does not satisfy the required number of channels or the minimum channels

channel

a

A Remote Shutdown System ~~division~~ is inoperable when ~~each~~ Function ~~is not accomplished by at least one designated Remote Shutdown System channel that satisfies the~~ OPERABILITY criteria for the channel's Function. These criteria are outlined in the LCO section of the Bases. 1

A Note has been added in the ACTIONS to clarify the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function. The Completion Time(s) of the inoperable channel(s)/train(s) of a Function will be tracked separately for each Function, starting from the time the Condition was entered for that Function.

A.1

required Functions

Condition A addresses the situation where one or more ~~channels~~ of the Remote Shutdown System are inoperable. This includes the control and transfer switches for any required Function. 1

required Functions

The Required Action is to restore the ~~divisions~~ to OPERABLE status within 30 days. The Completion Time is based on operating experience and the low probability of an event that would require evacuation of the control room. 1

B.1 and B.2

If the Required Action and associated Completion Time of Condition A are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required MODE from full power conditions in an orderly manner and without challenging plant systems. 2

SURVEILLANCE REQUIREMENTS

~~[~~ SR 3.3.~~12~~.1

10

2 3

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that

BASES

SURVEILLANCE REQUIREMENTS (continued)

the instrumentation continues to operate properly between each CHANNEL CALIBRATION. Agreement criteria are determined by the plant staff, based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit. As specified in the Surveillance, a CHANNEL CHECK is only required for those channels that are normally energized. If the channels are within the criteria, it is an indication that the channels are OPERABLE. If the channels are normally off scale during times when surveillance is required, the CHANNEL CHECK will only verify that they are off scale in the same direction. Off scale low current loop channels are verified to be reading at the bottom of the range and not failed downscale.

~~[The Frequency of 31 days is based on plant operating experience that demonstrates channel failure is rare.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 4

~~]~~

SR 3.3.~~12.2~~ 10.4 3

SR 3.3.~~12.2~~ verifies that each required Remote Shutdown System transfer switch and control circuit performs its intended function. This verification is performed from the reactor shutdown panel and locally, as appropriate. Operation of the equipment from the remote shutdown panel is not necessary. The Surveillance can be satisfied by performance of a continuity check. This will ensure that if the control room becomes inaccessible, the plant can be placed and maintained in MODE 3 from the reactor shutdown panel and the local control stations. ~~[The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~unplanned transient if the Surveillance were performed with the reactor at power. Operating experience demonstrates that Remote Shutdown System control channels seldom fail to pass the Surveillance when performed at a Frequency of once every [18] months.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 4
~~----------]~~

SR 3.3.~~12~~.3 3
10.2

CHANNEL CALIBRATION is a complete check of the instrument channel including the sensor. The Surveillance verifies that the channel responds to the measured parameter within the necessary range and accuracy. Whenever a sensing element is replaced, the next required CHANNEL CALIBRATION of the resistance temperature detectors (RTD) sensors is accomplished by an inplace cross calibration that compares the other sensing elements with the recently installed sensing element.

~~[The 18 month Frequency is based upon the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~ 4

The SR is modified by a Note, which excludes neutron detectors from the CHANNEL CALIBRATION.

[SR 3.3.~~12.4~~ 10.3 3

SR 3.3.~~12.4~~ is the performance of a CHANNEL FUNCTIONAL TEST. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. This Surveillance should verify the OPERABILITY of the reactor trip circuit breaker (RTCB) open/closed indication ~~on the remote shutdown panels~~ by actuating the RTCBs. ~~[The Frequency of 18 months was chosen because the RTCBs cannot be exercised while the unit is at power. Operating experience has shown that these components usually pass the Surveillance when performed at a Frequency of once every 18 months. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.~~ 1 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

NOTE
This Table is for illustration purposes only. It does not attempt to encompass every Function used at every unit, but does contain the types of Functions commonly found.

INSERT 1

FUNCTION/INSTRUMENT OR CONTROL PARAMETER	REQUIRED NUMBER OF DIVISIONS
1. Reactivity Control	
a. Log Power Neutron Flux	[1]
b. Source Range Neutron Flux	[1]
c. Reactor Trip Circuit Breaker Position	[1 per trip breaker]
d. Manual Reactor Trip	[2]
2. Reactor Coolant System Pressure Control	
a. Pressurizer Pressure or RCS Wide Range Pressure	[1]
b. Pressurizer Power Operated Relief Valve Control and Block Valve Control	[1, controls must be for power operated relief valve and block valves on same line]
3. Decay Heat Removal via Steam Generators	
a. Reactor Coolant\ Hot Leg Temperature	[1 per loop]
b. Reactor Coolant Cold Leg Temperature	[1 per loop]
c. Auxiliary Feedwater Controls	[1]
d. Steam Generator Pressure	[1 per steam generator]
e. Steam Generator Level or Auxiliary Feedwater Flow	[1 per steam generator]
f. Condensate Storage Tank Level	[1]
4. Reactor Coolant System Inventory Control	
a. Pressurizer Level	[1]
b. Reactor Coolant Charging Pump Controls	[1]

1

REVIEWER'S NOTE
The number of channels that fulfill GDC 19 requirements for the number of OPERABLE channels required depends upon the plant's licensing basis as described in the NRC plant specific Safety Evaluation Report (SER) (Ref. 2). Generally, two divisions are required to be OPERABLE. However, only one channel is required if the plant has justified such a design and the NRC's SER accepted the justification.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.10, BASES, REMOTE SUTDOWN SYSTEM

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the ITS Specification number and title.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. **Unit 1 only:** The ITS maintains one required channel for each Remote shutdown System Function consistent with the equivalent CTS requirement and licensing basis.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.3.10, REMOTE SHUTDOWN SYSTEM

~~(1) - If not performed in previous 7 days.~~

L01

(2) - Heat balance only, above 15% of RATED THERMAL POWER; adjust "Nuclear Power Calibrate" potentiometer to null "Nuclear Pwr – ΔT Pwr." During PHYSICS TESTS, these daily calibrations of nuclear power and ΔT power may be suspended provided these calibrations are performed upon reaching each major test power plateau and prior to proceeding to the next major test power plateau.

(3) - Above 15% of RATED THERMAL POWER, recalibrate the excore detectors which monitor the AXIAL SHAPE INDEX by using the incore detectors or restrict THERMAL POWER during subsequent operations to ≤ 90% of the maximum allowed THERMAL POWER level with the existing Reactor Coolant Pump combination.

(4) - Adjust "ΔT Pwr Calibrate" potentiometers to make ΔT power signals agree with calorimetric calculation.

(5) - Neutron detectors may be excluded from CHANNEL CALIBRATION.

(6) - If the as-found setpoint is either outside its predefined as-found acceptance criteria band or is not conservative with respect to the Allowable Value, then the channel shall be declared inoperable and shall be evaluated to verify that it is functioning as required before returning the channel to service.

(7) - The instrument channel setpoint shall be reset to a value that is within the as-left tolerance of the Field Trip Setpoint, otherwise that channel shall not be returned to OPERABLE status. The Field Trip Setpoint and the methodology used to determine the Field Trip Setpoint, the as-found acceptance criteria band, and the as-left acceptance criteria are specified in the UFSAR Section 7.2.

DISCUSSION OF CHANGES
ITS 3.3.11, LOGARITHMIC NEUTRON FLUX MONITORING

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.3.1.1 and Unit 2 CTS 3.3.1 specify requirements for reactor protective instrumentation and list the requirements for each functional unit in CTS Tables 3.3-1 and 4.3-1, including the Wide Range Logarithmic Neutron Flux Monitor – Shutdown instrumentation. ITS 3.3.11 provides requirements for Logarithmic Neutron Flux Monitoring and provides the requirements in the LCO, Applicability, ACTIONS, and Surveillance Requirements. This changes the CTS by presenting the instrument requirements without use of an instrument table. This change is acceptable as it results solely from the change in the format and presentation of the CTS necessary to conform to the ISTS. As the proposed change is the result of changes in the format and presentation of the CTS requirements, it is designated administrative.

A03 **Unit 2 only:** CTS 4.3.1.1 and Table 4.3-1, Functional Unit 13 (Wide Range Logarithmic Neutron Flux Monitor) require a CHANNEL CHECK, CHANNEL FUNCTIONAL TEST, and a CHANNEL CALIBRATION on a Frequency in accordance with the Surveillance Frequency Control Program (SFCP). ITS 3.3.11 only requires a CHANNEL CHECK and CHANNEL CALIBRATION and incorporates the CHANNEL FUNCTIONAL TEST into the CHANNEL CALIBRATION. This changes the CTS by incorporating the CHANNEL FUNCTIONAL TEST into the CHANNEL CALIBRATION requirement for the logarithmic neutron flux monitoring channels.

The purpose of the CHANNEL FUNCTIONAL TEST is to ensure components within the instrumentation circuitry are tested more frequently than a CHANNEL CALIBRATION due to the maximum calculated uncertainty of these components. The Frequency in accordance with the SFCP associated with the logarithmic neutron flux monitoring channels is 18 months for both the CHANNEL FUNCTIONAL TEST and CHANNEL CALIBRATION. The CTS 1.4 (ITS Section 1.1) definition for CHANNEL CALIBRATION states, in part: “The CHANNEL CALIBRATION shall encompass the entire channel… and shall include the CHANNEL FUNCTIONAL TEST.” Since the CHANNEL CALIBRATION encompasses the CHANNEL FUNCTIONAL TEST and the periodic Frequency for these Surveillances is equivalent when shutdown, it is unnecessary to present the CHANNEL FUNCTIONAL TEST as a separate test. This change is acceptable as it results solely in a format and presentation change to the CTS by incorporating the CHANNEL FUNCTIONAL TEST into the CHANNEL CALIBRATION. Both Surveillance Requirements are maintained in the ITS via the CHANNEL CALIBRATION (ITS SR 3.3.11.2). As the proposed change is the

result of a change in the format and presentation of the CTS requirements and not a technical change, it is designated administrative.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS Table 3.3-1 Action 3 provides actions for the Wide Range Logarithmic Neutron Flux Monitor – Shutdown Functional Unit (Functional Unit 11.b). Table 3.3-1, Action 3 requires verification of SHUTDOWN MARGIN (SDM) when the number of channels OPERABLE is one less than the required Minimum Channels Operable. ITS 3.3.11 ACTION A requires a similar action but also includes an additional action to immediately suspend all operations involving positive reactivity additions (Required Action A.1). The action includes a Note to allow limited plant cooldown or boron dilution activities provided the change is accounted for in the calculated SDM. This changes the CTS by adding an additional action when one or more required logarithmic neutron flux monitoring channels is inoperable when shutdown (i.e., MODES 3, 4, and 5).

The purpose of the additional required action is to eliminate many of the means by which SDM can be reduced, while allowing normal plant control operations (e.g., Reactor Coolant System inventory management and temperature control). This action is necessary because with one or more required logarithmic neutron flux monitoring channels inoperable, the ability to detect a boron dilution event is degraded. This change is designated as more restrictive because it provides an additional action requirement that is not required by the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* CTS Table 3.3-1 for reactor protective instrumentation has three columns stating various requirements for each function. These columns are labeled, "TOTAL NO. OF CHANNELS," "CHANNELS TO TRIP," and "MINIMUM CHANNELS OPERABLE." ITS Table 3.3.11 does not retain the "TOTAL NO. OF CHANNELS" or "CHANNELS TO TRIP" columns. This changes the CTS by moving the information of the "TOTAL NO. OF CHANNELS" and "CHANNELS TO TRIP" columns to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program

in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 **Unit 1 only:** (*Category 7- Relaxation of Surveillance Frequency*) CTS 4.3.1.1.1 and CTS Table 4.3-1 Functional Unit 11 (Wide Range Logarithmic Neutron Flux Monitor), require performance of a CHANNEL FUNCTIONAL TEST during startup if not performed in the previous 7 days in accordance with Table 4.3-1 Note (1). CTS does not require a CHANNEL CALIBRATION for the logarithmic neutron flux monitor channels. Performing the CHANNEL FUNCTIONAL TEST during startup if not performed in the previous 7 days would routinely equate to every 18 months if there was no other plant startup between refueling outages. The ITS does not require a CHANNEL FUNCTIONAL TEST "during startup if not performed in the previous 7 days," but rather, ITS SR 3.3.11.2 requires a CHANNEL CALIBRATION, which encompasses a CHANNEL FUNCTIONAL TEST, to be performed on a Frequency in accordance with the Surveillance Frequency Control Program (SFCP). A Note is included stating that the neutron detectors are excluded from the CHANNEL CALIBRATION. This changes the CTS by replacing the requirement to perform the CHANNEL FUNCTIONAL TEST during startup (routinely every 18 months) if not performed in the previous 7 days with a requirement to perform a CHANNEL CALIBRATION on a periodic frequency in accordance with the SFCP with an initial periodic Frequency of 18 months.

The purpose of the CTS Table 4.3-1 Functional Unit 11 CHANNEL FUNCTIONAL TEST is to ensure the logarithmic neutron flux monitoring channels are functioning properly. This change is acceptable because the CTS 1.4 (ITS Section) definition of a CHANNEL CALIBRATION encompasses a CHANNEL FUNCTIONAL TEST and also includes a complete check of the instrument channel and will continue to ensure the channels are functioning properly. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. The Note excluding the neutron detectors from the calibration is acceptable because they are passive devices with minimal drift and because of the difficulty of simulating a meaningful signal. CTS 4.0.4 (ITS SR 3.0.4) requires the normal periodic Surveillances to be performed and be current prior to entry into the applicable MODES. Once the applicable MODES are entered, the normal, periodic Surveillance Frequency provides adequate assurance of OPERABILITY. Performing the CHANNEL FUNCTIONAL TEST during startup if not performed in the previous 7 days, as specified in CTS Table 4.3-1 and Note (1) for Functional Unit 11, would routinely be every 18 months if there were no other plant startups between refueling outages. Therefore, replacing the specific Frequency of prior to startup if not performed in the previous 7 days with a specified Frequency of in accordance with the Surveillance Frequency Control Program with an initial periodic frequency of 18 months is considered acceptable.

Requiring a CHANNEL CALIBRATION instead of a CHANNEL FUNCTIONAL TEST is also acceptable because the CHANNEL CALIBRATION encompasses the CHANNEL FUNCTIONAL TEST as defined in Section 1.1 of the ITS.

PSL controls periodic Frequencies for Surveillances in accordance with the SFCP per CTS 6.8.4.o. Therefore, the initial periodic Frequency for SR 3.3.11.2 in accordance with the SFCP will be 18 months consistent with the CHANNEL FUNCTIONAL TEST and CHANNEL CALIBRATION testing frequencies for PSL Unit 2 CTS 4.3.1.1 and Table 4.3-1, Functional Unit 13; and ISTS SR 3.3.13.3. The periodic Frequency is acceptable based upon the assumption of a 22.5 month calibration interval (18 months plus 25% grace) for the determination of the magnitude of equipment drift and is consistent with the CHANNEL CALIBRATION and CHANNEL FUNCTIONAL TEST Frequencies for the PSL Unit 2 wide range neutron monitoring instrumentation.

The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) "Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program" (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066). This change is designated as less restrictive because the Surveillance will be performed less frequently under the ITS than under the CTS.

L02 (*Category 1 – Relaxation of LCO Requirements*) Unit 1 CTS 3.3.1.1 and Unit 2 CTS 3.3.1 specify requirements for reactor protective instrumentation and list the requirements for each functional unit in CTS Tables 3.3-1 and 4.3-1, including the Wide Range Logarithmic Neutron Flux Monitor – Shutdown instrumentation. CTS Table 3.3-1 lists a total of 4 channels and requires a minimum of 2 channels to be OPERABLE for the Wide Range Logarithmic Neutron Flux Monitor – Shutdown Function (Functional Unit 11.b (Unit 1) and 13.b (Unit 2)). TS 3.3.11 provides requirements for Logarithmic Neutron Flux Monitoring and also requires two channels neutron flux monitoring channels to be OPERABLE when shutdown. The ITS 3.3.11 Bases describes the channels required to meet the LCO and states that the excore wide range logarithmic monitoring channels (i.e., post accident and Appendix R monitors) can be substituted for the wide range logarithmic power range channels. Additionally for Unit 2, the startup logarithmic monitoring channels can be substituted for the wide range logarithmic power range channels. This changes the CTS by explicitly stating in the ITS Bases that instruments other than the wide range logarithmic power range monitoring instruments can be used to meet the LCO. This change results in a total of six logarithmic neutron flux monitoring channels that may be used to meet the LCO for Unit 1 and a total of eight logarithmic neutron flux monitoring channels that may be used to meet the LCO for Unit 2.

The purpose of requiring the wide range logarithmic neutron flux monitors to be OPERABLE during MODES 3, 4, and 5 is to alert the operator of reactivity transients (e.g., boron dilution event) initiated from conditions in which the Reactor Protective System is not required. For Unit 1, the excore wide range

logarithmic monitoring channels provide input into the boron dilution alarm and have a wide range of 2 X 10^{-8}% to 200%, which is equivalent to the wide range logarithmic power range channels, and a source range of 1 to 10^5 cps. For Unit 2, the excore wide range logarithmic monitoring channels also have a wide range of 2 X 10^{-8}% to 200%, which is equivalent to the wide range logarithmic power range channels, and a source range of 1 to 10^5 cps. However, separate startup logarithmic monitoring channels provide input to the boron dilution alarm for Unit 2. The startup logarithmic monitoring instruments have a source range of 1 to 10^5 cps. Specific neutron flux monitoring instruments are not assumed in shutdown accidents and transients. However, the timing for operators to take action to mitigate a boron dilution accident is evaluated for the shutdown modes and is based, in part, on alarms and indication of a reactivity increase. This change is acceptable because the excore wide range logarithmic monitoring channels have an instrument range equivalent to the wide range logarithmic power range channels and the Unit 1 excore wide range logarithmic monitoring channels and Unit 2 startup logarithmic monitoring channels provide input to the boron dilution alarm. Therefore, these logarithmic neutron flux monitoring instruments can also alert the operator of reactivity transients, including a boron dilution event, in MODES 3, 4, and 5. This change is designated as less restrictive because less stringent LCO requirements are being applied in ITS than were applied in the CTS.

L03 (*Category 3 - Relaxation of Completion Time*) CTS Table 3.3-1 Action 3 provides compensatory actions for the Wide Range Logarithmic Neutron Flux Monitor – Shutdown Functional Unit when the number of OPERABLE channels is less than the number of minimum required channels Operable. Action 3 requires verification of compliance with Shutdown Margin requirements within 1 hour and at least once per 12 hours thereafter. ITS Required Action A.2 specifies an equivalent action with a Completion Time of 4 hours and once per 12 hours thereafter. This changes the CTS by extending the time to initially verify SHUTDOWN MARGIN (SDM) from 1 hour to 4 hours.

The purpose of the action to verify compliance with SDM is to detect an inadvertent boron dilution of the Reactor Coolant System (RCS) providing operators with time to take action prior to a loss of SDM when the one or more required logarithmic neutron flux monitoring channels is inoperable. The proposed change is acceptable because the initial Completion Time of 4 hours to perform SDM verification takes into consideration that ITS 3.3.11, Required Action A.1 eliminates many of the means by which SDM can be reduced. In addition, the Completion Time extension is justified based on the low likelihood of an event occurring within the allowed Completion Time and the fact that plant conditions will change slowly. The proposed change is designated less restrictive as it results in additional time being allowed to perform a required action.

L04 **Unit 2 only:** *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)* CTS 4.3.1.1 and Table 4.3-1, Functional Unit 13 (Wide Range Logarithmic Neutron Flux Monitor) require, in part, a CHANNEL CALIBRATION on a Frequency in accordance with the Surveillance Frequency Control Program (SFCP). ITS SR 3.3.11.2 also requires a CHANNEL CALIBRATION but is modified by a Note stating, “Neutron detectors are excluded from CHANNEL

CALIBRATION.". This changes the CTS by excluding neutron detectors from the CHANNEL CALIBRATION requirement for the logarithmic neutron flux monitoring channels.

The purpose of a CHANNEL CALIBRATION is to ensure that the channel responds within the necessary range and accuracy to known values of the parameter that the channel monitors. Thus, to perform a channel calibration of a neutron flux channel would require including the neutron flux detector in the calibration. Inclusion of neutron flux detectors in the CHANNEL CALIBRATION process is impractical in power reactor applications because to do so would require subjecting the detectors to known neutron fluxes. Neutron detectors are typically excluded from CHANNEL CALIBRATIONS because of the hazards associated with exposing the neutron detectors; for example, CTS Table 4.3-1 Note (4) excludes the detectors of Functional Unit 2 (Variable Power Level High) from CHANNEL CALIBRATION. The logarithmic neutron flux monitoring channels also use neutron detectors, which are subject to the same hazards. The Note excluding the neutron detectors from the calibration is acceptable because they are passive devices with minimal drift and because of the difficulty of simulating a meaningful signal. This proposed change is consistent with historical and current NRC staff requirements as reflected in ISTS. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.11, LOGARITHMIC NEUTRON FLUX MONITORING

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The heading for ISTS 3.3.11 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2) and Chemical and Volume Control System (CVCS) Isolation Signal (ISTS 3.3.9). Therefore, ISTS 3.3.2 and ISTS 3.3.9 are not included in the PSL ITS. The successive Specifications are renumbered as necessary.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

4. The specified condition in the Applicability of ISTS 3.3.13 state states, “with the reactor trip circuit breakers open or Control Element Assembly (CEA) Drive System not capable of CEA withdrawal,” is not included in ITS 3.3.11. The ITS Applicability of MODES 3, 4, and 5 is consistent with the Applicable Mode in PSL CTS Table 3.3-1 for Functional Unit 11.b (Unit 1) and 13.b (Unit 2) and ensures capability to detect a boron dilution event while shutdown is available regardless of the status of the reactor trip circuit breakers.

5. ISTS 3.3.13.2 is not included in the PSL ITS. In the PSL Unit 2 CTS, the Frequency for the CHANNEL FUNCTIONAL TEST and the CHANNEL CALIBRATION is 18 months in accordance with the Surveillance Frequency Control Program. The definition for CHANNEL CALIBRATION in Section 1.1 states, in part, that the CHANNEL CALIBRATION encompasses the CHANNEL FUNCTIONAL TEST. Therefore, it is unnecessary to provide two separate requirements. This change is also made to PSL Unit 1 to be consistent with PSL Unit 2 since the instrumentation calibration tolerance is the same for both units. Refer to CTS Discussion of Change A03 for Unit 2 and L01 for Unit 1. The successive SR is renumbered to reflect this change.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.3 INSTRUMENTATION (Analog)

B 3.3.13 [Logarithmic] Power Monitoring Channels (Analog)

BASES

BACKGROUND

The [logarithmic] power monitoring channels provide neutron flux power indication from < 1E-7% RTP to > 100% RTP. They also provide reactor protection when the reactor trip circuit breakers (RTCBs) are shut, in the form of a Power Rate of Change - High trip (analog plants) or a [Logarithmic] Power Level - High trip (digital plants).

This LCO addresses MODES 3, 4, and 5 with the RTCBs open. When the RTCBs are shut, the [logarithmic] power monitoring channels are addressed by LCO 3.3.2, "Reactor Protective System (RPS) Instrumentation – Shutdown."

When the RTCBs are open, two of the four wide range power channels must be available to monitor neutron flux power. In this application, the RPS channels need not be OPERABLE since the reactor trip Function is not required. By monitoring neutron flux power when the RTCBs are open, loss of SDM caused by boron dilution can be detected as an increase in flux. Alarms are also provided when power increases above the fixed bistable setpoints. For plants employing separate post accident, [logarithmic] nuclear instrumentation channels with adequate range, these can be substituted for the [logarithmic] power range channels. Two channels must be OPERABLE to provide single failure protection and to facilitate detection of channel failure by providing CHANNEL CHECK capability.

APPLICABLE SAFETY ANALYSES

The [logarithmic] power monitoring channels are necessary to monitor core reactivity changes. They are the primary means for detecting and triggering operator actions to respond to reactivity transients initiated from conditions in which the RPS is not required to be OPERABLE. They also trigger operator actions to anticipate RPS actuation in the event of reactivity transients starting from shutdown or low power conditions. The [logarithmic] power monitoring channel's LCO requirements support compliance with 10 CFR 50, Appendix A, GDC 13 (Ref. 1). The FSAR, Chapters [7] and [15] (Refs. 2 and 3, respectively), describes the specific [logarithmic] power monitoring channel features that are critical to comply with the GDC.

The OPERABILITY of [logarithmic] power monitoring channels is necessary to meet the assumptions of the safety analyses and provide for the mitigation of accident and transient conditions.

The [logarithmic] power monitoring channels satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

Insert 1 (1)

in MODES 3, 4, and 5. The manual reactor trip Function is required in MODES 3, 4, and 5 with any RTCB closed and any control element assemblies (CEA) capable of being withdrawn. However, by | R1

Insert 2 (2)

The excore wide range logarithmic monitoring channels (i.e., post accident / Appendix R monitors) can be substituted for the wide range logarithmic power range channels. The excore wide range logarithmic monitoring instruments include fission detectors and have a wide range of 2 X 10^{-8}% to 200% RTP and a source range of 1 to 10^{5} cps. The boron dilution alarm channels utilize the excore wide range logarithmic monitoring channels, which subsequently provide an alarm signal to the plant annunciation system upon detection of a dilution event.

BASES

LCO

The LCO on the [logarithmic] power monitoring channels ensures that adequate information is available to verify core reactivity conditions while shut down.

neutron flux

3

A minimum of two [logarithmic] power monitoring channels are required to be OPERABLE. Some plants may have either four or six channels capable of performing this function. In these cases, multiple failures may be tolerated while the plants are still complying with LCO requirements.

neutron flux

3 1

are

APPLICABILITY

In MODES 3, 4, and 5, with RTCBs open or the Control Element Assembly (CEA) Drive System not capable of CEA withdrawal, [logarithmic] power monitoring channels must be OPERABLE to monitor core power for reactivity changes. In MODES 1 and 2, and in MODES 3, 4, and 5 with the RTCBs shut and the CEAs capable of withdrawal, the [logarithmic] power monitoring channels are addressed as part of the RPS in LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation - Operating."

neutron flux

wide range

3 1

In MODES 3, 4, and 5 with any RTCB closed and any CEA capable of being withdrawn, manual reactor trip channels are required and addressed by LCO 3.3.2, "Reactor Protection System (RPS) Logic and Trip Initiation."

The requirements for source range neutron flux monitoring in MODE 6 are addressed in LCO 3.9.2, "Nuclear Instrumentation." The source range nuclear instrumentation channels provide neutron flux coverage extending an additional one to two decades below the [logarithmic] channels for use during refueling, when neutron flux may be extremely low. They are built into the [logarithmic] neutron flux channels in the analog plants and in many of the post accident channels used in both the digital and analog plants.

3 1

ACTIONS

A.1 and A.2

With one required channel inoperable, it may not be possible to perform a CHANNEL CHECK to verify that the other required channel is OPERABLE. Therefore, with one or more required channels inoperable, the [logarithmic] power monitoring Function cannot be reliably performed. Consequently, the Required Actions are the same for one required channel inoperable or more than one required channel inoperable. The absence of reliable neutron flux indication makes it difficult to ensure SDM is maintained. Required Action [A.1] is modified by a Note to indicate that normal plant control operations that individually add limited positive reactivity (e.g., temperature or boron fluctuations associated with RCS inventory management or temperature control) are not precluded by this Action, provided they are accounted for in the calculated SDM.

neutron flux

3 1 1 3

BASES

ACTIONS (continued)

SDM must be verified periodically to ensure that it is being maintained. Both required channels must be restored as soon as possible. The initial Completion Time of 4 hours and once every 12 hours thereafter to perform SDM verification takes into consideration that Required Action A.1 eliminates many of the means by which SDM can be reduced. These Completion Times are also based on operating experience in performing the Required Actions and the fact that plant conditions will change slowly.

SURVEILLANCE REQUIREMENTS

SR 3.3.13.1 (1) 2

SR 3.3.13.1 is the performance of a CHANNEL CHECK on each required channel. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based upon the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff and should be based on a combination of the channel instrument uncertainties including control isolation, indication, and readability. If a channel is outside the criteria, it may be an indication that the transmitter or the signal processing equipment has drifted outside its limits. If the channels are within the criteria, it is an indication that the channels are OPERABLE.

[The Frequency, about once every shift, is based on operating experience that demonstrates the rarity of channel failure. Since the probability of two random failures in redundant channels in any 12 hour period is extremely low, CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of displays associated with the LCO required channels. 3

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

REVIEWER'S NOTE

Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.]

4

SR 3.3.13.2

A CHANNEL FUNCTIONAL TEST is performed to ensure that the entire channel is capable of properly indicating neutron flux. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. Internal test circuitry is used to feed preadjusted test signals into the preamplifier to verify channel alignment. It is not necessary to test the detector, because generating a meaningful test signal is difficult; the detectors are of simple construction, and any failures in the detectors will be apparent as change in channel output. [The Frequency of 92 days is the same as that employed for the same channels in the other applicable MODES.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

REVIEWER'S NOTE

Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.]

5

[At this unit, the channel trip Functions tested by the CHANNEL FUNCTIONAL TEST are as follows:]

There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.3.13.3

1.2

2 5 1

neutron flux

SR 3.3.13.3 is the performance of a CHANNEL CALIBRATION. A CHANNEL CALIBRATION is performed. The Surveillance is a complete check and readjustment of the [logarithmic] power channel from the preamplifier input through to the remote indicators. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive surveillances. There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

1 3

Consistent with the definition of a CHANNEL CALIBRATION, this SR encompasses a CHANNEL FUNCTIONAL TEST.

1

This SR is modified by a Note to indicate that it is not necessary to test the detector because generating a meaningful test signal is difficult; the detectors are of simple construction, and any failures in the detectors will be apparent as change in channel output. [The Frequency of 18 months is the same as that employed for the same channels in the other applicable MODES.

3

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

REVIEWER'S NOTE

Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

B 3.3 INSTRUMENTATION (Analog)

B 3.3.13 [Logarithmic] Power Monitoring Channels (Analog)

BASES

BACKGROUND

The [logarithmic] power monitoring channels provide neutron flux power indication from < 1E-7% RTP to > 100% RTP. They also provide reactor protection when the reactor trip circuit breakers (RTCBs) are shut, in the form of a Power Rate of Change - High trip (analog plants) or a [Logarithmic] Power Level - High trip (digital plants).

This LCO addresses MODES 3, 4, and 5 with the RTCBs open. When the RTCBs are shut, the [logarithmic] power monitoring channels are addressed by LCO 3.3.2, "Reactor Protective System (RPS) Instrumentation – Shutdown."

When the RTCBs are open, two of the four wide range power channels must be available to monitor neutron flux power. In this application, the RPS channels need not be OPERABLE since the reactor trip Function is not required. By monitoring neutron flux power when the RTCBs are open, loss of SDM caused by boron dilution can be detected as an increase in flux. Alarms are also provided when power increases above the fixed bistable setpoints. For plants employing separate post accident, [logarithmic] nuclear instrumentation channels with adequate range, these can be substituted for the [logarithmic] power range channels. Two channels must be OPERABLE to provide single failure protection and to facilitate detection of channel failure by providing CHANNEL CHECK capability.

APPLICABLE SAFETY ANALYSES

The [logarithmic] power monitoring channels are necessary to monitor core reactivity changes. They are the primary means for detecting and triggering operator actions to respond to reactivity transients initiated from conditions in which the RPS is not required to be OPERABLE. They also trigger operator actions to anticipate RPS actuation in the event of reactivity transients starting from shutdown or low power conditions. The [logarithmic] power monitoring channel's LCO requirements support compliance with 10 CFR 50, Appendix A, GDC 13 (Ref. 1). The FSAR, Chapters [7] and [15] (Refs. 2 and 3, respectively), describes the specific [logarithmic] power monitoring channel features that are critical to comply with the GDC.

The OPERABILITY of [logarithmic] power monitoring channels is necessary to meet the assumptions of the safety analyses and provide for the mitigation of accident and transient conditions.

The [logarithmic] power monitoring channels satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

Insert 1 (1)

in MODES 3, 4, and 5. The manual reactor trip Function is required in MODES 3, 4, and 5 with any RTCB closed and any control element assemblies (CEA) capable of being withdrawn. However, by | R1

Insert 2 (2)

The excore wide range logarithmic monitoring channels (i.e., post accident / Appendix R monitors) and the startup logarithmic monitoring channels can be substituted for the wide range logarithmic power range channels. The excore wide range logarithmic monitoring instruments include fission detectors and have a wide range of 2 X 10^{-8}% to 200% RTP and a source range of 1 to 10^5 cps. The startup logarithmic monitoring instruments include BF3 detectors and have a range of 1 to 10^5 cps. The boron dilution alarm channels utilize the startup logarithmic monitoring channels, which subsequently provide an alarm signal to the plant annunciation system upon detection of a dilution event.

Neutron Flux

1 3 2 1

BASES

LCO

neutron flux

The LCO on the [logarithmic] power monitoring channels ensures that adequate information is available to verify core reactivity conditions while shut down.

3

neutron flux

Eight

A minimum of two [logarithmic] power monitoring channels are required to be OPERABLE. Some plants may have either four or six channels capable of performing this function. In these cases, multiple failures may be tolerated while the plants are still complying with LCO requirements.

1 3 1

are

APPLICABILITY

In MODES 3, 4, and 5, with RTCBs open or the Control Element Assembly (CEA) Drive System not capable of CEA withdrawal, [logarithmic] power monitoring channels must be OPERABLE to monitor core power for reactivity changes. In MODES 1 and 2, and in MODES 3, 4, and 5 with the RTCBs shut and the CEAs capable of withdrawal, the [logarithmic] power monitoring channels are addressed as part of the RPS in LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation - Operating."

neutron flux

3 1

In MODES 3, 4, and 5 with any RTCB closed and any CEA capable of being withdrawn, manual reactor trip channels are required and addressed by LCO 3.3.2, “Reactor Protection System (RPS) Logic and Trip Initiation.”

The requirements for source range neutron flux monitoring in MODE 6 are addressed in LCO 3.9.2, "Nuclear Instrumentation." The source range nuclear instrumentation channels provide neutron flux coverage extending an additional one to two decades below the [logarithmic] channels for use during refueling, when neutron flux may be extremely low. They are built into the [logarithmic] neutron flux channels in the analog plants and in many of the post accident channels used in both the digital and analog plants.

3 1

ACTIONS

A.1 and A.2

With one required channel inoperable, it may not be possible to perform a CHANNEL CHECK to verify that the other required channel is OPERABLE. Therefore, with one or more required channels inoperable, the [logarithmic] power monitoring Function cannot be reliably performed. Consequently, the Required Actions are the same for one required channel inoperable or more than one required channel inoperable. The absence of reliable neutron flux indication makes it difficult to ensure SDM is maintained. Required Action [A.1] is modified by a Note to indicate that normal plant control operations that individually add limited positive reactivity (e.g., temperature or boron fluctuations associated with RCS inventory management or temperature control) are not precluded by this Action, provided they are accounted for in the calculated SDM.

neutron flux

3 1 1 3

St. Lucie Unit 2 1

Revision XXX 2 1

BASES

ACTIONS (continued)

SDM must be verified periodically to ensure that it is being maintained. Both required channels must be restored as soon as possible. The initial Completion Time of 4 hours and once every 12 hours thereafter to perform SDM verification takes into consideration that Required Action A.1 eliminates many of the means by which SDM can be reduced. These Completion Times are also based on operating experience in performing the Required Actions and the fact that plant conditions will change slowly.

SURVEILLANCE REQUIREMENTS

SR 3.3.13.1 (1) 2

SR 3.3.13.1 is the performance of a CHANNEL CHECK on each required channel. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based upon the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff and should be based on a combination of the channel instrument uncertainties including control isolation, indication, and readability. If a channel is outside the criteria, it may be an indication that the transmitter or the signal processing equipment has drifted outside its limits. If the channels are within the criteria, it is an indication that the channels are OPERABLE.

[The Frequency, about once every shift, is based on operating experience that demonstrates the rarity of channel failure. Since the probability of two random failures in redundant channels in any 12 hour period is extremely low, CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of displays associated with the LCO required channels. 3

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

----------] 4

SR 3.3.13.2

A CHANNEL FUNCTIONAL TEST is performed to ensure that the entire channel is capable of properly indicating neutron flux. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. Internal test circuitry is used to feed preadjusted test signals into the preamplifier to verify channel alignment. It is not necessary to test the detector, because generating a meaningful test signal is difficult; the detectors are of simple construction, and any failures in the detectors will be apparent as change in channel output. [The Frequency of 92 days is the same as that employed for the same channels in the other applicable MODES.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------] 5

[At this unit, the channel trip Functions tested by the CHANNEL FUNCTIONAL TEST are as follows:]

There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.3.13.3

1.2

2 5 1

neutron flux

SR 3.3.13.3 is the performance of a CHANNEL CALIBRATION. A CHANNEL CALIBRATION is performed. The Surveillance is a complete check and readjustment of the [logarithmic] power channel from the preamplifier input through to the remote indicators. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive surveillances. There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

1 3

Consistent with the definition of a CHANNEL CALIBRATION, this SR encompasses a CHANNEL FUNCTIONAL TEST.

1

This SR is modified by a Note to indicate that it is not necessary to test the detector because generating a meaningful test signal is difficult; the detectors are of simple construction, and any failures in the detectors will be apparent as change in channel output. [The Frequency of 18 months is the same as that employed for the same channels in the other applicable MODES.

3

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

REVIEWER'S NOTE

Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

JUSTIFICATION FOR DEVIATIONS
ISTS 3.3.2, REACTOR PROTECTIVE SYSTEM (RPS) INSTRUMENTATION - SHUTDOWN (ANALOG)

1. ISTS 3.3.2, "Reactor Protective System (RPS) Instrumentation - Shutdown (Analog)," Specification is not included in the St. Lucie Plant (PSL) Unit 1 and Unit 2 ITS because the RPS Rate of Change trip function is not credited in any UFSAR Chapter 15 accident analysis. Monitoring of the function is addressed by ITS 3.3.11, “Logarithmic Neutron Flux Monitoring.”

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

1

B 3.3 INSTRUMENTATION (Analog)

B 3.3.2 Reactor Protective System (RPS) Instrumentation - Shutdown (Analog)

BASES

BACKGROUND The RPS initiates a reactor trip to protect against violating the core specified acceptable fuel design limits and reactor coolant pressure boundary integrity during anticipated operational occurrences (AOOs). By tripping the reactor, the RPS also assists the Engineered Safety Features systems in mitigating accidents.

The protection and monitoring systems have been designed to ensure safe operation of the reactor. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the RPS, as well as LCOs on other reactor system parameters and equipment performance.

The LSSS, defined in this Specification as the Allowable Value, in conjunction with the LCOs, establish the threshold for protective system action to prevent exceeding acceptable limits during Design Basis Accidents.

During AOOs, which are those events expected to occur one or more times during the plant life, the acceptable limits are:

- The departure from nucleate boiling ratio shall be maintained above the Safety Limit (SL) value to prevent departure from nucleate boiling,
- Fuel centerline melting shall not occur, and
- The Reactor Coolant System pressure SL of [2750] psia shall not be exceeded.

Maintaining the parameters within the above values ensures that the offsite dose will be within the 10 CFR 50 (Ref. 1) and 10 CFR 100 (Ref. 2) criteria during AOOs.

Accidents are events that are analyzed even though they are not expected to occur during the plant life. The acceptable limit during accidents is that the offsite dose shall be maintained within an acceptable fraction of 10 CFR 100 (Ref. 2) limits. Different accident categories allow a different fraction of these limits based on probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event.

1

BASES

BACKGROUND (continued)

The RPS is segmented into four interconnected modules. These modules are:

- Measurement channels,
- Bistable trip units,
- RPS Logic, and
- Reactor trip circuit breakers (RTCBs).

This LCO applies only to the Power Rate of Change - High trip Functions and associated instrument channels in MODES 3, 4, and 5 with any of the RTCBs closed and any Control Element Assembly (CEA) capable of being withdrawn. In MODES 1 and 2, this trip Function is addressed in LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation - Operating." LCO 3.3.13, "[Logarithmic] Power Monitoring Channels," applies when the RTCBs are open or CEA Drive System is not capable of CEA withdrawal. In the case of LCO 3.3.13, the logarithmic power instrumentation channels are required for monitoring neutron flux, although the trip Function is not required.

Measurement Channels and Trip Units

The measurement channels providing input to the Power Rate of Change - High Function consist of wide range nuclear instrumentation channels using neutron flux leakage from the reactor vessel.

Other aspects of the Power Rate of Change - High trip are similar to the other measurement channels and bistable trip units. These are addressed in the Background section of LCO 3.3.1.

APPLICABLE SAFETY ANALYSES

Each of the analyzed accidents and transients can be detected by one or more RPS Functions. The accident analysis contained in Reference 3 takes credit for most RPS trip Functions. Functions not specifically credited in the accident analysis were qualitatively credited in the safety analysis and the NRC staff approved licensing basis for the plant. These Functions may provide protection for conditions that do not require dynamic transient analysis to demonstrate Function performance. Other Functions, such as the Loss of Load trip, are purely equipment protective, and their use minimizes the potential for equipment damage.

1

BASES

APPLICABLE SAFETY ANALYSES (continued)

The Power Rate of Change - High trip is used to trip the reactor when excore wide range power indicates an excessive rate of change.

The Power Rate of Change - High trip is not required for protection. It serves as a backup to the administratively enforced startup rate limit.

The Power Rate of Change - High Function minimizes transients for events such as a continuous CEA withdrawal or a boron dilution event from low power levels. The Power Rate of Change - High trip is automatically bypassed at < 1E-4% RTP, as sensed by the wide range nuclear instrument (NI) Level 2 bistable, when poor counting statistics may lead to erroneous indication. It is also bypassed at > 12% RTP, where moderator temperature coefficient and fuel temperature coefficient make high rate of change of power unlikely. This bypass is effected by the power range NI Level 1 bistable. Automatic bypass removal is also effected by these bistables. With the RTCBs open, the Power Rate of Change - High trip is not required to be OPERABLE; however, the indication and alarm Functions of at least two channels are required to be OPERABLE. LCO 3.3.13 ensures the wide range channels are available to detect and alert the operator to a boron dilution event.

The RPS instrumentation satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires all instrumentation performing an RPS Function to be OPERABLE. Failure of any required portion of the instrument channel or bypass removal channel renders the affected channel(s) inoperable and reduces the reliability of the affected Functions.

Actions allow maintenance (trip channel) bypass of individual channels, but the bypass activates interlocks that prevent operation with a second channel in the same Function bypassed. Plants are restricted to 48 hours in a trip channel bypass condition before either restoring the Function to four channel operation (two-out-of-four logic) or placing the channel in trip (one-out-of-three logic). At plants where adequate channel to channel independence has been demonstrated, specific exceptions have been approved by the NRC staff to permit one of the two-out-of-four channels to be bypassed for an extended period of time.

This LCO requires four channels of Power Rate of Change - High to be OPERABLE in MODES 3, 4, and 5, when the RTCBs are closed and the CEA Drive System is capable of CEA withdrawal. MODE 1 and 2 requirements are addressed in LCO 3.3.1. This trip is not credited in the safety analysis. Therefore, the Allowable Value specified in SR 3.3.4.2 is not derived from an analytical limit.

1

BASES

APPLICABILITY This LCO is applicable to the Power Rate of Change - High reactor trip in MODES 3, 4 and 5. MODES 1 and 2 are addressed in LCO 3.3.1.

The power rate of change trip is required in MODES 3, 4, and 5, with the RTCBs closed and a CEA capable of being withdrawn to provide backup protection for boron dilution and CEA withdrawal events. The power rate of change trip is not credited in the safety analysis, but is part of the NRC approved licensing basis for the plant.

The power rate of change trip has operating bypasses discussed in the LCO section. In MODES 3, 4, and 5, the emphasis is placed on return to power events. The reactor is protected in these MODES by ensuring adequate SDM.

ACTIONS The most common causes of channel inoperability are outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the plant specific setpoint analysis. Typically, the drift is found to be small and results in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the process instrument is set up for adjustment to bring it to within specification. If the trip setpoint is less conservative than the Allowable Value in Table 3.3.1-1, the channel is declared inoperable immediately, and the appropriate Condition(s) must be entered immediately.

In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value, or the transmitter, instrument loop, signal processing electronics, or RPS bistable is found inoperable, then all affected Functions provided by that channel must be declared inoperable and the plant must enter the Condition for the particular protection Function affected.

When the number of inoperable channels in a trip Function exceeds that specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 is immediately entered if applicable in the current MODE of operation.

A.1, A.2.1, and A.2.2

Condition A applies to the failure of a single channel of the Power Rate of Change - High RPS automatic trip Function.

BASES

ACTIONS (continued)

RPS coincidence logic is normally two-out-of-four. If one RPS bistable trip unit or associated instrument channel is inoperable, startup or power operation is allowed to continue, providing the inoperable trip unit is placed in bypass or trip within 1 hour (Required Action A.1). With one channel in bypass, no additional random failure of a single channel could spuriously trip the reactor and a valid trip signal can still trip the reactor. With one channel in trip, an additional random failure of a single channel could spuriously trip the reactor. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to restore, bypass, or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel, while ensuring that the risk involved in operating with the failed channel is acceptable.

For plants that have not demonstrated sufficient channel to channel independence, the failed channel is restored to OPERABLE status or is placed in trip within 48 hours (Required Action A.2.1 or Required Action A.2.2). Required Action A.2.1 restores the full capability of the Function. Required Action A.2.2 places the Function in a one-out-of-three configuration. In this configuration, common cause failure of dependent channels cannot prevent trip.

The [48] hour Completion Time is based on operating experience, which has demonstrated that a random failure of a second channel occurring during the [48] hour period is a low probability event.

B.1 and B.2

Condition B applies to the failure of two channels in the Power Rate of Change - High RPS automatic trip Function.

Required Action B.1 provides for placing one inoperable channel in bypass and the other channel in trip within the Completion Time of 1 hour. This Completion Time is sufficient to allow the operator to take all appropriate actions for the failed channels, while ensuring the risk involved in operating with the failed channels is acceptable. With one channel of protective instrumentation bypassed, the RPS is in a two-out-of-three logic; but with another channel failed, the RPS may be operating in a two-out-of-two logic. This is outside the assumptions made in the analyses and should be corrected. To correct the problem, the second channel is placed in trip. This places the RPS in a one-out-of-two logic. If any of the other OPERABLE channels receives a trip signal, the reactor will trip.

BASES

ACTIONS (continued)

[The bypassed channel should be restored to OPERABLE status within 48 hours for reasons similar to those stated under Condition A. After one channel is restored to OPERABLE status, the provisions of Condition A still apply to the remaining inoperable channel. Therefore, the channel that is still inoperable after completion of Required Action B.2 shall be placed in trip if more than 48 hours have elapsed since the initial channel failure.]

C.1, C.2.1, C.2.2.1, and C.2.2.2

Condition C applies to one automatic bypass removal channel inoperable. If the bypass removal channel cannot be restored to OPERABLE status, the associated Power Rate of Change - High RPS channel may be considered OPERABLE only if the bypass is not in effect. Otherwise, the affected RPS channel must be declared inoperable, as in Condition A, and the bypass either removed or the bypass removal channel repaired. The Bases for the Required Actions and Completion Times are the same as discussed for Condition A.

D.1, D.2.1, and D.2.2

Condition D applies to two inoperable automatic bypass removal channels. If the bypass removal channels cannot be restored to OPERABLE status, the associated Power Rate of Change - High RPS channel may be considered OPERABLE only if the bypass is not in effect. Otherwise, the affected RPS channels must be declared inoperable, as in Condition B, and the bypass either removed or the bypass removal channel repaired. Also, Required Action D.2.2 provides for the restoration of the one affected automatic trip channel to OPERABLE status within the rules of Completion Time specified under Condition B. Completion Times are consistent with Condition B.

E.1

Condition E is entered when the Required Actions and associated Completion Times of Condition A, B, C, or D are not met.

1

BASES

ACTIONS (continued)

If Required Actions associated with these Conditions cannot be completed within the required Completion Time, opening the RTCBs brings the reactor to a MODE where the LCO does not apply and ensures no CEA withdrawal will occur. The basis for the Completion Time of 6 hours is that it is adequate to complete the Required Actions without challenging plant systems, including the insertion of CEAs for plants that normally maintain CEAs withdrawn when shut down.

SURVEILLANCE REQUIREMENTS

----------REVIEWER'S NOTE----------
In order for a plant to take credit for topical reports as the basis for justifying Frequencies, topical reports must be supported by an NRC staff Safety Evaluation Report that establishes the acceptability of each topical report for that plant.

SR 3.3.2.1

Performance of the CHANNEL CHECK on each wide range channel ensures that gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on another channel. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including isolation, indication, and readability. If a channel is outside the criteria, it may be an indication that the transmitter or the signal processing equipment has drifted outside its limits.

[The Frequency, about once every shift, is based on operating experience that demonstrates the rarity of channel failure. Since the probability of two random failures in redundant channels in any 12 hour period is extremely low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of the displays associated with the LCO required channels.

SURVEILLANCE REQUIREMENTS (continued)

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

SR 3.3.2.2

A CHANNEL FUNCTIONAL TEST on the power rate of change channels is performed to ensure the entire channel will perform its intended function if required. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. The Power Rate of Change - High trip Function is required during startup operation and is bypassed when shut down or > 15% RTP. [Additionally, operating experience has shown that these components usually pass the Surveillance when performed at a Frequency of once every 92 days prior to each reactor startup. There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.3.2.3

SR 3.3.2.3 is a CHANNEL FUNCTIONAL TEST similar to SR 3.3.2.2, except SR 3.3.2.3 is applicable only to bypass Functions and is performed prior to each startup. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

Proper operation of bypass permissives is critical during plant startup because the bypasses must be in place to allow startup operation and must be removed at the appropriate points during power ascent to enable certain reactor trips. Consequently, the appropriate time to verify bypass removal function OPERABILITY is just prior to startup. [The allowance to conduct this Surveillance within 92 days of startup is based on the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 5).

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

Once the operating bypasses are removed, the bypasses must not fail in such a way that the associated trip Function gets inadvertently bypassed. This feature is verified by the trip Function CHANNEL FUNCTIONAL TEST, SR 3.3.2.2. Therefore, further testing of the bypass function after startup is unnecessary.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.3.2.4

SR 3.3.2.4 is the performance of a CHANNEL CALIBRATION.

CHANNEL CALIBRATION is a complete check of the instrument channel including the sensor. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

Only the Allowable Values are specified for each RPS trip Function. Nominal trip setpoints are specified in the plant specific setpoint calculations. The nominal setpoints are selected to ensure the setpoints measured by CHANNEL FUNCTIONAL TESTS do not exceed the Allowable Value if the bistable is performing as required. Operation with a trip setpoint less conservative than the nominal trip setpoint, but within its Allowable Value, is acceptable, provided that operation and testing are consistent with the assumptions of the plant specific setpoint calculations. Each Allowable Value specified is more conservative than the analytical limit assumed in the safety analysis in order to account for instrument uncertainties appropriate to the trip Function. These uncertainties are defined in the "Plant Protection System Selection of Trip Setpoint Values" (Ref. 4).

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the surveillance interval extension analysis. The requirements for this review are outlined in Reference 5.

[The Frequency is based upon the assumption of an [18] month calibration interval in the determination of the magnitude of equipment drift.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

The Surveillance is modified by a Note to indicate that the neutron detectors are excluded from CHANNEL CALIBRATION because they are passive devices with minimal drift and because of the difficulty of simulating a meaningful signal.

ISTS 3.3.2 BASES, REACTOR PROTECTIVE SYSTEM (RPS) INSTRUMENTATION - SHUTDOWN (ANALOG)

1. ISTS 3.3.2, "Reactor Protective System (RPS) Instrumentation - Shutdown (Analog)," Specification is not included in the St. Lucie Plant (PSL) Unit 1 and Unit 2 ITS because the RPS Rate of Change function is not credited in any UFSAR Chapter 15 accident analysis. Monitoring of the function is addressed by ITS 3.3.11, “Logarithmic Neutron Flux Monitoring.” Therefore, the Bases associated with ISTS 3.3.2 is not included in the PSL Unit 1 and Unit 2 ITS Bases.

B 3.3 INSTRUMENTATION (Analog)

B 3.3.9 Chemical and Volume Control System (CVCS) Isolation Signal (Analog)

BASES

BACKGROUND This LCO encompasses Chemical and Volume Control System (CVCS) Isolation Signal actuation. This is a plant specific instrumentation channel that performs an actuation Function required for plant protection and is not otherwise included in LCO 3.3.5, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual Trip," or LCO 3.3.6, "Diesel Generator (DG) - Loss of Voltage Start (LOVS)." This is a non-Nuclear Steam Supply System ESFAS Function that, because of differences in purpose, design, and operating requirements, is not included in LCOs 3.3.5 and 3.3.6. Details of this LCO are for illustration only. Individual plants shall include those Functions and LCO requirements that are applicable to them.

The CVCS Isolation Signal provides protection from radioactive contamination, as well as personnel and equipment protection in the event of a letdown line rupture outside containment.

Each of the two actuation subsystems will isolate a separate letdown isolation valve in response to a high pressure condition in either the West Penetration Room or Letdown Heat Exchanger Room. Two pressure detectors in each of these rooms feed the four sensor subsystems. On a two-out-of-four coincidence, both actuation subsystems will actuate.

Trip Setpoints and Allowable Values

Trip setpoints used in the bistables are based on the analytical limits stated in Reference 1. The selection of these trip setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, and instrument drift, Allowable Values specified in SR 3.3.9.2 are conservatively adjusted with respect to the analytical limits. A detailed description of the methodology used to calculate the trip setpoints, including their explicit uncertainties, is provided in "Plant Protection System Selection of Trip Setpoint Values" (Ref. 2). The actual nominal trip setpoint entered into the bistable is normally still more conservative than that specified by the Allowable Value to account for changes in random measurement errors detectable by a CHANNEL FUNCTIONAL TEST. One example of such a change in measurement error is drift during the interval. If the measured setpoint does not exceed the Allowable Value, the bistable is considered OPERABLE.

1

BASES

BACKGROUND (continued)

Setpoints in accordance with the Allowable Value will ensure that Safety Limits are not violated during anticipated operational occurrences (AOOs) and the consequences of Design Basis Accidents will be acceptable, providing the plant is operated from within the LCOs at the onset of the AOO or accident and the equipment functions as designed.

APPLICABLE SAFETY ANALYSES

The CVCS Isolation Signal is redundant to the Safety Injection Actuation Signal for letdown line breaks outside containment. In addition, an excess flow check valve is located in containment just downstream of the regenerative heat exchanger, which isolates letdown when flow exceeds 200 gpm.

[At this unit, the provision of two sensors in each room in a two-out-of-four logic configuration satisfies the single failure criterion as follows:]

The CVCS satisfies the requirements of Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Only the Allowable Values are specified for each trip Function in the LCO. Operation with a trip setpoint less conservative than the nominal trip setpoint, but within its Allowable Value, is acceptable, provided that the difference between the nominal trip setpoint and the Allowable Value is equal to or greater than the drift allowance assumed for each trip in the transient and accident analyses.

Each Allowable Value specified is more conservative than the analytical limit assumed in the transient and accident analysis, in order to account for instrument uncertainties appropriate to the trip Function. These uncertainties are defined in the "Plant Protection System Selection of Trip Setpoint Values" (Ref. 2).

CVCS isolation consists of closing the appropriate valve. This is undesirable at power, since letdown isolation will result. The absence of letdown flow will significantly decrease the charging flow temperature due to the absence of the regenerative heat exchanger preheating, causing unnecessary thermal stress to the charging nozzle. Therefore, the preferred action is to restore the valve function to OPERABLE status.

Four channels of West Penetration Room and Letdown Heat Exchanger Room pressure sensing and two Actuation Logic channels are required to be OPERABLE.

[For this unit, the Bases for the Allowable Values are as follows:]

[For this unit, the Bases for the LCO requirement are as follows:]

1

BASES

APPLICABILITY The CVCS Isolation Signal must be OPERABLE in MODES 1, 2, 3, and 4, since the possibility of a loss of coolant accident is greatest in these MODES. In MODE 5 or 6, the probability is greatly diminished, and there is time to manually isolate CVCS.

ACTIONS A CVCS isolation channel is inoperable when it does not satisfy the OPERABILITY criteria for the channel's Function. The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the plant specific setpoint analysis. Typically, the drift is not large and would result in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a CHANNEL FUNCTIONAL TEST, when the process instrument is set up for adjustment to bring it within specification. If the trip setpoint is not consistent with the Allowable Value in SR 3.3.9.2, the channel must be declared inoperable immediately and the appropriate Conditions must be entered.

In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value, or the sensor, instrument loop, signal processing electronics, or bistable is found inoperable, then all affected Functions provided by that channel should be declared inoperable and the LCO Condition entered for the particular protection Function affected.

When the number of inoperable channels in a trip Function exceeds those specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered if applicable in the current MODE of operation.

A.1

Condition A applies to the failure of one CVCS Actuation Logic channel associated with the CVCS Isolation Signal. Required Action A.1 requires restoration of the inoperable channel to restore redundancy of the affected Function. The Completion Time of 48 hours is consistent with the Completion Time of other ESFAS Functions and should be adequate for most repairs, while minimizing the risk of operating with an inoperable channel.

1

BASES

ACTIONS (continued)

B.1, B.2.1, and B.2.2

Condition B applies if one of the four CVCS instrument channels is inoperable. The Required Actions are identical to those of ESFAS Functions employing four redundant sensors specified in LCO 3.3.4, "Engineered Safety Features Actuation System (ESFAS) Instrumentation." The channel must be placed in bypass or trip if it cannot be repaired within 1 hour (Required Action B.1). The provision of four trip channels allows one channel to be bypassed (removed from service) during operations, placing the ESFAS in two-out-of-three coincidence logic. Placing the channel in bypass is preferred, since the CVCS isolation Function will be in two-out-of-three logic. This will avoid possible inadvertent CVCS isolation if an additional channel fails. The 1 hour Completion Time to bypass or trip the channel is sufficient time to perform the Required Actions.

Once the Required Action to trip or bypass the channel has been complied with, Required Action B.2.1 and Required Action B.2.2 provide for restoring the channel to OPERABLE status or placing it in trip within 48 hours. Required Action B.2.1 restores the full capability of the Function. Required Action B.2.2 places the Function in a one-out-of-three configuration. In this configuration, common cause failure of dependent channels cannot prevent CVCS isolation actuation. The Completion Time provides the operator with time to take appropriate actions and still ensures that any risk involved in operating with a failed channel is acceptable. It is improbable that a failure of a second channel will occur during any given 48 hour period.

C.1 and C.2

Condition C applies if two of the four CVCS West Penetration Room/Letdown Heat Exchanger Room Pressure - High channels are inoperable. The Required Actions are identical to those for other ESFAS Functions employing four redundant sensors in LCO 3.3.4.

Restoring at least one channel to OPERABLE status is the preferred Required Action. If this cannot be accomplished, one channel should be placed in bypass and the other channel in trip. The allowed Completion Time of 1 hour is sufficient time to perform the Required Actions.

Once the Required Action to trip or bypass the channel has been complied with, Required Action C.2 provides for restoring one channel to OPERABLE status within 48 hours. The justification of the 48 hour Completion Time is the same as for Condition B.

1

BASES

ACTIONS (continued)

After one channel is restored to OPERABLE status, the provisions of Condition C still apply to the remaining inoperable channel.

D.1 and D.2

---------- REVIEWER'S NOTE ----------
Adoption of a MODE 4 end state requires the licensee to make the following commitments:

1. [Licensee] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].

2. [Licensee] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.

Condition D is entered when the Required Actions and associated Completion Times of Condition A, B, or C are not met. The plant must be brought to a MODE in which overall plant risk is minimized. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours.

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 3). In MODE 4 there are more accident mitigation systems available and there is more redundancy and diversity in core heat removal mechanisms than in MODE 5. However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

Required Action D.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is

1

BASES

ACTIONS (continued)

not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

E.1 and E.2

Condition E specifies the shutdown track to be followed if two Actuation Logic channels are inoperable. The plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The Completion Times are reasonable, based on operating experience, to reach the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.3.9.1

Performance of the CHANNEL CHECK on each CVCS isolation pressure indicating channel ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value.

Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the transmitter or the signal processing equipment has drifted outside its limit.

[The Frequency, about once every shift, is based on operating experience that demonstrates the rarity of channel failure. Since the probability of two random failures in redundant channels in any 12 hour period is low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of the displays associated with the LCO required channels.

BASES

SURVEILLANCE REQUIREMENTS (continued)

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

SR 3.3.9.2

A CHANNEL FUNCTIONAL TEST is performed on each channel to ensure the entire channel will perform its intended function. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. Any setpoint adjustment shall be consistent with the assumptions of the current plant specific setpoint analysis. There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology.

[The Frequency of 31 days is based on plant operating experience with regard to channel OPERABILITY and drift, which demonstrates that failure of more than one channel of a given Function in any 31 day interval is a rare event.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

Proper operation of the individual subgroup relays is verified by de-energizing these relays during the CHANNEL FUNCTIONAL TEST of the Actuation Logic. This will actuate the Function, operating all associated equipment. Proper operation of the equipment actuated by each train is thus verified. Note 1 indicates this test includes verification of operation for each initiation relay. [At this unit, the verification is conducted as follows:]

Note 2 indicates that relays that cannot be tested at power are excepted from the SR while at power. These relays must, however, be tested during each entry into MODE 5 exceeding 24 hours unless they have been tested within the previous 6 months.

[At this unit, the basis for this test exception is as follows:]

[At this unit, the following relays excepted by this Note are:]

SR 3.3.9.3

CHANNEL CALIBRATION is a complete check of the instrument channel including the sensor. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. There is a plant specific program which verifies that the instrument channel functions as required by verifying the as-left and as-found setting are consistent with those established by the setpoint methodology. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

Radiation detectors may be removed and calibrated in a laboratory, calibrated in place using a transfer source or replaced with an equivalent laboratory calibrated unit.

[The Frequency is based upon the assumptions of an 18 month calibration interval for the determination of the magnitude of equipment drift in the setpoint analysis and includes operating experience as well as consistency with an 18 month fuel cycle.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

DISCUSSION OF CHANGES
ITS 3.4.1, RCS PRESSURE, TEMPERATURE, AND FLOW DEPARTURE FROM NUCLEATE BOILING (DNB) LIMITS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 7 – Relaxation Of Surveillance Frequency)* CTS 4.2.5.2 Note states "Not required to be performed until THERMAL POWER is ≥ 90% of RATED THERMAL POWER. ITS SR 3.4.1.4 states "Not required to be performed until 24 hours after ≥ 90% RTP. ITS SR 3.4.1.4 Note allows 24 hours after ≥ 90% RTP to perform the Surveillance. This is necessary to allow measurement of the flow rate at normal operating conditions at power in MODE 1. The Surveillance will not yield accurate results if performed below 90% RTP. ITS SR 3.0.1 states that SRs shall be met during the MODES or other specified conditions in the Applicability for individual LCOs, unless otherwise stated in the SR. Once the unit reaches 90% RTP, a 24 hour allowance is provided for completing the Surveillance. If the Surveillance were not performed within this 24 hour interval (plus the extension allowed by SR 3.0.2), there would then be a failure to perform a Surveillance within the specified Frequency, and the provisions of SR 3.0.3 would apply. This changes the CTS by allowing up to 24 hours after ≥ 90% RTP to perform the Surveillance.

The purpose of CTS 4.2.5.2 is to perform the Surveillance at normal operating conditions when ≥ 90% RTP. ITS SR 3.4.1.4 allows up to 24 hours after ≥ 90% RTP to perform the Surveillance. This change is acceptable because the "24 hours" allows a reasonable time to perform the Surveillance once establishing

the conditions at which the Surveillances can be performed. Additionally, the proposed time to perform the Surveillance is acceptable because there are other plant parameters available to indicate significant RCS low flow conditions. For example; reactor coolant pump running status indication, RCS low flow alarm, and Reactor Coolant Flow – low reactor trip. This change is designated as less restrictive because the Surveillances will be performed within an allowance of 24 hours after ≥ 90% RTP rather than immediately after ≥ 90% RTP.

L02 (*Category 3 – Relaxation of Completion Time*) CTS 3.2.5 Action requires the unit to reduce THERMAL POWER to ≤ 5% of RTP within the next 4 hours if the DNB parameters are not restored to within limit in 2 hours. ITS 3.4.1 ACTION B requires the power reduction to ≤ 5% RTP (MODE 2) within the next 6 hours if the DNB parameters are not restored to within limit in 2 hours. This changes the CTS by extending the time for the unit to be placed outside the MODE of Applicability. R1

The purpose of the CTS 3.2.5 Action is to limit the time the unit can be outside of the DNB parameter limits and remain within the Applicability of the Specification. This change is acceptable because the Completion Time is consistent with safe operation under the specified Condition, considering the low probability of a DBA occurring during the allowed Completion Time. The change extends the time the unit is allowed to be outside the DNB parameter limits and be in the Applicability of the Specification. The time extension from 4 hours to 6 hours is consistent with the ISTS Completion Time to place the unit in MODE 2 and is considered a reasonable time that permits the plant power to be reduced at an orderly rate in conjunction with even control of steam generator heat removal. This change is designated as less restrictive because additional time is allowed to be outside the DNB parameter limits and be in the Applicability of the Specification than was allowed in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.1, RCS PRESSURE, TEMPERATURE, AND FLOW DEPARTURE FROM NUCLEATE BOILING (DNB) LIMITS

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. ISTS 3.4.1 ACTIONS C and D are specific to RCS cold leg temperature and apply when operation may continue at a reduced RTP for an indefinite period of time. CTS 3.2.5 Actions for RCS cold leg temperature are the same as the Actions for pressurizer pressure and RCS flow rate which require a parameter not within limits be restored to within limits in 2 hours or be in MODE 2 within 6 hours. To reflect the current licensing basis, Condition A is revised to state, “RCS DNB parameter(s) not within limits,” Condition B deletes the phrase “of Condition A,” and ACTIONS C and D are deleted.

4. ISTS LCO 3.4.1 states that the RCS DNB parameters for pressurizer pressure, cold leg temperature, and RCS total flow rate shall be within the limits specified in the COLR. CTS LCO 3.2.5 states that the RCS total flow rate “shall be ≥ 375,000 gpm.” The NRC documented in Generic Letter 88-16, "Removal of Cycle-Specific Parameter Limits from Technical Specifications," that this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. However, NRC-approved Topical Report WCAP-14483, "Generic Methodology for Expanded Core Operating Limits Report," determined that the specific values for the DNB parameters may be relocated to the COLR as long as the limiting RCS total flow limit is retained in the LCO. Therefore, to reflect the CTS 3.2.5 current licensing basis, ISTS LCO 3.4.1 is changed to state that RCS total flow rate “shall be ≥ 375,000 gpm.”

5. The Note to ISTS SR 3.4.1.3 is deleted because it is unnecessary. SR 3.0.1 requires Surveillance to be met during the MODES or other specified conditions in the Applicability. Since ISTS LCO 3.4.1 is only applicable in MODE 1, there is no reason to modify SR 3.4.1.3 with a Note stating that the SR is only required to be met in MODE 1. This change is consistent with ISTS SR 3.4.1.3 in NUREG-1431, which does not contain this Note.

2

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.1 RCS Pressure, Temperature, and Flow [Departure from Nucleate Boiling (DNB)] Limits

2

BASES

BACKGROUND

These Bases address requirements for maintaining RCS pressure, temperature, and flow rate within limits assumed in the safety analyses. The safety analyses (Ref. 1) of normal operating conditions and anticipated operational occurrences assume initial conditions within the normal steady state envelope. The limits placed on departure from nucleate boiling (DNB) related parameters ensure that these parameters will not be less conservative than were assumed in the analyses and thereby provide assurance that the minimum departure from nucleate boiling ratio (DNBR) will meet the required criteria for each of the transients analyzed.

The LCO limits for minimum and maximum RCS pressures as measured at the pressurizer are consistent with operation within the nominal operating envelope and are bounded by those used as the initial pressures in the analyses.

The LCO limits for minimum and maximum RCS cold leg temperatures are consistent with operation at the indicated power level and are bounded by those used as the initial temperatures in the analyses.

The LCO limits for minimum RCS flow rate is bounded by the initial flow rate in the analyses. The RCS flow rate is not expected to vary during plant operation with all pumps running.

APPLICABLE SAFETY ANALYSES

The requirements of LCO 3.4.1 represent the initial conditions for DNB limited transients analyzed in the safety analyses (Ref. 1). The safety analyses have shown that transients initiated from the limits of this LCO will meet the DNBR criterion of ≥ [1.3]. This is the acceptance limit for the RCS DNB parameters. Changes to the facility that could impact these parameters must be assessed for their impact on the DNBR criterion. The transients analyzed for include loss of coolant flow events and dropped or stuck control element assembly (CEA) events. A key assumption for the analysis of these events is that the core power distribution is within the limits of [LCO 3.1.6, "Regulating CEA Insertion Limits," LCO 3.1.7, "Part Length CEA Insertion Limits," LCO 3.2.3, "AZIMUTHAL POWER TILT (Tq)," and LCO 3.2.5, "AXIAL SHAPE INDEX (ASI)"]. The safety analyses are performed over the following range of initial values: RCS pressure [1785-2400] psig, core inlet temperature [500-580]°F, and reactor vessel inlet coolant flow rate > [95]%.

The RCS DNB limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

1

2

BASES

LCO

This LCO specifies limits on the monitored process variables - RCS pressurizer pressure, RCS cold leg temperature, and RCS total flow rate - to ensure that the core operates within the limits assumed for the plant safety analyses. The~~se variables~~ are contained in the COLR to provide operating and analysis flexibility from cycle to cycle. Operating within these limits will result in meeting the DNBR criterion in the event of a DNB limited transient.

values for RCS pressurizer pressure and RCS cold leg temperature

4

The LCO numerical values for pressure, temperature, and flow rate ~~specified in the COLR~~ are given for the measurement location but have not been adjusted for instrument error. Plant specific limits of instrument error are established by the plant staff to meet the operational requirements of this LCO.

4

APPLICABILITY

In MODE 1, the limits on RCS pressurizer pressure, RCS cold leg temperature, and RCS flow rate must be maintained during steady state operation in order to ensure that DNBR criteria will be met in the event of an unplanned loss of forced coolant flow or other DNB limited transient. In all other MODES, the power level is low enough so that DNBR is not a concern.

A Note has been added to indicate the limit on pressurizer pressure may be exceeded during short term operational transients such as a THERMAL POWER ramp increase of > 5% RTP per minute or a THERMAL POWER step increase of > 10% RTP. These conditions represent short term perturbations where actions to control pressure variations might be counterproductive. Also, since they represent transients initiated from power levels < 100% RTP, an increased DNBR margin exists to offset the temporary pressure variations.

Another set of limits on DNB related parameters is provided in Safety Limit (SL) 2.1.1, "Reactor Core Safety Limits." Those limits are less restrictive than the limits of this LCO, but violation of SLs merits a stricter, more severe Required Action. Should a violation of this LCO occur, the operator should check whether or not an SL may have been exceeded.

ACTIONS

A.1

s

Pressurizer pressure ~~is a~~ controllable and measurable parameter. RCS flow rate is not a controllable parameter and is not expected to vary during steady state operation. With ~~either~~ parameter not within the LCO limits, action must be taken to restore the out of limit parameter.

and RCS cold leg temperature are

a

4

The 2 hour Completion Time for restoration of the parameters provides sufficient time to adjust plant parameters, to determine the cause of the off normal condition, and to restore the readings within limits. The Completion Time is based on plant operating experience that shows the parameter can be restored in this time period.

2

BASES

ACTIONS (continued)

B.1

If Required Action A.1 is not met within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 2 within 6 hours. In MODE 2, the reduced power condition eliminates the potential for violation of the accident analysis bounds.

Six hours is a reasonable time that permits the plant power to be reduced at an orderly rate in conjunction with even control of steam generator (SG) heat removal.

~~C.1~~

~~Cold leg temperature is a controllable and measurable parameter. If this parameter is not within the LCO limits, action must be taken to restore the parameter.~~

4

~~The 2 hour Completion Time is based on plant operating experience that shows that the parameter can be restored in this time period.~~

~~D.1~~

~~If Required Action C.1 is not met within the associated Completion Time, THERMAL POWER must be reduced to ≤ [30%] RTP. Plant operation may continue for an indefinite period of time in this condition. At the reduced power level, the potential for violation of the DNB limits is greatly reduced.~~

4

~~The 6 hour Completion Time is a reasonable time that permits power reduction at an orderly rate in conjunction with even control of SG heat removal.~~

SURVEILLANCE REQUIREMENTS

SR 3.4.1.1

2

~~[Since Required Action A.1 allows a Completion Time of 2 hours to restore parameters that are not within limits, the 12 hour Surveillance Frequency for pressurizer pressure is sufficient to ensure that the pressure can be restored to a normal operation, steady state condition following load changes and other expected transient operations. The 12 hour interval has been shown by operating practice to be sufficient to regularly assess for potential degradation and verify operation is within safety analysis assumptions~~.

~~b.~~ In accordance with the Surveillance Frequency Control Program when the reactor is critical and the Reactor Coolant System T_{avg} is less than 525°F.

Applicability

~~With~~ K_{eff} greater than or equal to 1.0.

DISCUSSION OF CHANGES
ITS 3.4.2, RCS MINIMUM TEMPERATURE FOR CRITICALITY

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 4.1.1.5.b requires a determination of RCS average temperature (Tavg) per the Frequency in accordance with the Surveillance Frequency Control Program when the reactor is critical and the RCS Tavg is < 525°F. ITS 3.4.2 Applicability states “MODE 1 with Tavg in one or more RCS loops < 525°F, MODE 2 with Tavg in one or more RCS loops < 525°F and Keff ≥ 1.0.” The ITS couples the monitoring temperature limit with the Applicability. This changes the CTS by moving the temperature monitoring requirement from the Surveillance Frequency to the Applicability. This change is designated as administrative, as it results in no technical change to the CTS.

A03 CTS 3.1.1.5 Action states that with a RCS operating loop temperature (Tavg) < 515°F, "restore (Tavg) to within its limit within 15 minutes or be in HOT STANDBY within the next 15 minutes." ITS 3.4.2, ACTION A, states that with Tavg in one or more RCS loops not within limit, be in MODE 2 with keff < 1.0 within 30 minutes. This changes the CTS by eliminating the redundant and unnecessary requirement to restore Tavg to within its limit within 15 minutes. The change associated with entering MODE 2 with keff < 1.0 instead of HOT STANDBY is discussed in DOC A04. R1

This change is acceptable because it results in no technical change to the Technical Specifications. Although CTS 3.1.1.5 Action appears to only allow 15 minutes to restore the parameter to within the limit, it actually allows the entire 30 minutes to either restore the parameter to within limits or to be in HOT STANDBY (essentially outside the Applicability of CTS 3.1.1.5). In addition, CTS 3.1.1.5 Action only requires actual steps to begin reducing reactor power at the beginning of the last 15 minutes of the 30-minute interval. However, CTS 3.0.2 states that if the LCO is restored prior to expiration of the specified interval, completion of the Action requirements is not required. Therefore, for this case, if the parameter is restored between 15 minutes and 30 minutes after the LCO is not met, completion of the CTS 3.1.1.5 Action to be in HOT STANDBY is not required. Thus, 30 minutes is currently allowed for either the parameter to be restored to within its limit or the unit to be in HOT STANDBY (i.e., only one of the two CTS Actions must be met within 30 minutes). The CTS 3.0.2 requirement is retained in proposed ITS LCO 3.0.2. Therefore, this change does not expand the total time interval allowed to restore the parameter, as a 30-minute interval is already allowed by the CTS. This change is designated as administrative as it results in no technical change to the CTS.

A04 CTS 3.1.1.5 Action states that with a RCS operating loop temperature (Tavg) < 515°F, restore Tavg to within its limit within 15 minutes or "be in HOT STANDBY within the next 15 minutes." ITS 3.4.2, ACTION A, states that with Tavg in one or more RCS loops not within limit, be in MODE 2 with keff < 1.0 within 30 minutes. This changes the CTS from requiring the unit to be in HOT STANDBY to be in MODE 2 with keff < 1.0. Other changes to this CTS Action are discussed in DOC A03.

This change is acceptable because it results in no technical change to the Technical Specifications. CTS 3.1.1.5 is applicable in MODE 1 and MODE 2 with keff ≥ 1.0. CTS 3.0.1 states that compliance with the LCO is required during the MODES or other conditions specified therein, except that upon failure to meet the LCO, the associated Action requirements shall be met. Additionally, CTS 3.0.2 states, in part, that if the LCO is met or no longer applicable prior to expiration of the specified time interval, completion of the actions is not required. Therefore, the CTS 3.1.1.5 Action to be in MODE 3 ceases to be applicable once the unit enters MODE 2 with keff < 1.0, and the Action is exited. As a result, changing the Action to "be in MODE 2 with keff < 1.0," results in no operational difference from the CTS Action. This change is designated as administrative, as it results in no technical change to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 7 – Relaxation Of Surveillance Frequency)* CTS 4.1.1.5.a states that the RCS temperature (Tavg) shall be determined to be ≥ 515°F within 15 minutes prior to achieving reactor criticality. ITS SR 3.4.2.1 requires RCS Tavg in each loop to be verified ≥ 515°F "In accordance with the Surveillance Frequency Control Program when the reactor is critical and the RCS temperature (Tavg) is < 525°F."

The purpose of CTS 4.1.1.5.a is to ensure RCS temperature (Tavg) is within limit when the reactor is critical. The requirement is that RCS Tavg be ≥ 515°F when the unit is operating in MODE 1 and MODE 2 with keff ≥ 1.0. CTS 4.0.4 (ITS SR 3.0.4) requires the SR to be met prior to entry into MODE 2 with keff ≥ 1.0 before

the reactor is critical. Therefore, the RCS Tavg must be determined prior to achieving criticality.

This change is acceptable because the Surveillance Frequency has been evaluated to ensure that it provides an acceptable level of assurance. With RCS temperature (Tavg) < 525°F, CTS 4.0.4 (ITS SR 3.0.4) requires the Surveillance to be performed within 30 minutes (i.e., periodic Frequency in accordance with the Surveillance Frequency Control Program) prior to achieving criticality. This Frequency is adequate to prevent an inadvertent violation of the LCO. In the approach to criticality, the reactor coolant pumps are adding heat to the RCS, so the conditions before and after criticality are similar. The approach to criticality is a carefully controlled evolution where RCS temperature is closely monitored. This change is designated as less restrictive because Surveillances will be performed less frequently under the ITS than under the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.2, RCS MINIMUM TEMPERATURE FOR CRITICALITY

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.2 RCS Minimum Temperature for Criticality

BASES

BACKGROUND

Establishing the value for the minimum temperature for reactor criticality is based upon considerations for:

a. Operation within the existing instrumentation ranges and accuracies,

b. Operation within the bounds of the existing accident analyses, and

c. Operation with the reactor vessel above its minimum nil ductility reference temperature when the reactor is critical.

The reactor coolant moderator temperature coefficient used in core operating and accident analysis is typically defined for the normal operating temperature range (532°F to ~~573°F~~). The Reactor Protection System receives inputs from the narrow range hot leg temperature and cold detectors, which have a range of ~~520°F to 620°F~~. The RCS loop average temperature (T_{avg}) is controlled using inputs of the same range. Nominal T_{avg} for making the reactor critical is 532°F. Safety and operating analyses for lower temperature have not been made.

580°F

515°F to 665°F and 465°F to 615°F, respectively

1

APPLICABLE SAFETY ANALYSES

There are no accident analyses that dictate the minimum temperature for criticality, but all low power safety analyses assume initial temperatures near the ~~[520]~~°F limit (Ref. 1).

515

2

The RCS minimum temperature for criticality satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The purpose of the LCO is to prevent criticality outside the normal operating range (532°F to ~~573~~°F) and to prevent operation in an unanalyzed condition.

580

1 R1

525

The LCO is only applicable below ~~[535]~~°F and provides a reasonable distance to the limit of ~~[520]~~°F. This allows adequate time to trend its approach and take corrective actions prior to exceeding the limit.

515

2

APPLICABILITY

The reactor has been designed and analyzed to be critical in MODES 1 and 2 only and in accordance with this specification. Criticality is not permitted in any other MODE. Therefore, this LCO is applicable in MODE 1, and MODE 2 when $K_{eff} \geq 1.0$. Coupled with the applicability definition for criticality is a temperature limit. Monitoring is required ~~at or~~ below a T_{avg} of ~~[535]~~°F. ~~The no load temperature of 544°F is maintained by the Steam Dump Control System.~~

525

2 3

BASES

ACTIONS

A.1

515

If T_{avg} is below ~~[520]~~°F, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE 2 with K_{eff} < 1.0 within 30 minutes. Rapid reactor shutdown can be readily and practically achieved within a 30 minute period. The allowed time reflects the ability to perform this action and to maintain the plant within the analyzed range.

2

SURVEILLANCE REQUIREMENTS

SR 3.4.2.1

515

RCS loop average temperature is required to be verified at or above ~~[520]~~°F. ~~[The SR to verify RCS loop average temperatures every 12 hours takes into account indications and alarms that are continuously available to the operator in the control room and is consistent with other routine Surveillances which are typically performed once per shift. In addition, operators are trained to be sensitive to RCS temperature during approach to criticality and will ensure that the minimum temperature for criticality is met as criticality is approached.~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

DISCUSSION OF CHANGES
ITS 3.4.3, RCS PRESSURE AND TEMPERATURE (P/T) LIMITS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.4.9.1 requires that the RCS temperature and pressure shall be limited in accordance with the limit lines shown in the applicable CTS figures “during heatup, cooldown, criticality, and inservice leak and hydrostatic testing.” CTS 3.4.9.1 is applicable “at all times.” ITS 3.4.3 states that the RCS pressure, RCS temperature, and RCS heatup and cooldown rates shall be maintained within the limits specified in Figures 3.4.3-1 and 3.4.3-2. ITS 3.4.3 is applicable "at all times". The CTS LCO is revised to conform to the ISTS. This changes the CTS by eliminating the LCO requirement that the limits must be met during heatup, cooldown, and inservice leak and hydrostatic testing.

This change is acceptable because the limits protecting the reactor vessel and RCS are applicable at all times, including heatup, cooldown, and inservice leak and hydrostatic testing. The RCS pressure and temperature limits are not Mode dependent but are always required to assure the safety of the reactor vessel without exception. Stating that the limits are applicable during heatup, cooldown, and inservice leak and hydrostatic testing in the LCO is not required with the applicability of "at all times" which encompasses the more specific and limited CTS conditions. The applicability provides assurance that the RCS is maintained within the required limits and that the plant will continue to be operated in a safe manner. The list of conditions is duplicative of the conditions stated in the Surveillance. This allowance is more appropriately retained in the Note to SR 3.4.3.1 stating that the SR is only required to be performed during RCS heatup and cooldown operations and RCS inservice leak and hydrostatic testing. These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A03 CTS 3.4.9.1 Action states, in part, that with any of the P/T limits exceeded, restore the temperature and/or pressure to within the limits within 30 minutes, perform an analysis to determine the effects of the out-of-limit condition on the fracture toughness properties of the Reactor Coolant System, and determine that the Reactor Coolant System remains acceptable for continued operations. ITS 3.4.3, Condition A and Condition C are modified by a Note which requires the determination that the RCS is acceptable for continued operation to be performed whenever the Condition is entered. This changes the CTS by explicitly stating that a determination that the RCS is acceptable for continued operation must be performed whenever the condition is entered. Other changes to the Actions are described in other DOCs. This change is acceptable because it is the current understanding and application of the CTS Action. The CTS 3.4.9.1 Action is currently interpreted as requiring a determination that the RCS is

acceptable for continued operation whenever the LCO is not met. This change is designated as administrative as it clarifies the current understanding of the CTS requirement while providing an "unless otherwise stated," to the requirements of CTS 3.0.2 (ITS LCO 3.0.2).

A04 **Unit 1 only:** CTS 3.4.9.1 Applicability is modified by a footnote that states "During hydrostatic testing operations above system design pressure, a maximum temperature change in any one hour period shall be limited to 5°F." ITS 3.4.3 does not contain this Note. The Note is reworded as "A maximum temperature change of ≤ 5°F in any one hour period during hydrostatic testing above system design pressure" and added statement to ITS LCO 3.4.3. This change is designated as an administrative change and is acceptable because it does do not result in technical changes to the CTS. | R1

MORE RESTRICTIVE CHANGES

M01 CTS 3.4.9.1 Action states, in part, that with any of the P/T limits exceeded, restore the temperature and/or pressure to within the limits within 30 minutes, perform an analysis to determine the effects of the out-of-limit condition on the fracture toughness properties of the Reactor Coolant System, and determine that the Reactor Coolant System remains acceptable for continued operations. ISTS 3.4.3 Required Action A.2 requires determination that RCS is acceptable for continued operation within 72 hours. The CTS is revised to incorporate the 72 hour Completion Time. This changes the CTS by requiring determination that RCS is acceptable for continued operation within 72 hours.

The change is acceptable because besides restoring operation to within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify the reactor coolant pressure boundary (RCPB) integrity remains acceptable and must be completed before continuing operation. The 72 hour Completion Time is reasonable to accomplish the evaluation. The evaluation for a mild violation is possible within this time, but more severe violations may require special, event specific stress analyses or inspections. CTS and ISTS provide shutdown Actions if the RCS is not determined to be acceptable for continued operation. This change is designated as more restrictive because it establishes a Completion Time that was not in the CTS.

M02 CTS 3.4.9.1 Action states, in part, that with any of the P/T limits exceeded, restore the temperature and/or pressure to within the limits within 30 minutes, perform an analysis to determine the effects of the out-of-limit condition on the fracture toughness properties of the Reactor Coolant System, and determine that the Reactor Coolant System remains acceptable for continued operations. The applicability for these Actions is "at all times." ITS 3.4.3 provides separate Conditions (Conditions A and C) to differentiate between ACTIONS in MODES 1, 2, 3, and 4 and ACTIONS in conditions other than MODES 1, 2, 3, and 4. ITS 3.4.3 ACTION C provides requirements for "immediate" restoration of parameters to within limits and determination that RCS is acceptable for continued operation "prior to entering MODE 4." This changes the CTS by requiring an RCS PT limit violation in conditions other than MODE 1, 2, 3, or 4 to be corrected immediately

and provides a time to complete the determination that the RCS is acceptable for continued operation.

The change is necessary because the actions of this LCO, anytime other than in MODE 1, 2, 3, or 4, consider the premise that a violation of the limits occurred during normal plant maneuvering. The CTS Action would appear to provide a half hour in which pressure and temperature requirements could exceed the limits, even if capable of being returned to within limits. Also, if the parameters are incapable of being restored within the limits within 30 minutes, the existing Action would appear to result in the requirement of a Licensee Event Report, since no additional Actions apply (the unit is already in MODE 5 or below). The Actions are more appropriately presented in ITS 3.4.3 ACTION C. Operation outside the P/T limits must be corrected so that the RCPB is returned to a condition that has been verified by stress analyses. The Completion Time of "immediately" reflects the urgency of restoring the parameters to within the analyzed range. Most violations will not be severe, and the activity can be accomplished in a short period of time in a controlled manner. Besides restoring operation to within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify that the RCPB integrity remains acceptable and must be completed before continuing operation. The Completion Time of prior to entering MODE 4 forces the evaluation prior to entering a MODE where temperature and pressure can be significantly increased. This change is designated as more restrictive because it establishes Actions with more restrictive Action Completion Times that are applicable anytime other than in MODE 1, 2, 3, or 4, and that are not in the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.4.9.1 states, that the reactor coolant system (except the pressurizer) temperature and pressure shall be limited in accordance with the limit lines shown on Figures 3.4-2a and 3.4 2b during heatup, cooldown, criticality, and inservice leak and hydrostatic testing." ITS 3.4.3 states that RCS pressure, RCS temperature, and RCS heatup and cooldown rates shall be maintained with limits shown in Figures 3.4.3-1 and 3.4.3-2. This changes the CTS by moving the statement "(except the pressurizer)" which excludes the pressurizer from the LCO limit, to the Bases.

The removal of these details, which are related to design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The RCS P/T limits are applicable to RCPB ferritic materials associated with 10 CFR 50, Appendix G and ASME Code, Section III, Appendix G. The ITS still retains the RCS P/T limits. Neither the CTS nor the ITS P/T limits apply to the pressurizer. It is the ITS convention to state this detail

in the ITS Bases. This detail of the LCO is not required to be in the Technical Specifications in order to provide adequate protection of the public health and safety. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 3.4.9 Action states, in part, to perform an analysis to determine the effects of the out-of-limit condition on the fracture toughness properties of the Reactor Coolant System and determine that the reactor coolant system remains acceptable for continued operation. ITS 3.4.3 also states to determine the RCS is acceptable for continued operation. This changes the CTS by removing these procedural details on how to determine the RCS is acceptable for continued operation, since details on how to make this determination are provided in the ITS 3.4.3 Bases.

The purpose of the CTS action requirements is to verify that the RCPB integrity remains acceptable and must be completed before continuing operation. Several methods may be used, including comparison with pre-analyzed transients in the stress analyses, new analyses, or inspection of the components. ITS 3.4.3 Bases Background and ACTIONS A.1 and A.2 discussions provide details for evaluating that the RCS is acceptable for continued operation. The removal of these procedural details from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the Action to determine the RCS is acceptable for continued operation. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of procedural detail because information relating to the method of performing an action is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 5 - Deletion of Surveillance Requirement)* Unit 1 CTS 4.4.9.1.c and Unit 2 CTS 4.4.9.1.2 specify "The reactor vessel material irradiation surveillance specimens shall be removed and examined, to determine changes in material properties as required by 10 CFR 50 Appendix H. The results of these examinations shall be used to update Figures 3.4-2a and 3.4-2b." ISTS 3.4.3 does not contain a corresponding requirement. The CTS is revised to conform to the ISTS. This changes the CTS by deleting Unit 1 CTS 4.4.9.1.c and Unit 2 CTS 4.4.9.1.2 surveillance requirements.

This change is acceptable because the CTS surveillance is not required to assure the pressure and temperature limits in the LCO are properly updated. The unit is required to remove material irradiation surveillance specimens and generate new pressure and temperature curves in accordance with 10 CFR 50, Appendix H. Therefore, the CTS surveillance is redundant to the applicable federal regulations and is not required to assure compliance with the requirements of the federal regulations. The Code of Federal Regulations provide sufficient assurance that the pressure and temperature limits are updated when required and the remaining TS requirements provide adequate assurance that the plant is operated within those pressure and temperature limits. Therefore, the proposed change does not adversely impact the safe operation of the plant. The proposed change is designated less restrictive because a surveillance that is required in the CTS will not be required in the ITS.

L02 **Unit 1 only:** *(Category 5 - Deletion of Surveillance Requirement)* CTS 4.4.9.1.b specifies that "the Reactor Coolant System temperature and pressure conditions shall be determined to be to the right of the criticality limit line within 15 minutes prior to achieving reactor criticality." ITS 3.4.3 does not contain a corresponding requirement. The CTS is revised to conform to the ISTS. This changes the CTS by deleting CTS 4.4.9.1.b.

The purpose of the CTS requirement is to ensure the RCS P/T criticality limits are not exceeded during the approach to criticality during a plant startup. The proposed change is acceptable because the remaining TS requirements continue to provide adequate assurance that the required pressure and temperature limits continue to be met. The TS contain a separate requirement (ITS 3.4.2) for the minimum temperature for criticality (515°F). The temperature limit for critical operation provides assurance that critical operation does not occur at temperatures lower than the RCS P/T limits shown in the applicable CTS figure. As stated in the ITS 3.4.3 bases, the RCS minimum temperature for criticality specified in ITS 3.4.2 is more restrictive than the RCS pressure and temperature limits for criticality. Therefore, the performance of CTS surveillance 4.4.9.1.b is not required to assure the plant is operated within the required pressure and temperature limits. The RCS minimum temperature for criticality requirements provide sufficient assurance that the plant is operated within the RCS pressure and temperature limits. The proposed change is designated as less restrictive because a surveillance that is required by the CTS will not be required in the ITS.

L03 **Unit 1 only**: (*Category 1 – Relaxation of LCO Requirements*) CTS Figures 3.4-2a and 3.4-2b describe the limiting material and limiting ART values at 54 EFPY used to determine the P/T limits. The ITS Figures 3.4.3-1 and 3.4.3-2 do not include this information. This changes the CTS by deleting this information from the CTS.

The purpose of this information is to provide additional detail as to how the P/T curves were generated. However, deleting this information is acceptable because it is not necessary to be listed in the Figures to use the Figures effectively. ITS 3.4.3 requires the Figure limits to be met. The details as to how the Figures are generated is not needed to comply with the LCO. The ITS 3.4.3 Bases describes that the Figures were generated to comply with the applicable regulatory requirements of 10 CFR 50, Appendix G and ASME Section III,

Appendix G. Therefore, since PSL is required to comply with 10 CFR 50, Appendix G and ASME Section III, Appendix G, this additional information is not required. This change is designated as less restrictive because certain details related to how the LCO was generated are being deleted.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.3, RCS PRESSURE AND TEMPERATURE (P/T) LIMITS

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. PSL is not adopting a Pressure Temperature Limits Report (PTLR) and is retaining the RCS Pressure and Temperature (P/T) limits in the ITS. Therefore, references to the PTLR have been changed to Figures 3.4.3-1 and 3.4.3-2. In addition, the CTS P/T figures have been added to ITS 3.4.3 as Figures 3.4.3-1 and 3.4.3-2.

4. **Unit 1 only:** ISTS LCO 3.4.3 is modified to include a statement that limits the temperature change allowed during hydrostatic testing operations above system design pressure. The ITS maintains a P/T limit restriction consistent with the equivalent CTS requirement and licensing basis.

5. ISTS 3.4.3, Required Action B.2 is modified to replace the requirement to reduce RCS pressure < [500] psig with the requirement for RCS pressure to be "within the limits specified in Figure 3.4.3-2," consistent with the equivalent CTS requirement and licensing basis. | R1

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.3 RCS Pressure and Temperature (P/T) Limits

BASES

BACKGROUND

All components of the RCS are designed to withstand effects of cyclic loads due to system pressure and temperature changes. These loads are introduced by startup (heatup) and shutdown (cooldown) operations, power transients, and reactor trips. This LCO limits the pressure and temperature changes during RCS heatup and cooldown, within the design assumptions and the stress limits for cyclic operation.

Figures 3.4.3-1 and 3.4.3-2

the

~~The PTLR~~ contain~~s~~ P/T limit curves for heatup, cooldown, and inservice leak and hydrostatic (ISLH) testing, and data for the maximum rate of change of reactor coolant temperature (Ref. 1).

core critical,

1

Each P/T limit curve defines an acceptable region for normal operation. The usual use of the curves is operational guidance during heatup or cooldown maneuvering, when pressure and temperature indications are monitored and compared to the applicable curve to determine that operation is within the allowable region.

The LCO establishes operating limits that provide a margin to brittle failure of the reactor vessel and piping of the reactor coolant pressure boundary (RCPB). The vessel is the component most subject to brittle failure, and the LCO limits apply mainly to the vessel. The limits do not apply to the pressurizer, which has different design characteristics and operating functions.

10 CFR 50, Appendix G (Ref. 2), requires the establishment of P/T limits for material fracture toughness requirements of the RCPB materials. Reference 2 requires an adequate margin to brittle failure during normal operation, anticipated operational occurrences, and system hydrostatic tests. It mandates the use of the ASME Code, Section III, Appendix G (Ref. 3).

The actual shift in the RT_{NDT} of the vessel material will be established periodically by removing and evaluating the irradiated reactor vessel material specimens, in accordance with ASTM E 185 (Ref. 4) and Appendix H of 10 CFR 50 (Ref. 5). The operating P/T limit curves will be adjusted, as necessary, based on the evaluation findings and the recommendations of Reference 3.

BASES

BACKGROUND (continued)

The P/T limit curves are composite curves established by superimposing limits derived from stress analyses of those portions of the reactor vessel and head that are the most restrictive. At any specific pressure, temperature, and temperature rate of change, one location within the reactor vessel will dictate the most restrictive limit. Across the span of the P/T limit curves, different locations are more restrictive, and, thus, the curves are composites of the most restrictive regions.

The heatup curve represents a different set of restrictions than the cooldown curve because the directions of the thermal gradients through the vessel wall are reversed. The thermal gradient reversal alters the location of the tensile stress between the outer and inner walls.

The criticality limit includes the Reference 2 requirement that the limit be no less than 40°F above the heatup curve or the cooldown curve and not less than the minimum permissible temperature for the ISLH testing. However, the criticality limit is not operationally limiting; a more restrictive limit exists in LCO 3.4.2, "RCS Minimum Temperature for Criticality."

The consequence of violating the LCO limits is that the RCS has been operated under conditions that can result in brittle failure of the RCPB, possibly leading to a nonisolable leak or loss of coolant accident. In the event these limits are exceeded, an evaluation must be performed to determine the effect on the structural integrity of the RCPB components. The ASME Code, Section XI, Appendix E (Ref. 6), provides a recommended methodology for evaluating an operating event that causes an excursion outside the limits.

APPLICABLE SAFETY ANALYSES

The P/T limits are not derived from Design Basis Accident (DBA) Analyses. They are prescribed during normal operation to avoid encountering pressure, temperature, and temperature rate of change conditions that might cause undetected flaws to propagate and cause nonductile failure of the RCPB, an unanalyzed condition. Reference 1 establishes the methodology for determining the P/T limits. Since the P/T limits are not derived from any DBA, there are no acceptance limits related to the P/T limits. Rather, the P/T limits are acceptance limits themselves since they preclude operation in an unanalyzed condition.

The RCS P/T limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The two elements of this LCO are:

a. The limit curves for heatup, cooldown, and ISLH testing and

b. Limits on the rate of change of temperature.

The LCO limits apply to all components of the RCS, except the pressurizer.

These limits define allowable operating regions and permit a large number of operating cycles while providing a wide margin to nonductile failure.

The limits for the rate of change of temperature control the thermal gradient through the vessel wall and are used as inputs for calculating the heatup, cooldown, and ISLH testing P/T limit curves. Thus, the LCO for the rate of change of temperature restricts stresses caused by thermal gradients and also ensures the validity of the P/T limit curves.

Violating the LCO limits places the reactor vessel outside of the bounds of the stress analyses and can increase stresses in other RCPB components. The consequences depend on several factors, as follows:

a. The severity of the departure from the allowable operating P/T regime or the severity of the rate of change of temperature,

b. The length of time the limits were violated (longer violations allow the temperature gradient in the thick vessel walls to become more pronounced), and

c. The existences, sizes, and orientations of flaws in the vessel material.

APPLICABILITY

The RCS P/T limits Specification provides a definition of acceptable operation for prevention of nonductile failure in accordance with 10 CFR 50, Appendix G (Ref. 2). Although the P/T limits were developed to provide guidance for operation during heatup or cooldown (MODES 3, 4, and 5) or ISLH testing, their Applicability is at all times in keeping with the concern for nonductile failure. The limits do not apply to the pressurizer.

During MODES 1 and 2, other Technical Specifications provide limits for operation that can be more restrictive than or can supplement these P/T limits. LCO 3.4.1, "RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits," LCO 3.4.2, "RCS Minimum

BASES

APPLICABILITY (continued)

Temperature for Criticality," and Safety Limit 2.1, "Safety Limits," also provide operational restrictions for pressure and temperature and maximum pressure. Furthermore, MODES 1 and 2 are above the temperature range of concern for nonductile failure, and stress analyses have been performed for normal maneuvering profiles, such as power ascension or descent.

The actions of this LCO consider the premise that a violation of the limits occurred during normal plant maneuvering. Severe violations caused by abnormal transients, at times accompanied by equipment failures, may also require additional actions from emergency operating procedures.

ACTIONS

A.1 and A.2

Operation outside the P/T limits must be corrected so that the RCPB is returned to a condition that has been verified by stress analyses.

The 30 minute Completion Time reflects the urgency of restoring the parameters to within the analyzed range. Most violations will not be severe, and the activity can be accomplished in this time in a controlled manner.

Besides restoring operation to within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify the RCPB integrity remains acceptable and must be completed ~~before continuing operation~~. Several methods may be used, including comparison with pre-analyzed transients in the stress analyses, new analyses, or inspection of the components.

within 72 hours

1

ASME Code, Section XI, Appendix E (Ref. 6), may be used to support the evaluation. However, its use is restricted to evaluation of the vessel beltline.

The 72 hour Completion Time is reasonable to accomplish the evaluation. The evaluation for a mild violation is possible within this time, but more severe violations may require special, event specific stress analyses or inspections. A favorable evaluation must be completed before continuing to operate.

Condition A is modified by a Note requiring Required Action A.2 to be completed whenever the Condition is entered. The Note emphasizes the need to perform the evaluation of the effects of the excursion outside the allowable limits. Restoration alone per Required Action A.1 is insufficient because higher than analyzed stresses may have occurred and may have affected the RCPB integrity.

BASES

ACTIONS (continued)

B.1 and B.2

If a Required Action and associated Completion Time of Condition A are not met, the plant must be placed in a lower MODE because:

a. The RCS remained in an unacceptable P/T region for an extended period of increased stress or

b. A sufficiently severe event caused entry into an unacceptable region.

Either possibility indicates a need for more careful examination of the event, best accomplished with the RCS at reduced pressure and temperature. With reduced pressure and temperature conditions, the possibility of propagation of undetected flaws is decreased.

Pressure and temperature are reduced by placing the plant in MODE 3 within 6 hours and in MODE 5 with RCS pressure ~~< [500] psig~~ within the limits specified in Figure 3.4.3-2 within 36 hours.

2 | R1

The Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

C.1 and C.2

The actions of this LCO, anytime other than in MODE 1, 2, 3, or 4, consider the premise that a violation of the limits occurred during normal plant maneuvering. Severe violations caused by abnormal transients, at times accompanied by equipment failures, may also require additional actions from emergency operating procedures. Operation outside the P/T limits must be corrected so that the RCPB is returned to a condition that has been verified by stress analyses.

The Completion Time of "immediately" reflects the urgency of restoring the parameters to within the analyzed range. Most violations will not be severe, and the activity can be accomplished in a short period of time in a controlled manner.

Besides restoring operation to within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify that the RCPB integrity remains acceptable and must be completed before continuing operation. Several methods may be used, including comparison with pre-analyzed transients in the stress analyses, new analyses, or inspection of the components.

BASES

ACTIONS (continued)

ASME Code, Section XI, Appendix E (Ref. 6), may be used to support the evaluation. However, its use is restricted to evaluation of the vessel beltline.

The Completion Time of prior to entering MODE 4 forces the evaluation prior to entering a MODE where temperature and pressure can be significantly increased. The evaluation for a mild violation is possible within several days, but more severe violations may require special, event specific stress analyses or inspections.

Condition C is modified by a Note requiring Required Action C.2 to be completed whenever the Condition is entered. The Note emphasizes the need to perform the evaluation of the effects of the excursion outside the allowable limits. Restoration alone per Required Action C.1 is insufficient because higher than analyzed stresses may have occurred and may have affected the RCPB integrity.

SURVEILLANCE REQUIREMENTS

SR 3.4.3.1

RCS P/T

Verification that operation is within the ~~PTLR~~ limits is required when RCS pressure and temperature conditions are undergoing planned changes. ~~[This Frequency of 30 minutes is considered reasonable in view of the control room indication available to monitor RCS status. Also, since temperature rate of change limits are specified in hourly increments, 30 minutes permits assessment and correction for minor deviations within a reasonable time.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 3

~~]~~

Surveillance for heatup, cooldown, or ISLH testing may be discontinued when the definition given in the relevant plant procedure for ending the activity is satisfied.

BASES

SURVEILLANCE REQUIREMENTS (continued)

This SR is modified by a Note that requires this SR be performed only during RCS system heatup, cooldown, and ISLH testing. No SR is given for criticality operations because LCO 3.4.2 contains a more restrictive requirement.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.3 RCS Pressure and Temperature (P/T) Limits

BASES

BACKGROUND

All components of the RCS are designed to withstand effects of cyclic loads due to system pressure and temperature changes. These loads are introduced by startup (heatup) and shutdown (cooldown) operations, power transients, and reactor trips. This LCO limits the pressure and temperature changes during RCS heatup and cooldown, within the design assumptions and the stress limits for cyclic operation.

Figures 3.4.3-1 and 3.4.3-2

the

~~The PTLR~~ contain~~s~~ P/T limit curves for heatup, cooldown, and inservice leak and hydrostatic (ISLH) testing, and data for the maximum rate of change of reactor coolant temperature (Ref. 1).

core critical,

1

Each P/T limit curve defines an acceptable region for normal operation. The usual use of the curves is operational guidance during heatup or cooldown maneuvering, when pressure and temperature indications are monitored and compared to the applicable curve to determine that operation is within the allowable region.

The LCO establishes operating limits that provide a margin to brittle failure of the reactor vessel and piping of the reactor coolant pressure boundary (RCPB). The vessel is the component most subject to brittle failure, and the LCO limits apply mainly to the vessel. The limits do not apply to the pressurizer, which has different design characteristics and operating functions.

10 CFR 50, Appendix G (Ref. 2), requires the establishment of P/T limits for material fracture toughness requirements of the RCPB materials. Reference 2 requires an adequate margin to brittle failure during normal operation, anticipated operational occurrences, and system hydrostatic tests. It mandates the use of the ASME Code, Section III, Appendix G (Ref. 3).

The actual shift in the RT_{NDT} of the vessel material will be established periodically by removing and evaluating the irradiated reactor vessel material specimens, in accordance with ASTM E 185 (Ref. 4) and Appendix H of 10 CFR 50 (Ref. 5). The operating P/T limit curves will be adjusted, as necessary, based on the evaluation findings and the recommendations of Reference 3.

BASES

BACKGROUND (continued)

The P/T limit curves are composite curves established by superimposing limits derived from stress analyses of those portions of the reactor vessel and head that are the most restrictive. At any specific pressure, temperature, and temperature rate of change, one location within the reactor vessel will dictate the most restrictive limit. Across the span of the P/T limit curves, different locations are more restrictive, and, thus, the curves are composites of the most restrictive regions.

The heatup curve represents a different set of restrictions than the cooldown curve because the directions of the thermal gradients through the vessel wall are reversed. The thermal gradient reversal alters the location of the tensile stress between the outer and inner walls.

The criticality limit includes the Reference 2 requirement that the limit be no less than 40°F above the heatup curve or the cooldown curve and not less than the minimum permissible temperature for the ISLH testing. However, the criticality limit is not operationally limiting; a more restrictive limit exists in LCO 3.4.2, "RCS Minimum Temperature for Criticality."

The consequence of violating the LCO limits is that the RCS has been operated under conditions that can result in brittle failure of the RCPB, possibly leading to a nonisolable leak or loss of coolant accident. In the event these limits are exceeded, an evaluation must be performed to determine the effect on the structural integrity of the RCPB components. The ASME Code, Section XI, Appendix E (Ref. 6), provides a recommended methodology for evaluating an operating event that causes an excursion outside the limits.

APPLICABLE SAFETY ANALYSES

The P/T limits are not derived from Design Basis Accident (DBA) Analyses. They are prescribed during normal operation to avoid encountering pressure, temperature, and temperature rate of change conditions that might cause undetected flaws to propagate and cause nonductile failure of the RCPB, an unanalyzed condition. Reference 1 establishes the methodology for determining the P/T limits. Since the P/T limits are not derived from any DBA, there are no acceptance limits related to the P/T limits. Rather, the P/T limits are acceptance limits themselves since they preclude operation in an unanalyzed condition.

The RCS P/T limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The two elements of this LCO are:

a. The limit curves for heatup, cooldown, and ISLH testing and

b. Limits on the rate of change of temperature.

The LCO limits apply to all components of the RCS, except the pressurizer.

These limits define allowable operating regions and permit a large number of operating cycles while providing a wide margin to nonductile failure.

The limits for the rate of change of temperature control the thermal gradient through the vessel wall and are used as inputs for calculating the heatup, cooldown, and ISLH testing P/T limit curves. Thus, the LCO for the rate of change of temperature restricts stresses caused by thermal gradients and also ensures the validity of the P/T limit curves.

Violating the LCO limits places the reactor vessel outside of the bounds of the stress analyses and can increase stresses in other RCPB components. The consequences depend on several factors, as follows:

a. The severity of the departure from the allowable operating P/T regime or the severity of the rate of change of temperature,

b. The length of time the limits were violated (longer violations allow the temperature gradient in the thick vessel walls to become more pronounced), and

c. The existences, sizes, and orientations of flaws in the vessel material.

APPLICABILITY

The RCS P/T limits Specification provides a definition of acceptable operation for prevention of nonductile failure in accordance with 10 CFR 50, Appendix G (Ref. 2). Although the P/T limits were developed to provide guidance for operation during heatup or cooldown (MODES 3, 4, and 5) or ISLH testing, their Applicability is at all times in keeping with the concern for nonductile failure. The limits do not apply to the pressurizer.

During MODES 1 and 2, other Technical Specifications provide limits for operation that can be more restrictive than or can supplement these P/T limits. LCO 3.4.1, "RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits," LCO 3.4.2, "RCS Minimum

BASES

APPLICABILITY (continued)

Temperature for Criticality," and Safety Limit 2.1, "Safety Limits," also provide operational restrictions for pressure and temperature and maximum pressure. Furthermore, MODES 1 and 2 are above the temperature range of concern for nonductile failure, and stress analyses have been performed for normal maneuvering profiles, such as power ascension or descent.

The actions of this LCO consider the premise that a violation of the limits occurred during normal plant maneuvering. Severe violations caused by abnormal transients, at times accompanied by equipment failures, may also require additional actions from emergency operating procedures.

ACTIONS

A.1 and A.2

Operation outside the P/T limits must be corrected so that the RCPB is returned to a condition that has been verified by stress analyses.

The 30 minute Completion Time reflects the urgency of restoring the parameters to within the analyzed range. Most violations will not be severe, and the activity can be accomplished in this time in a controlled manner.

Besides restoring operation to within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify the RCPB integrity remains acceptable and must be completed ~~before continuing operation~~. Several methods may be used, including comparison with pre-analyzed transients in the stress analyses, new analyses, or inspection of the components.

within 72 hours

1

ASME Code, Section XI, Appendix E (Ref. 6), may be used to support the evaluation. However, its use is restricted to evaluation of the vessel beltline.

The 72 hour Completion Time is reasonable to accomplish the evaluation. The evaluation for a mild violation is possible within this time, but more severe violations may require special, event specific stress analyses or inspections. A favorable evaluation must be completed before continuing to operate.

Condition A is modified by a Note requiring Required Action A.2 to be completed whenever the Condition is entered. The Note emphasizes the need to perform the evaluation of the effects of the excursion outside the allowable limits. Restoration alone per Required Action A.1 is insufficient because higher than analyzed stresses may have occurred and may have affected the RCPB integrity.

BASES

ACTIONS (continued)

B.1 and B.2

If a Required Action and associated Completion Time of Condition A are not met, the plant must be placed in a lower MODE because:

a. The RCS remained in an unacceptable P/T region for an extended period of increased stress or

b. A sufficiently severe event caused entry into an unacceptable region.

Either possibility indicates a need for more careful examination of the event, best accomplished with the RCS at reduced pressure and temperature. With reduced pressure and temperature conditions, the possibility of propagation of undetected flaws is decreased.

Pressure and temperature are reduced by placing the plant in MODE 3 within 6 hours and in MODE 5 with RCS pressure ~~< [500] psig~~ within the limits specified in Figure 3.4.3-2 within 36 hours. (2) R1

The Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

C.1 and C.2

The actions of this LCO, anytime other than in MODE 1, 2, 3, or 4, consider the premise that a violation of the limits occurred during normal plant maneuvering. Severe violations caused by abnormal transients, at times accompanied by equipment failures, may also require additional actions from emergency operating procedures. Operation outside the P/T limits must be corrected so that the RCPB is returned to a condition that has been verified by stress analyses.

The Completion Time of "immediately" reflects the urgency of restoring the parameters to within the analyzed range. Most violations will not be severe, and the activity can be accomplished in a short period of time in a controlled manner.

Besides restoring operation to within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify that the RCPB integrity remains acceptable and must be completed before continuing operation. Several methods may be used, including comparison with pre-analyzed transients in the stress analyses, new analyses, or inspection of the components.

BASES

ACTIONS (continued)

ASME Code, Section XI, Appendix E (Ref. 6), may be used to support the evaluation. However, its use is restricted to evaluation of the vessel beltline.

The Completion Time of prior to entering MODE 4 forces the evaluation prior to entering a MODE where temperature and pressure can be significantly increased. The evaluation for a mild violation is possible within several days, but more severe violations may require special, event specific stress analyses or inspections.

Condition C is modified by a Note requiring Required Action C.2 to be completed whenever the Condition is entered. The Note emphasizes the need to perform the evaluation of the effects of the excursion outside the allowable limits. Restoration alone per Required Action C.1 is insufficient because higher than analyzed stresses may have occurred and may have affected the RCPB integrity.

SURVEILLANCE REQUIREMENTS

SR 3.4.3.1

RCS P/T

Verification that operation is within the ~~PTLR~~ limits is required when RCS pressure and temperature conditions are undergoing planned changes. ~~[This Frequency of 30 minutes is considered reasonable in view of the control room indication available to monitor RCS status. Also, since temperature rate of change limits are specified in hourly increments, 30 minutes permits assessment and correction for minor deviations within a reasonable time.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 3

~~]~~

Surveillance for heatup, cooldown, or ISLH testing may be discontinued when the definition given in the relevant plant procedure for ending the activity is satisfied.

BASES

SURVEILLANCE REQUIREMENTS (continued)

This SR is modified by a Note that requires this SR be performed only during RCS system heatup, cooldown, and ISLH testing. No SR is given for criticality operations because LCO 3.4.2 contains a more restrictive requirement.

DISCUSSION OF CHANGES
ITS 3.4.4, RCS LOOPS – MODES 1 and 2

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.4.1.1 states that both reactor coolant loops and both reactor coolant pumps in each loop shall be in operation. ITS 3.4.4. states that two RCS loops shall be OPERABLE and in operation. This changes the CTS by requiring the RCS loops to be OPERABLE. This change is acceptable because it is consistent with the current use and understanding of the LCO. It is not sufficient for an RCS loop to be in operation if it is not capable of performing its safety function (i.e., OPERABLE). This change is designated as administrative as it clarifies the current understanding of a requirement.

A03 **Unit 2 only:** The Applicability of CTS 3.4.1.1 is modified by footnote * that states "See Special Test Exception 3.10.3." The ITS 3.4.4 Applicability does not contain the footnote or a reference to the Special Test Exceptions. This changes the CTS to not include the footnote "See Special Test Exception 3.10.3."

The purpose of the footnote reference is to alert the user that a Special Test Exception exists that may modify the Applicability of the Specification. It is an ITS convention to not include these types of footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS. See Unit 2 CTS 3/4.10.3 Discussion of Changes for changes to this Special Test Exception.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 - Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 3.4.1.1 states that both reactor coolant loops and both reactor coolant pumps in each loop shall be in operation. ITS 3.4.4. states that two RCS loops shall be OPERABLE and in operation. CTS 4.4.1.1 states, in part, that the above required reactor coolant loops shall be verified to be in

operation and circulating reactor coolant. ITS SR 3.4.4.1 states verify each RCS loop is in operation.

This changes the CTS by moving the LCO detail of two reactor coolant pumps in each loop, and by moving the Surveillance Requirement to verify that the reactor coolant loops are circulating reactor coolant, to the Bases.

The removal of this detail for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be in the Technical Specifications in order to provide adequate protection of the public health and safety. The ITS retains the requirement that two RCS loops be in operation. This will ensure adequate forced flow for core heat removal. Flow is represented by having both RCS loops with both RCPs in each loop in operation for removal of heat by the two SGs. To meet safety analysis acceptance criteria for DNB, four pumps are required at rated power. Each OPERABLE loop consists of two RCPs providing forced flow for heat transport to an SG that is OPERABLE. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 3 – Relaxation of Completion Time)* CTS 3.4.1.1 Action states that with less than the above required reactor coolant pumps in operation, be in at least HOT STANDBY within 1 hour. ITS 3.4.4 ACTION A states when the RCS loop requirements are not met, the unit must be in MODE 3 (i.e., HOT STANDBY) within 6 hours. This changes the CTS by relaxing the Completion Time from 1 hour to 6 hours.

The purpose of CTS 3.4.1.1 ACTION is to require a unit shutdown if the necessary reactor coolant loop flow is not available. This change is acceptable because the Completion Time is consistent with safe operation under the specified Condition, considering the low probability of a DBA occurring during the allowed Completion Time. Operating experience has shown that 6 hours is a reasonable time to reach MODE 3 from full power conditions in an orderly manner and without challenging unit systems. It is likely that failure to meet the LCO requirements will lead to a reactor trip on low flow. However, if the LCO is not met for a reason that does not lead to a reactor trip, then 6 hours to transition from full power operation to MODE 3 is consistent with the Completion Time provided for a loss of safety function for other systems and with LCO 3.0.3. This change is designated as less restrictive because additional time is allowed to restore parameters to within the LCO limits than was allowed in the CTS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.4 RCS Loops - MODES 1 and 2

BASES

BACKGROUND

The primary function of the RCS is removal of the heat generated in the fuel due to the fission process and transfer of this heat, via the steam generators (SGs), to the secondary plant.

The secondary functions of the RCS include:

a. Moderating the neutron energy level to the thermal state, to increase the probability of fission,

b. Improving the neutron economy by acting as a reflector,

c. Carrying the soluble neutron poison, boric acid,

d. Providing a second barrier against fission product release to the environment, and

e. Removing the heat generated in the fuel due to fission product decay following a unit shutdown.

The RCS configuration for heat transport uses two RCS loops. Each RCS loop contains a SG and two reactor coolant pumps (RCPs). An RCP is located in each of the two SG cold legs. The pump flow rate has been sized to provide core heat removal with appropriate margin to departure from nucleate boiling (DNB) during power operation and for anticipated transients originating from power operation. This Specification requires two RCS loops with both RCPs in operation in each loop. The intent of the Specification is to require core heat removal with forced flow during power operation. Specifying two RCS loops provides the minimum necessary paths (two SGs) for heat removal.

APPLICABLE SAFETY ANALYSES

Safety analyses contain various assumptions for the Design Bases Accident (DBA) initial conditions including RCS pressure, RCS temperature, reactor power level, core parameters, and safety system setpoints. The important aspect for this LCO is the reactor coolant forced flow rate, which is represented by the number of RCS loops in service.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Both transient and steady state analyses have been performed to establish the effect of flow on DNB. The transient or accident analysis for the plant has been performed assuming four RCPs are in operation. The majority of the plant safety analyses are based on initial conditions at high core power or zero power. The accident analyses that are of most importance to RCP operation are the four pump coastdown, single pump locked rotor, ~~single pump (broken shaft or coastdown),~~ and rod withdrawal events (Ref. 1). 1

Steady state DNB analysis had been performed for the ~~[~~four~~]~~ pump combination. For ~~[~~four~~]~~ pump operation, the steady state DNB analysis, which generates the pressure and temperature and Safety Limit (i.e., the departure from nucleate boiling ratio (DNBR) limit), assumes a maximum power level of ~~107~~% RTP. This is the design overpower condition for four pump operation. The ~~107~~% value is the accident analysis setpoint of the nuclear overpower (high flux) trip and is based on an analysis assumption that bounds possible instrumentation errors. The DNBR limit defines a locus of pressure and temperature points that result in a minimum DNBR greater than or equal to the critical heat flux correlation limit. 2 112 112 1

RCS Loops - MODES 1 and 2 satisfy Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The purpose of this LCO is to require adequate forced flow for core heat removal. Flow is represented by having both RCS loops with both RCPs in each loop in operation for removal of heat by the two SGs. To meet safety analysis acceptance criteria for DNB, four pumps are required at rated power.

Each OPERABLE loop consists of two RCPs providing forced flow for heat transport to an SG that is OPERABLE. SG, and hence RCS loop, OPERABILITY with regard to SG water level is ensured by the Reactor Protection System (RPS) in MODES 1 and 2. A reactor trip places the plant in MODE 3 if any SG level is ≤ ~~[25]~~% as sensed by the RPS. The minimum water level to declare the SG OPERABLE is ~~[25]~~%. narrow range 2 35 35

APPLICABILITY

In MODES 1 and 2, the reactor is critical and thus has the potential to produce maximum THERMAL POWER. Thus, to ensure that the assumptions of the accident analyses remain valid, all RCS loops are required to be OPERABLE and in operation in these MODES to prevent DNB and core damage.

BASES

APPLICABILITY (continued)

The decay heat production rate is much lower than the full power heat rate. As such, the forced circulation flow and heat sink requirements are reduced for lower, noncritical MODES as indicated by the LCOs for MODES 3, 4, 5, and 6.

Operation in other MODES is covered by:

LCO 3.4.5, "RCS Loops - MODE 3,"
LCO 3.4.6, "RCS Loops - MODE 4,"
LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled,"
LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled,"
LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level" ~~(MODE 6)~~, and
LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level" ~~(MODE 6)~~.

3
3

ACTIONS

A.1

If the requirements of the LCO are not met, the Required Action is to reduce power and bring the plant to MODE 3. This lowers power level and thus reduces the core heat removal needs and minimizes the possibility of violating DNB limits. It should be noted that the reactor will trip and place the plant in MODE 3 as soon as the RPS senses less than four RCPs operating.

The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging safety systems.

SURVEILLANCE REQUIREMENTS

SR 3.4.4.1

This SR requires verification of the required number of loops in operation. Verification includes flow rate, temperature, or pump status monitoring, which help to ensure that forced flow is providing heat removal while maintaining the margin to DNB. ~~[The Frequency of 12 hours has been shown by operating practice to be sufficient to regularly assess degradation and verify operation within safety analyses assumptions. In addition, control room indication and alarms will normally indicate loop status.~~

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.4 RCS Loops - MODES 1 and 2

BASES

BACKGROUND

The primary function of the RCS is removal of the heat generated in the fuel due to the fission process and transfer of this heat, via the steam generators (SGs), to the secondary plant.

The secondary functions of the RCS include:

a. Moderating the neutron energy level to the thermal state, to increase the probability of fission,

b. Improving the neutron economy by acting as a reflector,

c. Carrying the soluble neutron poison, boric acid,

d. Providing a second barrier against fission product release to the environment, and

e. Removing the heat generated in the fuel due to fission product decay following a unit shutdown.

The RCS configuration for heat transport uses two RCS loops. Each RCS loop contains a SG and two reactor coolant pumps (RCPs). An RCP is located in each of the two SG cold legs. The pump flow rate has been sized to provide core heat removal with appropriate margin to departure from nucleate boiling (DNB) during power operation and for anticipated transients originating from power operation. This Specification requires two RCS loops with both RCPs in operation in each loop. The intent of the Specification is to require core heat removal with forced flow during power operation. Specifying two RCS loops provides the minimum necessary paths (two SGs) for heat removal.

APPLICABLE SAFETY ANALYSES

Safety analyses contain various assumptions for the Design Bases Accident (DBA) initial conditions including RCS pressure, RCS temperature, reactor power level, core parameters, and safety system setpoints. The important aspect for this LCO is the reactor coolant forced flow rate, which is represented by the number of RCS loops in service.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Both transient and steady state analyses have been performed to establish the effect of flow on DNB. The transient or accident analysis for the plant has been performed assuming four RCPs are in operation. The majority of the plant safety analyses are based on initial conditions at high core power or zero power. The accident analyses that are of most importance to RCP operation are the four pump coastdown, single pump locked rotor, ~~single pump (broken shaft or coastdown),~~ and rod withdrawal events (Ref. 1). 1

Steady state DNB analysis had been performed for the ~~[~~four~~]~~ pump combination. For ~~[~~four~~]~~ pump operation, the steady state DNB analysis, which generates the pressure and temperature and Safety Limit (i.e., the departure from nucleate boiling ratio (DNBR) limit), assumes a maximum power level of 107% RTP. This is the design overpower condition for four pump operation. The 107% value is the accident analysis setpoint of the nuclear overpower (high flux) trip and is based on an analysis assumption that bounds possible instrumentation errors. The DNBR limit defines a locus of pressure and temperature points that result in a minimum DNBR greater than or equal to the critical heat flux correlation limit. 2

RCS Loops - MODES 1 and 2 satisfy Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The purpose of this LCO is to require adequate forced flow for core heat removal. Flow is represented by having both RCS loops with both RCPs in each loop in operation for removal of heat by the two SGs. To meet safety analysis acceptance criteria for DNB, four pumps are required at rated power.

Each OPERABLE loop consists of two RCPs providing forced flow for heat transport to an SG that is OPERABLE. SG, and hence RCS loop, OPERABILITY with regard to SG water level is ensured by the Reactor Protection System (RPS) in MODES 1 and 2. A reactor trip places the plant in MODE 3 if any SG level is ≤ ~~[25]~~% as sensed by the RPS. The minimum water level to declare the SG OPERABLE is ~~[25]~~%. 35 35 narrow range 2

APPLICABILITY

In MODES 1 and 2, the reactor is critical and thus has the potential to produce maximum THERMAL POWER. Thus, to ensure that the assumptions of the accident analyses remain valid, all RCS loops are required to be OPERABLE and in operation in these MODES to prevent DNB and core damage.

BASES

APPLICABILITY (continued)

The decay heat production rate is much lower than the full power heat rate. As such, the forced circulation flow and heat sink requirements are reduced for lower, noncritical MODES as indicated by the LCOs for MODES 3, 4, 5, and 6.

Operation in other MODES is covered by:

LCO 3.4.5, "RCS Loops - MODE 3,"
LCO 3.4.6, "RCS Loops - MODE 4,"
LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled,"
LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled,"
LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level" ~~(MODE 6)~~, and
LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level" ~~(MODE 6)~~.

3
3

ACTIONS

A.1

If the requirements of the LCO are not met, the Required Action is to reduce power and bring the plant to MODE 3. This lowers power level and thus reduces the core heat removal needs and minimizes the possibility of violating DNB limits. It should be noted that the reactor will trip and place the plant in MODE 3 as soon as the RPS senses less than four RCPs operating.

The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging safety systems.

SURVEILLANCE REQUIREMENTS

SR 3.4.4.1

This SR requires verification of the required number of loops in operation. Verification includes flow rate, temperature, or pump status monitoring, which help to ensure that forced flow is providing heat removal while maintaining the margin to DNB. ~~[The Frequency of 12 hours has been shown by operating practice to be sufficient to regularly assess degradation and verify operation within safety analyses assumptions. In addition, control room indication and alarms will normally indicate loop status.~~

DISCUSSION OF CHANGES
ITS 3.4.5, RCS LOOPS – MODE 3

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.4.1.2 Action b. states, in part, that with no reactor coolant loop in operation, take the actions specified therein. ITS 3.4.5 ACTION C states the Condition as two RCS loops inoperable or required RCS loop not in operation. This changes the CTS by adding the Condition “two RCS loops inoperable” and a Required Action to immediately initiate action to restore the RCS loops to OPERABLE status.

This change is acceptable because it provides appropriate actions if two RCS loops are inoperable. Under these conditions, immediate action is necessary to ensure certain unit transients do not occur, and action is immediately taken to restore one loop to OPERABLE status. This change is designated as more restrictive, because it requires an additional condition under which the actions must be taken, and an additional action that the RCS loop be restored to OPERABLE status.

M02 **Unit 1 only:** CTS 3.4.1.2 Action b. states, in part, within one (1) hour initiate corrective action to return the required reactor coolant loop to operation. ITS Required Action C.2 states immediately initiate action to restore one RCS loop to OPERABLE status and operation. This changes the CTS by revising the Actions to “immediately” require actions to be taken when a required RCS loop is not in operation. | R1

This change is acceptable because it provides appropriate immediate actions for a required RCS loop not in operation. This action is required to assure continued safe operation. Action to restore one RCS loop to OPERABLE status and operation is necessary to be able to remove the decay heat generated by the reactor. The immediate Completion Time reflects the importance of maintaining operation for decay heat removal.

M03 CTS 3.4.1.2 states, in part, that the reactor coolant loops listed shall be OPERABLE and at least one of these reactor coolant loops shall be in operation. CTS 3.4.1.2 is modified by a footnote (*) that states, in part, that all reactor coolant pumps may be de energized for up to 1 hour under the conditions specified therein. ITS 3.4.5 contains the same allowance, but limits the use of the 1 hour exception to once per 8 hour period. This changes the CTS by

modifying the 1 hour allowance that all reactor coolant pumps may be de-energized and limits the usage of the allowance to once per 8 hour period.

The purpose of the 1 hour allowance is to allow a reactor coolant loop to be removed from operation to support testing. This change is acceptable because it helps ensure that boron stratification and inadequate decay heat removal do not occur should multiple 1 hour periods be required. This change is designated as more restrictive because it limits the allowance to 1 hour per 8 hour period, and that restriction does not currently exist

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.4.1.2 states, that the reactor coolant loops listed below shall be OPERABLE and at least one of these reactor coolant loops shall be in operation. CTS 3.4.1.2 contains a description of what constitutes an OPERABLE RCS loop. ITS 3.4.5 does not include a description of what constitutes an OPERABLE RCS loop. This changes the CTS by moving the details of what constitutes an OPERABLE RCS loop, to the Bases.

The removal of these details related to system design from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains a requirement for two RCS loops to be OPERABLE and one RCS loop to be in operation. The removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change, because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 - Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.4.1.2.2 states, in part, that at least one reactor coolant loop shall be verified to be in operation and circulating reactor coolant. ITS SR 3.4.5.1 states verify one RCS loop is in operation. This changes the CTS by moving the detail to verify that the reactor coolant loops are circulating reactor coolant, to the Bases.

The removal of this detail for performing the Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be in the Technical Specifications in order to provide adequate protection of the public health and safety. The ITS retains the requirement that a RCS loop be in operation. This will require adequate forced flow for core heat removal. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5.

This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 7 – Relaxation Of Surveillance Frequency)* CTS 4.4.1.2.1 states that the required reactor coolant pumps, if not in operation, shall be determined to be OPERABLE by verifying correct breaker alignments and indicated power availability. ITS SR 3.4.5.3 requires verification of correct breaker alignment and indicated power availability to each required pump. ITS SR 3.4.5.3 is modified by a Note that states "Not required to be performed until 24 hours after a required pump is not in operation." This changes the CTS by not requiring the Surveillance Requirement to be performed until 24 hours after a required pump is not in operation.

The purpose of the Surveillance is to ensure that the standby reactor coolant pump is ready to operate. This change is acceptable because the Surveillance Frequency has been evaluated to ensure that it provides an acceptable level of equipment reliability. The Note provides time to perform the Surveillance to verify correct breaker alignment and indicated power availability. Without the Note, the Surveillance may not be performed within its Frequency immediately after taking a pump out of operation requiring the Surveillance to be declared not met per SR 3.0.1 (CTS 4.0.1). This change is designated as less restrictive because the Surveillance will be performed less frequently under the ITS than under the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.5, RCS LOOPS – MODE 3

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.5 RCS Loops - MODE 3

BASES

BACKGROUND

The primary function of the reactor coolant in MODE 3 is removal of decay heat and transfer of this heat, via the steam generators (SGs), to the secondary plant fluid. The secondary function of the reactor coolant is to act as a carrier for soluble neutron poison, boric acid.

In MODE 3, reactor coolant pumps (RCPs) are used to provide forced circulation heat removal during heatup and cooldown. The MODE 3 decay heat removal requirements are low enough that a single RCS loop with one RCP is sufficient to remove core decay heat. However, ~~[~~two~~]~~ RCS loops are required to be OPERABLE to provide redundant paths for decay heat removal. Only one RCP needs to be OPERABLE to declare the associated RCS loop OPERABLE. 2

Reactor coolant natural circulation is not normally used but is sufficient for core cooling. However, natural circulation does not provide turbulent flow conditions. Therefore, boron reduction in natural circulation is prohibited because mixing to obtain a homogeneous concentration in all portions of the RCS cannot be ensured.

APPLICABLE SAFETY ANALYSES

Analyses have shown that the rod withdrawal event from MODE 3 with one RCS loop in operation is bounded by the rod withdrawal initiated from MODE 2.

Failure to provide heat removal may result in challenges to a fission product barrier. The RCS loops are part of the primary success path that functions or actuates to prevent or mitigate a Design Basis Accident or transient that either assumes the failure of, or presents a challenge to, the integrity of a fission product barrier.

RCS Loops - MODE 3 satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The purpose of this LCO is to require both RCS loops to be available for heat removal, thus providing redundancy. The LCO requires both loops to be OPERABLE with the intent of requiring both SGs to be capable ~~(> 25% water level)~~ of transferring heat from the reactor coolant at a controlled rate. Forced reactor coolant flow is the required way to transport heat, although natural circulation flow provides adequate removal. A minimum of one running RCP meets the LCO requirement for one loop in operation. 1

BASES

LCO (continued)

The Note permits a limited period of operation without RCPs. All RCPs may be removed from operation for ≤ 1 hour per 8 hour period. This means that natural circulation has been established. When in natural circulation, a reduction in boron concentration with coolant at boron concentrations less than required to assure the SDM of LCO 3.1.1 is maintained is prohibited because an even concentration distribution throughout the RCS cannot be ensured. Core outlet temperature is to be maintained at least 10°F below the saturation temperature so that no vapor bubble may form and possibly cause a natural circulation flow obstruction.

In MODES 3, 4, and 5, it is sometimes necessary to stop all RCPs or shutdown cooling (SDC) pump forced circulation (e.g., to change operation from one SDC train to the other, to perform surveillance or startup testing, to perform the transition to and from SDC System cooling, or to avoid operation below the RCP minimum net positive suction head limit). The time period is acceptable because natural circulation is adequate for heat removal, or the reactor coolant temperature can be maintained subcooled and boron stratification affecting reactivity control is not expected.

An OPERABLE RCS loop consists of at least one OPERABLE RCP and an SG that is OPERABLE. A RCP is OPERABLE if it is capable of being powered and is able to provide forced flow if required.

APPLICABILITY

In MODE 3, the heat load is lower than at power; therefore, one RCS loop in operation is adequate for transport and heat removal. A second RCS loop is required to be OPERABLE but not in operation for redundant heat removal capability.

Operation in other MODES is covered by:

LCO 3.4.4, "RCS Loops - MODES 1 and 2,"
LCO 3.4.6, "RCS Loops - MODE 4,"
LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled,"
LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled,"
LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level" ~~(MODE 6)~~, and
LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level" ~~(MODE 6)~~.

3
3

BASES

ACTIONS

A.1

If one RCS loop is inoperable, redundancy for forced flow heat removal is lost. The Required Action is restoration of the RCS loop to OPERABLE status within a Completion Time of 72 hours ~~[or in accordance with the Risk Informed Completion Time Program]~~. This time allowance is a justified period to be without the redundant, nonoperating loop because a single loop in operation has a heat transfer capability greater than that needed to remove the decay heat produced in the reactor core. 2

B.1

If restoration for Required Action A.1 is not possible within 72 hours, the unit must be placed in MODE 4 within 12 hours. In MODE 4, the plant may be placed on the SDC System. The Completion Time of 12 hours is compatible with required operation to achieve cooldown and depressurization from the existing plant conditions in an orderly manner and without challenging plant systems.

C.1 and C.2

If two RCS loops are inoperable the or a required RCS loop is not in operation, except as provided in Note ~~1~~ in the LCO section, all operations involving introduction of coolant into the RCS with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 must be suspended. Action to restore one RCS loop to OPERABLE status and operation shall be initiated immediately and continued until one RCS loop is restored to OPERABLE status and operation. Suspending the introduction of coolant into the RCS of coolant with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 is required to assure continued safe operation. With coolant added without forced circulation, unmixed coolant could be introduced to the core, however coolant added with boron concentration meeting the minimum SDM maintains acceptable margin to subcritical operation. The immediate Completion Times reflect the importance of maintaining operation for decay heat removal. 1

SURVEILLANCE REQUIREMENTS

SR 3.4.5.1

This SR requires verification that one RCS loop is in operation. Verification includes flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing heat removal. ~~[The 12 hour interval has been shown by operating practice to be sufficient to regularly assess degradation and verify operation within safety analyses assumptions. In addition, control room indication and alarms will normally indicate loop status.~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.5.3

Verification that each required RCP is OPERABLE ensures that the single failure criterion is met and that an additional RCS loop can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power availability to each required RCP. Alternatively, verification that a pump is in operation also verifies proper breaker alignment and power availability. ~~[The Frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

This SR is modified by a Note that states the SR is not required to be performed until 24 hours after a required pump is not in operation.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.5 RCS Loops - MODE 3

BASES

BACKGROUND

The primary function of the reactor coolant in MODE 3 is removal of decay heat and transfer of this heat, via the steam generators (SGs), to the secondary plant fluid. The secondary function of the reactor coolant is to act as a carrier for soluble neutron poison, boric acid.

In MODE 3, reactor coolant pumps (RCPs) are used to provide forced circulation heat removal during heatup and cooldown. The MODE 3 decay heat removal requirements are low enough that a single RCS loop with one RCP is sufficient to remove core decay heat. However, ~~[~~two~~]~~ RCS loops are required to be OPERABLE to provide redundant paths for decay heat removal. Only one RCP needs to be OPERABLE to declare the associated RCS loop OPERABLE. 2

Reactor coolant natural circulation is not normally used but is sufficient for core cooling. However, natural circulation does not provide turbulent flow conditions. Therefore, boron reduction in natural circulation is prohibited because mixing to obtain a homogeneous concentration in all portions of the RCS cannot be ensured.

APPLICABLE SAFETY ANALYSES

Analyses have shown that the rod withdrawal event from MODE 3 with one RCS loop in operation is bounded by the rod withdrawal initiated from MODE 2.

Failure to provide heat removal may result in challenges to a fission product barrier. The RCS loops are part of the primary success path that functions or actuates to prevent or mitigate a Design Basis Accident or transient that either assumes the failure of, or presents a challenge to, the integrity of a fission product barrier.

RCS Loops - MODE 3 satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The purpose of this LCO is to require both RCS loops to be available for heat removal, thus providing redundancy. The LCO requires both loops to be OPERABLE with the intent of requiring both SGs to be capable ~~(> 25% water level)~~ of transferring heat from the reactor coolant at a controlled rate. Forced reactor coolant flow is the required way to transport heat, although natural circulation flow provides adequate removal. A minimum of one running RCP meets the LCO requirement for one loop in operation. 1

BASES

LCO (continued)

The Note permits a limited period of operation without RCPs. All RCPs may be removed from operation for ≤ 1 hour per 8 hour period. This means that natural circulation has been established. When in natural circulation, a reduction in boron concentration with coolant at boron concentrations less than required to assure the SDM of LCO 3.1.1 is maintained is prohibited because an even concentration distribution throughout the RCS cannot be ensured. Core outlet temperature is to be maintained at least 10°F below the saturation temperature so that no vapor bubble may form and possibly cause a natural circulation flow obstruction.

In MODES 3, 4, and 5, it is sometimes necessary to stop all RCPs or shutdown cooling (SDC) pump forced circulation (e.g., to change operation from one SDC train to the other, to perform surveillance or startup testing, to perform the transition to and from SDC System cooling, or to avoid operation below the RCP minimum net positive suction head limit). The time period is acceptable because natural circulation is adequate for heat removal, or the reactor coolant temperature can be maintained subcooled and boron stratification affecting reactivity control is not expected.

An OPERABLE RCS loop consists of at least one OPERABLE RCP and an SG that is OPERABLE. A RCP is OPERABLE if it is capable of being powered and is able to provide forced flow if required.

APPLICABILITY

In MODE 3, the heat load is lower than at power; therefore, one RCS loop in operation is adequate for transport and heat removal. A second RCS loop is required to be OPERABLE but not in operation for redundant heat removal capability.

Operation in other MODES is covered by:

LCO 3.4.6, "RCS Loops - MODE 4,"
LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled,"
LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled,"
LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level" ~~(MODE 6)~~, and
LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level" ~~(MODE 6)~~.

3
3

BASES

ACTIONS

A.1

If one RCS loop is inoperable, redundancy for forced flow heat removal is lost. The Required Action is restoration of the RCS loop to OPERABLE status within a Completion Time of 72 hours ~~[or in accordance with the Risk Informed Completion Time Program]~~. This time allowance is a justified period to be without the redundant, nonoperating loop because a single loop in operation has a heat transfer capability greater than that needed to remove the decay heat produced in the reactor core. 2

B.1

If restoration for Required Action A.1 is not possible within 72 hours, the unit must be placed in MODE 4 within 12 hours. In MODE 4, the plant may be placed on the SDC System. The Completion Time of 12 hours is compatible with required operation to achieve cooldown and depressurization from the existing plant conditions in an orderly manner and without challenging plant systems.

C.1 and C.2

If two RCS loops are inoperable the or a required RCS loop is not in operation, except as provided in Note ~~1~~ in the LCO section, all operations involving introduction of coolant into the RCS with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 must be suspended. Action to restore one RCS loop to OPERABLE status and operation shall be initiated immediately and continued until one RCS loop is restored to OPERABLE status and operation. Suspending the introduction of coolant into the RCS of coolant with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 is required to assure continued safe operation. With coolant added without forced circulation, unmixed coolant could be introduced to the core, however coolant added with boron concentration meeting the minimum SDM maintains acceptable margin to subcritical operation. The immediate Completion Times reflect the importance of maintaining operation for decay heat removal. 1

SURVEILLANCE REQUIREMENTS

SR 3.4.5.1

This SR requires verification that one RCS loop is in operation. Verification includes flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing heat removal. ~~[The 12 hour interval has been shown by operating practice to be sufficient to regularly assess degradation and verify operation within safety analyses assumptions. In addition, control room indication and alarms will normally indicate loop status.~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.5.3

Verification that each required RCP is OPERABLE ensures that the single failure criterion is met and that an additional RCS loop can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power availability to each required RCP. Alternatively, verification that a pump is in operation also verifies proper breaker alignment and power availability. ~~[The Frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

This SR is modified by a Note that states the SR is not required to be performed until 24 hours after a required pump is not in operation.

DISCUSSION OF CHANGES
ITS 3.4.6, RCS LOOPS – MODE 4

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 1 only:** CTS 3.4.14 Action states, in part, if a RCP is started when not within the limits, evaluate the subsequent transient to determine compliance with CTS 3.4.9.1, RCS Pressure and Temperature (P/T) Limits. ITS 3.4.6 does not contain a reference to specification 3.4.9.1. (i.e., ITS 3.4.3). This changes the CTS by not including this reference in the ITS.

The purpose of the reference is to alert the user that a determination must be made to ensure compliance with CTS 3.4.9.1, RCS P/T Limits. It is an ITS convention to not include these types of cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.4.1.3 Action a. states, in part, with less than the above required reactor coolant or shutdown cooling loops OPERABLE, within one (1) hour initiate corrective action to return the required loops to OPERABLE status. ITS 3.4.6 ACTION A states that with one required loop inoperable, “immediately” initiate action to restore a second loop to OPERABLE status. This changes the Unit 1 CTS by adding the requirement to “immediately” initiate action to restore a second loop to OPERABLE status.”

Unit 1 and Unit 2 CTS 3.4.1.3 Action b. states, in part, with no Reactor Coolant or shutdown cooling loop in operation, suspend operations that would cause introduction into the RCS, coolant with boron concentration less than required to meet SHUTDOWN MARGIN of Technical Specifications 3.1.1.1. ITS 3.4.6 ACTION B states that with two required loops inoperable or required loop not in operation, “immediately” suspend operations that would cause introduction of coolant into the RCS with boron concentration less than required to meet SDM of LCO 3.1.1. This changes the CTS by adding the requirement to “immediately” suspend operations that would cause introduction into the RCS. | R1 | R1

Unit 1 CTS 3.4.1.3 Action b. states, in part, and within one (1) hour initiate corrective action to return the required reactor coolant loop to operation. Unit 2 CTS Action b. states, in part, and immediately initiate corrective action to return the required coolant loop to operation. ITS 3.4.6 ACTION B states that with two required loops inoperable or required loop not in operation, immediately initiate action to restore one loop to OPERABLE status and operation. This changes the

Unit 1 CTS by adding the requirement to "immediately" initiate action to restore one loop to OPERABLE status and operation and changes the Unit 2 CTS and by adding the requirement to "immediately" initiate action to restore one loop to OPERABLE status and operation. | R1

This change is acceptable because it provides appropriate actions if one required loop is inoperable, and if two required loops or trains are inoperable or the required loop is not in operation. Under these conditions immediate action is necessary to ensure unit transients do not occur, and action is immediately taken to restore one loop to OPERABLE status and operation to be able to remove the decay heat generated by the reactor. These actions are required to assure continued safe operation. With coolant added without forced circulation, unmixed coolant could be introduced to the core, however coolant added with boron concentration meeting the minimum SDM maintains acceptable margin to subcritical operation. Action to restore one RCS loop to OPERABLE status and operation is necessary to be able to remove the decay heat generated by the reactor. The immediate Completion Times reflect the importance of maintaining operation for decay heat removal. This change is designated as more restrictive, because it requires immediate action to return the required reactor coolant loop to operation and adds the requirement to restore the loop to OPERABLE status.

M02 CTS 3.4.1.3 Action b. states, in part, that with no reactor coolant loop in operation, suspend operations that would cause introduction into the RCS, coolant with boron concentration less than required to meet SHUTDOWN MARGIN of Technical Specification 3.1.1.1. ITS 3.4.6 Action B states the Condition two required loops inoperable or required loop not in operation. This changes the CTS by adding the Condition "two required loops inoperable" to the CTS Condition no required loop in operation.

This change is acceptable because it provides appropriate actions if two required loops are inoperable or a required loop is not in operation. Under these conditions, immediate action is necessary to ensure certain unit transients do not occur, and action is immediately taken to restore one loop to OPERABLE status and operation to be able to remove the decay heat generated by the reactor. This change is designated as more restrictive because it requires an additional condition under which the actions must be taken.

M03 CTS 3.4.1.3 requires, in part, that at least two of the loops listed shall be OPERABLE and at least one shall be in operation. CTS 3.4.1.3 is modified by a footnote (*) that states, in part, that all reactor coolant pumps and shutdown cooling pumps may be de-energized for up to 1 hour under the conditions specified therein. ITS 3.4.6 contains the same allowance but limits the use of the 1 hour exception to once per 8 hour period. This changes the CTS by modifying the 1 hour allowance that all reactor coolant pumps and shutdown cooling (SDC) pumps may be removed from operation under the conditions specified therein and limits the usage of the allowance to once per 8 hour period. | R1

The purpose of the 1 hour allowance is to allow reactor coolant pumps and SDC pumps to be removed from operation to support testing. This means that natural circulation has been established using the SGs. This change is acceptable because it helps ensure that boron stratification and inadequate decay heat

removal do not occur should multiple 1 hour periods be required. This change is designated as more restrictive because it limits the allowance to 1 hour per 8 hour period, and that restriction does not currently exist

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.4.1.3 states, in part, that at least two of the loops listed shall be OPERABLE and at least one reactor coolant or shutdown cooling loop shall be in operation. Unit 2 CTS 3.4.1.3 states, in part, that at least two of the loop(s)/train(s) listed shall be OPERABLE and at least one reactor coolant and/or shutdown cooling loops shall be in operation. CTS 3.4.1.3 contains a description of what constitutes OPERABLE RCS loops and SDC loops. ITS 3.4.5 does not include a description of what constitutes OPERABLE RCS loops and SDC loops. This changes the CTS by moving the details of what constitutes OPERABLE RCS loops and SDC loops to the Bases. Additionally, Unit 2 CTS 3.4.1.3 is also changed by deletion of the descriptor "train(s)". Use of the descriptor "SDC loop(s)" is consistent with Unit 1 CTS 3.4.1.3, CTS 3.4.1.4.1, "Cold Shutdown – Loops Filled," CTS 3.4.1.4.2, "Cold Shutdown – Loops Not Filled," CTS 3.9.8.1, "Shutdown Cooling and Coolant Circulation," and CTS 3.9.8.2, "Low Water Level."

The removal of these details related to system design from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains a requirement for two loops consisting of any combination of RCS and SDC loops to be OPERABLE. The removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change, because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 - Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.4.1.3.2 states, in part, that the required steam generator(s) shall be determined OPERABLE by verifying the secondary side water level to be > 10% of narrow range indication. ITS 3.4.6.2 requires verifying secondary side water level in required SG(s) is > 10%. This changes the CTS by moving the Surveillance Requirement for the instrumentation to be used to verify secondary side level in required SGs, to the Bases. CTS 4.4.1.3.3 states, in part, that at least one reactor coolant or shutdown cooling loop shall be verified to be in operation and circulating reactor coolant. ITS SR 3.4.6.1 states verify required RCS loop or SDC loop is in operation. This changes the CTS by moving the Surveillance Requirement to verify that the reactor coolant loops or SDC loops are circulating reactor coolant, to the Bases.

The removal of this detail for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be in the Technical Specifications in order to provide adequate protection of the public health and safety. The ITS retains the requirement that two loops consisting of any combination of RCS loops and SDC loops shall be OPERABLE and one loop shall be in operation. Any one loop in operation provides enough flow to remove the decay heat from the core with forced circulation. An additional loop is required to be OPERABLE to provide redundancy for heat removal. Also, this change is acceptable because this type of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 (Category 7 – Relaxation of Surveillance Frequency) CTS 4.4.1.3.1 states, in part, that the required reactor coolant pump(s), if not in operation, shall be determined to be OPERABLE in accordance with the Surveillance Frequency Control Program by verifying correct breaker alignments and indicated power availability. ITS SR 3.4.6.3 requires verification of correct breaker alignment and indicated power availability to the pump not in operation in accordance with the Surveillance Frequency Control Program. It is modified by a Note that states "Not required to be performed until 24 hours after a required pump is not in operation." This changes the CTS by not requiring the Surveillance Requirement to be performed until 24 hours after a pump is taken out of operation.

The purpose of CTS 4.4.1.3.1 is to ensure that the standby pump is ready to operate. This change is acceptable because the new Surveillance Frequency has been evaluated to ensure that it provides an acceptable level of equipment reliability. The Note provides time to perform the Surveillance to verify correct breaker alignment and indicated power availability. Without the Note, the Surveillance would not be met immediately after taking a pump out of operation. This change is designated as less restrictive because Surveillances will be performed less frequently under the ITS than under the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.6, RCS LOOPS – MODE 4

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.6 RCS Loops - MODE 4

BASES

BACKGROUND

In MODE 4, the primary function of the reactor coolant is the removal of decay heat and transfer of this heat to the steam generators (SGs) or shutdown cooling (SDC) heat exchangers. The secondary function of the reactor coolant is to act as a carrier for soluble neutron poison, boric acid.

In MODE 4, either Reactor Coolant ~~pumps (RCPs)~~ or SDC ~~trains~~ can be used for coolant circulation. The intent of this LCO is to provide forced flow from at least one ~~RCP~~ or one SDC ~~train~~ for decay heat removal and transport. The flow provided by one RCP loop or SDC ~~train~~ is adequate for heat removal. The other intent of this LCO is to require that two paths be available to provide redundancy for heat removal. 1

System (RCS) loops; loops; reactor coolant pump (RCP); pump; loop

APPLICABLE SAFETY ANALYSES

In MODE 4, RCS circulation is considered in the determination of the time available for mitigation of the accidental boron dilution event. The RCS loops and SDC ~~trains~~ provide this circulation. 1

loops

RCS Loops - MODE 4 satisfies Criterion 4 of 10 CFR 50.36(c)(2)(ii).

LCO

The purpose of this LCO is to require that at least two loops ~~or trains~~, RCS or SDC, be OPERABLE in MODE 4 and one of these loops ~~or trains~~ be in operation. The LCO allows the two loops that are required to be OPERABLE to consist of any combination of RCS and SDC System loops. Any one loop ~~or train~~ in operation provides enough flow to remove the decay heat from the core with forced circulation. An additional loop ~~or train~~ is required to be OPERABLE to provide redundancy for heat removal. 1

Note 1 permits all RCPs and SDC pumps to be removed from operation ≤ 1 hour per 8 hour period. This means that natural circulation has been established using the SGs. The Note prohibits boron dilution with coolant at boron concentrations less than required to assure the SDM of LCO 3.1.1 is maintained when forced flow is stopped because an even concentration distribution cannot be ensured. Core outlet temperature is to be maintained at least 10°F below saturation temperature so that no vapor bubble may form and possibly cause a natural circulation flow obstruction. The response of the RCS without the RCPs or SDC pumps depends on the core decay heat load and the length of time that the

BASES

LCO (continued)

pumps are stopped. As decay heat diminishes, the effects on RCS temperature and pressure diminish. Without cooling by forced flow, higher heat loads will cause the reactor coolant temperature and pressure to increase at a rate proportional to the decay heat load. Because pressure can increase, the applicable system pressure limits (pressure and temperature (P/T) limits or low temperature overpressure protection (LTOP) limits) must be observed and forced SDC flow or heat removal via the SGs must be re-established prior to reaching the pressure limit. The circumstances for stopping both RCPs or SDC pumps are to be limited to situations where:

a. Pressure and temperature increases can be maintained well within the allowable pressure (P/T limits and LTOP) and 10°F subcooling limits or

b. An alternate heat removal path through the SGs is in operation.

Note 2 requires that ~~either of the following two conditions be satisfied~~ before an RCP may be started with any RCS cold leg temperature ~~less than or equal to the LTOP enable temperature specified in the PTLR:~~

two idle RCS loops and

1

≤ 300°F,

~~a. Pressurizer water level is < [60]% or~~

b. Secondary side water temperature in each SG is < [100]°F above each of the RCS cold leg temperatures.

30

1

Satisfying ~~either of~~ the above condition~~s~~ will preclude a large pressure surge in the RCS when the RCP is started.

An OPERABLE RCS loop consists of at least one OPERABLE RCP and an SG that is OPERABLE and has the minimum water level specified in SR 3.4.6.2.

loop

Similarly, for the SDC System, an OPERABLE SDC ~~train~~ is composed of the OPERABLE SDC pump~~(s)~~ capable of providing forced flow to the SDC heat exchanger~~(s)~~. RCPs and SDC pumps are OPERABLE if they are capable of being powered and are able to provide flow if required. Management of gas voids is important to SDC System OPERABILITY.

1

BASES

APPLICABILITY

In MODE 4, this LCO applies because it is possible to remove core decay heat and to provide proper boron mixing with either the RCS loops and SGs or the SDC System.

Operation in other MODES is covered by:

LCO 3.4.4, "RCS Loops - MODES 1 and 2,"
LCO 3.4.5, "RCS Loops - MODE 3,"
LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled,"
LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled,"
LCO 3.9.4, "Shutdown Cooling and Coolant Circulation - High Water Level" ~~(MODE 6)~~, and
LCO 3.9.5, "Shutdown Cooling and Coolant Circulation - Low Water Level" ~~(MODE 6)~~.

3
3

ACTIONS

A.1

If only one required ~~RCS~~ loop is OPERABLE and in operation ~~and no SDC trains are OPERABLE~~, redundancy for heat removal is lost. Action must be initiated immediately to restore a required non-operating loop ~~or train~~ to OPERABLE status. The immediate Completion Time reflects the importance of maintaining the availability of two paths for decay heat removal.

1

A.2

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~

4

loop

If only one required ~~SDC train~~ is OPERABLE and in operation ~~and no required RCS loops are OPERABLE~~, redundancy for heat removal is lost and the plant must be placed in a configuration that minimizes overall plant risk. This redundancy is obtained by making at least one SG available for decay heat removal via natural circulation because:

1

1

BASES

ACTIONS (continued)

1. MODE 4 operation poses overall lower risk of core damage and large early radiation release than does MODE 5 (Ref. 1). This is particularly true with SDC impaired.

2. In MODE 4, RCS and steam generator loop conditions may be maintained such that failure of the operating SDC ~~train~~ may be by natural circulation heat removal through one or more steam generators. 1

Remaining within the Applicability of the LCO is acceptable because the plant risk in MODE 4 is similar to or lower than MODE 5 (Ref. 1). However, voluntary entry into MODE 5 may be made as it is also an acceptable low-risk state.

Required Action A.2 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

B.1 and B.2

If two required loops ~~or trains~~ are inoperable or a required loop ~~or train~~ is not in operation except during conditions permitted by Note 1 in the LCO section, all operations involving introduction of coolant into the RCS with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 must be suspended and action to restore one ~~RCS~~ loop ~~or SDC train~~ to OPERABLE status and operation must be initiated. The required margin to criticality must not be reduced in this type of operation. Suspending the introduction of coolant into the RCS of coolant with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 is required to assure continued safe operation. With coolant added without forced circulation, unmixed coolant could be introduced to the core, however coolant added with boron concentration meeting the minimum SDM maintains acceptable margin to subcritical operations. The immediate Completion Times reflect the importance of decay heat removal. The action to restore must continue until one loop ~~or train~~ is restored to operation. 1 1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.6.3

loop

Verification that each required pump is OPERABLE ensures that an additional RCS loop or SDC ~~train~~ can be placed in operation, if needed to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power available to each required pump. Alternatively, verification that a pump is in operation also verifies proper breaker alignment and power availability. ~~[The Frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.~~

1

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

2

This SR is modified by a Note that states the SR is not required to be performed until 24 hours after a required pump is not in operation.

SR 3.4.6.4

SDC System piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the required SDC ~~train~~(s) and may also prevent water hammer, pump cavitation, and pumping of noncondensible gas into the reactor vessel.

loop

1

Selection of SDC System locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

The SDC System is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. If accumulated gas is discovered that exceeds the acceptance criteria for the susceptible location (or the volume of accumulated gas at one or more susceptible locations exceeds an acceptance criteria for gas volume at the suction or discharge of a pump), the Surveillance is not met. If the accumulated gas is eliminated or brought within the acceptance criteria limits during performance of the Surveillance, the Surveillance is met and past system OPERABILITY is evaluated under the Corrective Action Program. If it is determined by subsequent evaluation that the SDC System is not rendered inoperable by the accumulated gas (i.e., the system is sufficiently filled with water), the Surveillance may be declared met. Accumulated gas should be eliminated or brought within the acceptance criteria limits.

SDC System locations susceptible to gas accumulation are monitored and, if gas is found, the gas volume is compared to the acceptance criteria for the location. Susceptible locations in the same system flow path which are subject to the same gas intrusion mechanisms may be verified by monitoring a representative sub-set of susceptible locations. Monitoring may not be practical for locations that are inaccessible due to radiological or environmental conditions, the plant configuration, or personnel safety. For these locations alternative methods (e.g., operating parameters, remote monitoring) may be used to monitor the susceptible location. Monitoring is not required for susceptible locations where the maximum potential accumulated gas void volume has been evaluated and determined to not challenge system OPERABILITY. The accuracy of the method used for monitoring the susceptible locations and trending of the results should be sufficient to assure system OPERABILITY during the Surveillance interval.

This SR is modified by a Note that states the SR is not required to be performed until 12 hours after entering MODE 4. In a rapid shutdown, there may be insufficient time to verify all susceptible locations prior to entering MODE 4.

~~[The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the SDC System piping and the procedural controls governing system operation.~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. The Surveillance Frequency may vary by location susceptible to gas accumulation.

BASES

SURVEILLANCE REQUIREMENTS (continued)

DISCUSSION OF CHANGES
ITS 3.4.7, RCS LOOPS – MODE 5, LOOPS FILLED

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 ITS SR 3.4.7.3 Condition A requires one required shutdown cooling (SDC) loop inoperable and “one SDC loop OPERABLE.” ITS SR 3.4.7.3 Condition B requires one or more SGs with secondary water level not within limit and “one SDC loop OPERABLE.” The condition for “one SDC loop OPERABLE” is not in the CTS. This changes the CTS by adding an additional condition; however, this condition requires one “SDC loop be OPERABLE” which is expected if one SDC loop is inoperable, or if one or more SGs with secondary water level not within limit. The addition of this condition to ITS Condition A and Condition B allows entry into ITS 3.4.7 ACTION C, that is, no required SDC loops OPERABLE or required SDC loop not in operation, without requiring entry into ACTION A or ACTION B. These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.4.1.4.1 Action a. states, in part, with less than the above required loops OPERABLE or with less than the required steam generator level, within one (1) hour initiate corrective action to return the required loops to OPERABLE status or to restore the required level. ITS 3.4.7 Required Actions A.1 and B.1 each state “immediately” initiate action to restore a second SDC loop to OPERABLE status. ITS 3.4.7 Required Actions A.2 and B.2 each state “immediately” initiate action to restore required SGs secondary side water level to within limit. This changes the Unit 1 CTS by adding the requirement to “immediately” initiate the action to restore a second loop to OPERABLE status and to restore required SGs secondary side water level to within limit.

CTS 3.4.1.4.1 Action b. states, in part, with no shutdown cooling loop in operation, suspend operations that would cause introduction into the RCS, coolant with boron concentration less than required to meet SHUTDOWN MARGIN of Technical Specifications 3.1.1.1. ITS 3.4.7 ACTION C and Required Action C. 1 state that with no required SDC loop OPERABLE or required SDC loop is not in operation, “immediately” suspend operations that would cause introduction of coolant into the RCS with boron concentration less than required to meet SDM of LCO 3.1.1. This changes the Unit 1 and Unit 2 CTS by adding the requirement to “immediately” suspend operations that would cause introduction of coolant into the RCS with boron concentration less than required to meet SDM of LCO 3.1.1 to the CTS.

CTS 3.4.1.4.1 Action b. states, in part, with no shutdown cooling loop in operation, within one (1) hour (Unit 1) and immediately (Unit 2) initiate corrective action to return the required shutdown loop to operation. ITS 3.4.7 ACTION C and Required Action C. 2 state that with no required SDC loop OPERABLE or required SDC loop is not in operation, immediately initiate action to restore one SDC loop to OPERABLE status and operation. This changes the CTS by adding the requirement to restore the loop to OPERABLE status.

This change is acceptable because it provides appropriate actions if one SDC loop is inoperable, no required SDC loops are OPERABLE, or a required SDC loop in not is not in operation. Under these conditions immediate action is necessary to ensure unit transients do not occur, and action is immediately taken to restore one loop to OPERABLE status and operation to be able to remove the decay heat generated by the reactor. These actions are required to assure continued safe operation. With coolant added without forced circulation, unmixed coolant could be introduced to the core, however coolant added with boron concentration meeting the minimum SDM maintains acceptable margin to subcritical operation. Action to restore one SDC loop to OPERABLE status and operation is necessary to be able to remove the decay heat generated by the reactor. The immediate Completion Times reflect the importance of maintaining operation for decay heat removal. This change is designated as more restrictive, because it requires immediate action to return the required reactor coolant loop to operation and adds the requirement to restore the loop to OPERABLE status.

M02 ITS SR 3.4.7.3 requires verification that correct breaker alignment and indicated power are available to each required SDC pump. A Note further explains that the Surveillance is not required to be performed until 24 hours after a required pump is not in operation. This Surveillance is not required by the CTS. This changes the CTS by requiring verification of correct breaker alignment and indicated power availability on required SDC pumps that are not in operation.

The purpose of ITS SR 3.4.7.3 is to ensure a standby SDC pump is available to provide RCS cooling should the operating pump fail. This change is acceptable because the verification of proper breaker alignment and power availability ensures that an additional SDC pump can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. This change is designated as more restrictive because it adds a Surveillance Requirement to the CTS.

M03 CTS 3.4.1.4.1 states, in part, that at least one shutdown cooling loop shall be OPERABLE and in operation. CTS 3.4.1.4.1 is modified by a footnote (*) that states, in part, that the shutdown cooling pumps may be de-energized for up to 1 hour under the conditions specified therein. ITS 3.4.7 contains the same allowance but limits the use of the 1 hour exception to once per 8 hour period. This changes the CTS by modifying the 1 hour allowance that SDC pumps may be removed from operation under the conditions specified therein and limits the usage of the allowance to once per 8 hour period.

The purpose of the 1 hour allowance is to allow SDC pumps to be removed from operation to change operation from one SDC loop to the other, perform surveillance or startup testing, and perform the transition to and from the SDC.

This change is acceptable because it helps ensure that boron stratification and inadequate decay heat removal do not occur should multiple 1 hour periods be required. This change is designated as more restrictive because it limits the allowance to 1 hour per 8 hour period, and that restriction does not currently exist.

M04 **Unit 2 only:** CTS 3.4.1.4.1 Action a. states, in part, with one of the shutdown cooling loops inoperable "and" with less than the required steam generator level, immediately initiate the actions specified therein. ITS 3.4.7 ACTION A states that with one required SDC loop inoperable and one SDC loop OPERABLE, then immediately initiate the actions specified therein, of which, are the same as the CTS actions. Similarly, ITS 3.4.7 ACTION B states that with one or more required SGs with secondary side water level not within limit and one SDC loop OPERABLE, then immediately initiate the actions specified therein, of which, are the same as the CTS actions. This changes the CTS by requiring the actions specified therein be taken with one of the shutdown cooling loops inoperable "or" with less than the required steam generator level, rather than both Conditions being required before actions are taken (i.e., and).

This change is acceptable because the ITS retains the appropriate actions if one of the shutdown cooling loops inoperable or if steam generator level is less than the required steam generator level. Under these conditions, immediate action is necessary to ensure certain unit transients do not occur, and action is immediately taken to restore one loop to OPERABLE status and operation to be able to remove the decay heat generated by the reactor. This change is designated as more restrictive, because it adds separate Conditions than are required in the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 - Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.4.1.4.1.2 states, in part, that at least one shutdown cooling loop shall be determined to be in operation and circulating reactor coolant. ITS SR 3.4.7.1 states verify required SDC loop is in operation. This changes the CTS by moving the requirement to verify that the SDC loops are circulating reactor coolant, to the Bases. R1

The removal of this detail for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be in the Technical Specifications in order to provide adequate protection of the public health and safety. This change is acceptable because this type of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated

as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 1 – Relaxation of LCO Requirements)* CTS 3.4.1.4.1 states, in part, that at least one shutdown cooling loop shall be OPERABLE and in operation, and either of the specified requirements therein. ITS 3.4.7 specifies the same requirements; however, ITS LCO 3.4.7 Note 4 allows all SDC loops to be removed from operation during planned heatup to MODE 4 when at least one RCS loop is in operation. This changes the CTS by adding an allowance for all SDC loops to be removed from operation during planned heatup operations to MODE 4.

The purpose of CTS 3.4.1.4.1 is to ensure there is sufficient forced circulation to prevent boric acid stratification and to provide forced flow for decay heat removal and transport. This change is acceptable because the LCO requirements continue to ensure that the structures, systems, and components are maintained consistent with the safety analyses and licensing basis. This change allows an RCS loop to be in operation instead of a SDC loop. The RCS loop simply replaces the function of the SDC loop. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than were applied in the CTS.

L02 *(Category 1 – Relaxation of LCO Requirements)* CTS 3.4.1.4.1.b states, in part, that steam generator water level "shall be greater than 10%." ITS LCO 3.4.7.b states "The secondary side water level of each steam generator (SG) shall be ≥ 10%." This changes the CTS by setting the lower SG level limit at a specific value of 10% instead of "greater than" 10%. R1

The purpose of the secondary side steam generator minimum water level is to provide an alternative method of decay heat removal if a second SDC loop is not OPERABLE. The minimum secondary side SG level of ≥10% ensures an alternate method of decay heat removal is available via natural circulation. The value of ≥ 10% is consistent with CTS secondary side water level requirements for HOT STANDBY (MODE 3) and HOT SHUTDOWN (MODE 4) which are retained in ITS 3.4.5 and ITS 3.4.6, respectively. This change is acceptable because a secondary side SG level at ≥ 10% is sufficient to provide for natural circulation decay heat removal. This change is designated as less restrictive because less stringent requirements for OPERABILITY are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.7, RCS LOOPS – MODE 5, LOOPS FILLED

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.7 RCS Loops - MODE 5, Loops Filled

BASES

BACKGROUND

In MODE 5 with the RCS loops filled, the primary function of the reactor coolant is the removal of decay heat and the transfer of this heat either to the steam generator (SG) secondary side coolant via natural circulation (Ref. 1) or the component cooling water via the shutdown cooling (SDC) heat exchangers. While the principal means for decay heat removal is via the SDC System, the SGs via natural circulation (Ref. 1) are specified as a backup means for redundancy. Even though the SGs cannot produce steam in this MODE, they are capable of being a heat sink due to their large contained volume of secondary side water. As long as the SG secondary side water is at a lower temperature than the reactor coolant, heat transfer will occur. The rate of heat transfer is directly proportional to the temperature difference. The secondary function of the reactor coolant is to act as a carrier for soluble neutron poison, boric acid.

In MODE 5 with RCS loops filled, the SDC ~~trains~~ are the principal means for decay heat removal. The number of ~~trains~~ in operation can vary to suit the operational needs. The intent of this LCO is to provide forced flow from at least one SDC ~~train~~ for decay heat removal and transport. The flow provided by one SDC ~~train~~ is adequate for decay heat removal. The other intent of this LCO is to require that a second path be available to provide redundancy for decay heat removal. 1

The LCO provides for redundant paths of decay heat removal capability. The first path can be an SDC ~~train~~ that must be OPERABLE and in operation. The second path can be another OPERABLE SDC ~~train~~, or through the SGs via natural circulation (Ref. 1), each having an adequate water level. 1

APPLICABLE SAFETY ANALYSES

In MODE 5, RCS circulation is considered in the determination of the time available for mitigation of the accidental boron dilution event. The SDC ~~trains~~ provide this circulation. 1

RCS Loops - MODE 5 (Loops Filled) satisfies Criterion 4 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The purpose of this LCO is to require at least one of the SDC ~~trains~~ be OPERABLE and in operation with the other SDC ~~train~~ OPERABLE or secondary side water level of each SG shall be ≥ ~~[25]~~%. One SDC ~~train~~ provides sufficient forced circulation to perform the safety functions of the reactor coolant under these conditions. The second SDC ~~train~~ is normally maintained OPERABLE as a backup to the operating SDC ~~train~~ to provide redundant paths for decay heat removal. However, if the standby SDC ~~train~~ is not OPERABLE, a sufficient alternate method to provide redundant paths for decay heat removal is two SGs with their secondary side water levels ≥ ~~[25%]~~. Should the operating SDC ~~train~~ fail, the SGs could be used to remove the decay heat via natural circulation.

Note 1 permits all SDC pumps to be removed from operation ≤ 1 hour per 8 hour period. The circumstances for stopping both SDC ~~trains~~ are to be limited to situations where pressure and temperature increases can be maintained well within the allowable pressure (pressure and temperature and low temperature overpressure protection) and 10°F subcooling limits, or an alternate heat removal path through the SG(s) is in operation.

This LCO is modified by a Note that prohibits boron dilution with coolant at boron concentrations less than required to assure the SDM of LCO 3.1.1 is maintained when SDC forced flow is stopped because an even concentration distribution cannot be ensured. Core outlet temperature is to be maintained at least 10°F below saturation temperature, so that no vapor bubble would form and possibly cause a natural circulation flow obstruction. In this MODE, the SG(s) can be used as the backup for SDC heat removal. To ensure their availability, the RCS loop flow path is to be maintained with subcooled liquid.

In MODE 5, it is sometimes necessary to stop all ~~RCP or~~ SDC forced circulation. This is permitted to change operation from one SDC ~~train~~ to the other, perform surveillance or startup testing, perform the transition to and from the SDC~~, or to avoid operation below the RCP minimum net positive suction head limit~~. The time period is acceptable because natural circulation is acceptable for decay heat removal, the reactor coolant temperature can be maintained subcooled, and boron stratification affecting reactivity control is not expected.

Note 2 allows one SDC ~~train~~ to be inoperable for a period of up to 2 hours provided that the other SDC ~~train~~ is OPERABLE and in operation. This permits periodic surveillance tests to be performed on the inoperable ~~train~~ during the only time when such testing is safe and possible.

BASES

LCO (continued)

two idle RCS loops, the

Note 3 requires that ~~either of the following two conditions be satisfied~~ before an RCP may be started with ~~any RCS cold leg temperature less than or equal to the LTOP enable temperature specified in the PTLR:~~ 1

~~a. Pressurizer water level must be < [60]% or~~

~~b.~~ Secondary side water temperature in each SG must be < ~~[100]~~ 30 °F above each of the RCS cold leg temperatures. 2

Satisfying ~~either of~~ the ~~above~~ condition~~s~~ will preclude a low temperature overpressure event due to a thermal transient when the RCP is started. 1

loops

Note 4 provides for an orderly transition from MODE 5 to MODE 4 during a planned heatup by permitting SDC ~~trains~~ to not be in operation when at least one RCP is in operation. This Note provides for the transition to MODE 4 where an RCP is permitted to be in operation and replaces the RCS circulation function provided by the SDC ~~trains~~. 1

loops

loop

An OPERABLE SDC ~~train~~ is composed of an OPERABLE SDC pump and an OPERABLE SDC heat exchanger. Management of gas voids is important to SDC System OPERABILITY. 1

SDC pumps are OPERABLE if they are capable of being powered and are able to provide flow if required. A SG can perform as a heat sink via natural circulation when it has an adequate water level and is OPERABLE.

APPLICABILITY

loop

In MODE 5 with RCS loops filled, this LCO requires forced circulation to remove decay heat from the core and to provide proper boron mixing. One SDC ~~train~~ provides sufficient circulation for these purposes. 1

Operation in other MODES is covered by:

LCO 3.4.4, "RCS Loops - MODES 1 and 2,"
LCO 3.4.5, "RCS Loops - MODE 3,"
LCO 3.4.6, "RCS Loops – MODE 4,"
LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled,"
LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level" ~~(MODE 6)~~, and 3
LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level" ~~(MODE 6)~~. 3

BASES

ACTIONS

A.1, A.2, B.1 and B.2

If one SDC ~~train~~ is OPERABLE and any required SGs has secondary side water levels < ~~[25%]~~, or one required SDC ~~train~~ is inoperable, redundancy for heat removal is lost. Action must be initiated immediately to restore a second SDC ~~train~~ to OPERABLE status or to restore the water level in the required SGs. Either Required Action will restore redundant decay heat removal paths. The immediate Completion Times reflect the importance of maintaining the availability of two paths for decay heat removal.

C.1 and C.2

If a required SDC ~~train~~ is not in operation, or no required SDC ~~train~~ is OPERABLE, except as permitted in Note 1, all operations involving introduction of coolant into the RCS with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 must be suspended. Action to restore one SDC ~~train~~ to OPERABLE status and operation must be initiated. The required margin to criticality must not be reduced in this type of operation. Suspending the introduction of coolant into the RCS of coolant with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 is required to assure continued safe operation. With coolant added without forced circulation, unmixed coolant could be introduced to the core, however coolant added with boron concentration meeting the minimum SDM maintains acceptable margin to subcritical operations. The immediate Completion Times reflect the importance of maintaining operation for decay heat removal.

SURVEILLANCE REQUIREMENTS

SR 3.4.7.1

This SR requires verification that one SDC ~~train~~ is in operation. Verification includes flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing decay heat removal. ~~[The 12 hour Frequency has been shown by operating practice to be sufficient to regularly assess degradation and verify operation is within safety analyses assumptions. In addition, control room indication and alarms will normally indicate loop status.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

The SDC flow is established to ensure that core outlet temperature is maintained sufficiently below saturation to allow time for swapover to the pg 195standby SDC ~~train~~ should the operating ~~train~~ be lost.

loop

loop

SR 3.4.7.2

narrow range

Verifying the SGs are OPERABLE by ensuring their secondary side water levels are ≥ ~~[25%]~~ ensures that redundant heat removal paths are available if the second SDC ~~train~~ is inoperable. The Surveillance is required to be performed when the LCO requirement is being met by use of the SGs. If both SDC ~~trains~~ are OPERABLE, this SR is not needed. ~~[The 12 hour Frequency has been shown by operating practice to be sufficient to regularly assess degradation and verify operation within safety analyses assumptions.~~

loop

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~The Surveillance is required to be performed when the LCO requirement is being met by one of two SDC trains, e.g., both SGs have < [25]% water level. [The Frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.~~ 1 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~]~~

This SR is modified by a Note that states the SR is not required to be performed until 24 hours after a required pump is not in operation.

SR 3.4.7.4

SDC System piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the required SDC ~~train(s)~~ loop(s) and may also prevent water hammer, pump cavitation, and pumping of noncondensible gas into the reactor vessel. 1

Selection of SDC System locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The SDC System is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. If accumulated gas is discovered that exceeds the acceptance criteria for the susceptible location (or the volume of accumulated gas at one or more susceptible locations exceeds an acceptance criteria for gas volume at the suction or discharge of a pump), the Surveillance is not met. If the accumulated gas is eliminated or brought within the acceptance criteria limits during performance of the Surveillance, the Surveillance is met and past system OPERABILITY is evaluated under the Corrective Action Program. If it is determined by subsequent evaluation that the SDC System is not rendered inoperable by the accumulated gas (i.e., the system is sufficiently filled with water), the Surveillance may be declared met. Accumulated gas should be eliminated or brought within the acceptance criteria limits.

SDC System locations susceptible to gas accumulation are monitored and, if gas is found, the gas volume is compared to the acceptance criteria for the location. Susceptible locations in the same system flow path which are subject to the same gas intrusion mechanisms may be verified by monitoring a representative sub-set of susceptible locations. Monitoring may not be practical for locations that are inaccessible due to radiological or environmental conditions, the plant configuration, or personnel safety. For these locations alternative methods (e.g., operating parameters, remote monitoring) may be used to monitor the susceptible location. Monitoring is not required for susceptible locations where the maximum potential accumulated gas void volume has been evaluated and determined to not challenge system OPERABILITY. The accuracy of the method used for monitoring the susceptible locations and trending of the results should be sufficient to assure system OPERABILITY during the Surveillance interval.

~~[The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the SDC System piping and the procedural controls governing system operation.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. The Surveillance Frequency may vary by location susceptible to gas accumulation.

BASES

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.7 RCS Loops - MODE 5, Loops Filled

BASES

BACKGROUND

In MODE 5 with the RCS loops filled, the primary function of the reactor coolant is the removal of decay heat and the transfer of this heat either to the steam generator (SG) secondary side coolant via natural circulation (Ref. 1) or the component cooling water via the shutdown cooling (SDC) heat exchangers. While the principal means for decay heat removal is via the SDC System, the SGs via natural circulation (Ref. 1) are specified as a backup means for redundancy. Even though the SGs cannot produce steam in this MODE, they are capable of being a heat sink due to their large contained volume of secondary side water. As long as the SG secondary side water is at a lower temperature than the reactor coolant, heat transfer will occur. The rate of heat transfer is directly proportional to the temperature difference. The secondary function of the reactor coolant is to act as a carrier for soluble neutron poison, boric acid.

In MODE 5 with RCS loops filled, the SDC ~~trains~~ are the principal means for decay heat removal. The number of ~~trains~~ in operation can vary to suit the operational needs. The intent of this LCO is to provide forced flow from at least one SDC ~~train~~ for decay heat removal and transport. The flow provided by one SDC ~~train~~ is adequate for decay heat removal. The other intent of this LCO is to require that a second path be available to provide redundancy for decay heat removal. 1

The LCO provides for redundant paths of decay heat removal capability. The first path can be an SDC ~~train~~ that must be OPERABLE and in operation. The second path can be another OPERABLE SDC ~~train~~, or through the SGs via natural circulation (Ref. 1), each having an adequate water level. 1

APPLICABLE SAFETY ANALYSES

In MODE 5, RCS circulation is considered in the determination of the time available for mitigation of the accidental boron dilution event. The SDC ~~trains~~ provide this circulation. 1

RCS Loops - MODE 5 (Loops Filled) satisfies Criterion 4 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

The purpose of this LCO is to require at least one of the SDC ~~trains~~ be OPERABLE and in operation with the other SDC ~~train~~ OPERABLE or secondary side water level of each SG shall be ≥ ~~[25]~~%. One SDC ~~train~~ provides sufficient forced circulation to perform the safety functions of the reactor coolant under these conditions. The second SDC ~~train~~ is normally maintained OPERABLE as a backup to the operating SDC ~~train~~ to provide redundant paths for decay heat removal. However, if the standby SDC ~~train~~ is not OPERABLE, a sufficient alternate method to provide redundant paths for decay heat removal is two SGs with their secondary side water levels ≥ ~~[25%]~~. Should the operating SDC ~~train~~ fail, the SGs could be used to remove the decay heat via natural circulation.

Note 1 permits all SDC pumps to be removed from operation ≤ 1 hour per 8 hour period. The circumstances for stopping both SDC ~~trains~~ are to be limited to situations where pressure and temperature increases can be maintained well within the allowable pressure (pressure and temperature and low temperature overpressure protection) and 10°F subcooling limits, or an alternate heat removal path through the SG(s) is in operation.

This LCO is modified by a Note that prohibits boron dilution with coolant at boron concentrations less than required to assure the SDM of LCO 3.1.1 is maintained when SDC forced flow is stopped because an even concentration distribution cannot be ensured. Core outlet temperature is to be maintained at least 10°F below saturation temperature, so that no vapor bubble would form and possibly cause a natural circulation flow obstruction. In this MODE, the SG(s) can be used as the backup for SDC heat removal. To ensure their availability, the RCS loop flow path is to be maintained with subcooled liquid.

In MODE 5, it is sometimes necessary to stop all ~~RCP or~~ SDC forced circulation. This is permitted to change operation from one SDC ~~train~~ to the other, perform surveillance or startup testing, perform the transition to and from the SDC~~, or to avoid operation below the RCP minimum net positive suction head limit~~. The time period is acceptable because natural circulation is acceptable for decay heat removal, the reactor coolant temperature can be maintained subcooled, and boron stratification affecting reactivity control is not expected.

Note 2 allows one SDC ~~train~~ to be inoperable for a period of up to 2 hours provided that the other SDC ~~train~~ is OPERABLE and in operation. This permits periodic surveillance tests to be performed on the inoperable ~~train~~ during the only time when such testing is safe and possible.

BASES

LCO (continued)

two idle RCS loops, the

Note 3 requires that ~~either of the following two conditions be satisfied~~ before an RCP may be started with ~~any RCS cold leg temperature less than or equal to the LTOP enable temperature specified in the PTLR:~~ 1

~~a. Pressurizer water level must be < [60]% or~~

~~b.~~ Secondary side water temperature in each SG must be < ~~[100]~~ 40 °F above each of the RCS cold leg temperatures. 2

Satisfying ~~either of~~ the ~~above~~ condition~~s~~ will preclude a low temperature overpressure event due to a thermal transient when the RCP is started. 1

loops

Note 4 provides for an orderly transition from MODE 5 to MODE 4 during a planned heatup by permitting SDC ~~trains~~ to not be in operation when at least one RCP is in operation. This Note provides for the transition to MODE 4 where an RCP is permitted to be in operation and replaces the RCS circulation function provided by the SDC ~~trains~~. 1

loops

loop

An OPERABLE SDC ~~train~~ is composed of an OPERABLE SDC pump and an OPERABLE SDC heat exchanger. Management of gas voids is important to SDC System OPERABILITY. 1

SDC pumps are OPERABLE if they are capable of being powered and are able to provide flow if required. A SG can perform as a heat sink via natural circulation when it has an adequate water level and is OPERABLE.

APPLICABILITY

loop

In MODE 5 with RCS loops filled, this LCO requires forced circulation to remove decay heat from the core and to provide proper boron mixing. One SDC ~~train~~ provides sufficient circulation for these purposes. 1

Operation in other MODES is covered by:

LCO 3.4.4, "RCS Loops - MODES 1 and 2,"
LCO 3.4.5, "RCS Loops - MODE 3,"
LCO 3.4.6, "RCS Loops – MODE 4,"
LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled,"
LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level" ~~(MODE 6)~~, and 3
LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level" ~~(MODE 6)~~. 3

BASES

ACTIONS

A.1, A.2, B.1 and B.2

If one SDC ~~train~~ is OPERABLE and any required SGs has secondary side water levels < ~~[25%]~~, or one required SDC ~~train~~ is inoperable, redundancy for heat removal is lost. Action must be initiated immediately to restore a second SDC ~~train~~ to OPERABLE status or to restore the water level in the required SGs. Either Required Action will restore redundant decay heat removal paths. The immediate Completion Times reflect the importance of maintaining the availability of two paths for decay heat removal.

C.1 and C.2

If a required SDC ~~train~~ is not in operation, or no required SDC ~~train~~ is OPERABLE, except as permitted in Note 1, all operations involving introduction of coolant into the RCS with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 must be suspended. Action to restore one SDC ~~train~~ to OPERABLE status and operation must be initiated. The required margin to criticality must not be reduced in this type of operation. Suspending the introduction of coolant into the RCS of coolant with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 is required to assure continued safe operation. With coolant added without forced circulation, unmixed coolant could be introduced to the core, however coolant added with boron concentration meeting the minimum SDM maintains acceptable margin to subcritical operations. The immediate Completion Times reflect the importance of maintaining operation for decay heat removal.

SURVEILLANCE REQUIREMENTS

SR 3.4.7.1

This SR requires verification that one SDC ~~train~~ is in operation. Verification includes flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing decay heat removal. ~~[The 12 hour Frequency has been shown by operating practice to be sufficient to regularly assess degradation and verify operation is within safety analyses assumptions. In addition, control room indication and alarms will normally indicate loop status.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

DISCUSSION OF CHANGES
ITS 3.4.8, RCS LOOPS – MODE 5, LOOPS NOT FILLED

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.4.1.4.2 states, in part, that two shutdown cooling (SDC) loops shall be OPERABLE and at least one SDC loop shall be in operation. CTS 3.4.1.4.2 is modified by footnote * that states, in part, that the SDC pump "may be de-energized" for up to 1 hour. ITS 3.4.8 NOTE 1 states that the pumps "may be removed from operation." This changes the CTS by changing "de-energized" to "removed from operation." R1

The purpose of the NOTE is to allow for stopping flow for up to the specified period of 1 hour. This change is a clarification of the intended action to stop the pumps rather than fully de-energize the pumps (e.g., for a maintenance activity). This change is acceptable because it is consistent with the application of CTS footnote *. This change is designated as administrative because it does not result in a technical change.

MORE RESTRICTIVE CHANGES

M01 CTS 3.4.1.4.2 Action a. states, in part, with less than the above required loops OPERABLE, within one (1) hour initiate corrective action to return the required loops to OPERABLE status. ITS 3.4.8 ACTION A states that with one required SDC loop inoperable "immediately" initiate action to restore SDC loop to OPERABLE status. This changes the CTS by adding the requirement to "immediately" initiate corrective action to return the required loops to OPERABLE status.

CTS 3.4.1.4.2 Action b. states, with no shutdown cooling loop in operation, suspend operations that would cause introduction into the RCS, coolant with boron concentration less than required to meet SHUTDOWN MARGIN of Technical Specification 3.1.1.2 and within one (1) hour initiate corrective action to return the required shutdown cooling loop to operation. ITS 3.4.8 ACTION B states that with no required SDC loop OPERABLE or required SDC loop not in operation, "immediately" suspend operations that would cause introduction of coolant into the RCS with boron concentration less than required to meet SDM of LCO 3.1.1, and "immediately" initiate action to restore one SDC loop to OPERABLE status and operation. This changes the CTS by adding the requirement to "immediately" suspend operations that would cause introduction of coolant into the RCS with boron concentration less than required to meet SDM of LCO 3.1.1 and to "immediately" initiate corrective action to return the

required shutdown cooling loop to operation. Additionally, this changes the CTS by adding the requirement to restore the loop to OPERABLE status.

This change is acceptable because it provides appropriate actions if one required SDC loop is inoperable, no required SDC loop is OPERABLE, or a required SDC loop is not in operation. Under these conditions immediate action is necessary to ensure unit transients do not occur, and action is immediately taken to restore SDC to OPERABLE status and operation to be able to remove the decay heat generated by the reactor. These actions are required to assure continued safe operation. With coolant added without forced circulation, unmixed coolant could be introduced to the core, however coolant added with boron concentration meeting the minimum SDM maintains acceptable margin to subcritical operation. Action to restore one SDC loop to OPERABLE status and operation is necessary to be able to remove the decay heat generated by the reactor. The immediate Completion Times reflect the importance of maintaining operation for decay heat removal. This change is designated as more restrictive, because it requires immediate action to return the required reactor coolant loop to operation and adds the requirement to restore the loop to OPERABLE status.

M02 ITS SR 3.4.8.2 requires verification that correct breaker alignment and indicated power are available to each required SDC pump. A Note further explains that the Surveillance is not required to be performed until 24 hours after a required pump is not in operation. This Surveillance is not required by the CTS. This changes the CTS by requiring verification of correct breaker alignment and indicated power availability on required SDC pumps that are not in operation.

The purpose of ITS SR 3.4.8.2 is to ensure a standby SDC pump is available to provide RCS cooling should the operating pump fail. This change is acceptable because the verification of proper breaker alignment and power availability ensures that an additional SDC pump can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. This change is designated as more restrictive because it adds a Surveillance Requirement to the CTS.

M03 CTS 3.4.1.4.2 states, in part, that two shutdown cooling loops shall be OPERABLE and at least one shutdown cooling loop shall be in operation. CTS 3.4.1.4.2 is modified by a footnote * that states, in part, that the shutdown cooling pump may be de-energized for up to 1 hour under specified conditions. ITS 3.4.8 Note 1 allows all SDC pumps to be removed from operation “when switching from one loop to another” under specified conditions (i.e., part 1.a and 1.b which are the same as the conditions specified in the CTS) and also requires that no draining operations to further reduce the RCS water volume are permitted (part c). This changes the CTS by adding a restriction that “no draining operations to further reduce the RCS water volume are permitted.” R1 R1

The purpose of the CTS 3.4.1.4.2 Footnote * in MODE 5 with RCS loops not filled is to allow the SDC loops to be removed from operation to allow sufficient time to perform activities required to refill the RCS loops. Specifically, the SDC pumps are removed from service to allow reactor coolant pump operation to remove voids from the steam generator U-tubes. This change is acceptable because ITS LCO 3.4.8 Note 1 provides sufficient time to perform RCS loop refill R1

operations and provides adequate controls. Stopping all operating SDC loops when the RCS is not filled is limited to short periods of time because of the reduced inventory of water available to absorb decay heat. The additional condition that no draining operations be performed during the switching evolution is reasonable given the potential for low RCS water level. This change is more restrictive because it adds an additional restriction. R1

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 - Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.4.1.4.2 states, in part, at least one shutdown cooling loop shall be determined to be in operation and circulating reactor coolant. ITS SR 3.4.8.1 states verify required SDC loop is in operation. This changes the CTS by moving the Surveillance Requirement to verify that the SDC loops are circulating reactor coolant, to the Bases.

The removal of this detail for determining LCO requirements and performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be in the Technical Specifications in order to provide adequate protection of the public health and safety. The ITS retains the requirement that two shutdown cooling (SDC) loops shall be OPERABLE and one SDC loop shall be in operation. Any loop in operation provides enough flow to remove the decay heat from the core with forced circulation. An additional loop is required to be OPERABLE to provide redundancy for heat removal. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.8, RCS LOOPS – MODE 5, LOOPS NOT FILLED

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. ISTS LCO 3.4.8 NOTE 1 allows all shutdown cooling (SDC) pumps to be "removed from operation for ≤ 15 minutes when switching from one train to another." ISTS LCO 3.4.8 is modified consistent with CTS 3.4.1.4.2 allowing the SDC pumps to be removed from operation for ≤ 1 hour. R1

   This change to the ISTS is consistent with the CTS, which allows the SDC pumps to be "de-energized" for up to 1 hour under specific conditions. Maintaining the CTS allowance is necessary to allow sufficient time to perform activities required to refill the RCS loops. Specifically, the SDC pumps are removed from service to allow reactor coolant pump operation to remove voids from the steam generator (SG) U-tubes. Refilling the RCS loops and removing voids from the SG U-tubes provide the added benefit of thermal coupling between the RCS and SGs, which will provide an additional decay heat removal method (i.e., SG cooling). This deviation from the ISTS has also been previously approved for several plants. For example, Arkansas Nuclear One, Unit 1 and Wolf Creek Unit 1 allow the decay heat removal/residual heat removal pumps to be removed from operation for ≤ 1 hour (Refer to ADAMS Accession No. ML053130314 and MO 052720315, respectively), and Palo Verde, Units 1, 2, and 3 allow the SDC pumps to be removed from operation ≤ 1 hour per 8 hour period (Refer to ADAMS Accession No. ML053110045).

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.8 RCS Loops - MODE 5, Loops Not Filled

BASES

BACKGROUND

In MODE 5 with the RCS loops not filled, the primary function of the reactor coolant is the removal of decay heat and transfer of this heat to the shutdown cooling (SDC) heat exchangers. The steam generators (SGs) are not available as a heat sink when the loops are not filled. The secondary function of the reactor coolant is to act as a carrier for the soluble neutron poison, boric acid.

In MODE 5 with loops not filled, only the SDC System can be used for coolant circulation. The number of ~~trains~~ loops in operation can vary to suit the operational needs. The intent of this LCO is to provide forced flow from at least one SDC ~~train~~ loop for decay heat removal and transport and to require that two paths be available to provide redundancy for heat removal. 1 1

APPLICABLE SAFETY ANALYSES

In MODE 5, RCS circulation is considered in determining the time available for mitigation of the accidental boron dilution event. The SDC ~~trains~~ loops provide this circulation. The flow provided by one SDC ~~train~~ loop is adequate for decay heat removal and for boron mixing. 1

RCS loops - MODE 5 (loops not filled) satisfies Criterion 4 of 10 CFR 50.36(c)(2)(ii).

LCO

The purpose of this LCO is to require a minimum of two SDC ~~trains~~ loops be OPERABLE and one of these ~~trains~~ loops be in operation. An OPERABLE ~~train~~ loop is one that is capable of transferring heat from the reactor coolant at a controlled rate. Heat cannot be removed via the SDC System unless forced flow is used. A minimum of one running SDC pump meets the LCO requirement for one ~~train~~ loop in operation. An additional SDC ~~train~~ loop is required to be OPERABLE to meet the single failure criterion. 1 1

Note 1 permits the SDC pumps to be removed from operation for ≤ ~~15 minutes when switching from one train to another~~ 1 hour. The circumstances for stopping both SDC pumps are to be limited to situations when the outage time is short ~~[~~and the core outlet temperature is maintained > 10°F below saturation temperature~~]~~. The Note prohibits boron dilution with coolant at boron concentrations less than required to assure the SDM of LCO 3.1.1 is maintained or draining operations when SDC forced flow is stopped. 4 R1 2

Note 2 allows one SDC ~~train~~ loop to be inoperable for a period of 2 hours provided that the other ~~train~~ loop is OPERABLE and in operation. This permits periodic surveillance tests to be performed on the inoperable ~~train~~ loop during the only time when these tests are safe and possible. 1

BASES

LCO (continued)

loop

An OPERABLE SDC ~~train~~ is composed of an OPERABLE SDC pump capable of providing forced flow to an OPERABLE SDC heat exchanger, along with the appropriate flow and temperature instrumentation for control, protection, and indication. SDC pumps are OPERABLE if they are capable of being powered and are able to provide flow if required. Management of gas voids is important to SDC System OPERABILITY. 1

APPLICABILITY

In MODE 5 with loops not filled, this LCO requires core heat removal and coolant circulation by the SDC System.

Operation in other MODES is covered by:

LCO 3.4.4, "RCS Loops - MODES 1 and 2,"
LCO 3.4.5, "RCS Loops - MODE 3,"
LCO 3.4.6, "RCS Loops - MODE 4,"
LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled,"
LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level" ~~(MODE 6)~~, and 3
LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level" ~~(MODE 6)~~. 3

ACTIONS

A.1

loop

If one required SDC ~~train~~ is inoperable, redundancy for heat removal is lost. Action must be initiated immediately to restore a second ~~train~~ to OPERABLE status. The Completion Time reflects the importance of maintaining the availability of two paths for heat removal. 1

loop

B.1 and B.2

loop

If no required SDC ~~train~~ is OPERABLE or the required ~~train~~ is not in operation, except as provided in Note 1, all operations involving introduction of coolant into the RCS with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 must be suspended. 1

loop

Action to restore one SDC ~~train~~ to OPERABLE status and operation must be initiated immediately. The required margin to criticality must not be reduced in this type of operation. Suspending the introduction of coolant into the RCS of coolant with boron concentration less than required to meet the minimum SDM of LCO 3.1.1 is required to assure continued safe operation. With coolant added without forced circulation, unmixed coolant could be introduced to the core, however coolant added with boron concentration meeting the minimum SDM maintains acceptable margin to subcritical operations. The immediate Completion Time reflects the importance of maintaining operation for decay heat removal.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.8.1

This SR requires verification that the required SDC ~~train~~ is in operation. Verification includes flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing decay heat removal. ~~[The 12 hour Frequency has been shown by operating practice to be sufficient to regularly assess degradation and verify operation is within safety analyses assumptions.~~

loop

1

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

2

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

This SR is modified by a Note that states the SR is not required to be performed until 24 hours after a required pump is not in operation.

SR 3.4.8.3

SDC System piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the SDC ~~trains~~ loops and may also prevent water hammer, pump cavitation, and pumping of noncondensible gas into the reactor vessel. 1

Selection of SDC System locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

The SDC System is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. If accumulated gas is discovered that exceeds the acceptance criteria for the susceptible location (or the volume of accumulated gas at one or more susceptible locations exceeds an acceptance criteria for gas volume at the suction or discharge of a pump), the Surveillance is not met. If the accumulated gas is eliminated or brought within the acceptance criteria limits during performance of the Surveillance, the Surveillance is met and past system OPERABILITY is evaluated under the Corrective Action Program. If it is determined by subsequent evaluation that the SDC System is not rendered inoperable by the accumulated gas (i.e., the system is sufficiently filled with water), the Surveillance may be declared met. Accumulated gas should be eliminated or brought within the acceptance criteria limits.

SDC System locations susceptible to gas accumulation are monitored and, if gas is found, the gas volume is compared to the acceptance criteria for the location. Susceptible locations in the same system flow path which are subject to the same gas intrusion mechanisms may be verified by monitoring a representative sub-set of susceptible locations. Monitoring may not be practical for locations that are inaccessible due to radiological or environmental conditions, the plant configuration, or personnel safety. For these locations alternative methods (e.g., operating

BASES

SURVEILLANCE REQUIREMENTS (continued)

parameters, remote monitoring) may be used to monitor the susceptible location. Monitoring is not required for susceptible locations where the maximum potential accumulated gas void volume has been evaluated and determined to not challenge system OPERABILITY. The accuracy of the method used for monitoring the susceptible locations and trending of the results should be sufficient to assure system OPERABILITY during the Surveillance interval.

~~[The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the SDC System piping and the procedural controls governing system operation.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. The Surveillance Frequency may vary by location susceptible to gas accumulation.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.8 RCS Loops - MODE 5, Loops Not Filled

BASES

BACKGROUND

In MODE 5 with the RCS loops not filled, the primary function of the reactor coolant is the removal of decay heat and transfer of this heat to the shutdown cooling (SDC) heat exchangers. The steam generators (SGs) are not available as a heat sink when the loops are not filled. The secondary function of the reactor coolant is to act as a carrier for the soluble neutron poison, boric acid.

In MODE 5 with loops not filled, only the SDC System can be used for coolant circulation. The number of ~~trains~~ loops in operation can vary to suit the operational needs. The intent of this LCO is to provide forced flow from at least one SDC ~~train~~ loop for decay heat removal and transport and to require that two paths be available to provide redundancy for heat removal. 1 1

APPLICABLE SAFETY ANALYSES

In MODE 5, RCS circulation is considered in determining the time available for mitigation of the accidental boron dilution event. The SDC ~~trains~~ loops provide this circulation. The flow provided by one SDC ~~train~~ loop is adequate for decay heat removal and for boron mixing. 1

RCS loops - MODE 5 (loops not filled) satisfies Criterion 4 of 10 CFR 50.36(c)(2)(ii).

LCO

The purpose of this LCO is to require a minimum of two SDC ~~trains~~ loops be OPERABLE and one of these ~~trains~~ loops be in operation. An OPERABLE ~~train~~ loop is one that is capable of transferring heat from the reactor coolant at a controlled rate. Heat cannot be removed via the SDC System unless forced flow is used. A minimum of one running SDC pump meets the LCO requirement for one ~~train~~ loop in operation. An additional SDC ~~train~~ loop is required to be OPERABLE to meet the single failure criterion. 1 1

Note 1 permits the SDC pumps to be removed from operation for ≤ 1 hour ~~15 minutes when switching from one train to another~~. The circumstances for stopping both SDC pumps are to be limited to situations when the outage time is short ~~[~~and the core outlet temperature is maintained > 10°F below saturation temperature~~]~~. The Note prohibits boron dilution with coolant at boron concentrations less than required to assure the SDM of LCO 3.1.1 is maintained or draining operations when SDC forced flow is stopped. 4 | R1 2

Note 2 allows one SDC ~~train~~ loop to be inoperable for a period of 2 hours provided that the other ~~train~~ loop is OPERABLE and in operation. This permits periodic surveillance tests to be performed on the inoperable ~~train~~ loop during the only time when these tests are safe and possible. 1

BASES

LCO (continued)

loop

An OPERABLE SDC ~~train~~ is composed of an OPERABLE SDC pump capable of providing forced flow to an OPERABLE SDC heat exchanger, along with the appropriate flow and temperature instrumentation for control, protection, and indication. SDC pumps are OPERABLE if they are capable of being powered and are able to provide flow if required. Management of gas voids is important to SDC System OPERABILITY.

1

APPLICABILITY

In MODE 5 with loops not filled, this LCO requires core heat removal and coolant circulation by the SDC System.

Operation in other MODES is covered by:

LA01

DISCUSSION OF CHANGES
ITS 3.4.9, PRESSURIZER

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 1 only:** CTS 3.4.4 states that the pressurizer shall be OPERABLE with a steam bubble. ITS 3.4.9 requires that the pressurizer water level be ≤ 68% to be OPERABLE. This changes the CTS by replacing the generic statement, "…with a steam bubble," with a specific pressurizer water level requirement.

This change is acceptable because when the unit is in MODE 1, 2, or 3, maintaining pressurizer water level ≤ 68% ensures a steam bubble exists. Since the ITS continues to require a steam bubble (i.e., pressurizer water level ≤ 68%) there is no need to require a steam bubble in the pressurizer. The change is designated as administrative because it does not result in a technical change to the CTS but clarifies the maximum level to support a steam bubble.

A03 Unit 1 CTS 4.4.4 states the Surveillance is in accordance with 4.8.1.1.2. Unit 2 CTS 4.4.3.3.a states, in part, that the emergency power supply for the pressurizer heaters shall be demonstrated OPERABLE by verifying that upon an safety injection actuation signal (SIAS) test signal concurrent with a loss of offsite power, the pressurizer heaters are automatically shed from the emergency power sources. Unit 1 CTS 4.8.1.1.2.e.5 and Unit 2 CTS 4.8.1.1.2.e.6 verify that upon an actual or simulated loss of offsite power in conjunction with an SIAS actuation signal, load shedding from the emergency busses occurs. Similarly, ITS SR 3.8.1.17 verifies that upon an actual or simulated loss of offsite power in conjunction with an SIAS actuation signal, load shedding from the emergency busses occurs.

The purpose of Unit 1 CTS 4.4.4 and Unit 2 CTS 4.4.3.3.a is to demonstrate that the pressurizer heaters are automatically shed from the emergency power supplies upon an actual or simulated loss of offsite power in conjunction with an SIAS actuation signal. This requirement is addressed in Unit 1 CTS 4.8.1.1.2.e.5 and Unit 2 CTS 4.8.1.1.2.e.6 Surveillances, and in ITS Unit 1 and Unit 2 SR 3.8.1.17 Surveillances. This change is acceptable because the condition under which the CTS Surveillance applies has not changed. This change is designated as administrative as it results in no technical change to the CTS.

A04 **Unit 2 Only:** CTS 3.4.3 states the LCO requirements for pressurizer water level and pressurizer heater capacity. CTS 3.4.3 Actions a. and b. provide actions for one group of required pressurizer heaters inoperable and two groups of required pressurizer heaters, respectively. ITS 3.4.9 similarly, provides ACTIONS B, C, and D for inoperable group(s) of required pressure heaters. CTS 3.4.3 Action c. states, in part, with the "pressurizer otherwise inoperable" be in at least HOT

STANDBY (i.e., MODE 3) with the reactor trip breakers open within 6 hours and in HOT SHUTDOWN (i.e., MODE 4) within the following 6 hours. Similarly, ITS 3.4.9 ACTION A states that with the pressurizer level not within limit, be in MODE 3 with the reactor trip breakers open within 6 hours and MODE 4 within 12 hours. This changes the CTS to specifically state the reason the pressurizer is inoperable for reasons other than pressurizer heaters.

The purpose of CTS 3.4.3 is to require the pressurizer to be OPERABLE and two conditions of OPERABILITY are supplied. The conditions are pressurizer water level and pressurizer heater OPERABILITY. CTS 3.4.4 Action c. only applies when water level is not within limit. This is the same condition for which ITS 3.4.9 Condition A applies. This change is acceptable because the condition under which CTS 3.4.3 Action c. applies has not changed. This change is designated as administrative as it results in no technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS 3.4.4 only requires the pressurizer to be OPERABLE in MODES 1 and 2. If the pressurizer is inoperable, the CTS Action requires the unit be in at least HOT STANDBY (i.e., MODE 3) with the reactor trip breakers open within 6 hours. ITS 3.4.9 requires the pressurizer to be OPERABLE in MODES 1, 2, and 3. ITS ACTION A requires that if pressurizer water level is not within limits, the unit must be in MODE 3 with reactor trip breakers open within 6 hours and in MODE 4 within 12 hours. ITS ACTION C requires that if the heater capacity is not within limits and is not restored to OPERABLE status within 24 hours, the unit must be in MODE 3 within 6 hours and in MODE 4 within 12 hours. ITS 3.4.9 Required Action A.2 and Required Action C.2 each require the unit be in MODE 4 within 12 hours. This changes the CTS by expanding the Applicability of the Pressurizer to include MODE 3 and requiring the unit to exit this new Applicability within 12 hours when pressurizer water level is not within limits, or when pressurizer heater capacity is not within limits and is not restored to within limits within 24 hours.

The purpose of the ITS MODE 3 Applicability is to prevent solid water RCS operation during heatup and cooldown to avoid rapid pressure rises caused by normal operational perturbation. This change is acceptable because it provides appropriate requirements in MODE 3 to achieve this purpose. This change is designated as more restrictive because it requires the pressurizer and associated heaters to be OPERABLE under more conditions than is currently required.

M02 **Unit 1 only:** CTS 4.4.4 requires testing in accordance with CTS 4.8.1.1.2. ITS proposes additional Surveillances to verify the LCO is met. ITS SR 3.4.9.1 requires verification that the pressurizer water level is ≤ 68% and ITS SR 3.4.9.2 requires verification that the required pressurizer heater capacity is ≥ 150 kW. This changes the CTS by adding additional Surveillances.

This change is necessary to periodically verify pressurizer level is within the required limit to ensure conformance with a safety analysis assumption and to periodically verify the required pressurizer heater group has adequate capability to perform its function. The Frequencies for these SRs will be in accordance with

the Surveillance Frequency Control Program. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per CTS 6.8.4.o. Therefore, SR 3.4.9.1, and SR 3.4.9.2 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial 12 hour Frequency for SR 3.4.9.1, and an initial 18 month Frequency for SR 3.4.9.2, consistent with the ISTS SR 3.4.9.1 and SR 3.4.9.2, respectively.

M03 **Unit 1 only:** CTS 4.4.4 states that Surveillance Requirements are in accordance with 4.8.1.1.2. CTS 4.8.2.1.1 demonstrates the emergency power supplies for the pressurizer heaters are OPERABLE by verifying that on an SIAS test signal concurrent with a loss of offsite power, the pressurizer heaters shed from the emergency power supplies. ITS SR 3.4.9.3 demonstrates that the heaters are capable of being powered from an emergency power supply. This changes the CTS by adding a Surveillance. The Frequency for this SR will be in accordance with the Surveillance Frequency Control Program. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per CTS 6.8.4.o. Therefore, SR 3.4.9.3 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months consistent with the ISTS SR 3.4.9.3.

The purpose of the Surveillance, in part, is to demonstrate that the pressurizer heaters can be manually transferred to and energized by emergency power supplies after reset of the SIAS. ITS SR 3.4.9.3 is added to establish the requirement that the pressurizer heaters be capable of being powered from an emergency power supply, which will also demonstrate that the required pressurizer heater group can be reconnected to its respective bus manually from the control room after resetting the SIAS test signal. This change is designated as a more restrictive because a Surveillance is added to the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 **Unit 2 only:** *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.4.3.3 states, in part, that the emergency power supply for the pressurizer heaters shall be demonstrated OPERABLE by verifying that on an SIAS test signal concurrent with a loss of offsite power, the pressurizer heaters which have been shed from the emergency power supplies, can be reconnected to their respective buses manually from the control room after resetting of the SIAS test signal. ITS SR 3.4.9.3 requires that pressurizer heaters are capable of being powered from an emergency power supply. ITS SR 3.4.9.3 does not contain the detail for pressurizer heaters reconnection to emergency power. This changes the CTS by deleting these procedural details.

The purpose of CTS 4.4.3.3. is to demonstrate that the pressurizer heaters can be manually transferred to and energized by emergency power supplies after

reset of the SIAS. The requirement that the pressurizer heaters be automatically shed from the emergency power sources upon receipt of an SIAS test signal is provided in LCO 3.8.1 Surveillances. ITS SR 3.4.9.3 retains the requirement that the pressurizer heaters are capable of being powered from an emergency power supply. The requirement that the pressurizer heaters can be reconnected to their respective emergency buses manually after reset of the SIAS test signal is relocated to the ITS Bases, which states the Surveillance demonstrates that the heaters can be manually transferred to and energized by emergency power supplies following an actual or simulated loss of offsite power concurrent with an SIAS actuation signal. This change is acceptable because this type of procedural detail will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 **Unit 2 only:** *(Category 1 - Relaxation of LCO Requirements)* CTS 3.4.3 states, in part, that the pressurizer shall be OPERABLE with a minimum water level of ≥ 27% indicated level and a maximum water level of ≤ 68% indicated level. ITS LCO 3.4.9.a states that the pressurizer shall be OPERABLE with pressurizer water level ≤ 68%. This changes the CTS by eliminating the lower water level limit of ≥ 27%.

The purpose of the CTS 3.4.3 lower limit is to preserve the steam space during normal operation, allowing both sprays and heaters to maintain the design operating pressure. The lower level limit prevents the low level interlock from deenergizing the pressurizer heaters during steady state operations. This change is acceptable because the low water level limit is not necessary for accident mitigation and is not a process variable that is an initial condition of a design basis accident or transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier. The pressurizer water level is routinely monitored by operations personnel to ensure a low level in the pressurizer does not occur, similar to other plant parameters not specified in the Technical Specifications. Therefore, the low level limit is not necessary to be included in the Technical Specifications. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than are being applied in the CTS.

L02 **Unit 1 only:** *(Category 3 - Relaxation of Completion Time)* CTS 3.4.4 does not contain separate Actions for the pressurizer water level and the pressurizer heaters. ITS provides separate ACTIONS (A and B) for LCO 3.4.9.a (pressurizer water level) and LCO 3.4.9.b (pressurizer heaters capacity), respectively. ITS 3.4.9 ACTIONS A and B provide compensatory measures when the pressurizer water level > 68% (ACTION A) and when the capacity of the required pressurizer heaters is less than 150 kW (ACTION B). ITS 3.49 ACTION A requires the unit be in MODE 3 with reactor trip breakers open within 6 hours, and in MODE 4 within 12 hours. ITS 3.4.9 ACTION B requires restoration of the pressurizer

heater capability within 24 hours. If the required pressurizer heaters are not restored within 24 hours, ITS 3.4.9 ACTION C requires the unit be in MODE 3 within 6 hours and MODE 4 within 12 hours. This changes the CTS by separating out conditions when the LCO is not met and provides additional time to restore the required pressurizer heaters before a plant shutdown is required.

The purpose of the CTS actions is to provide appropriate remedial actions to ensure continued safe operation until the LCO can be restored. This change is acceptable because the proposed ITS Completion Time to restore the required pressurizer heaters to OPERABLE status has been shown to be acceptable based on the infrequent use of the Required Action and the small incremental effect on plant risk as discussed in WCAP-16125-NP-A, "Justification for Risk-Informed Modifications to Selected Technical Specifications for Conditions Leading to Exigent Plant Shutdown," Revision 2, August 2010. The ITS action is also consistent with the equivalent ISTS condition with no pressurizer heater groups OPERABLE. This change is designated as less restrictive because more time will be allowed to complete a Required Action in the ITS than is allowed in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.9, PRESSURIZER

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.9 Pressurizer

BASES

BACKGROUND

The pressurizer provides a point in the RCS where liquid and vapor are maintained in equilibrium under saturated conditions for pressure control purposes to prevent bulk boiling in the remainder of the RCS. Key functions include maintaining required primary system pressure during steady state operation and limiting the pressure changes caused by reactor coolant thermal expansion and contraction during normal load transients.

The pressure control components addressed by this LCO include the pressurizer water level, the required heaters and their backup heater controls, and emergency power supplies. Pressurizer safety valves and ~~pressurizer~~ power operated relief valves (PORVs) are addressed by LCO 3.4.10, "Pressurizer Safety Valves," and LCO 3.4.11, "~~Pressurizer~~ Power Operated Relief Valve~~s~~ (PORV~~s~~)," respectively.

block valves

Block Valves

1

The maximum water level limit has been established to ensure that a liquid to vapor interface exists to permit RCS pressure control, using the sprays and heaters during normal operation and proper pressure response for anticipated design basis transients. The water level limit serves two purposes:

a. Pressure control during normal operation maintains subcooled reactor coolant in the loops and thus in the preferred state for heat transport and

b. By restricting the level to a maximum, expected transient reactor coolant volume increases (pressurizer insurge) will not cause excessive level changes that could result in degraded ability for pressure control.

The maximum water level limit permits pressure control equipment to function as designed. The limit preserves the steam space during normal operation, thus, both sprays and heaters can operate to maintain the design operating pressure. The level limit also prevents filling the pressurizer (water solid) for anticipated design basis transients, thus ensuring that pressure relief devices (PORVs or pressurizer safety valves) can control pressure by steam relief rather than water relief. If the level limits were exceeded prior to a transient that creates a large pressurizer insurge volume leading to water relief, the maximum RCS pressure might exceed the Safety Limit of 2750 ~~psig~~.

psia

1

1

BASES

BACKGROUND (continued)

The requirement to have ~~two groups~~ of pressurizer heaters ≥ 150 kw capacity ensures that RCS pressure can be maintained. The pressurizer heaters maintain RCS pressure to keep the reactor coolant subcooled. Inability to control RCS pressure during natural circulation flow could result in loss of single phase flow and decreased capability to remove core decay heat. 1

APPLICABLE SAFETY ANALYSES

In MODES 1, 2, and 3, the LCO requirement for a steam bubble is reflected implicitly in the accident analyses. No safety analyses are performed in lower MODES. All analyses performed from a critical reactor condition assume the existence of a steam bubble and saturated conditions in the pressurizer. In making this assumption, the analyses neglect the small fraction of noncondensible gases normally present.

Safety analyses presented in the U FSAR do not take credit for pressurizer heater operation; however, an implicit initial condition assumption of the safety analyses is that the RCS is operating at normal pressure. 1

Although the heaters are not specifically used in accident analysis, the need to maintain subcooling in the long term during loss of offsite power, as indicated in NUREG-0737 (Ref. 1), is the reason for their inclusion. The requirement for emergency power supplies is based on NUREG-0737 (Ref. 1). The intent is to keep the reactor coolant in a subcooled condition with natural circulation at hot, high pressure conditions for an undefined, but extended, time period after a loss of offsite power. While loss of offsite power is a coincident occurrence assumed in the accident analyses, maintaining hot, high pressure conditions over an extended time period is not evaluated in the accident analyses.

The pressurizer satisfies Criterion 2 and Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

~~REVIEWER'S NOTE~~
~~Plants licensed prior to the issuance of NUREG-0737 may not have a requirement on the number of pressurizer groups.~~ 2

The LCO requirement for the pressurizer to be OPERABLE with water level ~~< [60]~~ ≤ 68 % ensures that a steam bubble exists. Limiting the maximum operating water level preserves the steam space for pressure control. The LCO has been established to minimize the consequences of potential overpressure transients. Requiring the presence of a steam bubble is also consistent with analytical assumptions. 2

BASES

LCO (continued)

The LCO requires ~~two groups of~~ OPERABLE pressurizer heaters~~, [each]~~ with a capacity ≥ ~~[~~150~~]~~ kW ~~[~~and capable of being powered from an emergency power supply~~]~~. The minimum heater capacity required is sufficient to maintain the RCS near normal operating pressure when accounting for heat losses through the pressurizer insulation. By maintaining the pressure near the operating conditions, a wide subcooling margin to saturation can be obtained in the loops. The exact design value of ~~[~~150~~]~~ kW is derived from the use of 12 heaters rated at 12.5 kW each. The amount needed to maintain pressure is dependent on the ambient heat losses.

APPLICABILITY

The need for pressure control is most pertinent when core heat can cause the greatest effect on RCS temperature resulting in the greatest effect on pressurizer level and RCS pressure control. Thus, Applicability has been designated for MODES 1 and 2. The Applicability is also provided for MODE 3. The purpose is to prevent solid water RCS operation during heatup and cooldown to avoid rapid pressure rises caused by normal operational perturbation, such as reactor coolant pump startup. ~~The LCO does not apply to MODE 5 (Loops Filled) because LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System," applies. The LCO does not apply to MODES 5 and 6 with partial loop operation.~~

In MODES 1, 2, and 3, there is the need to maintain the availability of pressurizer heaters capable of being powered from an emergency power supply. In the event of a loss of offsite power, the initial conditions of these MODES gives the greatest demand for maintaining the RCS in a hot pressurized condition with loop subcooling for an extended period. For MODE 4, 5, or 6, it is not necessary to control pressure (by heaters) to ensure loop subcooling for heat transfer when the Shutdown Cooling System is in service and therefore the LCO is not applicable.

ACTIONS

A.1 and A.2

With pressurizer water level not within the limit, action must be taken to restore the plant to operation within the bounds of the safety analyses. To achieve this status, the unit must be brought to MODE 3, with the reactor trip breakers open, within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. This takes the plant out of the applicable MODES and restores the plant to operation within the bounds of the safety analyses.

BASES

ACTIONS (continued)

Six hours is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems. Further pressure and temperature reduction to MODE 4 brings the plant to a MODE where the LCO is not applicable. The 12 hour time to reach the nonapplicable MODE is reasonable based on operating experience for that evolution.

~~B.1~~

~~If one required group of pressurizer heaters is inoperable, restoration is required within 72 hours [or in accordance with the Risk Informed Completion Time Program]. The Completion Time of 72 hours is reasonable considering that a demand caused by loss of offsite power would be unlikely in this period. Pressure control may be maintained during this time using normal station powered heaters.~~ 4

B
~~C~~.1
the
If ~~two~~ required ~~groups of~~ pressurizer heaters are inoperable, restoring ~~at least one group of~~ pressurizer heaters to OPERABLE status is required within 24 hours. ~~The Condition is modified by a Note stating it is not applicable if the second group of required pressurized heaters is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one group of required pressurized heaters is inoperable for any reason and the second group of required pressurized heaters is discovered to be inoperable, or if both groups of required pressurized heaters are discovered to be inoperable at the same time.~~ If ~~both~~ required ~~groups of~~ pressurizer heaters are inoperable, the pressurizer heaters may not be available to help maintain subcooling in the RCS loops during a natural circulation cooldown following a loss of offsite power. The inoperability of ~~two groups of~~ required pressurizer heaters during the 24 hour Completion Time has been shown to be acceptable based on the infrequent use of the Required Action and the small incremental effect on plant risk (Ref. 2).

the 4

the

C C
~~D~~.1 and ~~D~~.2
the
If ~~one or more~~ required ~~group of~~ pressurizer heaters ~~is~~ are inoperable and cannot be restored within the allowed Completion Times, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE 3 within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. The Completion Time of 6 hours is

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.9 Pressurizer

BASES

BACKGROUND

The pressurizer provides a point in the RCS where liquid and vapor are maintained in equilibrium under saturated conditions for pressure control purposes to prevent bulk boiling in the remainder of the RCS. Key functions include maintaining required primary system pressure during steady state operation and limiting the pressure changes caused by reactor coolant thermal expansion and contraction during normal load transients.

The pressure control components addressed by this LCO include the pressurizer water level, the required heaters and their backup heater controls, and emergency power supplies. Pressurizer safety valves and ~~pressurizer~~ power operated relief valves (PORVs) are addressed by LCO 3.4.10, "Pressurizer Safety Valves," and LCO 3.4.11, "~~Pressurizer~~ Power Operated Relief Valves (PORV~~s~~)," respectively.

block valves

Block Valves

1

The maximum water level limit has been established to ensure that a liquid to vapor interface exists to permit RCS pressure control, using the sprays and heaters during normal operation and proper pressure response for anticipated design basis transients. The water level limit serves two purposes:

a. Pressure control during normal operation maintains subcooled reactor coolant in the loops and thus in the preferred state for heat transport and

b. By restricting the level to a maximum, expected transient reactor coolant volume increases (pressurizer insurge) will not cause excessive level changes that could result in degraded ability for pressure control.

The maximum water level limit permits pressure control equipment to function as designed. The limit preserves the steam space during normal operation, thus, both sprays and heaters can operate to maintain the design operating pressure. The level limit also prevents filling the pressurizer (water solid) for anticipated design basis transients, thus ensuring that pressure relief devices (PORVs or pressurizer safety valves) can control pressure by steam relief rather than water relief. If the level limits were exceeded prior to a transient that creates a large pressurizer insurge volume leading to water relief, the maximum RCS pressure might exceed the Safety Limit of 2750 ~~psig~~.

psia

1

1

BASES

BACKGROUND (continued)

The requirement to have two groups of pressurizer heaters ensures that RCS pressure can be maintained. The pressurizer heaters maintain RCS pressure to keep the reactor coolant subcooled. Inability to control RCS pressure during natural circulation flow could result in loss of single phase flow and decreased capability to remove core decay heat.

APPLICABLE SAFETY ANALYSES

In MODES 1, 2, and 3, the LCO requirement for a steam bubble is reflected implicitly in the accident analyses. No safety analyses are performed in lower MODES. All analyses performed from a critical reactor condition assume the existence of a steam bubble and saturated conditions in the pressurizer. In making this assumption, the analyses neglect the small fraction of noncondensible gases normally present.

Safety analyses presented in the U FSAR do not take credit for pressurizer heater operation; however, an implicit initial condition assumption of the safety analyses is that the RCS is operating at normal pressure. 1

Although the heaters are not specifically used in accident analysis, the need to maintain subcooling in the long term during loss of offsite power, as indicated in NUREG-0737 (Ref. 1), is the reason for their inclusion. The requirement for emergency power supplies is based on NUREG-0737 (Ref. 1). The intent is to keep the reactor coolant in a subcooled condition with natural circulation at hot, high pressure conditions for an undefined, but extended, time period after a loss of offsite power. While loss of offsite power is a coincident occurrence assumed in the accident analyses, maintaining hot, high pressure conditions over an extended time period is not evaluated in the accident analyses.

The pressurizer satisfies Criterion 2 and Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

~~REVIEWER'S NOTE~~
~~Plants licensed prior to the issuance of NUREG-0737 may not have a requirement on the number of pressurizer groups.~~ 2

The LCO requirement for the pressurizer to be OPERABLE with water level ~~< [60]~~ ≤ 68 % ensures that a steam bubble exists. Limiting the maximum operating water level preserves the steam space for pressure control. The LCO has been established to minimize the consequences of potential overpressure transients. Requiring the presence of a steam bubble is also consistent with analytical assumptions. 2

BASES

LCO (continued)

The LCO requires two groups of OPERABLE pressurizer heaters, ~~[~~each~~]~~ with a capacity ≥ ~~[~~150~~]~~ kW ~~[~~and capable of being powered from an emergency power supply~~]~~. The minimum heater capacity required is sufficient to maintain the RCS near normal operating pressure when accounting for heat losses through the pressurizer insulation. By maintaining the pressure near the operating conditions, a wide subcooling margin to saturation can be obtained in the loops. The exact design value of ~~[~~150~~]~~ kW is derived from the use of ~~12~~ heaters rated at ~~12.5~~ kW each. The amount needed to maintain pressure is dependent on the ambient heat losses.

APPLICABILITY

The need for pressure control is most pertinent when core heat can cause the greatest effect on RCS temperature resulting in the greatest effect on pressurizer level and RCS pressure control. Thus, Applicability has been designated for MODES 1 and 2. The Applicability is also provided for MODE 3. The purpose is to prevent solid water RCS operation during heatup and cooldown to avoid rapid pressure rises caused by normal operational perturbation, such as reactor coolant pump startup. ~~The LCO does not apply to MODE 5 (Loops Filled) because LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System," applies. The LCO does not apply to MODES 5 and 6 with partial loop operation.~~

In MODES 1, 2, and 3, there is the need to maintain the availability of pressurizer heaters capable of being powered from an emergency power supply. In the event of a loss of offsite power, the initial conditions of these MODES gives the greatest demand for maintaining the RCS in a hot pressurized condition with loop subcooling for an extended period. For MODE 4, 5, or 6, it is not necessary to control pressure (by heaters) to ensure loop subcooling for heat transfer when the Shutdown Cooling System is in service and therefore the LCO is not applicable.

ACTIONS

A.1 and A.2

With pressurizer water level not within the limit, action must be taken to restore the plant to operation within the bounds of the safety analyses. To achieve this status, the unit must be brought to MODE 3, with the reactor trip breakers open, within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. This takes the plant out of the applicable MODES and restores the plant to operation within the bounds of the safety analyses.

BASES

ACTIONS (continued)

Six hours is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems. Further pressure and temperature reduction to MODE 4 brings the plant to a MODE where the LCO is not applicable. The 12 hour time to reach the nonapplicable MODE is reasonable based on operating experience for that evolution.

B.1

If one required group of pressurizer heaters is inoperable, restoration is required within 72 hours ~~[or in accordance with the Risk Informed Completion Time Program]~~. The Completion Time of 72 hours is reasonable considering that a demand caused by loss of offsite power would be unlikely in this period. Pressure control may be maintained during this time using normal station powered heaters. 2

C.1

If two required groups of pressurizer heaters are inoperable, restoring at least one group of pressurizer heaters to OPERABLE status is required within 24 hours. The Condition is modified by a Note stating it is not applicable if the second group of required pressurized heaters is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one group of required pressurized heaters is inoperable for any reason and the second group of required pressurized heaters is discovered to be inoperable, or if both groups of required pressurized heaters are discovered to be inoperable at the same time. If both required groups of pressurizer heaters are inoperable, the pressurizer heaters may not be available to help maintain subcooling in the RCS loops during a natural circulation cooldown following a loss of offsite power. The inoperability of two groups of required pressurizer heaters during the 24 hour Completion Time has been shown to be acceptable based on the infrequent use of the Required Action and the small incremental effect on plant risk (Ref. 2).

D.1 and D.2

If one or more required group of pressurizer heaters is inoperable and cannot be restored within the allowed Completion Times, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE 3 within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. The Completion Time of 6 hours is 2

2

1

BASES

ACTIONS (continued)

reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging safety systems. Similarly, the Completion Time of ~~[~~12~~]~~ hours is reasonable, based on operating experience, to reach MODE 4 from full power in an orderly manner and without challenging plant systems. 2

SURVEILLANCE REQUIREMENTS

DISCUSSION OF CHANGES
ITS 3.4.10, PRESSURIZER SAFETY VALVES

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.4.3 and Unit 2 CTS 3.4.2.2 Action a. requires, with one pressurizer safety valve inoperable, either restore the inoperable valve to OPERABLE status within 15 minutes or be in HOT STANDBY (i.e., MODE 3) within 6 hours and in HOT SHUTDOWN (i.e., MODE 4) within the next 6 hours.

ITS 3.4.10 ACTION A states, with one pressurizer safety valve inoperable, the valve must be restored to OPERABLE status within 15 minutes. If this cannot be met, ITS 3.4.10 ACTION B requires the unit to be in MODE 3 in 6 hours and MODE 4 with any RCS cold leg temperature < 281°F (Unit 1) and < 230°F (Unit 2) in 12 hours. This changes the CTS by requiring the unit, in addition to transitioning to MODE 4, to also reduce RCS cold leg temperature < 281°F (Unit 1) and < 230°F (Unit 2) when only one pressurizer safety valve is inoperable and cannot be restored to OPERABLE status.

The purpose of Unit 1 CTS 3.4.3 and Unit 2 CTS 3.4.2.2 actions is to provide requirements on pressurizer safety valves during MODES 1, 2, 3, and MODE 4 with all RCS cold leg temperatures > 281°F (Unit 1) and > 230°F (Unit 2), and if the Required Action cannot be met within the required Completion Time, the plant must be brought to a MODE in which the requirement does not apply. This change is designated as more restrictive as it provides an explicit RCS cold leg temperature that must be met in MODE 4 to exit the MODE of Applicability when one safety valve is inoperable and cannot be restored to OPERABLE status.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 4.4.3 and Unit 2 CTS 4.4.2.2 require verification that each pressurizer code safety valve is OPERABLE with an additional statement that following testing, as left lift settings shall be within ± 1% of 2500 psia. ITS SR 3.4.10.1 provides a similar requirement. However, the design pressure of

2500 psia is moved to the ITS Bases. This changes the CTS by moving the RCS system design pressure from the CTS to the ITS Bases.

The purpose of the Surveillance is to ensure the pressurizer safety valves setpoints are within ± 1% of their setpoint, which corresponds to the RCS system design pressure of 2500 psia. The removal of the system design pressure from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for the pressurizer safety valves to be verified OPERABLE in accordance with the INSERVICE TESTING PROGRM and that following testing, the lift settings shall be within ± 1%. The RCS system design pressure corresponding to the lift setting is described in the Bases. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 **Unit 2 only:** *(Type 3 - Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 3.4.2.2 is modified by a note that states that the pressurizer safety valves lift setting pressure shall correspond to ambient conditions of the valve at nominal operating temperature and pressure. This information is not provided in ITS 3.4.10. This changes the CTS by moving this information to the Bases.

The removal of these details for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 3.4.10 still retains a requirement for the pressurizer safety valves to be OPERABLE. Under the definition of OPERABILITY, the pressurizer safety valves must be capable of lifting at the assumed conditions, which includes the ambient operating conditions of the pressurizer safety valves themselves. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being moved from the Technical Specifications to the ITS Bases.

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* Unit 1 CTS 3.4.3 and Unit 2 CTS 3.4.2.2, in part, provide requirements for the pressurizer code safety valves. ITS LCO 3.4.10 Applicability is modified by a Note that allows the lift settings to not be within the LCO limits during MODES 3 and 4 for the purpose of (in-situ) setting of the pressurizer safety valves under ambient (hot) conditions. The exception is allowed for 54 hours following entry into MODE 3 provided a

preliminary cold setting was made prior to heatup. This changes the CTS by allowing entry into MODES 3 and 4 without verifying that the pressurizer code safety valve lift settings are within the LCO limits.

The purpose of the Applicability Note is to allow entry into MODE 3 to perform testing and examination of the safety valves at high pressure and temperature near their normal operating range, but only after the valves have had a preliminary cold setting. This change is acceptable because the requirements continue to ensure that the components are maintained in the MODES and other specified conditions assumed in the safety analyses and licensing basis. The cold lift settings give assurance that the valves are OPERABLE near their design condition during the short period of time allowed to verify the settings at the hot condition. While PSL does not set pressurizer safety valves while installed at this time, this Applicability Note provides the flexibility to utilize this method in the future. This change is designated as less restrictive because the LCO requirements are applicable in fewer operating conditions than in the CTS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.10 Pressurizer Safety Valves

BASES

BACKGROUND

three The purpose of the ~~two~~ spring loaded pressurizer safety valves is to provide RCS overpressure protection. Operating in conjunction with the

three Reactor Protection System, ~~two~~ valves are used to ensure that the Safety Limit (SL) of 2750 psia is not exceeded for analyzed transients during

Three operation in MODES 1 and 2. ~~Two~~ safety valves are used for MODE 3 and portions of MODE 4. For the remainder of MODE 4, MODE 5, and MODE 6 with the head on, overpressure protection is provided by operating procedures and the LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System." 1

The self actuated pressurizer safety valves are designed in accordance with the requirements set forth in the ASME, Boiler and Pressure Vessel Code, Section III (Ref. 1). The required lift pressure is 2500 psia ± 1%. The safety valves discharge steam from the pressurizer to a quench tank located in the containment. The discharge flow is indicated by an increase in temperature downstream of the safety valves and by an increase in the quench tank temperature and level.

The upper and lower pressure limits are based on the ± 1%-tolerance requirement (Ref. 1) for lifting pressures above 1000 psig. The lift setting is for the ambient conditions associated with MODES 1, 2, and 3. This requires either that the valves be set hot or that a correlation between hot and cold settings be established.

The pressurizer safety valves are part of the primary success path and mitigate the effects of postulated accidents. OPERABILITY of the safety valves ensures that the RCS pressure will be limited to 110% of design pressure. The consequences of exceeding the ASME pressure limit (Ref. 1) could include damage to RCS components, increased leakage, or a requirement to perform additional stress analyses prior to resumption of reactor operation.

APPLICABLE SAFETY ANALYSES

U All accident analyses in the FSAR that require safety valve actuation

three assume operation of ~~both~~ pressurizer safety valves to limit increasing reactor coolant pressure. The overpressure protection analysis is also

all based on operation of ~~both~~ safety valves and assumes that the valves open at the high range of the setting (2500-psia system design pressure plus 1%). These valves must accommodate pressurizer insurges that 1 1 1

BASES

APPLICABLE SAFETY ANALYSES (continued)

could occur during a startup, rod withdrawal, ejected rod, loss of main feedwater, or main feedwater line break accident. The startup accident establishes the minimum safety valve capacity. The startup accident is assumed to occur at < 15% power. Single failure of a safety valve is neither assumed in the accident analysis nor required to be addressed by the ASME Code. Compliance with this specification is required to ensure that the accident analysis and design basis calculations remain valid.

The pressurizer safety valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

three

The ~~[two]~~ pressurizer safety valves are set to open at the RCS design pressure (2500 psia) and within the ASME specified tolerance to avoid exceeding the maximum RCS design pressure SL, to maintain accident analysis assumptions, and to comply with ASME Code requirements. The upper and lower pressure tolerance limits are based on the ± 1% tolerance requirements (Ref. 1) for lifting pressures above 1000 psig. The limit protected by this specification is the reactor coolant pressure boundary (RCPB) SL of 110% of design pressure. Inoperability of one or

more

~~both~~ valves could result in exceeding the SL if a transient were to occur. The consequences of exceeding the ASME pressure limit could include damage to one or more RCS components, increased leakage, or additional stress analysis being required prior to resumption of reactor operation.

APPLICABILITY

In MODES 1, 2, and 3, and portions of MODE 4 above ~~the LTOP~~ ~~temperature~~, OPERABILITY of ~~[two]~~ valves is required because the combined capacity is required to keep reactor coolant pressure below 110% of its design value during certain accidents. MODE 3 and portions of MODE 4 are conservatively included, although the listed accidents may not require ~~both~~ safety valves for protection.

281°F

three

three

The LCO is not applicable in MODE 4 when any RCS cold leg temperature is ~~less than or equal to the LTOP enable temperature specified in the PTLR and~~ MODE 5 because LTOP protection is provided. ~~Overpressure protection is not required in MODE 6 with the reactor vessel head detensioned.~~

≤ 281°F,

, and MODE 6 when the reactor vessel head is on

The Note allows entry into MODES 3 and 4 with the lift settings outside the LCO limits. This permits testing and examination of the safety valves at high pressure and temperature near their normal operating range, but only after the valves have had a preliminary cold setting. The cold setting gives assurance that the valves are OPERABLE near their design condition. Only one valve at a time will be removed from service for testing. The ~~[36]~~ hour exception is based on 18 hour outage time for each of the ~~two~~ valves. The 18 hour period is derived from operating experience that hot testing can be performed within this timeframe.

54

BASES

ACTIONS

A.1

With one pressurizer safety valve inoperable, restoration must take place within 15 minutes. The Completion Time of 15 minutes reflects the importance of maintaining the RCS overpressure protection system. An inoperable safety valve coincident with an RCS overpressure event could challenge the integrity of the RCPB.

B.1 and B.2

If the Required Action cannot be met within the required Completion Time or if two or more pressurizer safety valves are inoperable, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 with any RCS cold leg temperature ~~less than or equal to the LTOP enable temperature specified in the PTLR~~ within ~~[24~~] hours. The 6 hours allowed is reasonable, based on operating experience, to reach MODE 3 from full power without challenging plant systems. Similarly, the ~~[24]~~ hours allowed is reasonable, based on operating experience, to reach MODE 4 without challenging plant systems. With any RCS cold leg temperature ~~less than or equal to the LTOP enable temperature specified in the PTLR~~, overpressure protection is provided by LTOP. The change from MODE 1, 2, or 3 to MODE 4 reduces the RCS energy (core power and pressure), lowers the potential for large pressurizer insurges, and thereby removes the need for overpressure protection by ~~[two]~~ pressurizer safety valves.

2

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.10 Pressurizer Safety Valves

BASES

BACKGROUND

three The purpose of the ~~two~~ spring loaded pressurizer safety valves is to provide RCS overpressure protection. Operating in conjunction with the three Reactor Protection System, ~~two~~ valves are used to ensure that the Safety Limit (SL) of 2750 psia is not exceeded for analyzed transients during Three operation in MODES 1 and 2. ~~Two~~ safety valves are used for MODE 3 and portions of MODE 4. For the remainder of MODE 4, MODE 5, and MODE 6 with the head on, overpressure protection is provided by operating procedures and the LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System." 1

The self actuated pressurizer safety valves are designed in accordance with the requirements set forth in the ASME, Boiler and Pressure Vessel Code, Section III (Ref. 1). The required lift pressure is 2500 psia ± 1%. The safety valves discharge steam from the pressurizer to a quench tank located in the containment. The discharge flow is indicated by an increase in temperature downstream of the safety valves and by an increase in the quench tank temperature and level.

The upper and lower pressure limits are based on the ± 1%-tolerance requirement (Ref. 1) for lifting pressures above 1000 psig. The lift setting is for the ambient conditions associated with MODES 1, 2, and 3. This requires either that the valves be set hot or that a correlation between hot and cold settings be established.

The pressurizer safety valves are part of the primary success path and mitigate the effects of postulated accidents. OPERABILITY of the safety valves ensures that the RCS pressure will be limited to 110% of design pressure. The consequences of exceeding the ASME pressure limit (Ref. 1) could include damage to RCS components, increased leakage, or a requirement to perform additional stress analyses prior to resumption of reactor operation.

APPLICABLE SAFETY ANALYSES

U All accident analyses in the FSAR that require safety valve actuation three assume operation of ~~both~~ pressurizer safety valves to limit increasing reactor coolant pressure. The overpressure protection analysis is also all based on operation of ~~both~~ safety valves and assumes that the valves open at the high range of the setting (2500-psia system design pressure plus 1%). These valves must accommodate pressurizer insurges that 1 1 1

BASES

APPLICABLE SAFETY ANALYSES (continued)

could occur during a startup, rod withdrawal, ejected rod, loss of main feedwater, or main feedwater line break accident. The startup accident establishes the minimum safety valve capacity. The startup accident is assumed to occur at < 15% power. Single failure of a safety valve is neither assumed in the accident analysis nor required to be addressed by the ASME Code. Compliance with this specification is required to ensure that the accident analysis and design basis calculations remain valid.

The pressurizer safety valves satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

three

The ~~[two]~~ pressurizer safety valves are set to open at the RCS design pressure (2500 psia) and within the ASME specified tolerance to avoid exceeding the maximum RCS design pressure SL, to maintain accident analysis assumptions, and to comply with ASME Code requirements. The upper and lower pressure tolerance limits are based on the ± 1% tolerance requirements (Ref. 1) for lifting pressures above 1000 psig. The limit protected by this specification is the reactor coolant pressure boundary (RCPB) SL of 110% of design pressure. Inoperability of one or more ~~both~~ valves could result in exceeding the SL if a transient were to occur. The consequences of exceeding the ASME pressure limit could include damage to one or more RCS components, increased leakage, or additional stress analysis being required prior to resumption of reactor operation.

2

1

APPLICABILITY

In MODES 1, 2, and 3, and portions of MODE 4 above ~~the LTOP temperature~~ 230°F, OPERABILITY of three ~~[two]~~ valves is required because the combined capacity is required to keep reactor coolant pressure below 110% of its design value during certain accidents. MODE 3 and portions of MODE 4 are conservatively included, although the listed accidents may not require three ~~both~~ safety valves for protection.

1

2

1

The LCO is not applicable in MODE 4 when any RCS cold leg temperature is ≤ 230°F, ~~less than or equal to the LTOP enable temperature specified in the PTLR and~~ MODE 5 because LTOP protection is provided. ~~Overpressure protection is not required in MODE 6 with the reactor vessel head detensioned.~~ , and MODE 6 when the reactor vessel head is on

1

The Note allows entry into MODES 3 and 4 with the lift settings outside the LCO limits. This permits testing and examination of the safety valves at high pressure and temperature near their normal operating range, but only after the valves have had a preliminary cold setting. The cold setting gives assurance that the valves are OPERABLE near their design condition. Only one valve at a time will be removed from service for testing. The 54 ~~[36]~~ hour exception is based on 18 hour outage time for each of the ~~two~~ valves. The 18 hour period is derived from operating experience that hot testing can be performed within this timeframe.

DISCUSSION OF CHANGES
ITS 3.4.11, POWER OPERATED RELIEF VALVE (PORV) BLOCK VALVES

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.4.12 Action and Unit 2 CTS 3.4.4 Action a. state that with one or more block valve(s) inoperable, within 1 hour or in accordance with the Risk Informed Completion Time Program either restore the block valve(s) to OPERABLE status or close the block valve(s) and remove power from the block valve(s); otherwise, be in at least HOT STANDBY (i.e., MODE 3) within the next 6 hours and in COLD SHUTDOWN (i.e., MODE 5) within the following 30 hours. ITS 3.4.11 ACTION A states that with one or more PORV block valves inoperable, close the PORV block valve and remove power from the PORV block valve within 1 hour or in accordance with the Risk Informed Completion Time Program, otherwise ITS 3.4.11 ACTION B requires the unit be in MODE 3 within 6 hours and MODE 4 within 12 hours. This changes the CTS by changing the requirement to be in COLD SHUTDOWN (i.e., MODE 5) within 36 hours, to be in MODE 4 in 12 hours.

The purpose of Unit 1 CTS 3.4.12 Action and Unit 2 CTS 3.4.4 Action a. is to provide the appropriate compensatory actions for one or more inoperable PORV block valves inoperable. However, if the Required Action and Completion Time are not met, the current action places the unit in MODE 5 within 36 hours, rather than placing the unit outside the MODE of Applicability (i.e., MODE 4) if the Required Action and Completion Time are not met. Therefore, in accordance with CTS 3.0.2 (ITS LCO 3.0.2) when the unit is in MODE 4, the requirements to be in MODE 5 in Unit 1 CTS 3.4.12 Action and Unit 2 CTS 3.4.4 Action a. are no longer required to be completed. The PORV block valves, when in MODE 4, are no longer required to be OPERABLE. Additionally, the Completion Time to exit the MODE of Applicability is reduced to 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

These changes are designated as administrative changes and are acceptable because they maintain the current requirement to place the unit in a condition in which the PORV block valves are no longer required consistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2) and, therefore, do not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

None

DISCUSSION OF CHANGES
ITS 3.4.11, POWER OPERATED RELIEF VALVE (PORV) BLOCK VALVES

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.4.12 Action and Unit 2 CTS 3.4.4 Action a. describe the Actions to be taken when PORV block valve(s) are inoperable. ITS 3.4.11 also describes Actions to be taken when PORV block valve(s) are inoperable and contains a statement (ITS 3.4.11 ACTION Note 1) that separate condition entry is allowed for each PORV block valve. This changes the CTS by adding a Note stating that separate condition entry is allowed for each PORV block valve.

The purpose of the Unit 1 CTS 3.4.12 and Unit 2 CTS 3.4.4 Actions are to provide the appropriate compensatory actions for inoperable PORV block valves. This proposed change will allow separate condition entry for each PORV block valve. The Note clarifies that PORV block valves are treated as separate entities, each with separate Completion Times. These changes are acceptable since the proposed Required Actions provide sufficient time to satisfy the Required Actions. Valve inoperabilities are normally found one at a time, not concurrently. Therefore, the actions to close a PORV block valve and remove its power will apply as each valve is found to be inoperable and not at the same time. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 **Unit 1 Only:** *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.4.12 states, in part, that each PORV block valve be demonstrated OPERABLE by operating the valve through one complete cycle of full travel. ITS SR 3.4.11.1 states, in part, that each PORV block valve be demonstrated OPERABLE by performing a complete cycle of each PORV block valve. It is modified by Note 1 that states "Not required to be performed with block valve closed in accordance with the Required Actions of this LCO." This changes the CTS by not requiring the Surveillance Requirement to be performed with the block valve closed in accordance with the Actions.

The purpose of CTS 4.4.12 is to ensure that the PORV block valve is ready to operate. This change is acceptable because the new Surveillance Frequency has been evaluated to ensure that it provides an acceptable level of equipment reliability. The Note provides time to perform the Surveillance to verify the PORV block valve can operate through a complete cycle. Without the Note, the Surveillance would not be met immediately after closing and removing power from the PORV block valve. This change is designated as less restrictive

because Surveillances will be performed less frequently under the ITS than under the CTS.

L03 *(Category 7 – Relaxation of Surveillance Frequency)* Unit 1 CTS 4.4.12 and Unit 2 CTS 4.4.4 state, in part, that each PORV block valve be demonstrated OPERABLE by operating the valve through one complete cycle of full travel. ITS SR 3.4.11.1 states, in part, that each PORV block valve be demonstrated OPERABLE by performing a complete cycle of each PORV block valve. It is modified by Note 2 that states "Only required to be performed in MODES 1 and 2." This changes the CTS by not requiring the Surveillance Requirement to be performed in certain MODES.

The purpose of Unit 1 CTS 4.4.12 and Unit 2 CTS 4.4.4 is to perform the complete cycle of each PORV block valve in accordance with the Surveillance Frequency Control Program. This change is acceptable because the new Surveillance Frequency has been evaluated to ensure that it provides an acceptable level of equipment reliability. The ITS SR 3.4.11.1 Note 2 states that the PORV block valve Surveillance is only required to be performed in MODES 1 and 2. Note 2 modifies this SR to allow entry into and operation in MODE 3 prior to performing the SR. This allows the test to be performed in MODE 3 under operating temperature and pressure conditions, prior to entering MODE 1 or 2. This change is designated as less restrictive because Surveillances will be performed less frequently under the ITS than under the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.11, POWER OPERATED RELIEF VALVE (PORV) BLOCK VALVES

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.11 ~~Pressurizer~~ Power Operated Relief Valve~~s~~ (PORV~~s~~)

Block Valves

BASES

BACKGROUND

The pressurizer is equipped with two types of devices for pressure relief: pressurizer safety valves and PORVs. The PORV is ~~an air-operated valve that is~~ automatically opened at a specific set pressure when the pressurizer pressure increases and is automatically closed on decreasing pressure. ~~The PORV may also be manually operated using controls installed in the control room.~~

An electric, motor operated, normally open, block valve is installed between the pressurizer and the PORV. The function of the block valve is to isolate the PORV. Block valve closure is accomplished manually using controls in the control room ~~and may be used to isolate a leaking PORV to permit continued power operation~~. Most importantly, the block ~~valve is~~ used to isolate ~~a stuck open PORV to isolate the resulting small break loss of coolant accident (LOCA)~~. Closure terminates the RCS depressurization and coolant inventory loss.

valves are

an inadvertent opening of one or both PORVs.

The ~~PORV and its~~ block valve controls are powered from normal power supplies. Their controls are also capable of being powered from emergency supplies. ~~Power supplies for the PORV are separate from those for the block valve.~~ Power supply requirements are defined in NUREG-0737, Paragraph II, G.1 (Ref. 1).

~~The PORV setpoint is above the high pressure reactor trip setpoint and below the opening setpoint for the pressurizer safety valves as required by Reference 2. The purpose of the relationship of these setpoints is to limit the number of transient pressure increase challenges that might open the PORV, which, if opened, could fail in the open position. The PORV setpoint thus limits the frequency of challenges from transients and limits the possibility of a small break LOCA from a failed open PORV. Placing the setpoint below the pressurizer safety valve opening setpoint reduces the frequency of challenges to the safety valves, which, unlike the PORV, cannot be isolated if they were to fail to open.~~

The primary purpose of this LCO is to ensure that the PORV ~~and the~~ block valve~~s~~ are operating correctly so the ~~potential for a small break LOCA through the PORV pathway is minimized, or if a small break LOCA were to occur through a failed open PORV, the~~ block valve could be manually operated to isolate the ~~path~~.

s

pathway from an inadvertent opening of one or both PORVs. The PORV block valves are maintained open during power operation to ensure the PORV function is available.

BASES

BACKGROUND (continued)

~~The PORV may be manually operated to depressurize the RCS as deemed necessary by the operator in response to normal or abnormal transients. The PORV may be used for depressurization when the pressurizer spray is not available, a condition that may be encountered during loss of offsite power. Operators can manually open the PORVs to reduce RCS pressure in the event of a steam generator tube rupture (SGTR) with offsite power unavailable.~~ 3

~~The PORV may also be used for feed and bleed core cooling in the case of multiple equipment failure events that are not within the design basis, such as a total loss of feedwater.~~ 3

The PORV functions as an automatic overpressure device and limits challenges to the safety valves. Although the PORV acts as an overpressure device for operational purposes, safety analyses ~~[~~do not take credit for PORV actuation~~, but] do take credit for the safety valves~~. 2

The PORV also provides low temperature overpressure protection (LTOP) during heatup and cooldown. LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System," addresses this function.

APPLICABLE SAFETY ANALYSES

Insert 1

~~The PORV small break LOCA break size is bounded by the spectrum of piping breaks analyzed for plant licensing. Because the PORV small break LOCA is located at the top of the pressurizer, the RCS response characteristics are different from RCS loop piping breaks; analyses have been performed to investigate these characteristics.~~ 1

~~The possibility of a small break LOCA through the PORV is reduced when the PORV flow path is OPERABLE and the PORV opening setpoint is established to be reasonably remote from expected transient challenges. The possibility is minimized if the flow path is isolated.~~

~~The PORV opening setpoint has been established in accordance with Reference 2. It has been set so expected RCS pressure increases from anticipated transients will not challenge the PORV, minimizing the possibility of small break LOCA through the PORV.~~

~~Overpressure protection is provided by safety valves, and analyses do not take credit for the PORV opening for accident mitigation.~~

block valves

~~Pressurizer~~ PORV~~s~~ satisfy Criterion ~~3~~ 4 of 10 CFR 50.36(c)(2)(ii). 1

1

INSERT 1

The PORV block valves are not credited to mitigate any design basis accident or transient specified in Reference 2. NRC Regulatory Issue Summary 2005-29 (Ref. 3) describes limiting the probability of initiating a more safety significant event as a result of an anticipated transient. The inadvertent PORV opening is an anticipated operational occurrence (AOO) and could result in a pressurizer overfill condition. Such a condition could lead to an inability to isolate the PORV, resulting in a condition similar to a small break LOCA.

An accidental depressurization of the RCS could occur as a result of an inadvertent opening of both pressurizer PORVs. Initially the event results in a loss of RCS fluid and a rapid RCS depressurization. The challenge to the specified acceptable fuel design limits is terminated by the thermal margin / low pressure reactor trip signal, however, the RCS fluid loss and depressurization continue. Safety injection is actuated, and the pressurizer level increases with the potential to result in pressurizer overfill and liquid discharge through the stuck open PORV(s). The minimum time from event initiation to the pressurizer dome becoming liquid filled is 7 minutes. To prevent liquid discharge through the open PORV(s), the operator closes the associated open PORV block valve(s) within 7 minutes prior to the pressurizer dome becoming liquid filled.

1

BASES to terminate a pressurizer overfill event following an inadvertent PORV opening. An OPERABLE block valve may be either closed and energized or open and energized.

LCO

The LCO requires the PORV ~~and its associated~~ block valve to be OPERABLE. The block valve is required to be OPERABLE so it may be used to isolate the flow path ~~if the PORV is not OPERABLE~~.

1

~~Valve OPERABILITY also means the PORV setpoint is correct. By ensuring that the PORV opening setpoint is correct, the PORV is not subject to frequent challenges from possible pressure increase transients, and therefore the possibility of a small break LOCA through a failed open PORV is not a frequent event.~~

3

APPLICABILITY

In MODES 1, 2, and 3, the PORV ~~and its~~ block valve~~s~~ are required to be OPERABLE to limit the potential for a small break LOCA through the flow path. A likely cause for PORV small break LOCA is a result of pressure increase transients that cause the PORV to open. Imbalances in the energy output of the core and heat removal by the secondary system can cause the RCS pressure to increase to the PORV opening setpoint. Pressure increase transients can occur any time the steam generators are used for heat removal. The most rapid increases will occur at higher operating power and pressure conditions of MODES 1 and 2.

1

Pressure increases are less prominent in MODE 3 because the core input energy is reduced, but the RCS pressure is high. Therefore, this LCO is applicable in MODES 1, 2, and 3. The LCO is not applicable in MODE 4 when both pressure and core energy are decreased and the pressure surges become much less significant. The PORV setpoint is reduced for LTOP in MODES 4, 5, and 6 with the reactor vessel head in place. LCO 3.4.12 addresses the PORV requirements in these MODES.

ACTIONS

The ACTIONS are modified by a Note. The Note clarifies that ~~all~~ ~~pressurizer~~ PORV~~s and~~ block valves are treated as separate entities, each with separate Completion Times (i.e., the Completion Time is on a component basis).

1

~~A.1~~

~~With the PORV inoperable and capable of being manually cycled, either the PORV must be restored or the flow path isolated within 1 hour. The block valve should be closed but power must be maintained to the associated block valve, since removal of power would render the block valve inoperable. Although the PORV may be designated inoperable, it may be able to be manually opened and closed and in this manner can be used to perform its function. PORV inoperability may be due to seat leakage, instrumentation problems, automatic control problems, or other causes that do not prevent manual use and do not create a possibility for~~

3

1

BASES

ACTIONS (continued)

~~a small break LOCA. For these reasons, the block valve may be closed but the Action requires power be maintained to the valve. This Condition is only intended to permit operation of the plant for a limited period of time not to exceed the next refueling outage (MODE 6) so that maintenance can be performed on the PORVs to eliminate the problem condition. The PORVs should normally be available for automatic mitigation of overpressure events and should be returned to OPERABLE status prior to entering startup (MODE 2).~~

~~Quick access to the PORV for pressure control can be made when power remains on the closed block valve. The Completion Time of 1 hour is based on plant operating experience that minor problems can be corrected or closure can be accomplished in this time period.~~

~~B.1, B.2, and B.3~~

~~If one PORV is inoperable and not capable of being manually cycled, it must either be isolated, by closing the associated block valve and removing the power from the block valve, or restored to OPERABLE status. The Completion Time of 1 hour is reasonable, based on challenges to the PORVs during this time period, and provides the operator adequate time to correct the situation. If the inoperable valve cannot be restored to OPERABLE status, it must be isolated within the specified time of 1 hour. Because there is at least one PORV that remains OPERABLE, an additional 72 hours is provided to restore the inoperable PORV to OPERABLE status. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~

A A

~~C~~.1 and ~~C~~.2

or more PORV | s are | it must be closed with power removed

If one block valve ~~is~~ inoperable, ~~then~~ it must be restored to OPERABLE status, or ~~the associated PORV placed in manual control~~. The prime importance for the capability to close the block valve is to isolate a stuck open PORV. Therefore, if the block valve cannot be restored to OPERABLE status within 1 hour, the Required Action is to place the PORV ~~in manual control to preclude its automatic opening for an overpressure event and to avoid the potential for a stuck open PORV at a time that the block valve is inoperable~~. The Completion Times of 1 hour are reasonable based on the small potential for challenges to the system during this time period and provide the operator time to correct the situation. ~~Because at least one PORV remains OPERABLE, the operator~~

or in accordance with the Risk Informed Completion Time Program

block valve in the closed position with power removed

BASES

ACTIONS (continued)

~~is permitted a Completion Time of 72 hours to restore the inoperable block valve to OPERABLE status.~~ [Alternatively, ~~a~~ Completion Time can be determined in accordance with the Risk Informed Completion Time Program.] ~~The time allowed to restore the block valve is based upon the Completion Time for restoring an inoperable PORV in Condition B since the PORVs are not capable of automatically mitigating an overpressure event when placed in manual control. If the block valve is restored within the Completion Time of 72 hours, the power will be restored and the PORV restored to OPERABLE status.~~

~~D~~.1 and ~~D~~.2

If the Required Action cannot be met within the associated Completion Time, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

~~E.1, E.2, E.3, and E.4~~

~~If two PORVs are inoperable and not capable of being manually cycled, it is necessary to isolate the flow path by closing and removing the power to the associated block valves within 1 hour and restore at least one PORV within 8 hours. The Condition is modified by a Note stating it is not applicable if the second PORV train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is applicable if one PORV is inoperable for any reason and the second PORV is discovered to be inoperable, or if both PORVs are discovered to be inoperable at the same time.~~

~~In the event of a loss of feedwater, the PORVs would be used to remove core heat. In order to minimize the consequences of a loss of feedwater while two PORVs are inoperable, Required Action E.3 requires that LCO 3.7.5, "Auxiliary Feedwater System," be met to ensure AFW is available. The inoperability of two PORVs during the 8 hour Completion Time has been shown to be acceptable based on the infrequent use of the Required Action and the small incremental effect on plant risk (Ref. 3). If one PORV is restored and one PORV remains inoperable, then the plant will be in Condition B with the time clock started at the original declaration of having two PORVs inoperable.~~

BASES

ACTIONS (continued)

~~F.1 and F.2~~

~~If two PORVs are inoperable and are not capable of being manually cycled and are not restored within the Completion Time, then the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems. Similarly, the Completion Time of 12 hours to reach MODE 4 is reasonable, considering that a plant can cool down within that time frame on one safety system train. In MODES 4 and 5, maintaining PORV OPERABILITY may be required. See LCO 3.4.12.~~

~~G.1 and G.2~~

~~If two block valves are inoperable, it is necessary to restore at least one block valve to OPERABLE status within 8 hours. The Condition is modified by a Note stating it is not applicable if the second block valve is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one block valve is inoperable for any reason and the second block valve is discovered to be inoperable, or if both block valves are discovered to be inoperable at the same time. In the event of a loss of feedwater, the PORVs would be used to remove core heat. In order to minimize the consequences of a loss of feedwater while two block valves are inoperable, Required Action G.2 requires that LCO 3.7.5, "Auxiliary Feedwater System," be verified to be met within 1 hour. The inoperability of two block valves during the 8 hour Completion Time has been shown to be acceptable based on the infrequent use of the Required Actions and the small incremental effect on plant risk (Ref. 3).~~

3

~~H.1 and H.2~~

~~If the Required Actions and associated Completion Times of Condition F or G are not met, then the plant must be brought to a MODE in which the LCO does not apply. The plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3~~

BASES

ACTIONS (continued)

~~from full power in an orderly manner and without challenging safety systems. Similarly, the Completion Time of 12 hours to reach MODE 4 is reasonable considering that a plant can cool down within that time frame on one safety system train. In MODES 4 and 5, maintaining PORV OPERABILITY may be required. See LCO 3.4.12.~~

SURVEILLANCE REQUIREMENTS

SR 3.4.11.1

PORV

Block valve cycling verifies that it can be closed if necessary. ~~[The basis for the Frequency of [92 days] is the ASME Code (Ref. 4).~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

This SR is modified by two Notes. Note 1 modifies this SR by stating that this SR is not required to be performed with the block valve closed in accordance with the Required Actions of this LCO. ~~Opening the block valve in this condition increases the risk of an unisolable leak from the RCS since the PORV is already inoperable.~~ Note 2 modifies this SR to allow entry into and operation in MODE 3 prior to performing the SR. This allows the test to be performed in MODE 3 under operating temperature and pressure conditions, prior to entering MODE 1 or 2. ~~[In accordance with Reference 5, administrative controls require this test be performed in MODE 3 or 4 to adequately simulate operating temperature and pressure effects on PORV operation.]~~

~~SR 3.4.11.2~~

~~SR 3.4.11.2 requires complete cycling of each PORV. PORV cycling demonstrates its function. [The Frequency of [18] months is based on a typical refueling cycle and industry accepted practice.~~

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.11 ~~Pressurizer~~ Power Operated Relief Valve~~s~~ (PORV~~s~~) Block Valves 1

BASES

BACKGROUND

The pressurizer is equipped with two types of devices for pressure relief: pressurizer safety valves and PORVs. The PORV is ~~an air-operated valve that is~~ automatically opened at a specific set pressure when the pressurizer pressure increases and is automatically closed on decreasing pressure. ~~The PORV may also be manually operated using controls installed in the control room.~~ 1 3

An electric, motor operated, normally open, block valve is installed between the pressurizer and the PORV. The function of the block valve is to isolate the PORV. Block valve closure is accomplished manually using controls in the control room ~~and may be used to isolate a leaking PORV to permit continued power operation~~. Most importantly, the block ~~valve is~~ used to isolate ~~a stuck open PORV to isolate the resulting small break loss of coolant accident (LOCA)~~. Closure terminates the RCS depressurization and coolant inventory loss. 1

valves are

an inadvertent opening of one or both PORVs.

The ~~PORV and its~~ block valve controls are powered from normal power supplies. Their controls are also capable of being powered from emergency supplies. ~~Power supplies for the PORV are separate from those for the block valve.~~ Power supply requirements are defined in NUREG-0737, Paragraph II, G.1 (Ref. 1). 1

~~The PORV setpoint is above the high pressure reactor trip setpoint and below the opening setpoint for the pressurizer safety valves as required by Reference 2. The purpose of the relationship of these setpoints is to limit the number of transient pressure increase challenges that might open the PORV, which, if opened, could fail in the open position. The PORV setpoint thus limits the frequency of challenges from transients and limits the possibility of a small break LOCA from a failed open PORV. Placing the setpoint below the pressurizer safety valve opening setpoint reduces the frequency of challenges to the safety valves, which, unlike the PORV, cannot be isolated if they were to fail to open.~~ 3

The primary purpose of this LCO is to ensure that the PORV ~~and the~~ block valve are operating correctly so the ~~potential for a small break LOCA through the PORV pathway is minimized, or if a small break LOCA were to occur through a failed open PORV, the~~ block valve could be manually operated to isolate the ~~path~~. 1

s

pathway from an inadvertent opening of one or both PORVs. Each PORV capacity is sufficient to avoid lifting the safety valves during power operations. Therefore, one PORV block valve is maintained open during power operation to ensure the PORV function is available. The second PORV block valve is closed to avoid excessive loss of reactor coolant inventory upon PORV actuation.

BASES

BACKGROUND (continued)

~~The PORV may be manually operated to depressurize the RCS as deemed necessary by the operator in response to normal or abnormal transients. The PORV may be used for depressurization when the pressurizer spray is not available, a condition that may be encountered during loss of offsite power. Operators can manually open the PORVs to reduce RCS pressure in the event of a steam generator tube rupture (SGTR) with offsite power unavailable.~~

~~The PORV may also be used for feed and bleed core cooling in the case of multiple equipment failure events that are not within the design basis, such as a total loss of feedwater.~~

The PORV functions as an automatic overpressure device and limits challenges to the safety valves. Although the PORV acts as an overpressure device for operational purposes, safety analyses ~~[~~do not take credit for PORV actuation~~, but] do take credit for the safety valves~~.

The PORV also provides low temperature overpressure protection (LTOP) during heatup and cooldown. LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System," addresses this function.

APPLICABLE SAFETY ANALYSES

Insert 1

~~The PORV small break LOCA break size is bounded by the spectrum of piping breaks analyzed for plant licensing. Because the PORV small break LOCA is located at the top of the pressurizer, the RCS response characteristics are different from RCS loop piping breaks; analyses have been performed to investigate these characteristics.~~

~~The possibility of a small break LOCA through the PORV is reduced when the PORV flow path is OPERABLE and the PORV opening setpoint is established to be reasonably remote from expected transient challenges. The possibility is minimized if the flow path is isolated.~~

~~The PORV opening setpoint has been established in accordance with Reference 2. It has been set so expected RCS pressure increases from anticipated transients will not challenge the PORV, minimizing the possibility of small break LOCA through the PORV.~~

~~Overpressure protection is provided by safety valves, and analyses do not take credit for the PORV opening for accident mitigation.~~

block valves

~~Pressurizer~~ PORV~~s~~ satisfy Criterion ~~3~~ 4 of 10 CFR 50.36(c)(2)(ii).

1

INSERT 1

The PORV block valves are not credited to mitigate any design basis accident or transient specified in Reference 2. NRC Regulatory Issue Summary 2005-29 (Ref. 3) describes limiting the probability of initiating a more safety significant event as a result of an anticipated transient. The inadvertent PORV opening is an anticipated operational occurrence (AOO) and could result in a pressurizer overfill condition. Such a condition could lead to an inability to isolate the PORV, resulting in a condition similar to a small break LOCA.

An accidental depressurization of the RCS could occur as a result of an inadvertent opening of one pressurizer PORV. Initially the event results in a loss of RCS fluid and a rapid RCS depressurization. The challenge to the specified acceptable fuel design limits is terminated by the thermal margin / low pressure reactor trip signal, however, the RCS fluid loss and depressurization continue. Safety injection is actuated, and the pressurizer level increases with the potential to result in pressurizer overfill and liquid discharge through the stuck open PORV(s). The minimum time from event initiation to the pressurizer dome becoming liquid filled is just under 3 minutes. To prevent liquid discharge through the open PORV(s), the operator closes the associated open PORV block valve(s) within just under 3 minutes prior to the pressurizer dome becoming liquid filled.

1

BASES

to terminate a pressurizer overfill event following an inadvertent PORV opening. An OPERABLE PORV block valve may be either closed and energized or open and energized. Additionally, one PORV block valve must be closed to preclude RCS blowdown from both PORV pathways as a result of inadvertent opening of both PORVs.

LCO

The LCO requires the PORV ~~and its associated~~ block valve to be OPERABLE. The block valve is required to be OPERABLE so it may be used to isolate the flow path ~~if the PORV is not OPERABLE~~.

1

~~Valve OPERABILITY also means the PORV setpoint is correct. By ensuring that the PORV opening setpoint is correct, the PORV is not subject to frequent challenges from possible pressure increase transients, and therefore the possibility of a small break LOCA through a failed open PORV is not a frequent event.~~

3

APPLICABILITY

s

In MODES 1, 2, and 3, the PORV ~~and its~~ block valve are required to be OPERABLE to limit the potential for a small break LOCA through the flow path. A likely cause for PORV small break LOCA is a result of pressure increase transients that cause the PORV to open. Imbalances in the energy output of the core and heat removal by the secondary system can cause the RCS pressure to increase to the PORV opening setpoint. Pressure increase transients can occur any time the steam generators are used for heat removal. The most rapid increases will occur at higher operating power and pressure conditions of MODES 1 and 2.

1

Pressure increases are less prominent in MODE 3 because the core input energy is reduced, but the RCS pressure is high. Therefore, this LCO is applicable in MODES 1, 2, and 3. The LCO is not applicable in MODE 4 when both pressure and core energy are decreased and the pressure surges become much less significant. The PORV setpoint is reduced for LTOP in MODES 4, 5, and 6 with the reactor vessel head in place. LCO 3.4.12 addresses the PORV requirements in these MODES.

ACTIONS

the

The ACTIONS are modified by a Note. The Note clarifies that ~~all~~ ~~pressurizer~~ PORV~~s and~~ block valves are treated as separate entities, each with separate Completion Times (i.e., the Completion Time is on a component basis).

1

~~A.1~~

~~With the PORV inoperable and capable of being manually cycled, either the PORV must be restored or the flow path isolated within 1 hour. The block valve should be closed but power must be maintained to the associated block valve, since removal of power would render the block valve inoperable. Although the PORV may be designated inoperable, it may be able to be manually opened and closed and in this manner can be used to perform its function. PORV inoperability may be due to seat leakage, instrumentation problems, automatic control problems, or other causes that do not prevent manual use and do not create a possibility for~~

3

1

BASES

ACTIONS (continued)

~~a small break LOCA. For these reasons, the block valve may be closed but the Action requires power be maintained to the valve. This Condition is only intended to permit operation of the plant for a limited period of time not to exceed the next refueling outage (MODE 6) so that maintenance can be performed on the PORVs to eliminate the problem condition. The PORVs should normally be available for automatic mitigation of overpressure events and should be returned to OPERABLE status prior to entering startup (MODE 2).~~

~~Quick access to the PORV for pressure control can be made when power remains on the closed block valve. The Completion Time of 1 hour is based on plant operating experience that minor problems can be corrected or closure can be accomplished in this time period.~~

~~B.1, B.2, and B.3~~

~~If one PORV is inoperable and not capable of being manually cycled, it must either be isolated, by closing the associated block valve and removing the power from the block valve, or restored to OPERABLE status. The Completion Time of 1 hour is reasonable, based on challenges to the PORVs during this time period, and provides the operator adequate time to correct the situation. If the inoperable valve cannot be restored to OPERABLE status, it must be isolated within the specified time of 1 hour. Because there is at least one PORV that remains OPERABLE, an additional 72 hours is provided to restore the inoperable PORV to OPERABLE status. [Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~

A A

~~C~~.1 and ~~C~~.2

or more PORV | s are | it must be closed with power removed

If one block valve ~~is~~ inoperable, ~~then~~ it must be restored to OPERABLE status, or ~~the associated PORV placed in manual control~~. The prime importance for the capability to close the block valve is to isolate a stuck open PORV. Therefore, if the block valve cannot be restored to OPERABLE status within 1 hour, the Required Action is to place the PORV ~~in manual control to preclude its automatic opening for an overpressure event and to avoid the potential for a stuck open PORV at a time that the block valve is inoperable~~. The Completion Times of 1 hour are reasonable based on the small potential for challenges to the system during this time period and provide the operator time to correct the situation. ~~Because at least one PORV remains OPERABLE, the operator~~

or in accordance with the Risk Informed Completion Time Program

block valve in the closed position with power removed

BASES

ACTIONS (continued)

~~is permitted a Completion Time of 72 hours to restore the inoperable block valve to OPERABLE status.~~ ~~[~~Alternatively, ~~a~~ Completion Time s can be determined in accordance with the Risk Informed Completion Time Program.~~]~~ ~~The time allowed to restore the block valve is based upon the Completion Time for restoring an inoperable PORV in Condition B since the PORVs are not capable of automatically mitigating an overpressure event when placed in manual control. If the block valve is restored within the Completion Time of 72 hours, the power will be restored and the PORV restored to OPERABLE status.~~ 3

C C

~~D~~.1 and ~~D~~.2

B.1
If both PORV block valves are open, it is necessary to isolate one PORV flow path by closing one PORV block valve within 1 hour. The Completion Time of 1 hour is reasonable based on the small potential for challenges to the system during this time period and provide the operator time to correct the situation. 1

If the Required Action cannot be met within the associated Completion Time, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

~~E.1, E.2, E.3, and E.4~~

~~If two PORVs are inoperable and not capable of being manually cycled, it is necessary to isolate the flow path by closing and removing the power to the associated block valves within 1 hour and restore at least one PORV within 8 hours. The Condition is modified by a Note stating it is not applicable if the second PORV train is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is applicable if one PORV is inoperable for any reason and the second PORV is discovered to be inoperable, or if both PORVs are discovered to be inoperable at the same time.~~

~~In the event of a loss of feedwater, the PORVs would be used to remove core heat. In order to minimize the consequences of a loss of feedwater while two PORVs are inoperable, Required Action E.3 requires that LCO 3.7.5, "Auxiliary Feedwater System," be met to ensure AFW is available. The inoperability of two PORVs during the 8 hour Completion Time has been shown to be acceptable based on the infrequent use of the Required Action and the small incremental effect on plant risk (Ref. 3). If one PORV is restored and one PORV remains inoperable, then the plant will be in Condition B with the time clock started at the original declaration of having two PORVs inoperable.~~ 3

BASES

ACTIONS (continued)

~~F.1 and F.2~~

~~If two PORVs are inoperable and are not capable of being manually cycled and are not restored within the Completion Time, then the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems. Similarly, the Completion Time of 12 hours to reach MODE 4 is reasonable, considering that a plant can cool down within that time frame on one safety system train. In MODES 4 and 5, maintaining PORV OPERABILITY may be required. See LCO 3.4.12.~~

~~G.1 and G.2~~

~~If two block valves are inoperable, it is necessary to restore at least one block valve to OPERABLE status within 8 hours. The Condition is modified by a Note stating it is not applicable if the second block valve is intentionally declared inoperable. The Condition does not apply to voluntary removal of redundant systems or components from service. The Condition is only applicable if one block valve is inoperable for any reason and the second block valve is discovered to be inoperable, or if both block valves are discovered to be inoperable at the same time. In the event of a loss of feedwater, the PORVs would be used to remove core heat. In order to minimize the consequences of a loss of feedwater while two block valves are inoperable, Required Action G.2 requires that LCO 3.7.5, "Auxiliary Feedwater System," be verified to be met within 1 hour. The inoperability of two block valves during the 8 hour Completion Time has been shown to be acceptable based on the infrequent use of the Required Actions and the small incremental effect on plant risk (Ref. 3).~~

3

~~H.1 and H.2~~

~~If the Required Actions and associated Completion Times of Condition F or G are not met, then the plant must be brought to a MODE in which the LCO does not apply. The plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3~~

BASES

ACTIONS (continued)

~~from full power in an orderly manner and without challenging safety systems. Similarly, the Completion Time of 12 hours to reach MODE 4 is reasonable considering that a plant can cool down within that time frame on one safety system train. In MODES 4 and 5, maintaining PORV OPERABILITY may be required. See LCO 3.4.12.~~

SURVEILLANCE REQUIREMENTS

SR 3.4.11.1

PORV

Block valve cycling verifies that it can be closed if necessary. ~~[The basis for the Frequency of [92 days] is the ASME Code (Ref. 4).~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

This SR is modified by two Notes. Note 1 modifies this SR by stating that this SR is not required to be performed with the block valve closed in accordance with the Required Actions of this LCO. ~~Opening the block valve in this condition increases the risk of an unisolable leak from the RCS since the PORV is already inoperable.~~ Note 2 modifies this SR to allow entry into and operation in MODE 3 prior to performing the SR. This allows the test to be performed in MODE 3 under operating temperature and pressure conditions, prior to entering MODE 1 or 2. ~~[In accordance with Reference 5, administrative controls require this test be performed in MODE 3 or 4 to adequately simulate operating temperature and pressure effects on PORV operation.]~~

~~SR 3.4.11.2~~

~~SR 3.4.11.2 requires complete cycling of each PORV. PORV cycling demonstrates its function. [The Frequency of [18] months is based on a typical refueling cycle and industry accepted practice.~~

~~OR~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.11, BASES, POWER OPERATED RELIEF VALVE (PORV) BLOCK VALVES

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to reflect the changes to the Specification.

EMERGENCY CORE COOLING SYSTEMS

ECCS SUBSYSTEMS - SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.5.3 As a minimum, one ECCS subsystem comprised of the following shall be OPERABLE:

a. In MODES 3* and 4#, one ECCS subsystem composed of one OPERABLE high pressure safety injection pump and one OPERABLE flow path capable of taking suction from the refueling water storage tank on a safety injection actuation signal and automatically transferring suction to the containment sump on a sump recirculation actuation signal.

See ITS 3.5.3

300

LCO 3.4.12

~~b.~~ Prior to decreasing the reactor coolant system temperature below ~~270~~°F a maximum of only one high pressure safety injection pump shall be OPERABLE with its associated header stop valve open.

M01

LCO 3.4.12 NOTE 3

~~c.~~ Prior to decreasing the reactor coolant system temperature below 236°F all high pressure safety injection pumps shall be disabled and their associated header stop valves closed except as allowed by Specifications 3.1.2.1 and 3.1.2.3.

APPLICABILITY: MODES 3* and 4.

Applicability

MODES 5 and 6 when the Pressurizer manway cover is in place and the reactor vessel head is on.

ACTION:

a. With no ECCS subsystems OPERABLE in MODES 3* and 4#, immediately restore one ECCS subsystem to OPERABLE status or be in COLD SHUTDOWN within 20 hours.

300

ACTION A

b. With RCS temperature below ~~270~~°F and with more than the allowed high pressure safety injection pump OPERABLE or injection valves and header isolation valves open, immediately disable the high pressure safety injection pump(s) or close the header isolation valves.

M01

c. In the event the ECCS is actuated and injects water into the Reactor Coolant System, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days describing the circumstances of the actuation and the total accumulated actuation cycles to date.

d. LCO 3.0.4.b is not applicable to ECCS High Pressure Safety Injection subsystem when entering MODE 4.

SURVEILLANCE REQUIREMENTS

4.5.3.1 The ECCS subsystem shall be demonstrated OPERABLE per the applicable Surveillance Requirements of 4.5.2.

SR 3.4.12.1

~~4.5.3.2~~ The high pressure safety injection pumps shall be verified inoperable and the associated header stop valves closed prior to decreasing below the above specified Reactor Coolant System temperature and once per month when the Reactor Coolant System is at refueling temperatures.

* With pressurizer pressure < 1750 psia.

EMERGENCY CORE COOLING SYSTEMS

3/4.5.3 ECCS SUBSYSTEMS - SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.5.3 As a minimum, one ECCS subsystem comprised of the following shall be OPERABLE:

a. One OPERABLE high-pressure safety injection pump, and

b. An OPERABLE flow path capable of taking suction from the refueling water tank on a Safety Injection Actuation Signal and automatically transferring suction to the containment sump on a Sump Recirculation Actuation Signal.

See ITS 3.5.3

APPLICABILITY: MODES 3* and 4#.

Applicability

Footnote # shall remain applicable in MODES 5 and 6 when the Pressurizer manway cover is in place and the reactor vessel head is on.

ACTION:

a. With no ECCS subsystems OPERABLE, restore at least one ECCS subsystem to OPERABLE status within 1 hour or be in COLD SHUTDOWN within the next 20 hours.

b. In the event the ECCS is actuated and injects water into the Reactor Coolant System, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days describing the circumstances of the actuation and the total accumulated actuation cycles to date. The current value of the usage factor for each affected safety injection nozzle shall be provided in this Special Report whenever its value exceeds 0.70.

c. LCO 3.0.4.b is not applicable to ECCS High Pressure Safety Injection subsystem when entering MODE 4.

SURVEILLANCE REQUIREMENTS

4.5.3 The ECCS subsystem shall be demonstrated OPERABLE per the applicable Surveillance Requirements of 4.5.2.

---

* With pressurizer pressure less than 1750 psia.

LCO 3.4.12

\# ~~One HPSI shall be rendered inoperable prior to entering MODE 5.~~

M01

DISCUSSION OF CHANGES
ITS 3.4.12, LOW TEMPERATURE OVERPRESSURE PROTECTION (LTOP) SYSTEM

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 2 only:** CTS 3.4.9.3 Action a. and b. state, in part, that given the Conditions specified, depressurize and vent the RCS, or be at a temperature above the low temperature RCS overpressure protection range of Table 3.4-3 within the 8 hours. ITS 3.4.12, ACTION F retains the requirement to depressurize the RCS and establish an RCS vent; however, it does not contain the requirement to be at a temperature above the low temperature RCS overpressure protection range of Table 3.4-3.

The purpose of CTS 3.4.9.3 Action a.2 and b.2 is to place the unit in a condition in which the equipment is no longer required. CTS 3.4.9.3 Action a.1 provides appropriate actions (depressurize and vent the RCS) to take with an inoperable PORV or an SDCRV being used for LTOP, and at least one of the two overpressure protection devices is not restored to OPERABLE status within 7 days. CTS 3.4.9.3 Action b.1 provides appropriate actions (depressurize and vent the RCS) to take with none of the overpressure protection devices being used for LTOP are OPERABLE. The overpressure protection devices being used for LTOP are not required to be OPERABLE when the RCS cold leg temperatures are > 252°F, the temperature referenced in CTS Table 3.4-3, because the Mode of Applicability is exited. Therefore, in accordance with CTS 3.0.2 (ITS LCO 3.0.2), when RCS cold leg temperatures are > 252°F, the CTS Actions are no longer required to be completed.

These changes are designated as administrative changes and are acceptable because they maintain the current requirement to place the unit in a condition in which the overpressure protection devices (PORVs and SDCRVs) are no longer required consistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2) and, therefore, do not result in a technical change to the CTS.

A03 **Unit 2 only:** CTS 4.4.9.3.1.b states, in part, that each PORV shall be demonstrated OPERABLE by performance of a CHANNEL FUNCTIONAL TEST on the PORV actuation channel, “within 31 days prior to entering a condition in which the PORV is required OPERABLE” and in accordance with the Surveillance Frequency Control Program thereafter when the PORV is required OPERABLE. The statement “within 31 days prior to entering a condition in which the PORV is required OPERABLE,” is not included in ITS SR 3.4.16.6. This changes the CTS by removing a Frequency which is duplicative of CTS 4.0.4 (ITS SR 3.0.4). ITS SR 3.0.4 states, in part, that entry into a MODE or other specified condition in the Applicability of an LCO shall only be made when the LCO's Surveillances have been met within their specified Frequency. Therefore,

ITS SR 3.0.4 will continue to require the Surveillance to be performed within 31 days prior to entering a condition in which the PORV is required OPERABLE.

This change is designated as an administrative change and is acceptable because it does not result in technical changes to the CTS.

A04 **Unit 2 only:** CTS 3.4.9.3 references Table 3.4-3, Low Temperature Overpressure Protection (LTOP) Range, and Table 3.4-4, Minimum cold Leg Temperature for PORV Use for LTOP. The "Operating Period, EFPY" and its value of "≤ 55" is deleted from both Tables. ITS 3.4.3, RCS Pressure and Temperature (P/T) Limits, retains the Operating Period and its value in ITS Figures 3.4.3-1 and 3.4.3-2.

This change is designated as an administrative change and is acceptable because it does not result in technical changes to the CTS.

A05 **Unit 2 only:** CTS 3.4.9.3 references Table 3.4-3, Low Temperature Overpressure Protection (LTOP) Range, and Table 3.4-4, Minimum cold Leg Temperature for PORV Use for LTOP. Table 3.4-3 provides RCS cold leg temperature requirements for LTOP protection. CTS Table 3.4-3 is deleted, and the specific values are provided in the ITS 3.4.12 Applicability. To ensure LTOP is applicable when required, "during cooldown" specified in Table 3.4-3 is changed to "following entry from MODE 3" and "during heatup" specified in Table 3.4-3 is changed to "following entry from MODE 5." This change in presentation maintains the intent that during a plant cooldown when transitioning from MODE 3 to MODE 4, LTOP is required when RCS temperature is ≤ 240°F and remains in effect until RCS temperature reaches 252°F during a plant heatup when transitioning from MODE 5 to MODE 4 to MODE 3. CTS Table 3.4-4 provides minimum RCS cold leg temperature requirements for PORV use for LTOP. Table 3.4-4 is deleted and the values in the table are provided as ITS LCO 3.4.12 Note 3.

These presentation changes are designated as an administrative change and are acceptable because they do not result in technical changes to the CTS.

A06 CTS 4.1.1.2.c requires, in part, with the RCS drained below the hot leg centerline, a verification of SDM once per 24 hours by consideration of the factors in 4.1.1.2.b. CTS 4.1.1.2.b also requires a verification of SDM in accordance with the Surveillance Frequency Control Program while in MODE 5 regardless of the drained status of the RCS. The CTS 4.1.1.2.b Frequency specified in the Surveillance Frequency Control Program is 24 hours. ITS 3.4.12 does not include a verification of SDM once per 24 hours with the RCS drained below the hot leg centerline because it is duplicative to the requirement of CTS 4.1.1.2.b which is retained in ITS (SR 3.1.1.1). This change is designated as an administrative change and is acceptable because removal of a duplicative surveillance requirement does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.5.3 limits the OPERABILITY of high pressure safety injection (HPSI) pumps during LTOP conditions based on temperature. Unit 2 CTS 3.5.3, Footnote # requires rendering a HPSI pump inoperable prior to entering MODE 5. Neither Unit 1 CTS 3.4.13 nor Unit 2 CTS 3.4.9.3 (i.e., LTOP Specifications) require a restriction on HPSI pumps. Additionally, Unit 1 CTS 3.4.13 and 3.5.3, and Unit 2 CTS 3.4.9.3 and 3.5.3 do not place any limits on charging pumps. Unit 1 CTS 3.1.1.2 and Footnote * requires, in part, with the RCS drained below the hot leg centerline one charging pump shall be rendered inoperable with the breaker racked out and requires a verification once per 24 hours as specified in CTS 4.1.1.2.c. Unit 2 CTS 4.1.1.2.c provides a similar requirement to verify at least two charging pumps are rendered inoperable when the RCS is drained below the hot leg centerline. ITS LCO 3.4.12 states, in part, that an LTOP System shall be OPERABLE with a maximum of one HPSI pump and one charging pump capable of injecting into the RCS. The ITS LCO contains a Note (Note 1) that states two charging pumps may be made capable of injecting for ≤ 1 hour for pump swap operations. ITS 3.4.12 ACTION A states that if two HPSI pumps are capable of injecting into the RCS, immediately initiate action to verify a maximum of one HPSI pump is capable of injecting into the RCS. ITS 3.4.12 ACTION B states that if two or more charging pumps are capable of injecting into the RCS, immediately initiate action to verify a maximum of one charging pump is capable of injecting into the RCS. If the HPSI pumps or charging pumps Required Action is not met, then ITS 3.4.12 ACTION G states depressurize the RCS and establish an RCS vent of ≥ 1.75 square inches (Unit 1) and ≥ 3.58 square inches (Unit 2). Additionally, ITS SR 3.4.12.1 requires verification that a maximum of one HPSI pump is capable of injecting into the RCS and ITS SR 3.4.12.2 requires verification that a maximum of one charging pump is capable of injecting into the RCS. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per Unit 1 CTS 6.8.4.o and Unit 2 CTS 6.8.4.q. Therefore, SR 3.4.12.1 and SR 3.4.12.2 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program. An initial Frequency of 12 hours will be established for SR 3.4.12.1 consistent with the ISTS SR 3.4.12.1 and an initial Frequency of 24 hours will be established for SR 3.4.12.2 consistent with the Frequency specified in CTS 4.1.1.2.c.

This changes the CTS by requiring all but one charging pump be made incapable of injecting into the RCS during LTOP conditions and provides additional restriction on HPSI pumps during LTOP conditions (i.e., requiring one HPSI pump to be incapable of injecting into the RCS instead of just rendering the pump inoperable) and expands the temperature range on when one HPSI pump must be incapable of injecting into the RCS. This also changes the CTS by adding appropriate actions and Surveillances regarding the HPSI and charging pumps.

The purpose of the LCO is to provide RCS overpressure protection at low temperature conditions by having minimum coolant input capability and adequate RCS pressure relief capacity. Limiting coolant input capability is accomplished by isolating the safety injection tanks (SITs) and restricting high pressure pumps capable of injection into the RCS to a maximum of one high pressure safety injection (HPSI) pump and one charging pump. See DOC M02 for SIT

discussion of change. The Completion Times are reasonable for the ACTIONS to be performed and minimize the time in which the design assumptions for the LTOP System are not being met. The Surveillance Frequency of in accordance with the Surveillance Frequency Control Program considers operating practice to regularly assess potential degradation and to verify operation within the safety analysis.

This change is designated as more restrictive because it adds additional requirements to the CTS.

M02 Unit 1 CTS 3.4.13 and Unit 2 CTS 3.4.9.3 do not place any limits on the safety injection tanks (SITs) during LTOP conditions. ITS LCO 3.4.12 states that the SITs shall be isolated. The ITS LCO contains a Note (Note 2) that states, "SIT may be unisolated when SIT pressure is less than the maximum RCS pressure for the existing RCS cold leg temperature allowed by the P/T limit curves provided in ITS 3.4.3, “RCS Pressure and Temperature (P/T) Limits.” ITS 3.4.12 ACTION C states that if a SIT is not isolated when SIT pressure is greater than or equal to the maximum RCS pressure for existing cold leg temperature allowed by the P/T limit curves in LCO 3.4.3, the affected SIT must be isolated within 1 hour. If this isolation is not accomplished, ITS 3.4.12 ACTION D states that the RCS cold leg temperature must be increased to > 300°F (Unit 1) and > 252°F (Unit 2) or the affected SIT must be depressurized and vented within 12 hours. ITS SR 3.4.12.3 requires verification that each SIT is isolated. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per Unit 1 CTS 6.8.4.o and Unit 2 CTS 6.8.4.q. Therefore, SR 3.4.12.3 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 12 hours consistent with the ISTS SR 3.4.12.3. This changes the CTS by adding specific limits on the SITs during LTOP conditions, including appropriate ACTIONS and Surveillance Requirements.

The purpose of the LCO is to provide RCS overpressure protection at low temperature conditions. These changes are necessary because the LTOP analyses assume that the SITs are isolated and therefore not capable of initiating a mass addition transient. The Completion Times are reasonable for the ACTIONS to be performed and minimize the time in which the design assumptions for the LTOP System are not being met. The SR 3.4.12.3 Frequency of in accordance with the Surveillance Frequency Control Program considers operating practice to regularly assess potential degradation and to verify operation within the safety analysis.

The initial frequency established in accordance with the SFCP will be 12 hours for SR 3.1.4.3. See FPL (PSL Unit 1 and Unit 2) “Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program” (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066).

This change is designated as more restrictive because it adds additional requirements to the CTS.

M03 **Unit 1 only:** CTS 3.4.13 Action c. states, in part, that with both PORVs inoperable, actions must be completed within 24 hours. ITS 3.4.12 ACTION G requires the RCS to be depressurized and to establish an RCS vent within 12 hours. Optionally, to exit Condition G, one PORV can be restored to OPERABLE status within 12 hours, under the same conditions. This changes the CTS by allowing 12 hours instead of 24 hours to perform the necessary actions.

The purpose of CTS Actions a. and b. is to place the unit in a condition in which the PORVs are not needed. This change is acceptable because the time with inadequate pressure relief capability is minimized to the time required to establish an adequate RVS vent path. Twelve hours is a sufficient amount of time to allow to plan and execute the maintenance activity of opening an RCS vent. This change allows the necessary activities to be performed in a controlled manner. This change is designated as more restrictive because the required response was changed from 24 hours to 12 hours.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 **Unit 2 only:** (*Type 1 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements*) CTS 3.4.9.3 requires, in part, that the PORVs be OPERABLE with lift settings as specified and their associated block valves open. ITS LCO 3.4.12 does not explicitly require the associated block valve of a required PORV to be open. This changes the CTS by moving the procedural detail that the PORV block valves must be open to the ITS Bases.

The removal of these details for meeting Technical Specification requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for the required PORVs to be OPERABLE. The ITS definition of OPERABLE requires other auxiliary equipment that are required for the system, subsystem, train, component, or device to perform its specified safety function(s) are also capable of performing their related support function(s). For a PORV to be capable of performing its relief function, its associated block valve must be open to support OPERABILITY. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA02 **Unit 2 only:** *(Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program, or Surveillance Frequency Control Program)* CTS 4.4.9.3.1.a requires, in part, that the PORVs be operated through one complete cycle of full travel in accordance with the Surveillance Frequency Control Program. ITS LCO 3.4.12 does not explicitly require the PORVs be manually operated through one complete cycle of full travel. This changes the CTS by moving the Surveillance Requirement that manually operates the PORVs through one complete cycle to the Technical Requirements Manual (TRM).

The removal of this Surveillance Requirement for meeting Technical Specification requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the PORV block valve, CHANNEL FUNCTIONAL TEST and CHANNEL CALIBRATION Surveillances to demonstrate automatic actuation for the PORVs to be OPERABLE consistent with the ISTS. The ITS definition of OPERABLE requires other auxiliary equipment that are required for the system, subsystem, train, component, or device to perform its specified safety function(s) are also capable of performing their related support function(s). For a PORV to be capable of performing its pressure relief function, its automatic relief actuation must be demonstrated to support OPERABILITY. Also, this change is acceptable because these types of procedural details will be adequately controlled in the TRM. Changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because a Surveillance Requirement for meeting Technical Specification requirements is being removed from the Technical Specifications. | R1

LA03 (*Type 1 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements*) Unit 1 CTS 3.1.1.2 requires, in part, with the RCS drained below the hot leg centerline one charging pump shall be rendered inoperable. Unit 1 CTS 4.1.1.2.c also requires verification that at least one charging pump is rendered inoperable. The word inoperable is modified by Footnote * that clarifies the breaker racked out. Unit 2 CTS 4.1.1.2.c provides a similar requirement to render at least two charging pumps inoperable by racking out their motor circuit breakers. ITS SR 3.4.12.2 requires verifying a maximum of one charging pump is capable of injecting into the RCS. This changes the CTS by moving the procedural detail of how to make a charging pump inoperable (i.e., incapable of injecting into the RCS) to the ITS Bases.

The removal of these details for meeting Technical Specification requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for limiting the number of charging pumps capable of injecting into the RCS. The charging pumps are rendered incapable of injecting into the RCS through removing the power from the pumps by racking the breakers out under administrative control. An alternate method of LTOP control may also be employed using at least two independent means to prevent a pump start such that a single failure or single action will not result in an injection into the RCS.

This may be accomplished through the pump control switch being placed in stop and at least one valve in the discharge flow path being closed. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 3 – Relaxation of Completion Time)* Unit 1 CTS 3.4.13 Action a. states, in part, that with one PORV inoperable in MODE 4 for > 7 days depressurize and vent the RCS within the next 8 hours. Unit 1 CTS 3.4.13 Action b. states, in part, that with one PORV inoperable in MODES 5 or 6 for > 24 hours depressurize and vent the RCS within a total of 32 hours (essentially 8 hours to depressurize and vent the RCS). Unit 1 ITS 3.4.12 ACTION G requires the RCS to be depressurized and to establish an RCS vent within 12 hours under the same conditions. This changes the CTS by allowing 12 hours instead of 8 hours to perform the required action.

Unit 2 CTS 3.4.9.3 Action a. states, in part, that with either a PORV or an SDCRV being used for LTOP inoperable for > 7 days either depressurize and vent the RCS or be at a temperature above the LTOP enabling temperature of 252°F within the next 8 hours. Unit 2 CTS 3.4.9.3 Action b. states, in part, that with none of the overpressure protection devices being used for LTOP OPERABLE, either restore at least one overpressure protection device to OPERABLE status, or vent the RCS, or be at a temperature above the LTOP enabling temperature of 252°F, within the next 8 hours. Unit 2 ITS 3.4.12 ACTION F requires the RCS to be depressurized and to establish an RCS vent within 12 hours under the same conditions. Optionally, to exit Condition F, RCS cold leg temperature can be raised above the LTOP enabling temperature of 252°F or restore the required relief valves to OPERABLE status. This changes the CTS by allowing 12 hours instead of 8 hours to perform the necessary actions.

The purpose of the Unit 1 CTS Actions a. and b. is to place the unit in a condition in which the PORVs are not needed for LTOP. Similarly, the purpose of the Unit 2 CTS Actions a. and b. is to place the unit in a condition in which the PORVs and SDC relief valves are not needed for LTOP. This change is acceptable because the Completion Time is consistent with safe operation under the specified Condition and considers the low probability of a DBA occurring during the allowed Completion Time. Any reduction in the margin of safety due to the extending the time to perform the remedial actions by 4 hours is offset by providing a reasonable time to perform the action to establish an adequate RCS vent path in a controlled manner, thus, minimizing the likelihood of human performance errors that may exacerbate the degraded condition. Twelve hours is a sufficient amount of time to allow to cool and depressurize the RCS (following the unit cooldown rate limits), change MODES, and plan and execute

the maintenance activity of establishing an RCS vent path, or raise RCS cold leg temperature above the LTOP enabling temperature. This change allows the necessary activities to be performed in a controlled manner. This change is designated as less restrictive because additional time is allowed to complete Required Actions than was allowed in the CTS.

L02 *(Category 9 – Deletion of Reporting Requirements)* Unit 1 CTS 3.4.13 Action e and Unit 2 CTS 3.4.9.3 Action c. state that in the event either the PORVs, SDCRVs (Unit 2), or the RCS vent(s) are used to mitigate an RCS pressure transient, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 30 days. The report shall describe the circumstances initiating the transient, the effect of the PORVs, SDCRVs (Unit 2), or RCS vent(s) on the transient, and any corrective action necessary to prevent recurrence. The ITS does not have a similar requirement. This changes the CTS by eliminating a Special Report.

The purpose of Unit 1 CTS 3.4.13 Action e and Unit 2 CTS 3.4.9.3 Action c is to inform the NRC of challenges to the RCS pressure relief capabilities. This change is acceptable because the regulations provide adequate reporting requirements, or the reports do not affect continued plant operation. The regulatory reporting requirements in 10 CFR 50 are adequate to inform the NRC of challenges to the PORVs, the SDCRVs, or RCS vents, when necessary. Neither the safety analysis assumptions or conditions for continued operation are dependent on the NRC review of the provided information. This change is designated as less restrictive because reports that would be submitted under the CTS will not be required under the ITS.

L03 **Unit 2 only:** *(Category 2 – Relaxation of Applicability)* CTS 3.4.9.3 Applicability states that the LCO is applicable in MODE 6. ITS 3.4.12 Applicability states that the LCO is applicable in MODE 6 when the reactor vessel head is on. This changes the CTS by only requiring the LCO Applicability in MODE 6 when the reactor vessel head is on.

The purpose of CTS 3.4.9.3 is to ensure there is sufficient low temperature overpressurization protection in all conditions. The definition of MODE 6 included in ITS Table 1.1-1 states that MODE 6 is when one or more reactor vessel head closure bolts are less than fully tensioned. The ITS 3.4.12 Applicability states that the LCO is applicable in MODE 6 when the reactor vessel head is on. This MODE 6 Applicability includes the situation when all reactor vessel head closure bolts are removed, and the vessel head is still on. This change is acceptable since a low temperature overpressurization event is precluded because of the large vent path that is established when the reactor vessel head is removed. This change is designated as less restrictive because it relaxes the Applicability in which the CTS applies.

Improved Standard Technical Specifications (ISTS) Markup and Justification for Deviations (JFDs)

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.12 Low Temperature Overpressure Protection (LTOP) System

3.5.3.b, M01
3.1.1.2

LCO 3.4.12 An LTOP System shall be OPERABLE with a maximum of one high pressure safety injection (HPSI) pump and one charging pump capable of injecting into the RCS and the safety injection tanks (SITs) isolated, and:

M02

----------NOTES----------

M01

1. ~~[~~Two charging pumps~~]~~ may be made capable of injecting for ≤ 1 hour for pump swap operations. (2)

M02

2. SIT may be unisolated when SIT pressure is less than the maximum RCS pressure for the existing RCS cold leg temperature allowed by the P/T limit curves provided in ~~the PTLR~~. (LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits")

3.5.3 Action C

3. All HPSI pumps shall be incapable of injecting into the RCS when any RCS cold leg temperature is ≤ 236°F except when no charging pumps are available for boration in MODES 5 and 6.

---------- (1)

a. Two OPERABLE power operated relief valves (PORVs) with lift settings ~~within the limits specified in the PTLR~~ or (1)

Applicability

b. The RCS depressurized and an RCS vent of ≥ ~~[~~1.3~~]~~ square inches. (2)

1.75

≤ 530 psia when all RCS cold leg temperatures are > 200°F and
≤ 350 psia when any RCS cold leg temperature is ≤ 200°F

3.4.13 Applicability

APPLICABILITY: MODE 4 when any RCS cold leg temperature is ~~less than or equal to the LTOP enable temperature specified in the PTLR,~~ ≤ 300°F (1)
MODE 5,
MODE 6 when the reactor vessel head is on.

ACTIONS

----------NOTE----------

3.4.13 Action f.

LCO 3.0.4.b is not applicable to PORVs when entering MODE 4.

CONDITION	REQUIRED ACTION	COMPLETION TIME
M01 A. Two ~~or more~~ HPSI pumps capable of injecting into the RCS.	A.1 Initiate action to verify a maximum of one HPSI pump capable of injecting into the RCS.	Immediately (1)

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
M01 B. Two or more charging pumps capable of injecting into the RCS.	B.1 Initiate action to verify a maximum of one charging pump capable of injecting into the RCS.	Immediately
M02 C. A SIT not isolated when SIT pressure is greater than or equal to the maximum RCS pressure for existing cold leg temperature allowed in ~~the PTLR~~. LCO 3.4.3	C.1 Isolate affected SIT.	1 hour 1
D. Required Action and associated Completion Time of Condition C not met.	D.1 Increase RCS cold leg temperature to > ~~[175]~~°F. 300 OR D.2 Depressurize affected SIT to less than the maximum RCS pressure for existing cold leg temperature allowed in ~~the PTLR~~. LCO 3.4.3	12 hours 2 12 hours 1
3.4.13 Action a. E. One required PORV inoperable in MODE 4.	E.1 Restore required PORV to OPERABLE status.	7 days
3.4.13 Action b. F. One required PORV inoperable in MODE 5 or 6. when the reactor vessel head is on	F.1 Restore required PORV to OPERABLE status.	24 hours

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
3.4.13 Action c. G. Two required PORVs inoperable. OR Required Action and associated Completion Time of Condition A, [B], D, E, or F not met. OR LTOP System inoperable for any reason other than Condition A, [B], C, D, E, or F.	G.1 Depressurize RCS and establish RCS vent of ≥ [1.3] square inches. (1.75)	12 hours (2) (2) (2)

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
M01 SR 3.4.12.1	Verify a maximum of one HPSI pump is capable of injecting into the RCS.	[12 hours OR In accordance with the Surveillance Frequency Control Program] (2)

SURVEILLANCE REQUIREMENTS (continued)

	SURVEILLANCE		FREQUENCY	
M01 4.1.1.2.c	SR 3.4.12.2	Verify a maximum of one charging pump is capable of injecting into the RCS.	~~[12 hours~~ ~~OR~~ In accordance with the Surveillance Frequency Control Program ~~]~~	2
M02	SR 3.4.12.3	Verify each SIT is isolated.	~~[12 hours~~ ~~OR~~ In accordance with the Surveillance Frequency Control Program ~~]~~	2
3.4.13 Action d.	SR 3.4.12.4	Verify required RCS vent ≥ ~~[~~1.3~~]~~ square inches is open. (1.75)	~~[~~ 12 hours for unlocked open vent valve(s) AND 31 days for other vent path(s) ~~OR~~ ~~In accordance with the Surveillance Frequency Control Program]~~	2 2

SURVEILLANCE REQUIREMENTS (continued)

	SURVEILLANCE		FREQUENCY	
4.4.13.a	SR 3.4.12.5	Verify PORV block valve is open for each required PORV.	~~[72 hours~~ ~~OR~~ In accordance with the Surveillance Frequency Control Program ~~]~~	2
M03	SR 3.4.12.6	~~NOTE~~ ~~Not required to be performed until [12] hours after decreasing RCS cold leg temperature to less than or equal to the LTOP enable temperature specified in the PTLR.~~		3
4.4.13.b		Perform CHANNEL FUNCTIONAL TEST on each required PORV, excluding actuation.	~~[31 days~~ ~~OR~~ In accordance with the Surveillance Frequency Control Program ~~]~~	2
4.4.13.c	SR 3.4.12.7	Perform CHANNEL CALIBRATION on each required PORV actuation channel.	~~[[18] months~~ ~~OR~~ In accordance with the Surveillance Frequency Control Program ~~]~~	2

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.12 Low Temperature Overpressure Protection (LTOP) System

3.5.3, M01 LCO 3.4.12 An LTOP System shall be OPERABLE with a maximum of one high pressure safety injection (HPSI) pump and one charging pump capable of injecting into the RCS and the safety injection tanks (SITs) isolated, and:

M02

----------NOTES----------

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.12, LOW TEMPERATURE OVERPRESSURE PROTECTION (LTOP) SYSTEM

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description. Conditions, Required Actions, and Surveillances are renumbered in the ITS, as applicable.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The Note to ISTS SR 3.4.12.6 is not included in the ITS consistent with current licensing basis. The purpose of the ISTS Note is to allow 12 hours after decreasing Reactor Coolant System (RCS) cold leg temperature to less than or equal to the LTOP enable temperature to perform the test. Per the ISTS Bases, this Note is necessary because the test cannot be performed until the unit is in a condition where the PORV lift setpoint can be reduced to the LTOP setting. At St. Lucie Plant Unit 1 and Unit 2, the PORVs are not required to be OPERABLE for opening in MODE 1, 2, or 3 to support a design basis accident or transient. Therefore, the CHANNEL FUNCTIONAL TEST is currently performed prior to decreasing RCS cold leg temperature to less than or equal to the LTOP enable temperature. Testing includes steps performed to minimize the potential for inadvertently opening a PORV and depressurizing the RCS during performance (e.g., closing the PORV block valve and deactivating the PORV from opening). As a result, the CHANNEL FUNCTIONAL TEST can be performed prior to placing the unit in a condition where LTOP is required rendering the ISTS Note unnecessary.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.12 Low Temperature Overpressure Protection (LTOP) System

BASES

BACKGROUND

The LTOP System controls RCS pressure at low temperatures so the integrity of the reactor coolant pressure boundary (RCPB) is not compromised by violating the pressure and temperature (P/T) limits of 10 CFR 50, Appendix G (Ref. 1). The reactor vessel is the limiting RCPB component for demonstrating such protection. LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits," provides the allowable combinations for operational pressure and temperature during cooldown, shutdown, and heatup to keep from violating the Reference 1 requirements during the LTOP MODES.

The reactor vessel material is less tough at low temperatures than at normal operating temperatures. As the vessel neutron exposure accumulates, the material toughness decreases and becomes less resistant to pressure stress at low temperatures (Ref. 2). RCS pressure, therefore, is maintained low at low temperatures and is increased only as temperature is increased.

The potential for vessel overpressurization is most acute when the RCS is water solid, occurring only while shutdown; a pressure fluctuation can occur more quickly than an operator can react to relieve the condition. Exceeding the RCS P/T limits by a significant amount could cause brittle cracking of the reactor vessel. LCO 3.4.3 requires administrative control of RCS pressure and temperature during heatup and cooldown to prevent exceeding the P/T limits.

This LCO provides RCS overpressure protection by having a minimum coolant input capability and having adequate pressure relief capacity. Limiting coolant input capability requires all but one high pressure safety injection (HPSI) pump and one charging pump incapable of injection into the RCS and isolating the safety injection tanks (SITs). The pressure relief capacity requires either two OPERABLE redundant power operated relief valves (PORVs) or the RCS depressurized and an RCS vent of sufficient size. One PORV or the RCS vent is the overpressure protection device that acts to terminate an increasing pressure event.

BASES

BACKGROUND (continued)

With minimum coolant input capability, the ability to provide core coolant addition is restricted. The LCO does not require the makeup control system deactivated or the safety injection (SI) actuation circuits blocked. Due to the lower pressures in the LTOP MODES and the expected core decay heat levels, the makeup system can provide adequate flow via the makeup control valve. If conditions require the use of more than one ~~[~~HPI or~~]~~ charging pump for makeup in the event of loss of inventory, then pumps can be made available through manual actions. S 1

The LTOP System for pressure relief consists of two PORVs with reduced lift settings or an RCS vent of sufficient size. Two relief valves are required for redundancy. One PORV has adequate relieving capability to prevent overpressurization for the required coolant input capability.

PORV Requirements

As designed for the LTOP System, each PORV is signaled to open if the RCS pressure approaches a limit determined by the LTOP actuation logic. The actuation logic monitors RCS pressure and determines when the LTOP overpressure setting is approached. If the indicated pressure meets or exceeds the calculated value, a PORV is signaled to open.

The LCO presents the PORV setpoints for LTOP. The setpoints are normally staggered so only one valve opens during a low temperature overpressure transient. Having the setpoints of both valves within the limits of the LCO ensures the P/T limits will not be exceeded in any analyzed event.

When a PORV is opened in an increasing pressure transient, the release of coolant causes the pressure increase to slow and reverse. As the PORV releases coolant, the system pressure decreases until a reset pressure is reached and the valve is signaled to close. The pressure continues to decrease below the reset pressure as the valve closes.

RCS Vent Requirements

Once the RCS is depressurized, a vent exposed to the containment atmosphere will maintain the RCS at containment ambient pressure in an RCS overpressure transient, if the relieving requirements of the transient do not exceed the capabilities of the vent. Thus, the vent path must be capable of relieving the flow resulting from the limiting LTOP mass or heat input transient and maintaining pressure below the P/T limits. The required vent capacity may be provided by one or more vent paths.

BASES

BACKGROUND (continued)

~~For an RCS vent to meet the specified flow capacity, it requires removing a pressurizer safety valve, removing a PORV's internals, and disabling its block valve in the open position, or similarly establishing a vent by opening an RCS vent valve.~~ The vent path(s) must be above the level of reactor coolant, so as not to drain the RCS when open.

APPLICABLE SAFETY ANALYSES

~~Safety~~ analyses (Ref. 3) demonstrate that the reactor vessel is adequately protected against exceeding the Reference 1 P/T limits during shutdown. In MODES 1, 2, and 3, and in MODE 4 with any RCS cold leg temperature greater than the LTOP enable temperature ~~specified in the PTLR~~, the pressurizer safety valves prevent RCS pressure from exceeding the Reference 1 limits. At the LTOP enable temperature ~~specified in the PTLR~~ and below, overpressure prevention falls to the OPERABLE PORVs ~~[~~or to a depressurized RCS and a sufficient sized RCS vent~~]~~. Each of these means has a limited overpressure relief capability.

The actual temperature at which the pressure in the P/T limit curve falls below the pressurizer safety valve setpoint increases as the reactor vessel material toughness decreases due to neutron embrittlement. Each time the P/T limit curves are revised, the LTOP System will be re-evaluated to ensure its functional requirements can still be satisfied using the PORV method or the depressurized and vented RCS condition.

Reference 3 contains the acceptance limits that satisfy the LTOP requirements. Any change to the RCS must be evaluated against these analyses to determine the impact of the change on the LTOP acceptance limits.

Transients that are capable of overpressurizing the RCS are categorized as either mass or heat input transients, examples of which follow:

Mass Input Type Transients

~~a.~~ Inadvertent safety injection ~~or~~

~~b. Charging/letdown flow mismatch~~.

Heat Input Type Transients

~~a. Inadvertent actuation of pressurizer heaters,~~

~~b. Loss of shutdown cooling (SDC), or~~

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~c.~~ Reactor coolant pump (RCP) startup with temperature asymmetry within the RCS or between the RCS and steam generators. 1

The following are required during the LTOP MODES to ensure that mass and heat input transients do not occur, which either of the LTOP overpressure protection means cannot handle:

a. Rendering all but one HPSI pump, and all but one charging pump incapable of injection and

b. Deactivating the SIT discharge isolation valves in their closed positions.

The Reference 3 analyses demonstrate that either one PORV or the RCS vent can maintain RCS pressure below limits when only one HPSI pump and one charging pump are actuated. Thus, the LCO allows only one HPSI pump and one charging pump ~~OPERABLE~~ during the LTOP MODES. Since neither the PORV nor the RCS vent can handle the pressure transient produced from ~~accumulator~~ injection, when RCS temperature is low, the LCO also requires the SITs isolation when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed in the PTLR. 1

capable of injecting into the RCS

SIT

The isolated SITs must have their discharge valves closed and the valve power supply breakers fixed in their open positions. The analyses show the effect of SIT discharge is over a narrower RCS temperature range ~~([175]°F and below)~~ than that of the LCO ~~(less than or equal to the LTOP enable temperature specified in the PTLR and below)~~. 1

Fracture mechanics analyses established the temperature of LTOP Applicability at less than or equal to the LTOP enable temperature ~~specified in the PTLR~~. Above this temperature, the pressurizer safety valves provide the reactor vessel pressure protection. ~~The vessel materials were assumed to have a neutron irradiation accumulation equal to 21 effective full power years of operation.~~ 1

The consequences of a small break loss of coolant accident (LOCA) in LTOP MODE 4 conform to 10 CFR 50.46 and 10 CFR 50, Appendix K (Refs. 4 and 5), requirements by having a maximum of one HPSI pump and one charging pump ~~OPERABLE and SI actuation enabled for these pumps~~. 1

capable of injecting into the RCS

BASES

APPLICABLE SAFETY ANALYSES (continued)

PORV Performance

The fracture mechanics analyses show that the vessel is protected when the PORVs are set to open at or below the limits specified in the ~~PTLR~~. The setpoint is derived by modeling the performance of the LTOP System, assuming the limiting allowed LTOP transient of one HPSI pump and one charging pump injecting into the RCS. These analyses consider pressure overshoot and undershoot beyond the PORV opening and closing setpoints, resulting from signal processing and valve stroke times. The PORV setpoints at or below the derived limit ensure the Reference 1 limits will be met.

The PORV setpoints will be re-evaluated for compliance when the revised P/T limits conflict with the LTOP analysis limits. The P/T limits are periodically modified as the reactor vessel material toughness decreases due to embrittlement caused by neutron irradiation. Revised P/T limits are determined using neutron fluence projections and the results of examinations of the reactor vessel material irradiation surveillance specimens. The Bases for LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits," discuss these examinations.

The PORVs are considered active components. Thus, the failure of one PORV represents the worst case, single active failure.

RCS Vent Performance

With the RCS depressurized, analyses show a vent size of [~~1.3~~] square inches is capable of mitigating the limiting allowed LTOP overpressure transient. In that event, this ~~-~~size vent maintains RCS pressure less than the maximum RCS pressure on the P/T limit curve.

The RCS vent size will also be re-evaluated for compliance each time the P/T limit curves are revised based on the results of the vessel material surveillance.

The RCS vent is passive and is not subject to active failure.

LTOP System satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

This LCO is required to ensure that the LTOP System is OPERABLE. The LTOP System is OPERABLE when the minimum coolant input and pressure relief capabilities are OPERABLE. Violation of this LCO could lead to the loss of low temperature overpressure mitigation and violation of the Reference 1 limits as a result of an operational transient.

To limit the coolant input capability, the LCO requires that a maximum of one HPSI pump and one charging pump be capable of injecting into the RCS, and the SITs isolated (when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed in ~~the PTLR~~).

LCO 3.4.3

three

1

The LCO is modified by ~~two~~ Notes. Note 1 allows ~~[~~two charging pumps~~]~~ to be made capable of injecting for ≤ 1 hour during pump swap operations. One hour provides sufficient time to safely complete the actual transfer and to complete the administrative controls and Surveillance Requirements associated with the swap. The intent is to minimize the actual time that more than ~~[~~one~~]~~ charging pump is physically capable of injection. Note 2 states that SIT isolation is only required when the SIT pressure is greater than or equal to the RCS pressure for the existing temperature, as allowed by the P/T limit curves provided in ~~the PTLR~~. This Note permits the SIT discharge valve surveillance performed only under these pressure and temperature conditions.

2

2

LCO 3.4.3

1

Note 3 states that all HPSI pumps shall be incapable of injecting into the RCS when any RCS cold leg temperature is ≤ 236°F except when no charging pumps are available for boration in MODES 5 and 6. This Note allows a flow path from the refueling water tank to the RCS via a single HPSI pump if the RCS pressure boundary does not exist, or the RCS pressure boundary integrity exists and no charging pumps are OPERABLE. In the latter case, all charging pumps shall be incapable of injecting into the RCS.

The elements of the LCO that provide overpressure mitigation through pressure relief are:

a. Two OPERABLE PORVs or

1

b. The depressurized RCS and an RCS vent.

LCO

A PORV is OPERABLE for LTOP when its block valve is open, its lift setpoint is set within the limits specified in the ~~PTLR~~ and testing has proven its ability to open at that setpoint, and motive power is available to the two valves and their control circuits.

1

1.75

An RCS vent is OPERABLE when open with an area ≥ ~~[~~1.3~~]~~ square inches.

2

Each of these methods of overpressure prevention is capable of mitigating the limiting LTOP transient.

BASES

APPLICABILITY

This LCO is applicable in MODE 4 when the temperature of any RCS cold leg is ~~less than or equal to the LTOP enable temperature specified in the PTLR~~, in MODE 5, and in MODE 6 when the reactor vessel head is on. The pressurizer safety valves provide overpressure protection that meets the Reference 1 P/T limits above the LTOP enable temperature and below. When the reactor vessel head is off, overpressurization cannot occur.

≤ 300°F

1

LCO 3.4.3 provides the operational P/T limits for all MODES.
LCO 3.4.10, "Pressurizer Safety Valves," requires the OPERABILITY of the pressurizer safety valves that provide overpressure protection during MODES 1, 2, and 3, and MODE 4 ~~above the LTOP enable temperature specified in the PTLR~~.

when any RCS cold leg temperature is > 300°F

1

Low temperature overpressure prevention is most critical during shutdown when the RCS is water solid, and a mass or heat input transient can cause a very rapid increase in RCS pressure when little or no time allows operator action to mitigate the event.

ACTIONS

A Note prohibits the application of LCO 3.0.4.b to inoperable PORVs used for LTOP. There is an increased risk associated with entering MODE 4 from MODE 5 with PORVs used for LTOP inoperable and the provisions of LCO 3.0.4.b, which allow entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, should not be applied in this circumstance.

A.1 and B.1

or two or more charging pumps

1

With two or more HPSI pumps capable of injecting into the RCS, overpressurization is possible.

The immediate Completion Time to initiate actions to restore restricted coolant input capability to the RCS reflects the importance of maintaining overpressure protection of the RCS.

C.1, D.1, and D.2

An unisolated SIT requires isolation within 1 hour. This is only required when the SIT pressure is greater than or equal to the maximum RCS pressure for the existing cold leg temperature allowed in ~~the PTLR~~.

LCO 3.4.3

1

BASES

ACTIONS (continued)

If isolation is needed and cannot be accomplished within 1 hour, Required Action D.1 and Required Action D.2 provide two options, either of which must be performed within 12 hours. ~~By increasing the RCS temperature to > [175]°F, a SIT pressure of [600] psig cannot exceed the LTOP limits if the tanks are fully injected. Depressurizing the SIT below the LTOP limit stated in the PTLR also protects against such an event.~~ 1

Raising RCS pressure above the SIT pressure or venting the SIT pressure below the RCS pressure, protects against an LTOP event.

The Completion Times are based on operating experience that these activities can be accomplished in these time periods and on engineering evaluations indicating that an event requiring LTOP is not likely in the allowed times.

E.1

In MODE 4 when any RCS cold leg temperature is ≤ ~~[285]~~ 300 °F, with one PORV inoperable, two PORVs must be restored to OPERABLE status within a Completion Time of 7 days. Two valves are required to meet the LCO requirement and to provide low temperature overpressure mitigation while withstanding a single failure of an active component. 2

The Completion Time is based on the facts that only one PORV is required to mitigate an overpressure transient and that the likelihood of an active failure of the remaining valve path during this time period is very low.

F.1

The consequences of operational events that will overpressure the RCS are more severe at lower temperature (Ref. 6). Thus, one required PORV inoperable in MODE 5 or in MODE 6 with the head on, the Completion Time to restore two valves to OPERABLE status is 24 hours.

The 24 hour Completion Time to restore two PORVs OPERABLE in MODE 5 or in MODE 6 when the vessel head is on is a reasonable amount of time to investigate and repair several types of PORV failures without exposure to a lengthy period with only one PORV OPERABLE to protect against overpressure events.

BASES

ACTIONS (continued)

G.1

If two required PORVs are inoperable, or if a Required Action and the associated Completion Time of Condition A, B, D, E, or F are not met, or if the LTOP System is inoperable for any reason other than Condition A through Condition F, the RCS must be depressurized and a vent established within 12 hours. The vent must be sized at least ~~[1.3]~~ 1.75 square inches to ensure the flow capacity is greater than that required for the worst case mass input transient reasonable during the applicable MODES. This action protects the RCPB from a low temperature overpressure event and a possible brittle failure of the reactor vessel. 2

The Completion Time of 12 hours to depressurize and vent the RCS is based on the time required to place the plant in this condition and the relatively low probability of an overpressure event during this time period due to increased operator awareness of administrative control requirements.

SURVEILLANCE REQUIREMENTS

SR 3.4.12.1, SR 3.4.12.2, and SR 3.4.12.3

To minimize the potential for a low temperature overpressure event by limiting the mass input capability, only one HPSI pump and all but ~~[~~one~~]~~ charging pump are verified ~~OPERABLE~~ capable of injecting into the RCS with the other pumps locked out with power removed and the SIT discharge incapable of injecting into the RCS. The ~~[~~HPI~~]~~ pump~~[s]~~ and charging pump~~[s]~~ S are rendered incapable of injecting into the RCS through removing the power from the pumps by racking the breakers out under administrative control. An alternate method of LTOP control may be employed using at least two independent means to prevent a pump start such that a single failure or single action will not result in an injection into the RCS. This may be accomplished through the pump control switch being placed in ~~[pull to lock]~~ stop and caution tag attached, and at least one valve in the discharge flow path being closed and caution tag attached,. 2 1 2 2

~~[The 12 hour interval considers operating practice to regularly assess potential degradation and to verify operation within the safety analysis.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

2

SR 3.4.12.4

1.75

SR 3.4.12.4 requires verifying that the required RCS vent is open ≥ ~~[1.3]~~ square inches is proven OPERABLE by verifying its open condition ~~[~~ either:

2

a. Once every 12 hours for a valve that is unlocked open (valves that are sealed or secured in the open position are considered "locked" in this context) or

b. Once every 31 days for other vent path(s) (e.g., a vent valve that is locked, sealed, or secured in position, a removed pressurizer safety valve, or open manway).

~~OR~~

2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

2

The passive vent path arrangement must only be open to be OPERABLE. This Surveillance need only be performed if the vent is being used to satisfy the requirements of this LCO. The Frequencies consider operating experience with mispositioning of unlocked and locked vent valves, respectively.

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.12.5

The PORV block valve must be verified open to provide the flow path for each required PORV to perform its function when actuated. The valve can be remotely verified open in the main control room.

The block valve is a remotely controlled, motor operated valve. The power to the valve motor operator is not required to be removed, and the manual actuator is not required locked in the inactive position. Thus, the block valve can be closed in the event the PORV develops excessive leakage or does not close (sticks open) after relieving an overpressure event.

~~[The 72 hour Frequency considers operating experience with accidental movement of valves having remote control and position indication capabilities available where easily monitored. These considerations include the administrative controls over main control room access and equipment control.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~]~~

SR 3.4.12.6

Performance of a CHANNEL FUNCTIONAL TEST is required to verify and, as necessary, adjust the PORV open setpoints. The CHANNEL FUNCTIONAL TEST will verify on a monthly basis that the PORV lift setpoints are within the LCO limit. A successful test of the required contact(s) of a channel relay may be performed by the verification of the

BASES

SURVEILLANCE REQUIREMENTS (continued)

change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. PORV actuation could depressurize the RCS and is not required. ~~[The 31 day Frequency considers experience with equipment reliability.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~----------]~~

~~A Note has been added indicating this SR is required to be performed [12] hours after decreasing RCS cold leg temperature to less than or equal to the LTOP enable temperature specified in the PTLR. The test cannot be performed until the RCS is in the LTOP MODES when the PORV lift setpoint can be reduced to the LTOP setting. The test must be performed within 12 hours after entering the LTOP MODES.~~ 3

SR 3.4.12.7

Performance of a CHANNEL CALIBRATION on each required PORV actuation channel is required to adjust the whole channel so that it responds and the valve opens within the required LTOP range and with accuracy to known input.

~~[The [18] month Frequency considers operating experience with equipment reliability and matches the typical refueling outage schedule.~~ 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.12 Low Temperature Overpressure Protection (LTOP) System

BASES

BACKGROUND

The LTOP System controls RCS pressure at low temperatures so the integrity of the reactor coolant pressure boundary (RCPB) is not compromised by violating the pressure and temperature (P/T) limits of 10 CFR 50, Appendix G (Ref. 1). The reactor vessel is the limiting RCPB component for demonstrating such protection. LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits," provides the allowable combinations for operational pressure and temperature during cooldown, shutdown, and heatup to keep from violating the Reference 1 requirements during the LTOP MODES.

The reactor vessel material is less tough at low temperatures than at normal operating temperatures. As the vessel neutron exposure accumulates, the material toughness decreases and becomes less resistant to pressure stress at low temperatures (Ref. 2). RCS pressure, therefore, is maintained low at low temperatures and is increased only as temperature is increased.

The potential for vessel overpressurization is most acute when the RCS is water solid, occurring only while shutdown; a pressure fluctuation can occur more quickly than an operator can react to relieve the condition. Exceeding the RCS P/T limits by a significant amount could cause brittle cracking of the reactor vessel. LCO 3.4.3 requires administrative control of RCS pressure and temperature during heatup and cooldown to prevent exceeding the P/T limits.

This LCO provides RCS overpressure protection by having a minimum coolant input capability and having adequate pressure relief capacity. Limiting coolant input capability requires all but one high pressure safety injection (HPSI) pump and one charging pump incapable of injection into the RCS and isolating the safety injection tanks (SITs). The pressure relief capacity requires ~~either~~ two OPERABLE redundant power operated relief valves (PORVs) or the RCS depressurized and an RCS vent of sufficient size. One ~~PORV~~ or the RCS vent is the overpressure protection device that acts to terminate an increasing pressure event.

any combination of
and shutdown cooling relief valves (SDCRVs).
relief valve

1

1

BASES

BACKGROUND (continued)

With minimum coolant input capability, the ability to provide core coolant addition is restricted. The LCO does not require the makeup control system deactivated or the safety injection (SI) actuation circuits blocked. Due to the lower pressures in the LTOP MODES and the expected core decay heat levels, the makeup system can provide adequate flow via the makeup control valve. If conditions require the use of more than one ~~[~~HPI or~~]~~ charging pump for makeup in the event of loss of inventory, then pumps can be made available through manual actions.

S

relief valves including

The LTOP System for pressure relief consists of two PORVs with reduced lift settings or an RCS vent of sufficient size. Two relief valves are required for redundancy. One ~~PORV~~ has adequate relieving capability to prevent overpressurization for the required coolant input capability.

, two SDCRVs, one PORV with reduced settings and one SDCRV,

relief valve

PORV Requirements

As designed for the LTOP System, each PORV is signaled to open if the RCS pressure approaches a limit determined by the LTOP actuation logic. The actuation logic monitors RCS pressure and determines when the LTOP overpressure setting is approached. If the indicated pressure meets or exceeds the calculated value, a PORV is signaled to open.

1

The LCO presents the PORV setpoints for LTOP. ~~The setpoints are normally staggered so only one valve opens during a low temperature overpressure transient.~~ Having the setpoints of both valves within the limits of the LCO ensures the P/T limits will not be exceeded in any analyzed event.

required

When a PORV is opened in an increasing pressure transient, the release of coolant causes the pressure increase to slow and reverse. As the PORV releases coolant, the system pressure decreases until a reset pressure is reached and the valve is signaled to close. The pressure continues to decrease below the reset pressure as the valve closes.

SDCRV Requirements

The LCO presents the SDCRV setpoints for LTOP. The SDCRVs may be used to provide for LTOP protection when a SDC loop is aligned to the RCS.

Each SDCRV opens when the RCS pressure exceeds the relief valve setpoint, eliminating the potential for water volume changes and the resulting pressurization effects. The relief valve capacity is greater than the water volume that can be injected into the RCS following a spurious safety injection actuation signal (SIAS) that starts two HPSI pumps, three charging pumps, and isolates the letdown control valves.

RCS Vent Requirements

Once the RCS is depressurized, a vent exposed to the containment atmosphere will maintain the RCS at containment ambient pressure in an RCS overpressure transient, if the relieving requirements of the transient do not exceed the capabilities of the vent. Thus, the vent path must be capable of relieving the flow resulting from the limiting LTOP mass or heat input transient and maintaining pressure below the P/T limits. The required vent capacity may be provided by one or more vent paths.

BASES

BACKGROUND (continued)

~~For an RCS vent to meet the specified flow capacity, it requires removing a pressurizer safety valve, removing a PORV's internals, and disabling its block valve in the open position, or similarly establishing a vent by opening an RCS vent valve.~~ The vent path(s) must be above the level of reactor coolant, so as not to drain the RCS when open.

APPLICABLE SAFETY ANALYSES

~~Safety~~ analyses (Ref. 3) demonstrate that the reactor vessel is adequately protected against exceeding the Reference 1 P/T limits during shutdown. In MODES 1, 2, and 3, and in MODE 4 with any RCS cold leg temperature greater than ~~the LTOP enable temperature specified in the PTLR~~, the pressurizer safety valves prevent RCS pressure from exceeding the Reference 1 limits. ~~At the LTOP enable temperature specified in the PTLR and below~~, overpressure prevention falls to the OPERABLE ~~PORVs~~ ~~[~~or to a depressurized RCS and a sufficient sized RCS vent~~]~~. Each of these means has a limited overpressure relief capability.

The actual temperature at which the pressure in the P/T limit curve falls below the pressurizer safety valve setpoint increases as the reactor vessel material toughness decreases due to neutron embrittlement. Each time the P/T limit curves are revised, the LTOP System will be re-evaluated to ensure its functional requirements can still be satisfied using the ~~PORV~~ method or the depressurized and vented RCS condition.

Reference 3 contains the acceptance limits that satisfy the LTOP requirements. Any change to the RCS must be evaluated against these analyses to determine the impact of the change on the LTOP acceptance limits.

Transients that are capable of overpressurizing the RCS are categorized as either mass or heat input transients, examples of which follow:

Mass Input Type Transients

~~a.~~ Inadvertent safety injection ~~or~~

~~b. Charging/letdown flow mismatch~~.

Heat Input Type Transients

~~a. Inadvertent actuation of pressurizer heaters,~~

~~b.~~ ~~Loss of shutdown cooling (SDC)~~, or

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~c.~~ Reactor coolant pump (RCP) startup with temperature asymmetry within the RCS or between the RCS and steam generators. 1

The following are required during the LTOP MODES to ensure that mass and heat input transients do not occur, which either of the LTOP overpressure protection means cannot handle:

a. Rendering all but one HPSI pump, and all but one charging pump incapable of injection and

b. Deactivating the SIT discharge isolation valves in their closed positions.

relief valve

The Reference 3 analyses demonstrate that either one ~~PORV~~ or the RCS vent can maintain RCS pressure below limits when only one HPSI pump and one charging pump are actuated. Thus, the LCO allows only one HPSI pump and one charging pump ~~OPERABLE~~ during the LTOP MODES. Since neither the ~~PORV~~ nor the RCS vent can handle the pressure transient produced from ~~accumulator~~ injection, when RCS temperature is low, the LCO also requires the SITs isolation when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed in the PTLR. 1

capable of injecting into the RCS

relief valve

SIT

The isolated SITs must have their discharge valves closed and the valve power supply breakers fixed in their open positions. The analyses show the effect of SIT discharge is over a narrower RCS temperature range ~~([175]°F and below)~~ than that of the LCO ~~(less than or equal to the LTOP enable temperature specified in the PTLR and below)~~. 1

Fracture mechanics analyses established the temperature of LTOP Applicability at less than or equal to the LTOP enable temperature ~~specified in the PTLR~~. Above this temperature, the pressurizer safety valves provide the reactor vessel pressure protection. ~~The vessel materials were assumed to have a neutron irradiation accumulation equal to 21 effective full power years of operation.~~ 1

The consequences of a small break loss of coolant accident (LOCA) in LTOP MODE 4 conform to 10 CFR 50.46 and 10 CFR 50, Appendix K (Refs. 4 and 5), requirements by having a maximum of one HPSI pump and one charging pump ~~OPERABLE and SI actuation enabled for these pumps~~. 1

capable of injecting into the RCS

BASES

APPLICABLE SAFETY ANALYSES (continued)

PORV Performance

The fracture mechanics analyses show that the vessel is protected when the PORVs are set to open at or below the limits specified in the ~~PTLR~~. The setpoint is derived by modeling the performance of the LTOP System, assuming the limiting allowed LTOP transient of one HPSI pump and one charging pump injecting into the RCS. These analyses consider pressure overshoot and undershoot beyond the PORV opening and closing setpoints, resulting from signal processing and valve stroke times. The PORV setpoints at or below the derived limit ensure the Reference 1 limits will be met.

The PORV setpoints will be re-evaluated for compliance when the revised P/T limits conflict with the LTOP analysis limits. The P/T limits are periodically modified as the reactor vessel material toughness decreases due to embrittlement caused by neutron irradiation. Revised P/T limits are determined using neutron fluence projections and the results of examinations of the reactor vessel material irradiation surveillance specimens. The Bases for LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits," discuss these examinations.

The PORVs are considered active components. Thus, the failure of one PORV represents the worst case, single active failure.

SDCRV Performance

The SDCRVs are sized for a flow capacity of 2300 gpm at a lift set pressure of 350 psia. Each of two SDC relief valves is sufficient to provide LTOP during low temperature operation when the SDCRVs are aligned to the RCS.

The SDCRVs are passive components of the shutdown cooling system.

RCS Vent Performance

With the RCS depressurized, analyses show a vent size of [~~1.3~~] square inches is capable of mitigating the limiting allowed LTOP overpressure transient. In that event, this ~~-~~size vent maintains RCS pressure less than the maximum RCS pressure on the P/T limit curve.

The RCS vent size will also be re-evaluated for compliance each time the P/T limit curves are revised based on the results of the vessel material surveillance.

The RCS vent is passive and is not subject to active failure.

LTOP System satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

BASES

LCO

This LCO is required to ensure that the LTOP System is OPERABLE. The LTOP System is OPERABLE when the minimum coolant input and pressure relief capabilities are OPERABLE. Violation of this LCO could lead to the loss of low temperature overpressure mitigation and violation of the Reference 1 limits as a result of an operational transient.

To limit the coolant input capability, the LCO requires that a maximum of one HPSI pump and one charging pump be capable of injecting into the RCS, and the SITs isolated (when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed in ~~the PTLR~~).

LCO 3.4.3

three

The LCO is modified by ~~two~~ Notes. Note 1 allows ~~[~~two charging pumps~~]~~ to be made capable of injecting for ≤ 1 hour during pump swap operations. One hour provides sufficient time to safely complete the actual transfer and to complete the administrative controls and Surveillance Requirements associated with the swap. The intent is to minimize the actual time that more than ~~[~~one~~]~~ charging pump is physically capable of injection. Note 2 states that SIT isolation is only required when the SIT pressure is greater than or equal to the RCS pressure for the existing temperature, as allowed by the P/T limit curves provided in ~~the PTLR~~. This Note permits the SIT discharge valve surveillance performed only under these pressure and temperature conditions.

LCO 3.4.3

Note 3 allows the PORVs to be used when all RCS cold leg temperatures are ≥ 149°F during cooldown and when all RCS cold leg temperatures are ≥ 60°F during heatup. As a result, LCO 3.4.12.a and c pressure relief options are not allowed below 149°F during cooldown following a reactor shutdown. The SDCRVs or an RCS vent path of > 3.58 square inches are utilized for LTOP protection below 149°F. This restriction is necessary because the required relief capability of a PORV during a cooldown is not sufficient to overcome coolant input capability. During vessel heatup operations, the relief capability of the PORVs are sufficient. Use of PORVs below 60°F was not analyzed and therefore not acceptable for use below that value.

The elements of the LCO that provide overpressure mitigation through pressure relief are:

a. Two OPERABLE PORVs or

two OPERABLE SDCRVs, or one OPERABLE PORV and one OPERABLE SDCRV, and

b. The depressurized RCS and an RCS vent.

LCO

A PORV is OPERABLE for LTOP when its block valve is open, its lift setpoint is set within the limits specified in the ~~PTLR~~ and testing has proven its ability to open at that setpoint, and motive power is available to the ~~two~~ valve~~s~~ and their control circuits.

3.58

An RCS vent is OPERABLE when open with an area ≥ ~~[1.3]~~ square inches.

Each of these methods of overpressure prevention is capable of mitigating the limiting LTOP transient.

A SDCRV is OPERABLE for LTOP when its lift setpoint is set within the limits specified in the LCO and the SDC system is aligned to the RCS.

The LTOP enable temperature is dependent on RCS thermal transient conditions. LTOP analyses indicate that LTOP may be enabled at a lower RCS temperature during an RCS cooldown following a reactor shutdown than during an RCS heatup from cold conditions due to the lower reactor vessel fracture toughness when the reactor vessel is cold. Therefore, the LCO is applicable in MODE 4 when any RCS cold leg temperature is less or equal to the LTOP cooldown temperature of 240°F following entry into MODE 4 from MODE 3 and in MODE 4 when any RCS cold leg temperature is less or equal to the LTOP heatup temperature of 252°F following entry into MODE 4 from MODE 5.

BASES

APPLICABILITY

≤ 240°F following entry from MODE 3 and when any RCS cold leg temperature is ≤ 252°F following entry from MODE 5.

This LCO is applicable in MODE 4 when the temperature of any RCS cold leg is ~~less than or equal to the LTOP enable temperature specified in the PTLR~~, in MODE 5, and in MODE 6 when the reactor vessel head is on. The pressurizer safety valves provide overpressure protection that meets the Reference 1 P/T limits above the LTOP enable temperature and below. When the reactor vessel head is off, overpressurization cannot occur.

LCO 3.4.3 provides the operational P/T limits for all MODES.
LCO 3.4.10, "Pressurizer Safety Valves," requires the OPERABILITY of the pressurizer safety valves ~~that provide overpressure protection~~ during MODES 1, 2, and 3, and MODE 4 ~~above the LTOP enable temperature specified in the PTLR~~.

when all RCS cold leg temperatures are > 230°F to ensure uninterrupted overpressure protection.

Low temperature overpressure prevention is most critical during shutdown when the RCS is water solid, and a mass or heat input transient can cause a very rapid increase in RCS pressure when little or no time allows operator action to mitigate the event.

ACTIONS

A Note prohibits the application of LCO 3.0.4.b to inoperable PORVs used for LTOP. There is an increased risk associated with entering MODE 4 from MODE 5 with PORVs used for LTOP inoperable and the provisions of LCO 3.0.4.b, which allow entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, should not be applied in this circumstance.

A.1 and B.1

or two or more charging pumps

With two or more HPSI pumps capable of injecting into the RCS, overpressurization is possible.

The immediate Completion Time to initiate actions to restore restricted coolant input capability to the RCS reflects the importance of maintaining overpressure protection of the RCS.

C.1, D.1, and D.2

An unisolated SIT requires isolation within 1 hour. This is only required when the SIT pressure is greater than or equal to the maximum RCS pressure for the existing cold leg temperature allowed in ~~the PTLR~~.

LCO 3.4.3

BASES

ACTIONS (continued)

If isolation is needed and cannot be accomplished within 1 hour, Required Action D.1 and Required Action D.2 provide two options, either of which must be performed within 12 hours. ~~By increasing the RCS temperature to > [175]°F, a SIT pressure of [600] psig cannot exceed the LTOP limits if the tanks are fully injected. Depressurizing the SIT below the LTOP limit stated in the PTLR also protects against such an event.~~ 1

Raising RCS pressure above the SIT pressure or venting the SIT pressure below the RCS pressure, protects against an LTOP event.

The Completion Times are based on operating experience that these activities can be accomplished in these time periods and on engineering evaluations indicating that an event requiring LTOP is not likely in the allowed times.

E.1

or one required SDCRV inoperable,

required relief valves

required

~~In MODE 4 when any RCS cold leg temperature is ≤ [285]°F,~~ with one PORV inoperable, two ~~PORVs~~ must be restored to OPERABLE status within a Completion Time of 7 days. Two valves are required to meet the LCO requirement and to provide low temperature overpressure mitigation while withstanding a single failure of an active component. 1 2

relief valve

The Completion Time is based on the facts that only one ~~PORV~~ is required to mitigate an overpressure transient and that the likelihood of an active failure of the remaining valve path during this time period is very low. 1

~~F.1~~

~~The consequences of operational events that will overpressure the RCS are more severe at lower temperature (Ref. 6). Thus, one required PORV inoperable in MODE 5 or in MODE 6 with the head on, the Completion Time to restore two valves to OPERABLE status is 24 hours.~~ 1

~~The 24 hour Completion Time to restore two PORVs OPERABLE in MODE 5 or in MODE 6 when the vessel head is on is a reasonable amount of time to investigate and repair several types of PORV failures without exposure to a lengthy period with only one PORV OPERABLE to protect against overpressure events.~~

BASES

ACTIONS (continued)

F

~~G~~.1

or one required PORV and one required SDCRV are inoperable, or two required SDCRVs are inoperable,

or

If two required PORVs are inoperable, or if a Required Action and the associated Completion Time of Condition A, B, D, E, ~~or F~~ are not met, or if the LTOP System is inoperable for any reason other than Condition A through Condition ~~F~~, the RCS must be depressurized and a vent established within 12 hours. The vent must be sized at least ~~[1.3]~~ square inches to ensure the flow capacity is greater than that required for the worst case mass input transient reasonable during the applicable MODES. This action protects the RCPB from a low temperature overpressure event and a possible brittle failure of the reactor vessel.

1

E

3.58

2

The Completion Time of 12 hours to depressurize and vent the RCS is based on the time required to place the plant in this condition and the relatively low probability of an overpressure event during this time period due to increased operator awareness of administrative control requirements.

SURVEILLANCE REQUIREMENTS

SR 3.4.12.1, SR 3.4.12.2, and SR 3.4.12.3

To minimize the potential for a low temperature overpressure event by limiting the mass input capability, only one HPSI pump and all but ~~[~~one~~]~~ charging pump are verified ~~OPERABLE~~ with the other pumps locked out with power removed and the SIT discharge incapable of injecting into the RCS. The ~~[~~HPI~~]~~ pump~~[s]~~ and charging pump~~[s]~~ are rendered incapable of injecting into the RCS through removing the power from the pumps by racking the breakers out under administrative control. An alternate method of LTOP control may be employed using at least two independent means to prevent a pump start such that a single failure or single action will not result in an injection into the RCS. This may be accomplished through the pump control switch being placed in ~~[pull to lock]~~ and at least one valve in the discharge flow path being closed.

2

SR 3.4.12.4

3.58

SR 3.4.12.4 requires verifying that the required RCS vent is open ≥ ~~[1.3]~~ square inches is proven OPERABLE by verifying its open condition [either:

2

~~a. Once every 12 hours for a valve that is unlocked open (valves that are sealed or secured in the open position are considered "locked" in this context) or~~

~~b. Once every 31 days for other vent path(s) (e.g., a vent valve that is locked, sealed, or secured in position, a removed pressurizer safety valve, or open manway).~~

~~OR~~

2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

2

The passive vent path arrangement must only be open to be OPERABLE. This Surveillance need only be performed if the vent is being used to satisfy the requirements of this LCO. The Frequencies consider operating experience with mispositioning of unlocked and locked vent valves, respectively.

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.12.5

The PORV block valve must be verified open to provide the flow path for each required PORV to perform its function when actuated. The valve can be remotely verified open in the main control room.

The block valve is a remotely controlled, motor operated valve. The power to the valve motor operator is not required to be removed, and the manual actuator is not required locked in the inactive position. Thus, the block valve can be closed in the event the PORV develops excessive leakage or does not close (sticks open) after relieving an overpressure event.

~~[The 72 hour Frequency considers operating experience with accidental movement of valves having remote control and position indication capabilities available where easily monitored. These considerations include the administrative controls over main control room access and equipment control.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~----------]~~

SR 3.4.12.6

Performance of a CHANNEL FUNCTIONAL TEST is required to verify and, as necessary, adjust the PORV open setpoints. The CHANNEL FUNCTIONAL TEST will verify on a monthly basis that the PORV lift setpoints are within the LCO limit. A successful test of the required contact(s) of a channel relay may be performed by the verification of the

BASES

SURVEILLANCE REQUIREMENTS (continued)

change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. PORV actuation could depressurize the RCS and is not required. ~~[The 31 day Frequency considers experience with equipment reliability.~~ 2

~~OR~~ 2

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

~~A Note has been added indicating this SR is required to be performed [12] hours after decreasing RCS cold leg temperature to less than or equal to the LTOP enable temperature specified in the PTLR. The test cannot be performed until the RCS is in the LTOP MODES when the PORV lift setpoint can be reduced to the LTOP setting. The test must be performed within 12 hours after entering the LTOP MODES.~~ 3

SR 3.4.12.7

Performance of a CHANNEL CALIBRATION on each required PORV actuation channel is required to adjust the whole channel so that it responds and the valve opens within the required LTOP range and with accuracy to known input.

~~[The [18] month Frequency considers operating experience with equipment reliability and matches the typical refueling outage schedule.~~ 2

NOTES

(a) Maximum Allowable Leakage (each valve):

1. Leakage rates less than or equal to 1.0 gpm are acceptable.

2. Leakage rates greater than 1.0 gpm but less than or equal to 5.0 gpm are acceptable if the latest measured rate has not exceeded the rate determined by the previous test by an amount the reduces the margin between previous measured leakage rate and the maximum permissible rate of 5.0 gpm by 50% or greater.

3. Leakage rates greater than 1.0 gpm but less than or equal to 5.0 gpm are unacceptable if the latest measured rate exceeded the rate determined by the previous test by an amount that reduces the margin between measured leakage rate and the maximum permissible rate of 5.0 gpm by 50% or greater.

4. Leakage rates greater than 5.0 gpm are unacceptable.

(b) To satisfy ALARA requirements, leakage may be measured indirectly (as from the performance of pressure indicators) if accomplished in accordance with approved procedures and supported by computations showing that the method is capable of demonstrating valve compliance with the leakage criteria.

(c) Minimum test differential pressure shall not be less than 150 psid.

NOTES

(a) Maximum Allowable Leakage (each valve):

1. Except as noted below leakage rates greater than 1.0 gpm are unacceptable.

2. For motor-operated valves (MOVs) only, leakage rates greater than 1.0 gpm but less than or equal to 5.0 gpm are acceptable if the latest measured rate has not exceeded the rate determined by the previous test by an amount the reduces the margin between previous measured leakage rate and the maximum permissible rate of 5.0 gpm by 50% or greater.

3. For motor-operated valves (MOVs) only, leakage rates greater than 1.0 gpm but less than or equal to 5.0 gpm are unacceptable if the latest measured rate exceeded the rate determined by the previous test by an amount that reduces the margin between measured leakage rate and the maximum permissible rate of 5.0 gpm by 50% or greater.

4. Leakage rates greater than 5.0 gpm are unacceptable.

(b) To satisfy ALARA requirements, leakage may be measured indirectly (as from the performance of pressure indicators) if accomplished in accordance with approved procedures and supported by computations showing that the method is capable of demonstrating valve compliance with the leakage criteria.

(c) Minimum test differential pressure shall not be less than 200 psid.

DISCUSSION OF CHANGES
ITS 3.4.13, RCS OPERATIONAL LEAKAGE

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* CTS 3.4.6.2 Action a. states, in part, with any PRESSURE BOUNDARY LEAKAGE, be in at least HOT STANDBY (i.e., MODE 3) within 6 hours and in COLD SHUTDOWN (i.e., MODE 5) within the following 30 hours. ITS 3.4.13 ACTION A states that if pressure boundary LEAKAGE exists, isolate the affected component, pipe, or vessel from the RCS by use of a closed manual valve, closed and de-activated automatic valve, blind flange, or check valve within 4 hours. Additionally, ITS 3.4.13 ACTION C states that with the Required Action and associated Completion Time not met, be in MODE 3 within 6 hours and MODE 5 within 36 hours. This changes the CTS by allowing 4 hours to isolate the leakage before requiring Actions to exit the applicable MODES, consistent with Technical Specification Task Force (TSTF) traveler TSTF-554-A, Revision 1, “Revise Reactor Coolant Leakage Requirements.”

TSTF traveler TSTF-554-A incorporated changes to the Standard Technical Specifications (STSs) under the consolidated line item improvement process (CLIIP). TSTF-554-A was approved for use by the NRC as documented in staff Safety Evaluation (SE) dated December 18, 2020 (ADAMS Accession No. ML20322A361, ML20322A024). PSL has reviewed the NRC staff SE and concluded that the justification presented in TSTF-554-A and the SE prepared by the NRC staff are applicable to PSL and justify this change.

TSTF-554-A revised the technical specifications related to reactor coolant system (RCS) operational leakage by adding Condition A that applies when pressure boundary LEAKAGE exists and Required Action A.1 that requires isolation of the affected component, pipe, or vessel from the RCS by use of a closed manual valve, closed and de-activated automatic valve, blind flange, or check valve, within a Completion Time of 4 hours. If the 4-hour Completion Time cannot be met, the plant must initiate shutdown in accordance with ACTION C. The Required Action requires the flaw to be isolated from the reactor coolant pressure source to prevent further degradation of the flaw, which could result in additional leakage. If Required Action A.1 cannot be completed within the 4-hour Completion Time, ISTS 3.4.13 Condition C requires that the reactor be brought to lower pressure conditions to reduce the severity of the LEAKAGE and its potential consequences (i.e., be in MODE 3 within 6 hours and MODE 5 within 36 hours. ISTS 3.4.13 Condition A, including its associated Required Action A.1 and Completion Time, is acceptable because it continues to meet the requirements of 10 CFR 50.36(c)(2)(i), by providing remedial actions and shutting down the reactor if the remedial actions cannot be met.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 (Category 5 – Deletion of Surveillance Requirement) Unit 1 CTS 4.4.6.2.a and Unit 2 CTS 4.4.6.2.1.a require monitoring of the containment atmosphere gaseous and particulate radioactivity in accordance with the Surveillance Frequency Control Program. Unit 1 CTS 4.4.6.2.b and Unit 2 CTS 4.4.6.2.1.b require monitoring the containment sump inventory and discharge in accordance with the Surveillance Frequency Control Program. Unit 1 CTS 4.4.6.2.d and Unit 2 CTS 4.4.6.2.1.d require monitoring the reactor head flange leakoff system in accordance with the Surveillance Frequency Control Program. The ITS does not contain these Surveillance Requirements. This changes the CTS by deleting these Surveillance Requirements.

This change is acceptable because the deleted Surveillance Requirements are not necessary to verify that the LCO is being met. Appropriate Surveillance Requirements continue to be performed in a manner and at a Frequency necessary to give confidence that the LCO is being met. The indications in the deleted Surveillance Requirements are not necessarily indications of failure to meet the LCO on RCS operational leakage. These items do provide useful information and the containment atmosphere gaseous and particulate radioactivity monitors, and the containment sump monitors are required to be OPERABLE by ITS 3.4.15, "RCS Leakage Detection Instrumentation." However, under ITS SR 3.0.1, failure to meet the Surveillance results in failure to meet the LCO. As these indications do not necessarily indicate a failure to meet the LCO, it is not appropriate to retain these indications in this Specification. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

L03 **Unit 1 only:** *(Category 5 – Deletion of Surveillance Requirement)* CTS 4.4.6.2.c requires performance of a Reactor Coolant System water inventory balance in accordance with the Surveillance Frequency Control Program "except when operating in the shutdown cooling mode" and is modified by a footnote that states not required to be performed until 12 hours after establishment of steady state operation. ITS SR 3.4.13.1 does not contain the exception that states "except when operating in the shutdown cooling mode." This changes the CTS by deleting the exception for performance of the Surveillance when operating in the shutdown cooling mode.

The purpose of CTS 4.4.6.2.c is to verify RCS LEAKAGE within the LCO limits to ensure the integrity of the RCPB is maintained. Steady state operation is required to perform a proper water inventory balance since calculations during maneuvering are not useful. For RCS operational LEAKAGE determination by water inventory balance, steady state is defined as stable RCS pressure, temperature, power level, pressurizer and makeup tank levels, and makeup and letdown. An early warning of pressure boundary LEAKAGE or unidentified LEAKAGE is provided by the automatic systems that monitor the containment atmosphere radioactivity and the containment sump level. These leakage detection systems are specified in LCO 3.4.15, "RCS Leakage Detection Instrumentation. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify that the values used to meet the LCO are consistent with the safety analysis. ITS SR 3.4.13.1 retains the Surveillance Requirement to verify RCS operation LEAKAGE is within limits by performance of RCS water inventory balance. This change is designated as less restrictive because a Surveillance required in the CTS will not be required in the ITS.

L04 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* CTS 3.4.6.2 Action d. states that with RCS leakage alarmed and confirmed in a flow path with no flow indication, commence an RCS water inventory balance within 1 hour to determine the leak rate. ITS 3.4.13 does not contain a requirement for an RCS water inventory balance in response to system alarms. This changes the CTS by deleting the explicit requirement for an RCS water inventory balance in response to system alarms.

The purpose of CTS 3.4.6.2 is to verify RCS LEAKAGE within the LCO limits and take appropriate actions in response to operational LEAKGE not within limits, to ensure the integrity of the RCPB is maintained. An early warning of pressure boundary LEAKAGE or unidentified LEAKAGE is provided by the automatic systems that monitor the containment atmosphere radioactivity and the containment sump level. These leakage detection systems are specified in LCO 3.4.15, "RCS Leakage Detection Instrumentation." ITS 3.4.15 provides ACTIONS that include performance of SR 3.4.13.1 (i.e., RCS water inventory balance). This change is acceptable because the deleted requirement is not necessary to verify that the values used to meet the LCO are consistent with the safety analysis. ITS SR 3.4.13.1 retains the Surveillance Requirement to verify RCS operation LEAKAGE is within limits by performance of RCS water inventory balance. This change is designated as less restrictive because an Action required in the CTS will not be required in the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.13, RCS OPERATIONAL LEAKAGE

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.13 RCS Operational LEAKAGE

BASES

BACKGROUND

Components that contain or transport the coolant to or from the reactor core make up the RCS. Component joints are made by welding, bolting, rolling, or pressure loading, and valves isolate connecting systems from the RCS.

During plant life, the joint and valve interfaces can produce varying amounts of reactor coolant LEAKAGE, through either normal operational wear or mechanical deterioration. The purpose of the RCS Operational LEAKAGE LCO is to limit system operation in the presence of LEAKAGE from these sources to amounts that do not compromise safety. This LCO specifies the types and amounts of LEAKAGE.

10 CFR 50, Appendix A, GDC 30 (Ref. 1), requires means for detecting and, to the extent practical, identifying the source of reactor coolant LEAKAGE. Regulatory Guide 1.45 (Ref. 2) describes acceptable methods for selecting leakage detection systems.

The safety significance of RCS LEAKAGE varies widely depending on its source, rate, and duration. Therefore, detecting and monitoring reactor coolant LEAKAGE into the containment area is necessary. Quickly separating the identified LEAKAGE from the unidentified LEAKAGE is necessary to provide quantitative information to the operators, allowing them to take corrective action should a leak occur detrimental to the safety of the facility and the public.

A limited amount of leakage inside containment is expected from auxiliary systems that cannot be made 100% leaktight. Leakage from these systems should be detected, located, and isolated from the containment atmosphere, if possible, to not interfere with RCS LEAKAGE detection.

This LCO deals with protection of the reactor coolant pressure boundary (RCPB) from degradation and the core from inadequate cooling, in addition to preventing the accident analysis radiation release assumptions from being exceeded. The consequences of violating this LCO include the possibility of a loss of coolant accident (LOCA).

BASES

APPLICABLE SAFETY ANALYSES

Except for primary to secondary LEAKAGE, the safety analyses do not address operational LEAKAGE. However, other operational LEAKAGE is related to the safety analyses for LOCA; the amount of leakage can affect the probability of such an event. The safety analysis for an event resulting in steam discharge to the atmosphere assumes that primary to secondary LEAKAGE from ~~all~~ steam generators (SGs) is ~~[1~~ gallon per minute~~]~~ or increases to ~~[1~~ gallon per minute~~]~~ as a result of accident induced conditions. The LCO requirement to limit primary to secondary LEAKAGE through any one SG to less than or equal to 150 gallons per day is significantly less than the conditions assumed in the safety analysis. (0.25, 0.25, 2)

Primary to secondary LEAKAGE is a factor in the dose releases outside containment resulting from a steam line break (SLB) accident. To a lesser extent, other accidents or transients involve secondary steam release to the atmosphere, such as a steam generator tube rupture (SGTR). The leakage contaminates the secondary fluid.

The FSAR (Ref. 3) analysis for SGTR assumes the contaminated secondary fluid is only briefly released via safety valves and the majority is steamed to the condenser. The ~~[1~~ gpm~~]~~ primary to secondary LEAKAGE safety analysis assumption is relatively inconsequential. (0.25, 2)

The SLB is more limiting for site radiation releases. The safety analysis for the SLB accident assumes ~~the entire~~ ~~[1~~ gpm~~]~~ primary to secondary LEAKAGE is through the affected generator as an initial condition. The dose consequences resulting from the SLB accident are well within the limits defined in 10 CFR 50 or the staff approved licensing basis (i.e., a small fraction of these limits). (0.25, 2)

RCS operational LEAKAGE satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

RCS operational LEAKAGE shall be limited to:

a. Pressure Boundary LEAKAGE

Pressure boundary LEAKAGE is prohibited as the leak itself could cause further RCPB deterioration, resulting in higher LEAKAGE.

BASES

LCO (continued)

b. Unidentified LEAKAGE

One gallon per minute (gpm) of unidentified LEAKAGE is allowed as a reasonable minimum detectable amount that the containment air monitoring and containment sump level monitoring equipment can detect within a reasonable time period. Separating the sources of leakage (i.e., leakage from an identified source versus leakage from an unidentified source) is necessary for prompt identification of potentially adverse conditions, assessment of the safety significance, and corrective action.

c. Identified LEAKAGE

Up to 10 gpm of identified LEAKAGE is considered allowable because LEAKAGE is from known sources that do not interfere with detection of unidentified LEAKAGE and is well within the capability of the RCS makeup system. Identified LEAKAGE includes LEAKAGE to the containment from specifically known and located sources, but does not include controlled reactor coolant pump (RCP) seal leakoff (a normal function not considered LEAKAGE).

LCO 3.4.14, "RCS Pressure Isolation Valve (PIV) Leakage," measures leakage through each individual PIV and can impact this LCO. Of the two PIVs in series in each isolated line, leakage measured through one PIV does not result in RCS LEAKAGE when the other is leaktight. If both valves leak and result in a loss of mass from the RCS, the loss must be included in the allowable identified LEAKAGE.

d. Primary to Secondary LEAKAGE Through Any One SG

The limit of 150 gallons per day per SG is based on the operational LEAKAGE performance criterion in NEI 97-06, Steam Generator Program Guidelines (Ref. 4). The Steam Generator Program operational LEAKAGE performance criterion in NEI 97-06 states, "The RCS operational primary to secondary leakage through any one SG shall be limited to 150 gallons per day." The limit is based on operating experience with SG tube degradation mechanisms that result in tube leakage. The operational leakage rate criterion in conjunction with the implementation of the Steam Generator Program is an effective measure for minimizing the frequency of steam generator tube ruptures.

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, the potential for RCPB LEAKAGE is greatest when the RCS is pressurized.

In MODES 5 and 6, LEAKAGE limits are not required because the reactor coolant pressure is far lower, resulting in lower stresses and reduced potentials for LEAKAGE.

ACTIONS

A.1

If pressure boundary LEAKAGE exists, the affected component, pipe, or vessel must be isolated from the RCS by a closed manual valve, closed and de-activated automatic valve, blind flange, or check valve within 4 hours. While in this condition, structural integrity of the system should be considered because the structural integrity of the part of the system within the isolation boundary must be maintained under all licensing basis conditions, including consideration of the potential for further degradation of the isolated location. Normal LEAKAGE past the isolation device is acceptable as it will limit RCS LEAKAGE and is included in identified or unidentified LEAKAGE. This action is necessary to prevent further deterioration of the RCPB.

B.1

Unidentified LEAKAGE or identified LEAKAGE in excess of the LCO limits must be reduced to within limits within 4 hours. This Completion Time allows time to verify leakage rates and either identify unidentified LEAKAGE or reduce LEAKAGE to within limits before the reactor must be shut down. This action is necessary to prevent further deterioration of the RCPB.

C.1 and C.2

If primary to secondary LEAKAGE is not within limit, or if any of the Required Actions and associated Completion Times cannot be met, the reactor must be brought to lower pressure conditions to reduce the severity of the LEAKAGE and its potential consequences. The reactor must be brought to MODE 3 within 6 hours and to MODE 5 within 36 hours. This action reduces the LEAKAGE and also reduces the factors that tend to degrade the pressure boundary.

The allowed Completion Times are reasonable, based on operating experience, to reach the required conditions from full power conditions in an orderly manner and without challenging plant systems. In MODE 5, the pressure stresses acting on the RCPB are much lower, and further deterioration is much less likely.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.13.1

Verifying RCS LEAKAGE to be within the LCO limits ensures the integrity of the RCPB is maintained. Pressure boundary LEAKAGE would at first appear as unidentified LEAKAGE and can only be positively identified by inspection. Unidentified LEAKAGE and identified LEAKAGE are determined by performance of an RCS water inventory balance.

The RCS water inventory balance must be performed with the reactor at steady state operating conditions (stable temperature, power level, pressurizer and makeup tank levels, makeup and letdown, ~~[and RCP seal injection and return flows]~~). The Surveillance is modified by two Notes. Note 1 states that this SR is not required to be performed until 12 hours after establishing steady state operation. The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established. 2

Steady state operation is required to perform a proper water inventory balance since calculations during maneuvering are not useful. For RCS operational LEAKAGE determination by water inventory balance, steady state is defined as stable RCS pressure, temperature, power level, pressurizer and makeup tank levels, makeup and letdown~~, and RCP seal injection and return flows~~. 2

An early warning of pressure boundary LEAKAGE or unidentified LEAKAGE is provided by the automatic systems that monitor the containment atmosphere radioactivity and the containment sump level. These leakage detection systems are specified in LCO 3.4.15, "RCS Leakage Detection Instrumentation."

Note 2 states that this SR is not applicable to primary to secondary LEAKAGE because LEAKAGE of 150 gallons per day cannot be measured accurately by an RCS water inventory balance.

~~[The 72 hour Frequency is a reasonable interval to trend LEAKAGE and recognizes the importance of early leakage detection in the prevention of accidents.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

2

SR 3.4.13.2

This SR verifies that primary to secondary LEAKAGE is less or equal to 150 gallons per day through any one SG. Satisfying the primary to secondary LEAKAGE limit ensures that the operational LEAKAGE performance criterion in the Steam Generator Program is met. If this SR is not met, compliance with LCO 3.4.~~18~~, "Steam Generator Tube Integrity," should be evaluated. The 150 gallons per day limit is measured at room temperature as described in Reference 5. The operational LEAKAGE rate limit applies to LEAKAGE through any one SG. If it is not practical to assign the LEAKAGE to an individual SG, all the primary to secondary LEAKAGE should be conservatively assumed to be from one SG.

17

1

The Surveillance is modified by a Note which states that the Surveillance is not required to be performed until 12 hours after establishment of steady state operation. For RCS primary to secondary LEAKAGE determination, steady state is defined as stable RCS pressure, temperature, power level, pressurizer and makeup tank levels, makeup and letdown~~, and RCP seal injection and return flows~~.

1

~~[The Surveillance Frequency of 72 hours is a reasonable interval to trend primary to secondary LEAKAGE and recognizes the importance of early leakage detection in the prevention of accidents. The primary to secondary LEAKAGE is determined using continuous process radiation monitors or radiochemical grab sampling in accordance with the EPRI guidelines (Ref. 5).~~

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.13 RCS Operational LEAKAGE

BASES

BACKGROUND

Components that contain or transport the coolant to or from the reactor core make up the RCS. Component joints are made by welding, bolting, rolling, or pressure loading, and valves isolate connecting systems from the RCS.

During plant life, the joint and valve interfaces can produce varying amounts of reactor coolant LEAKAGE, through either normal operational wear or mechanical deterioration. The purpose of the RCS Operational LEAKAGE LCO is to limit system operation in the presence of LEAKAGE from these sources to amounts that do not compromise safety. This LCO specifies the types and amounts of LEAKAGE.

10 CFR 50, Appendix A, GDC 30 (Ref. 1), requires means for detecting and, to the extent practical, identifying the source of reactor coolant LEAKAGE. Regulatory Guide 1.45 (Ref. 2) describes acceptable methods for selecting leakage detection systems.

The safety significance of RCS LEAKAGE varies widely depending on its source, rate, and duration. Therefore, detecting and monitoring reactor coolant LEAKAGE into the containment area is necessary. Quickly separating the identified LEAKAGE from the unidentified LEAKAGE is necessary to provide quantitative information to the operators, allowing them to take corrective action should a leak occur detrimental to the safety of the facility and the public.

A limited amount of leakage inside containment is expected from auxiliary systems that cannot be made 100% leaktight. Leakage from these systems should be detected, located, and isolated from the containment atmosphere, if possible, to not interfere with RCS LEAKAGE detection.

This LCO deals with protection of the reactor coolant pressure boundary (RCPB) from degradation and the core from inadequate cooling, in addition to preventing the accident analysis radiation release assumptions from being exceeded. The consequences of violating this LCO include the possibility of a loss of coolant accident (LOCA).

BASES

APPLICABLE SAFETY ANALYSES

Except for primary to secondary LEAKAGE, the safety analyses do not address operational LEAKAGE. However, other operational LEAKAGE is related to the safety analyses for LOCA; the amount of leakage can affect the probability of such an event. The safety analysis for an event resulting in steam discharge to the atmosphere assumes that primary to secondary LEAKAGE from ~~all~~ steam generators (SGs) is ~~[1~~ gallon per minute~~]~~ or increases to ~~[1~~ gallon per minute~~]~~ as a result of accident induced conditions. The LCO requirement to limit primary to secondary LEAKAGE through any one SG to less than or equal to 150 gallons per day is significantly less than the conditions assumed in the safety analysis. 0.25 0.25 2

Primary to secondary LEAKAGE is a factor in the dose releases outside containment resulting from a steam line break (SLB) accident. To a lesser extent, other accidents or transients involve secondary steam release to the atmosphere, such as a steam generator tube rupture (SGTR). The leakage contaminates the secondary fluid.

The FSAR (Ref. 3) analysis for SGTR assumes the contaminated secondary fluid is only briefly released via safety valves and the majority is steamed to the condenser. The ~~[1~~ gpm~~]~~ primary to secondary LEAKAGE safety analysis assumption is relatively inconsequential. 0.25 2

The SLB is more limiting for site radiation releases. The safety analysis for the SLB accident assumes ~~the entire~~ ~~[1~~ gpm~~]~~ primary to secondary LEAKAGE is through the affected generator as an initial condition. The dose consequences resulting from the SLB accident are well within the limits defined in 10 CFR 50 or the staff approved licensing basis (i.e., a small fraction of these limits). 0.25 2

RCS operational LEAKAGE satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

RCS operational LEAKAGE shall be limited to:

a. Pressure Boundary LEAKAGE

Pressure boundary LEAKAGE is prohibited as the leak itself could cause further RCPB deterioration, resulting in higher LEAKAGE.

BASES

LCO (continued)

b. Unidentified LEAKAGE

One gallon per minute (gpm) of unidentified LEAKAGE is allowed as a reasonable minimum detectable amount that the containment air monitoring and containment sump level monitoring equipment can detect within a reasonable time period. Separating the sources of leakage (i.e., leakage from an identified source versus leakage from an unidentified source) is necessary for prompt identification of potentially adverse conditions, assessment of the safety significance, and corrective action.

c. Identified LEAKAGE

Up to 10 gpm of identified LEAKAGE is considered allowable because LEAKAGE is from known sources that do not interfere with detection of unidentified LEAKAGE and is well within the capability of the RCS makeup system. Identified LEAKAGE includes LEAKAGE to the containment from specifically known and located sources, but does not include controlled reactor coolant pump (RCP) seal leakoff (a normal function not considered LEAKAGE).

LCO 3.4.14, "RCS Pressure Isolation Valve (PIV) Leakage," measures leakage through each individual PIV and can impact this LCO. Of the two PIVs in series in each isolated line, leakage measured through one PIV does not result in RCS LEAKAGE when the other is leaktight. If both valves leak and result in a loss of mass from the RCS, the loss must be included in the allowable identified LEAKAGE.

d. Primary to Secondary LEAKAGE Through Any One SG

The limit of 150 gallons per day per SG is based on the operational LEAKAGE performance criterion in NEI 97-06, Steam Generator Program Guidelines (Ref. 4). The Steam Generator Program operational LEAKAGE performance criterion in NEI 97-06 states, "The RCS operational primary to secondary leakage through any one SG shall be limited to 150 gallons per day." The limit is based on operating experience with SG tube degradation mechanisms that result in tube leakage. The operational leakage rate criterion in conjunction with the implementation of the Steam Generator Program is an effective measure for minimizing the frequency of steam generator tube ruptures.

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, the potential for RCPB LEAKAGE is greatest when the RCS is pressurized.

In MODES 5 and 6, LEAKAGE limits are not required because the reactor coolant pressure is far lower, resulting in lower stresses and reduced potentials for LEAKAGE.

ACTIONS

A.1

If pressure boundary LEAKAGE exists, the affected component, pipe, or vessel must be isolated from the RCS by a closed manual valve, closed and de-activated automatic valve, blind flange, or check valve within 4 hours. While in this condition, structural integrity of the system should be considered because the structural integrity of the part of the system within the isolation boundary must be maintained under all licensing basis conditions, including consideration of the potential for further degradation of the isolated location. Normal LEAKAGE past the isolation device is acceptable as it will limit RCS LEAKAGE and is included in identified or unidentified LEAKAGE. This action is necessary to prevent further deterioration of the RCPB.

B.1

Unidentified LEAKAGE or identified LEAKAGE in excess of the LCO limits must be reduced to within limits within 4 hours. This Completion Time allows time to verify leakage rates and either identify unidentified LEAKAGE or reduce LEAKAGE to within limits before the reactor must be shut down. This action is necessary to prevent further deterioration of the RCPB.

C.1 and C.2

If primary to secondary LEAKAGE is not within limit, or if any of the Required Actions and associated Completion Times cannot be met, the reactor must be brought to lower pressure conditions to reduce the severity of the LEAKAGE and its potential consequences. The reactor must be brought to MODE 3 within 6 hours and to MODE 5 within 36 hours. This action reduces the LEAKAGE and also reduces the factors that tend to degrade the pressure boundary.

The allowed Completion Times are reasonable, based on operating experience, to reach the required conditions from full power conditions in an orderly manner and without challenging plant systems. In MODE 5, the pressure stresses acting on the RCPB are much lower, and further deterioration is much less likely.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.13.1

Verifying RCS LEAKAGE to be within the LCO limits ensures the integrity of the RCPB is maintained. Pressure boundary LEAKAGE would at first appear as unidentified LEAKAGE and can only be positively identified by inspection. Unidentified LEAKAGE and identified LEAKAGE are determined by performance of an RCS water inventory balance.

The RCS water inventory balance must be performed with the reactor at steady state operating conditions (stable temperature, power level, pressurizer and makeup tank levels, makeup and letdown, ~~[and RCP seal injection and return flows]~~). The Surveillance is modified by two Notes. Note 1 states that this SR is not required to be performed until 12 hours after establishing steady state operation. The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established. 2

Steady state operation is required to perform a proper water inventory balance since calculations during maneuvering are not useful. For RCS operational LEAKAGE determination by water inventory balance, steady state is defined as stable RCS pressure, temperature, power level, pressurizer and makeup tank levels, makeup and letdown~~, and RCP seal injection and return flows~~. 2

An early warning of pressure boundary LEAKAGE or unidentified LEAKAGE is provided by the automatic systems that monitor the containment atmosphere radioactivity and the containment sump level. These leakage detection systems are specified in LCO 3.4.15, "RCS Leakage Detection Instrumentation."

Note 2 states that this SR is not applicable to primary to secondary LEAKAGE because LEAKAGE of 150 gallons per day cannot be measured accurately by an RCS water inventory balance.

~~[The 72 hour Frequency is a reasonable interval to trend LEAKAGE and recognizes the importance of early leakage detection in the prevention of accidents.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

2

SR 3.4.13.2

This SR verifies that primary to secondary LEAKAGE is less or equal to 150 gallons per day through any one SG. Satisfying the primary to secondary LEAKAGE limit ensures that the operational LEAKAGE performance criterion in the Steam Generator Program is met. If this SR is not met, compliance with LCO 3.4.~~18~~, "Steam Generator Tube Integrity," should be evaluated. The 150 gallons per day limit is measured at room temperature as described in Reference 5. The operational LEAKAGE rate limit applies to LEAKAGE through any one SG. If it is not practical to assign the LEAKAGE to an individual SG, all the primary to secondary LEAKAGE should be conservatively assumed to be from one SG.

17

1

The Surveillance is modified by a Note which states that the Surveillance is not required to be performed until 12 hours after establishment of steady state operation. For RCS primary to secondary LEAKAGE determination, steady state is defined as stable RCS pressure, temperature, power level, pressurizer and makeup tank levels, makeup and letdown~~, and RCP seal injection and return flows~~.

1

~~[The Surveillance Frequency of 72 hours is a reasonable interval to trend primary to secondary LEAKAGE and recognizes the importance of early leakage detection in the prevention of accidents. The primary to secondary LEAKAGE is determined using continuous process radiation monitors or radiochemical grab sampling in accordance with the EPRI guidelines (Ref. 5).~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.13, BASES, RCS OPERATIONAL LEAKAGE

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.4.13, RCS OPERATIONAL LEAKAGE

There are no specific No Significant Hazards Considerations for this Specification.

SR 3.4.14.3

1. Verifying automatic isolation and interlock action of the shutdown cooling system from Reactor Coolant System when RCS pressure (actual or simulated) is greater than or equal to 515 psia, and that the interlocks prevent opening the shutdown

SR 3.4.14.2

cooling system isolation valves when RCS pressure (actual or simulated) is greater than or equal to 276 psia.

* Not required to be met for system vent flow paths opened under administrative control.

See ITS 3.5.2

DISCUSSION OF CHANGES
ITS 3.4.14, RCS PRESSURE ISOLATION VALVE (PIV) LEAKAGE

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.4.6.2 Action c specifies the compensatory actions to take when the leakage by any RCS PIV(s) is greater than the specified limit. ITS 3.4.14 ACTIONS A and B also state the appropriate compensatory actions under the same condition, however, ITS 3.4.14 ACTIONS Note 1 has been added. ITS 3.4.14 ACTIONS Note 1 allows separate entry condition for each RCS PIV flow path. This changes the CTS by explicitly stating that the Action is to be taken separately for each inoperable RCS PIV flow path.

The purpose of the Note is to provide explicit instructions for proper application of the ACTION for Technical Specification compliance. In conjunction with proposed Specification 1.3, "Completion Times," this Note provides direction consistent with the intent of the existing Action for inoperable PIVs. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 Unit 1 CTS 4.5.2.d.1 requires verification that proper operation of the open permissive interlock (OPI) and the valve open/high Shutdown Cooling (SDC) System pressure alarms for isolation valves V3651, V3652, V3480, V3481. ITS SR 3.4.14.2 and SR 3.4.14.3 provide similar requirements. ITS SR 3.4.12.2 requires verification that the SDC System interlock prevents the valves from being opened with a simulated or actual RCS pressure signal > 267 psia. ITS SR 3.4.12.3 requires verification that the SDC System interlock function high pressure alarm is OPERABLE. This changes the Unit 1 CTS by clarifying how to verify proper operation of the OPI.

Unit 2 CTS 4.5.2.e.1 requires verifying automatic isolation and interlock action of the shutdown cooling system from Reactor Coolant System when RCS pressure (actual or simulated) is greater than or equal to 515 psia, and that the interlocks prevent opening the shutdown cooling system isolation valves when RCS pressure (actual or simulated) is greater than or equal to 276 psia. ITS SR 3.4.14.2 and SR 3.4.14.3 provide similar requirements.

In addition, a new LCO has been added which requires the SDC System interlock function to be OPERABLE. This changes the CTS by including the SDC System interlock Surveillance Requirement with the RCS PIV leakage limits and adding a new LCO and ACTION for the interlock function.

The purpose of CTS Surveillance is to ensure the SDC System interlock function is available to prevent overpressurization of the low pressure SDC System

piping. The OPERABILITY of the low pressure safety injection (LPSI)/SDC system is affected by the position of the SDC return isolation valves, not when the interlock is inoperable. Therefore, the transfer of this requirement to the RCS PIV Specification is appropriate. A discussion of the change to the Applicability of the SDC System interlock (including high pressure alarm for Unit 1) is discussed in DOC M04. A discussion of a change to the Required Actions when the SDC System interlock (including high pressure alarm for Unit 1) is inoperable is discussed in DOC L05. This change is acceptable since the SDC System interlock function is retained in the Technical Specifications. This change is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.4.6.2 Action c. specify the compensatory actions to take when the leakage through any RCS PIV(s) is greater than the specified limit. The compensatory action is to isolate the high pressure portion of the affected system from the low pressure portion of the affected system by use of a combination of at least two closed valves. The CTS does not include any leakage restrictions concerning the valves that may be used to satisfy the isolation requirement of this action. ITS 3.4.14 ACTION A is consistent with the requirement in CTS 3.4.6.2 Action c., however, a Note has been added to the Required Actions (ITS 3.4.14 Required Actions A.1 and A.2 Note) which specifies that each valve used to satisfy ITS 3.4.14 Required Actions A.1 and A.2 must have been verified to meet SR 3.4.14.1, the RCS PIV maximum leakage limit Surveillance Requirement, and either be in the RCS pressure boundary or the high pressure portion of the system. This changes the CTS by providing a Note which explicitly states that the valves used to satisfy Required Action must satisfy the same leakage requirements of the RCS PIVs and provides an option for them to be in the RCS pressure boundary.

The purpose of CTS 3.4.6.2 Action c. is to isolate the flow path in order to minimize the leakage from the high pressure portion of the RCS to the low pressure piping. The ITS 3.4.14 Required Actions A.1 and A.2 Note requires the valves used to provide isolation between the high pressure and low pressure portions of the affected system to have been verified to meet the RCS PIV maximum leakage limits within the required Surveillance Frequency. The addition of the Note represents an additional restriction on unit operation necessary to help ensure the valves used to isolate the high pressure portion from the low pressure portion of the affected system are capable of preventing the overpressurization of the low pressure portion of the system. The ITS 3.4.14 Required Actions A.1 and A.2 Note also provides the option for the valves to be in the RCS pressure boundary, which is considered an acceptable alternative to the high pressure portion of the system. This change is designated as more restrictive because it adds a new requirement to the CTS.

M02 **Unit 1 only:** CTS 4.4.6.2.e provides a verification that the RCS PIV leakage is within limits but provides no Frequency other than “prior to entering MODE 2 after refueling” and “prior to entering MODE 2, whenever the plant has been in COLD SHUTDOWN for 7 days or more if leakage testing has not been

performed in the previous 9 months." ITS SR 3.4.14.1 requires performance on a periodic Frequency or in accordance with the Surveillance Frequency Control Program and within 24 hours following valve actuation due to automatic or manual action or flow through the valve. This changes the CTS by adding a periodic Frequency in accordance with the Surveillance Frequency Control Program and adding the Frequency of within 24 hours following valve actuation due to automatic or manual action or flow through the valve. PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program per CTS 6.8.4.o. Therefore, SR 3.4.14.1 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 18 months consistent with the ISTS SR 3.4.14.1.

The purpose of CTS 4.4.6.2.e is to perform leakage testing on each RCS PIV to verify that leakage is below the specified limit and to identify each leaking valve. The Frequency in accordance with the Surveillance Frequency Control Program is consistent with 10 CFR 50.55a(g) and the INSERVICE TESTING PROGRAM and is based on the need to perform the Surveillance under conditions that apply during a plant outage. In addition, testing must be performed once after the valve has been opened by flow or exercised to ensure tight reseating. Testing must be performed within 24 hours after the valve has been reseated. Twenty-four hours is a reasonable and practical time limit for performing this test after opening or reseating a valve.

This change is designated as more restrictive because it adds new requirements to the CTS.

M03 **Unit 1 only:** CTS Table 3.4.6-1 provides a list of RCS PIVs. ITS 3.4.14 does not contain a list of the RCS PIVs or their associated valve numbers. The list of RCS PIVs in CTS Table 3.4.6-1 are proposed to be relocated to the ITS Bases (See Discussion of Change LA01). The proposed list of RCS PIVs relocated to the ITS Bases includes the shutdown cooling (SDC) return isolation valves and safety injection tank (SIT) discharge check valves consistent with the current licensing basis. In response to NRC Generic Letter 87-06, "Periodic Verification of Leak Tight Integrity of Pressure Isolation Valves," FPL provides testing exception for these additional PIVs (NRC ADAMS Accession No. ML20214W254). The SDC return isolation valves are tested to verify ≤ 1 gpm using indication of differential pressure in isolated downstream piping not to exceed 200 psid. If a leakage rate of > 1 gpm is indicated by > 200 psid, a volumetric leakage test is conducted and verified to be ≤ 50% of the margin between the rate determined by the previous measured leakage rate and 5 gpm. The SIT discharge check valves isolate the SIT from the safety injection header when safety injection header pressure is greater than SIT pressure. SIT pressures and levels are monitored and alarmed. This instrumentation and alarm scheme may indicate possible check valve leakage if it were to occur. As a result, a Note is included in ITS SR 3.4.14.1 (proposed Note 2) to waive performance of the PIV leakage test for the SIT discharge check valves. This change aligns the CTS list of RCS PIVs with the current licensing basis and is designated as more restrictive because it adds additional components to the CTS RCS PIV list.

M04 Unit 1 CTS 4.5.2.d.1 requires, in MODES 1, 2, and 3 with pressurizer pressure ≥ 1750 psia, verification of the proper operation of the open permissive interlock (OPI) and the valve open/high Shutdown Cooling (SDC) System pressure alarms for isolation valves V3651, V3652, V3480, V3481. Unit 2 CTS 4.5.2.e.1 requires, in MODES 1, 2, and 3 with pressurizer pressure ≥ 1750 psia, verifying automatic isolation and interlock action of the shutdown cooling system from Reactor Coolant System when RCS pressure (actual or simulated) is greater than or equal to 515 psia, and that the interlocks prevent opening the shutdown cooling system isolation valves when RCS pressure (actual or simulated) is greater than or equal to 276 psia. ITS SR 3.4.14.2 and SR 3.4.14.3 provide similar requirements. However, ITS requires the SDC System interlock function and associated Surveillances to be applicable in MODES 1, 2, and 3, and MODE 4 except valves in the SDC flow path when in, or during the transition to or from, the SDC mode of operation. This changes the CTS by expanding the applicability of the SDC System interlock function to include conditions with pressurizer pressure < 1750 psia.

The purpose of the SDC System interlock function and associated Surveillances is to preclude the SDC return isolation valves from being opened when RCS pressure is above the SDC System design pressure of 350 psig. The SDC System interlock function, along with the PIV leakage requirements support the dominant accident sequence in the intersystem LOCA category of the failure of the low pressure portion of the SDC System outside of containment. Therefore, this change expands the applicability of the interlock function to include MODES where RCS pressure could be greater than SDC System design pressure. This change is consistent with the ISTS Applicability for RCS PIVs and is designated as more restrictive because it expands the CTS applicability for this interlock function.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 - Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.4.6.2.e, 4.4.6.2.e require each RCS PIV leakage be within the limits for the RCS PIVs listed in Table 3.4.6-1. Unit 2 CTS 3.4.6.2.e, 4.4.6.2.2 and 4.6.2.2.3 require each RCS PIV leakage to be within the limits for the RCS PIVs listed in Table 3.4-1. ITS 3.4.14 does not contain a list of the RCS PIVs or their associated valve numbers. This changes the CTS by relocating the list of RCS PIVs and their associated valve numbers to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 3.4.14 requires the RCS PIVs to be OPERABLE, and ITS SR 3.4.14.1 requires periodic Surveillances to determine RCS PIV leakage. It is not necessary for the list of RCS PIVs to be in the Technical Specifications in order to ensure that the RCS PIVs are OPERABLE.

Other lists of components, such as containment isolation valves and equipment response time, have been relocated from the Technical Specification to licensee-controlled documents while retaining the requirements on these components in Technical Specifications. Also, this change is acceptable because these types of description details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system description is being removed from the Technical Specifications.

LA02 *(Type 3 - Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS Table 3.4.6-1 and Unit 2 CTS Table 3.4-1 are modified by Note (b). Note (b) explains an alternative method of testing the PIVs to satisfy the ALARA requirements. ITS 3.4.14 does not retain this Note. This changes the CTS by relocating the information in the Note to the Bases.

The removal of these details for performing Surveillance Requirements from the Technical Specification is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 3.4.14 still retains the requirements that RCS PIV leakage must be within limit and provides the appropriate Surveillance that includes the leakage limit. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA03 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS Table 3.4.6-1 and Unit 2 CTS Table 3.4-1 are modified by Note (c). Note (c) specifies the minimum test differential pressure for the RCS PIVs to not be below (150 psid on Unit 1, 200 psid on Unit 2). ITS 3.4.14 does not specify this limit. This changes the CTS by relocating the RCS PIV minimum test differential pressure to the Bases.

The removal of these details for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 3.4.14 retains the requirement that the RCS PIV leakage must be within limit and provides the appropriate Surveillance that includes the leakage limit. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA04 **Unit 1 only:** *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 4.5.2.d.1 requires, in part, verification that the valve open/high Shutdown Cooling (SDC) System pressure alarms for isolation valves V3651, V3652, V3480, V3481. ITS SR 3.4.12.3 requires verification that the SDC System interlock function high pressure alarm is OPERABLE. This changes the CTS by relocating detail related to the specific valve numbers associated with the RCS high pressure alarm that is actuated when the SDC return isolation valves are open.

The removal of these details, which are related to detail system design and description, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS LCO 3.4.14 requires the SDC System interlock function of be OPERABLE and ITS SR 3.4.14.3 requires periodic verification that the SDC System interlock function high pressure alarm is OPERABLE. It is not necessary to state the valve numbers associated with the alarm function in the Technical Specifications in order to ensure that the SDC System interlock function high pressure alarm is OPERABLE. This change is acceptable because these type of description details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system description is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 3 - Relaxation of Completion Time)* CTS 3.4.6.2 Action c. requires, in part, that if the RCS PIV leakage is not within limits, the high pressure to low pressure boundary must be isolated by at least two valves as specified in CTS 3.4.6.2 Action c. Specifically, Unit 1 CTS 3.4.6.2 Action c. states, in part, that with the integrity of any pressure isolation valve specified in Table 3.4.6-1 not demonstrated, power operation may continue provided at least two valves in each high pressure line that has a non-functional valve are in and remain in, the mode corresponding to the isolated condition. Unit 2 CTS 3.4.6.2 Action c. states, in part, that with the integrity of any pressure isolation valve specified in Table 3.4-1 not demonstrated, power operation may continue provided that the high pressure portion of the affected system is isolated from the low pressure portion by use of at least two closed manual or deactivated automatic valves. The two CTS Actions ultimately result in requiring the two valves to be in the isolated condition within 4 hours. ITS 3.4.14 ACTION A contains similar requirements but allows 4 hours to isolate the first valve (Required Action A.1) and 72 hours to isolate the second valve (Required Action A.2). This changes the CTS by extending the time requirement to close the second valve from 4 hours to 72 hours.

The purpose of CTS 3.4.6.2 Action c is to allow time to reduce leakage before isolating the pathway. This change is acceptable because the Completion Time

is consistent with safe operation under the specified Condition, considering the low probability of a DBA occurring during the allowed Completion Time. This includes the fact that the high pressure to low pressure boundary is isolated by at least one isolation device. The time to close the first valve remains the same and the time to close the second valve has been changed from 4 hours to 72 hours. The 4 hour Completion Time to close the first valve ensures leakage in excess of the allowable limit is reduced. The 4 hour time allows time for these actions and restricts the time of operation with leaking valves. The 72 hours Completion Time to close the second valve considers the time required to complete the Required Action and the low probability of the first valve failing during this period. This change is designated as less restrictive because additional time is allowed to perform a required action than was allowed in the CTS.

L02 *(Category 2 - Relaxation of Applicability)* CTS 3.4.6.2 is applicable in MODES 1, 2, 3, and 4. ITS 3.4.14 is applicable in MODES 1, 2, 3, and MODE 4, except valves in the shutdown cooling (SDC) flow path when in, or during the transition to or from, the SD mode of operation. This changes the CTS by exempting the SDC flow path PIVs from the leakage requirements when in or during the transition to or from the SDC mode of operation. | R1

The purpose of CTS 3.4.6.2.e is to ensure the RCS PIVs are within leakage limits. This change is acceptable because the LCO requirements continue to ensure that the components are maintained consistent with the safety analyses and licensing basis. It is not necessary for the SDC PIVs to meet the leakage limits when in or during transition to or from the SDC mode of operation. These check valves cannot open until the SDC system is placed in service, which is not until RCS pressure is less than the SDC permissive. Thus, overpressurization of the SDC piping is not a concern. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than are being applied in the CTS.

L03 *(Category 5 - Deletion of Surveillance Requirement)* Unit 1 CTS 4.4.6.2.e.3 and Unit 2 CTS 4.4.6.2.2.c and 4.4.6.2.3.b require testing of RCS PIVs following maintenance, repair, or replacement work on the valve. ITS 3.4.14 does not include this requirement. This changes the CTS by eliminating a post-maintenance Surveillance Requirement. | R1

The purpose of the Surveillance requirements is to ensure the RCS PIV leakage is within limits prior to returning the valve to service. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a frequency necessary to give confidence that the equipment can perform its assumed safety function. Whenever, the OPERABILITY of a system or component has been affected by repair, maintenance, modification, or replacement of a component, post maintenance testing is required to demonstrate the OPERABILITY of a system or component. This is described in the Bases for ITS SR 3.0.1 and required under SR 3.0.1. In addition, the requirements of 10 CFR 50, Appendix B, Section XI (Test Control), provide adequate controls for test programs to ensure that testing incorporates applicable acceptance criteria. Compliance with 10 CFR 50, Appendix B is required under the unit operating license. As a result,

post-maintenance testing will continue to be performed and an explicit requirement in the Technical Specifications is not necessary. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

L04 **Unit 1 only:** *(Category 5 - Deletion of Surveillance Requirement)* CTS 4.4.6.2.f provides additional compensatory measures to take, above those required by CTS 3.6.4.2 Action c., when leakage through an RCS PIV is not within limit. The CTS requires a daily leakage test of the remaining OPERABLE RCS PIV in the flow path or a combined leakage test of the two valves used to comply with CTS 3.6.4.2 Action c. In addition, the position of the second, non-RCS PIV valve is required to be recorded on a daily basis. ITS 3.4.14 does not include these additional compensatory measures. This changes the CTS by deleting the additional Surveillance compensatory measures taken when leakage through an RCS PIV is not within limit.

The purpose of CTS 4.4.6.2.f is to help ensure that the leakage through the valves used to isolate the penetration with an inoperable RCS PIV is minimized so that an overpressurization event of the downstream piping cannot occur. The change is acceptable since the requirements to ensure the leakage through the two closed valves is within the RCS PIV leakage limit and to ensure closure of the valves are maintained in the ITS. The RCS PIV leakage is ensured prior to using each of the valves as an isolation boundary, as required by the ITS 3.4.14 Required Action A.1 and A.2 Note. Once leakage is checked, it is not expected to change since the valve cannot be manipulated (ITS 3.4.14 ACTION A requires the valves to be isolated, thus they must remain isolated to comply with the ACTION). Manipulation of manual valves that have been closed and automatic valves that have been deactivated to comply with Technical Specification Actions is a controlled evolution and the valves are not expected to be inadvertently moved from the isolated condition. Furthermore, these valves will be verified to be in the correct position when first isolated to comply with ITS 3.4.14 ACTIONS A and B. This change is designated as less restrictive because a Surveillance compensatory measure required by the CTS will not be required in the ITS.

L05 (*Category 4 – Relaxation of Required Action*) Unit 1 CTS 4.5.2.d.1 requires verification that proper operation of the open permissive interlock (OPI) and the valve open/high SDC System pressure alarms for isolation valves V3651, V3652, V3480, V3481. Unit 2 CTS 4.5.2.e.1 requires verifying automatic isolation and interlock action of the shutdown cooling system from Reactor Coolant System when RCS pressure (actual or simulated) is greater than or equal to 515 psia, and that the interlocks prevent opening the shutdown cooling system isolation valves when RCS pressure (actual or simulated) is greater than or equal to 276 psia. When the interlock is inoperable (i.e., the Surveillance not met), LCO 3.0.3 entry is required since this inoperability affects both LPSI trains. ITS 3.4.14 ACTION C requires the isolation of the penetration by use of one closed manual or deactivated automatic valve within 4 hours. This changes the CTS by allowing the penetration to be isolated and to continue operation of the unit for an unlimited amount of time without entry into LCO 3.0.3.

At PSL, the LPSI and SDC systems share the same components. The purpose of ITS 3.4.14 ACTION C is to isolate the penetration to ensure the LPSI/SDC

System is not overpressurized by the RCS. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded condition in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the action of isolating the penetration by use of at least one closed manual or deactivated automatic valve accomplishes the function of ensuring the valves are not inadvertently opened when RCS pressure is above the SDC System design pressure. The 4-hour Completion Time is reasonable based on the consideration that the associated valves are closed when the SDC System is not aligned for the SDC function and the low probability of a failure that could inadvertently open the isolation valves. This change allows the unit to continue to operate and avoids an unnecessary plant transient as a result of entry into LCO 3.0.3. Closing and deactivating an automatic valve or closing a manual valve will ensure the function of the interlock is met. Therefore, the actions provide sufficient remedial measures to preclude overpressurization of the LPSI/SDC System by the RCS thereby allowing continued safe operation pursuant the requirements of 10 CFR 50.36(c)(2). This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.14, RCS PRESSURE ISOLATION VALVE (PIV) LEAKAGE

1. The second part of the LCO has been added to ensure consistency between the LCO, ACTIONS, and Surveillance Requirements. The ISTS LCO, Actions, and Surveillances do not match up since there is no explicit statement in the LCO requiring the Shutdown Cooling (SDC) System interlock function to be OPERABLE. In the ISTS, if the SDC System interlock function is inoperable, the LCO is not affected since RCS PIV leakage is not directly affected by an inoperable interlock function. Therefore, the inclusion of the second portion of the LCO ensures consistency between the LCO, ACTIONS, and Surveillance Requirements. In addition, due to the addition of the term "SDC" into the LCO statement, the use of the term " Shutdown Cooling (SDC)" in the Applicability has been changed to "SDC."

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

4. Note 2 to ISTS SR 3.4.14.1 has been deleted since it is not necessary. The ISTS 3.4.14 Applicability does not require leakage to be met for SDC valves in the flow path when in MODE 4 and when in, or during the transition to or from, the SDC Mode of operation.

5. Note 3 to ISTS SR 3.4.14.1 has been deleted since it is not required by the current licensing basis.

6. Verification of RCS PIV leakage is required by the INSERVICE TESTING PROGRAM, which fulfills the requirements of 10 CFR 50.55a(g). Therefore, it is duplicative to require ISTS SR 3.4.14.1 to be performed in accordance with the INSERVICE TESTING PROGRAM. Since compliance with 10 CFR 50.55a is required by the operating licenses of PSL Unit 1 and Unit 2, this Frequency is not included in ITS SR 3.4.14.1.

7. **Unit 1 only:** A Note is added to ISTS 3.4.14.1 (Note 2 to ITS SR 3.4.14.1). This Note waives performance of the PIV leakage test for the safety injection tank (SIT) discharge check valves. The SIT discharge check valves are added to the list of RCS PIVs consistent with the current licensing basis. In response to NRC Generic Letter 87-06, “Periodic Verification of Leak Tight Integrity of Pressure Isolation Valves,” an exception to PIV testing was provided for the SIT discharge check valves (NRC ADAMS Accession No. ML20214W254). The SIT discharge check valves isolate the SIT from the safety injection header when safety injection header pressure is greater than SIT pressure. SIT pressures and levels are monitored and alarmed. This instrumentation and alarm scheme may indicate possible check valve leakage if it were to occur. As a result, periodic performance of the leakage testing is not required for the SIT discharge check valves consistent with current licensing basis.

8. The Note to ISTS SRs 3.4.14.2 and 3.4.14.3 is deleted and not included in the ITS because ISTS SR 3.4.12.7 is not related to SRs 3.4.14.2 and 3.4.14.3. The Note to

the SRs is also included in NUREG-1431, “Standard Technical Specifications, Westinghouse Plants,” and refers to an SR that requires the associated residual heat removal (RHR) suction isolation valve to be locked open with operator power removed for each required RHR suction relief valve. There is no equivalent SR in NUREG-1432 or the PSL Unit 1 and Unit 2 current Technical Specifications. Therefore, the Note is not included in the PSL Unit 1 and Unit 2 ITS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.14 RCS Pressure Isolation Valve (PIV) Leakage

BASES

BACKGROUND

10 CFR 50.2, 10 CFR 50.55a(c), and GDC 55 of 10 CFR 50, Appendix A (Refs. 1, 2, and 3), define RCS PIVs as any two normally closed valves in series within the RCS pressure boundary that separate the high pressure RCS from an attached low pressure system. During their lives, these valves can produce varying amounts of reactor coolant leakage through either normal operational wear or mechanical deterioration. The RCS PIV LCO allows RCS high pressure operation when leakage through these valves exists in amounts that do not compromise safety.

The PIV leakage limit applies to each individual valve. Leakage through both PIVs in series in a line must be included as part of the identified LEAKAGE, governed by LCO 3.4.13, "RCS Operational LEAKAGE." This is true during operation only when the loss of RCS mass through two valves in series is determined by a water inventory balance (SR 3.4.13.1). A known component of the identified LEAKAGE before operation begins is the least of the two individual leakage rates determined for leaking series PIVs during the required surveillance testing; leakage measured through one PIV in a line is not RCS operational LEAKAGE if the other is leaktight.

Although this specification provides a limit on allowable PIV leakage rate, its main purpose is to prevent overpressure failure of the low pressure portions of connecting systems. The leakage limit is an indication that the PIVs between the RCS and the connecting systems are degraded or degrading. PIV leakage could lead to overpressure of the low pressure piping or components. Failure consequences could be a loss of coolant accident (LOCA) outside of containment, an unanalyzed condition that could degrade the ability for low pressure injection.

The basis for this LCO is the 1975 NRC "Reactor Safety Study" (Ref. 4) that identified potential intersystem LOCAs as a significant contributor to the risk of core melt. A subsequent study (Ref. 5) evaluated various PIV configurations to determine the probability of intersystem LOCAs.

PIVs are provided to isolate the RCS from the following typically connected systems:

BASES

BACKGROUND (continued)

a. Shutdown Cooling (SDC) System,

b. Safety Injection System, and

c. Chemical and Volume Control System.

The PIVs are listed in Table B 3.4.14-1 ~~FSAR section (Ref. 6)~~. 1

Violation of this LCO could result in continued degradation of a PIV, which could lead to overpressurization of a low pressure system and the loss of the integrity of a fission product barrier. Insert 1 1

APPLICABLE SAFETY ANALYSES

Reference 4 identified potential intersystem LOCAs as a significant contributor to the risk of core melt. The dominant accident sequence in the intersystem LOCA category is the failure of the low pressure portion of the SDC System outside of containment. The accident is the result of a postulated failure of the PIVs, which are part of the reactor coolant pressure boundary (RCPB), and the subsequent pressurization of the SDC System downstream of the PIVs from the RCS. Because the low pressure portion of the SDC System is ~~typically~~ designed for ~~[600]~~ psig, overpressurization failure of the SDC low pressure line would result in a LOCA outside containment and subsequent risk of core melt. 350 2

Reference 5 evaluated various PIV configurations, leakage testing of the valves, and operational changes to determine the effect on the probability of intersystem LOCAs. This study concluded that periodic leakage testing of the PIVs can substantially reduce the probability of an intersystem LOCA.

RCS PIV leakage satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

RCS PIV leakage is identified LEAKAGE into closed systems connected to the RCS. Isolation valve leakage is usually on the order of drops per minute. Leakage that increases significantly suggests that something is operationally wrong and corrective action must be taken.

The LCO PIV leakage limit is ~~0.5 gpm per nominal inch of valve size, with a maximum limit of 5 gpm. The previous criterion of 1 gpm for all valve sizes imposed an unjustified penalty on the larger valves without providing information on potential valve degradation and resulted in higher personnel radiation exposures. A study concluded a leakage rate limit based on valve size was superior to a single allowable value.~~ 1

< 5.0 gpm. However, when the current measured rate is > 1.0 gpm, the current measured rate shall not exceed the rate determined by the previous test by an amount that reduces the margin between measured leakage rate and the maximum permissible rate (5.0 gpm) by 50%. 1

1

1

INSERT 1

Two motor operated valves are included in series in the suction piping of the two SDC trains to isolate the high pressure RCS from the low pressure piping of the SDC System when the RCS pressure is above the design pressure of the SDC System piping and components. Ensuring the SDC interlock that prevents the valves from being opened is OPERABLE ensures that RCS pressure will not pressurize the SDC System beyond its design pressure of 350 psig.

BASES

LCO (continued)

Ensuring the SDC System interlock function is OPERABLE, including the open permissive interlock that prevents the valves from being opened and the high pressure alarm on RCS high pressure when the valves are open, ensures that RCS pressure will not pressurize the SDC System beyond its design pressure.

6

Reference ~~7~~ permits leakage testing at a lower pressure differential than between the specified maximum RCS pressure and the normal pressure of the connected system during RCS operation (the maximum pressure differential) in those types of valves in which the higher service pressure will tend to diminish the overall leakage channel opening. In such cases, the observed rate may be adjusted to the maximum pressure differential by assuming leakage is directly proportional to the pressure differential to the one half power.

1

APPLICABILITY

In MODES 1, 2, 3, and 4, this LCO applies because the PIV leakage potential is greatest when the RCS is pressurized. In MODE 4, valves in the SDC flow path are not required to meet the requirements of this LCO when in, or during the transition to or from, the SDC mode of operation.

In MODES 5 and 6, leakage limits are not provided because the lower reactor coolant pressure results in a reduced potential for leakage and for a LOCA outside the containment.

ACTIONS

The Actions are modified by two Notes. Note 1 is added to provide clarification that each flow path allows separate entry into a Condition. This is allowed based on the functional independence of the flow path. Note 2 requires an evaluation of affected systems if a PIV is inoperable. The leakage may have affected system operability or isolation of a leaking flow path with an alternate valve may have degraded the ability of the interconnected system to perform its safety function.

A.1 and A.2

The flow path must be isolated by two valves. Required Actions A.1 and A.2 are modified by a Note stating that the valves used for isolation must meet the same leakage requirements as the PIVs and must be in the RCPB ~~[~~or the high pressure portion of the system~~]~~.

2

Required Action A.1 requires that the isolation with one valve must be performed within 4 hours. Four hours provides time to reduce leakage in excess of the allowable limit and to isolate if leakage cannot be reduced. The 4 hours allows the actions and restricts the operation with leaking isolation valves.

BASES

ACTIONS (continued)

[Required Action A.2 specifies that the double isolation barrier of two valves be restored by closing some other valve qualified for isolation or restoring one leaking PIV. The 72 hour Completion Time after exceeding the limit considers the time required to complete the action and the low probability of a second valve failing during this time period.

~~or~~

~~The 72 hour Completion Time after exceeding the limit allows for the restoration of the leaking PIV to OPERABLE status. This timeframe considers the time required to complete this Action and the low probability of a second valve failing during this period.]~~

~~REVIEWER'S NOTE~~
~~Two options are provided for Required Action A.2. The second option (72 hour restoration) is appropriate if isolation of a second valve would place the unit in an unanalyzed condition.~~

B.1 and B.2

any Required Action of Condition A cannot be met within the required Completion Time

If ~~leakage cannot be reduced [,the system isolated,] or other Required Actions accomplished~~, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE 3 within 6 hours and to MODE 5 within 36 hours. This Action reduces the leakage and also reduces the potential for a LOCA outside the containment. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

C.1

or incapable of alerting the operator of increasing RCS pressure with the SDC return isolation valves open

The inoperability of the SDC ~~autoclosure~~ interlock renders the SDC suction isolation valves incapable of~~: isolating in response to a high pressure condition and~~ preventing inadvertent opening of the valves at RCS pressures in excess of the SDC systems design pressure. If the SDC ~~autoclosure~~ interlock is inoperable, operation may continue as long as the affected SDC suction penetration is closed by at least one closed manual or deactivated automatic valve within 4 hours. This Action accomplishes the purpose of the ~~autoclosure~~ function.

The RCS PIV leakage limit is < 5.0 gpm. However, RCS PIV leakage is also limited when the current measured rate is > 1.0 gpm, such that the current measured rate shall not exceed the rate determined by the previous test by an amount that reduces the margin between measured leakage rate and 5.0 gpm by 50%. The minimum differential test pressure across each valve shall be ≥ 150 psid.

1

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.14.1

Performance of leakage testing on each RCS PIV or isolation valve used to satisfy Required Action A.1 or A.2 is required to verify that leakage is below the specified limit and to identify each leaking valve. ~~The leakage limit of 0.5 gpm per inch of nominal valve diameter up to 5 gpm maximum applies to each valve.~~ Leakage testing requires a stable pressure condition.

1

For the two PIVs in series, the leakage requirement applies to each valve individually and not to the combined leakage across both valves. If the PIVs are not individually leakage tested, one valve may have failed completely and not be detected if the other valve in series meets the leakage requirement. In this situation, the protection provided by redundant valves would be lost.

Testing is to be performed every 9 months, but may be extended if the plant does not go into MODE 5 for at least 7 days. ~~[The [18] month Frequency is consistent with 10 CFR 50.55a(g) (Ref. 8) and the INSERVICE TESTING PROGRAM and is within frequency allowed by the American Society of Mechanical Engineers (ASME) Code (Ref. 7), and is based on the need to perform the Surveillance under conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power.~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~----------]~~

2

In addition, testing must be performed once after the valve has been opened by flow or exercised to ensure tight reseating. ~~PIVs disturbed in the performance of this Surveillance should also be tested unless documentation shows that an infinite testing loop cannot practically be avoided.~~ Testing must be performed within 24 hours after the valve has been reseated. Within 24 hours is a reasonable and practical time limit for performing this test after opening or reseating a valve.

1

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

This SR is modified by two Notes. Note 1 states that the Surveillance is not required to be performed in MODES 3 and 4.

The leakage limit is to be met at the RCS pressure associated with MODES 1 and 2. This permits leakage testing at high differential pressures with stable conditions not possible in the MODES with lower pressures.

3

Entry into MODES 3 and 4 is allowed to establish the necessary differential pressures and stable conditions to allow for performance of this Surveillance. ~~The Note that allows this provision is complimentary to the Frequency of prior to entry into MODE 2 whenever the unit has been in MODE 5 for 7 days or more, if leakage testing has not been performed in the previous 9 months. In addition, this Surveillance is not required to be performed on the SDC System when the SDC System is aligned to the RCS in the shutdown cooling mode of operation. PIVs contained in the SDC shutdown cooling flow path must be leakage rate tested after SDC is secured and stable unit conditions and the necessary differential pressures are established.~~

3

Insert 2

1

SR 3.4.14.2 and SR 3.4.14.3

function, which includes the open permissive interlock and the high pressure alarm, is

Verifying that the SDC ~~autoclosure~~ interlock~~s~~ are OPERABLE ensures that RCS pressure will not pressurize the SDC system beyond ~~125% of~~ its design pressure of ~~[600]~~ psig. The interlock setpoint that prevents the valves from being opened is set so the actual RCS pressure must be ~~< [425] psig~~ to open the valves. This setpoint ensures the SDC design pressure will not be exceeded and the SDC relief valves will not lift. ~~[The 18 month Frequency is based on the need to perform these Surveillances under conditions that apply during a plant outage. The 18 month Frequency is also acceptable based on consideration of the design reliability (and confirming operating experience) of the equipment.~~

350

≤ 267 psia

Verifying the SDC interlock function high pressure alarm is OPERABLE ensures that when RCS pressure exceeds the high pressure setpoint and one or more SDC return isolation valves (i.e., V3651, V3652, V3480, V3481) are open, an alarm will annunciate in the control room to alert the operator.

1

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

2

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

1

1

INSERT 2

Note 2 modifies this SR to waive performance of the PIV leakage test for the safety injection tank (SIT) discharge check valves. In response to NRC Generic Letter 87-06, an exception to PIV leakage testing was provided for the SIT discharge check valves (Ref. 7). SIT pressures and levels are monitored and alarmed. The SIT pressure and level instrumentation and alarm scheme may be used to indicate possible check valve leakage if it were to occur. As a result, periodic performance of the leakage testing for the SIT discharge check valves is not required.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~The SRs are modified by Notes allowing the SDC autoclosure function to be disabled when using the SDC System suction relief valves for cold overpressure protection in accordance with SR 3.4.12.7.~~

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.14 RCS Pressure Isolation Valve (PIV) Leakage

BASES

BACKGROUND

10 CFR 50.2, 10 CFR 50.55a(c), and GDC 55 of 10 CFR 50, Appendix A (Refs. 1, 2, and 3), define RCS PIVs as any two normally closed valves in series within the RCS pressure boundary that separate the high pressure RCS from an attached low pressure system. During their lives, these valves can produce varying amounts of reactor coolant leakage through either normal operational wear or mechanical deterioration. The RCS PIV LCO allows RCS high pressure operation when leakage through these valves exists in amounts that do not compromise safety.

The PIV leakage limit applies to each individual valve. Leakage through both PIVs in series in a line must be included as part of the identified LEAKAGE, governed by LCO 3.4.13, "RCS Operational LEAKAGE." This is true during operation only when the loss of RCS mass through two valves in series is determined by a water inventory balance (SR 3.4.13.1). A known component of the identified LEAKAGE before operation begins is the least of the two individual leakage rates determined for leaking series PIVs during the required surveillance testing; leakage measured through one PIV in a line is not RCS operational LEAKAGE if the other is leaktight.

Although this specification provides a limit on allowable PIV leakage rate, its main purpose is to prevent overpressure failure of the low pressure portions of connecting systems. The leakage limit is an indication that the PIVs between the RCS and the connecting systems are degraded or degrading. PIV leakage could lead to overpressure of the low pressure piping or components. Failure consequences could be a loss of coolant accident (LOCA) outside of containment, an unanalyzed condition that could degrade the ability for low pressure injection.

The basis for this LCO is the 1975 NRC "Reactor Safety Study" (Ref. 4) that identified potential intersystem LOCAs as a significant contributor to the risk of core melt. A subsequent study (Ref. 5) evaluated various PIV configurations to determine the probability of intersystem LOCAs.

PIVs are provided to isolate the RCS from the following typically connected systems:

BASES

BACKGROUND (continued)

a. Shutdown Cooling (SDC) System,

b. Safety Injection System, and

c. Chemical and Volume Control System.

The PIVs are listed in ~~FSAR section (Ref. 6)~~ Table B 3.4.14-1. 1

Violation of this LCO could result in continued degradation of a PIV, which could lead to overpressurization of a low pressure system and the loss of the integrity of a fission product barrier. Insert 1 1

APPLICABLE SAFETY ANALYSES

Reference 4 identified potential intersystem LOCAs as a significant contributor to the risk of core melt. The dominant accident sequence in the intersystem LOCA category is the failure of the low pressure portion of the SDC System outside of containment. The accident is the result of a postulated failure of the PIVs, which are part of the reactor coolant pressure boundary (RCPB), and the subsequent pressurization of the SDC System downstream of the PIVs from the RCS. Because the low pressure portion of the SDC System is ~~typically~~ designed for ~~[600]~~ psig, overpressurization failure of the SDC low pressure line would result in a LOCA outside containment and subsequent risk of core melt. 350 2

Reference 5 evaluated various PIV configurations, leakage testing of the valves, and operational changes to determine the effect on the probability of intersystem LOCAs. This study concluded that periodic leakage testing of the PIVs can substantially reduce the probability of an intersystem LOCA.

RCS PIV leakage satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

RCS PIV leakage is identified LEAKAGE into closed systems connected to the RCS. Isolation valve leakage is usually on the order of drops per minute. Leakage that increases significantly suggests that something is operationally wrong and corrective action must be taken.

The LCO PIV leakage limit is ~~0.5 gpm per nominal inch of valve size, with a maximum limit of 5 gpm. The previous criterion of 1 gpm for all valve sizes imposed an unjustified penalty on the larger valves without providing information on potential valve degradation and resulted in higher personnel radiation exposures. A study concluded a leakage rate limit based on valve size was superior to a single allowable value.~~ 1

< 5.0 gpm. However, when the current measured rate is > 1.0 gpm, the current measured rate shall not exceed the rate determined by the previous test by an amount that reduces the margin between measured leakage rate and the maximum permissible rate (5.0 gpm) by 50%. 1

1

1

INSERT 1

Two motor operated valves are included in series in the suction piping of the two SDC trains to isolate the high pressure RCS from the low pressure piping of the SDC System when the RCS pressure is above the design pressure of the SDC System piping and components. Ensuring the SDC interlock that prevents the valves from being opened is OPERABLE ensures that RCS pressure will not pressurize the SDC System beyond its design pressure of 350 psig.

Ensuring the SDC System interlock function is OPERABLE ensures that RCS pressure will not pressurize the SDC System beyond its design pressure by providing an open permissive interlock. The SDC System interlock function also automatically closes the SDC suction line isolation valves on high pressurizer pressure with a setpoint high enough to preclude premature isolation of the SDC System. 1

BASES

LCO (continued)

6

Reference ~~7~~ permits leakage testing at a lower pressure differential than between the specified maximum RCS pressure and the normal pressure of the connected system during RCS operation (the maximum pressure differential) in those types of valves in which the higher service pressure will tend to diminish the overall leakage channel opening. In such cases, the observed rate may be adjusted to the maximum pressure differential by assuming leakage is directly proportional to the pressure differential to the one half power. 1

APPLICABILITY

In MODES 1, 2, 3, and 4, this LCO applies because the PIV leakage potential is greatest when the RCS is pressurized. In MODE 4, valves in the SDC flow path are not required to meet the requirements of this LCO when in, or during the transition to or from, the SDC mode of operation.

In MODES 5 and 6, leakage limits are not provided because the lower reactor coolant pressure results in a reduced potential for leakage and for a LOCA outside the containment.

ACTIONS

The Actions are modified by two Notes. Note 1 is added to provide clarification that each flow path allows separate entry into a Condition. This is allowed based on the functional independence of the flow path. Note 2 requires an evaluation of affected systems if a PIV is inoperable. The leakage may have affected system operability or isolation of a leaking flow path with an alternate valve may have degraded the ability of the interconnected system to perform its safety function.

A.1 and A.2

The flow path must be isolated by two valves. Required Actions A.1 and A.2 are modified by a Note stating that the valves used for isolation must meet the same leakage requirements as the PIVs and must be in the RCPB ~~[~~or the high pressure portion of the system~~]~~. 2

Required Action A.1 requires that the isolation with one valve must be performed within 4 hours. Four hours provides time to reduce leakage in excess of the allowable limit and to isolate if leakage cannot be reduced. The 4 hours allows the actions and restricts the operation with leaking isolation valves.

BASES

ACTIONS (continued)

[Required Action A.2 specifies that the double isolation barrier of two valves be restored by closing some other valve qualified for isolation or restoring one leaking PIV. The 72 hour Completion Time after exceeding the limit considers the time required to complete the action and the low probability of a second valve failing during this time period. 2

~~or~~

~~The 72 hour Completion Time after exceeding the limit allows for the restoration of the leaking PIV to OPERABLE status. This timeframe considers the time required to complete this Action and the low probability of a second valve failing during this period.]~~ 2

~~REVIEWER'S NOTE~~
~~Two options are provided for Required Action A.2. The second option (72 hour restoration) is appropriate if isolation of a second valve would place the unit in an unanalyzed condition.~~ 1

B.1 and B.2

any Required Action of Condition A cannot be met within the required Completion Time

If ~~leakage cannot be reduced [the system isolated] or other Required Actions accomplished~~, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE 3 within 6 hours and to MODE 5 within 36 hours. This Action reduces the leakage and also reduces the potential for a LOCA outside the containment. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. 3

C.1

The inoperability of the SDC ~~autoclosure~~ interlock renders the SDC suction isolation valves incapable of: isolating in response to a high pressure condition and preventing inadvertent opening of the valves at RCS pressures in excess of the SDC systems design pressure. If the SDC ~~autoclosure~~ interlock is inoperable, operation may continue as long as the affected SDC suction penetration is closed by at least one closed manual or deactivated automatic valve within 4 hours. This Action accomplishes the purpose of the ~~autoclosure~~ function. 1

The RCS PIV leakage limit is < 5.0 gpm. However, RCS PIV leakage is also limited when the current measured rate is > 1.0 gpm, such that the current measured rate shall not exceed the rate determined by the previous test by an amount that reduces the margin between measured leakage rate and 5.0 gpm by 50%. The minimum differential test pressure across each valve shall be ≥ 200 psid.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.14.1

Performance of leakage testing on each RCS PIV or isolation valve used to satisfy Required Action A.1 or A.2 is required to verify that leakage is below the specified limit and to identify each leaking valve. ~~The leakage limit of 0.5 gpm per inch of nominal valve diameter up to 5 gpm maximum applies to each valve.~~ Leakage testing requires a stable pressure condition.

For the two PIVs in series, the leakage requirement applies to each valve individually and not to the combined leakage across both valves. If the PIVs are not individually leakage tested, one valve may have failed completely and not be detected if the other valve in series meets the leakage requirement. In this situation, the protection provided by redundant valves would be lost.

Testing is to be performed every 9 months, but may be extended if the plant does not go into MODE 5 for at least 7 days. ~~[The [18] month Frequency is consistent with 10 CFR 50.55a(g) (Ref. 8) and the INSERVICE TESTING PROGRAM and is within frequency allowed by the American Society of Mechanical Engineers (ASME) Code (Ref. 7), and is based on the need to perform the Surveillance under conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~----------]~~

In addition, testing must be performed once after the valve has been opened by flow or exercised to ensure tight reseating. ~~PIVs disturbed in the performance of this Surveillance should also be tested unless documentation shows that an infinite testing loop cannot practically be avoided.~~ Testing must be performed within 24 hours after the valve has been reseated. Within 24 hours is a reasonable and practical time limit for performing this test after opening or reseating a valve.

BASES

SURVEILLANCE REQUIREMENTS (continued)

This SR is modified by a Note that states the Surveillance is not required to be performed in MODES 3 and 4.

The leakage limit is to be met at the RCS pressure associated with MODES 1 and 2. This permits leakage testing at high differential pressures with stable conditions not possible in the MODES with lower pressures.

3

Entry into MODES 3 and 4 is allowed to establish the necessary differential pressures and stable conditions to allow for performance of this Surveillance. ~~The Note that allows this provision is complimentary to the Frequency of prior to entry into MODE 2 whenever the unit has been in MODE 5 for 7 days or more, if leakage testing has not been performed in the previous 9 months. In addition, this Surveillance is not required to be performed on the SDC System when the SDC System is aligned to the RCS in the shutdown cooling mode of operation. PIVs contained in the SDC shutdown cooling flow path must be leakage rate tested after SDC is secured and stable unit conditions and the necessary differential pressures are established.~~

3

SR 3.4.14.2 and SR 3.4.14.3

automatic closure of the suction isolation valves

System while precluding premature isolation of the system

276 psia

System design pressure of 350 psig

System suction

Verifying ~~that~~ the SDC ~~autoclosure~~ interlock~~s are~~ ~~OPERABLE~~ ensures that RCS pressure will not pressurize the SDC ~~system beyond 125% of its design pressure of [600] psig~~. The interlock setpoint that prevents the valves from being opened is set so the actual RCS pressure must be < ~~[425] psig~~ to open the valves. This setpoint ensures the SDC ~~design pressure~~ will not be exceeded and the SDC relief valves will not lift. ~~[The 18 month Frequency is based on the need to perform these Surveillances under conditions that apply during a plant outage. The 18 month Frequency is also acceptable based on consideration of the design reliability (and confirming operating experience) of the equipment.~~

1

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

2

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.14 BASES, RCS PRESSURE ISOLATION VALVE (PIV) LEAKAGE

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Changes are made to be consistent with changes made to the Specification.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.4.14, RCS PRESSURE ISOLATION VALVE (PIV) LEAKAGE

There are no specific No Significant Hazards Considerations for this Specification.

DISCUSSION OF CHANGES
ITS 3.4.15, RCS LEAKAGE DETECTION INSTRUMENTATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.4.6.1 Actions a, b, and c, state, in part, perform a RCS water inventory balance at least once per 24 hours. Unit 1 CTS 4.4.6.2.c and Unit 2 CTS 4.4.6.2.1c (i.e., RCS Operational Leakage) require demonstration that the RCS operational LEAKAGE is within limits by performance of a Reactor Coolant System water inventory balance. ITS 3.4.15 states “Perform SR 3.4.13.1 once per 24 hours.” ITS SR 3.4.13.1 requires verification that the RCS operational LEAKAGE is within limits by performance of an RCS water inventory balance.” This changes the CTS by explicitly requiring that the RCS water balance Surveillance be performed.

CTS 4.4.6.1.a requires performance of the CHANNEL CHECK, CHANNEL FUNCTIONAL TEST, and CHANNEL CALIBRATION of the required containment atmosphere radioactivity monitor in accordance with Surveillance Requirement 4.3.3.1. The CTS 4.3.3.1 Surveillance Frequency for the CHANNEL CHECK, CHANNEL CALIBRATION and CHANNEL FUNCTIONAL TEST of each radiation monitoring instrumentation channel is in accordance with the Surveillance Frequency Control Program. Therefore, the Surveillance Frequency for CTS 4.4.6.1.a is changed to “in accordance with the Surveillance Frequency Control Program” consistent with the referenced CTS 4.3.3.1 Surveillance Requirement. ITS SR 3.4.15.1, SR 3.4.15,2, and SR 3.4.15.4 Frequencies are annotated “in accordance with the Surveillance Frequency Control Program” consistent with CTS 4.4.3.1.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A03 CTS 3.4.6.1 Action b states, in part, with the reactor cavity sump inlet flow monitoring system inoperable with only the containment gaseous radioactivity monitor operable, perform an RCS water inventory balance at least once per 24 hours and analyze grab samples of the containment atmosphere at least once per 12 hours, and either restore the containment particulate radioactivity monitor to OPERABLE status within 7 days, and enter action a. above with the time in this action applied against the allowed outage time of action a.

ITS 3.4.15 ACTION C does not include the requirement “perform an RCS water inventory balance at least once per 24 hours” since with the reactor cavity sump inlet flow monitoring system inoperable, ACTION A is also entered (LCO 3.0.2), and Required Action A.1 performs the RCS water inventory balance using SR 3.4.13.1.

ITS 3.4.15 ACTION C does not include the requirement to "restore the containment particulate radioactivity monitor to OPERABLE status within 7 days." ITS Required Action C.2 restores the reactor cavity sump inlet flow monitor to OPERABLE status within 7 days. The Condition C note implies that the containment particulate radioactivity monitor is inoperable, and though not a Required Action, it remains an option to restore the containment particulate radioactivity monitor to OPERABLE status. Required Action C.2 allows 7 days to restore the reactor cavity sump inlet flow monitor to OPERABLE status before entering Condition D; therefore, the Completion Time of 7 days is also allowed to restore the containment particulate radioactivity monitor to OPERABLE status.

ITS 3.4.15 ACTION C does not include an action similar to the CTS Action b., which requires entry into Action a. and applying the time in Action b. to the allowed outage time of Action a. This is not necessary since with the reactor cavity sump inlet flow monitoring system inoperable, ACTION A is also entered (LCO 3.0.2), therefore, the allowed outage time is also accrued for ACTION A.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A04 CTS 3.3.3.1 specifies requirements for radiation monitoring instrumentation and list the requirements for each instrument in CTS Table 3.3-6, including the containment gaseous and particulate activity RCS leakage detection instrumentation. ITS 3.4.15 provides, in part, requirements for the containment gaseous and particulate activity RCS leakage detection instrumentation consistent with the requirements of CTS 3.4.6.1 and provides the requirements in the LCO, Applicability, ACTIONS, and Surveillance Requirements. This changes the CTS by presenting the gaseous and particulate activity RCS leakage detection instrument requirements without use of an instrument table. This change is acceptable as it results solely from the change in the format and presentation of the CTS necessary to conform to the ISTS. As the proposed change is the result of changes in the format and presentation of the CTS requirements, it is designated administrative.

A05 CTS 3.3.3.1 Action c states that the provisions of Specification 3.0.3 are not applicable. ITS 3.4.15 does not include an allowance waving the provisions of LCO 3.0.3. This changes the CTS by eliminating an instrumentation action requirement that conflicts with an action in Specification 3.4.6.1.

The purpose of CTS 3.3.3.1 Action c is to preclude action be taken per Specification 3.0.3 (ITS LCO 3.0.3) to shutdown the unit in the event there are no actions to perform, or the actions cannot be performed within the required time when radiation monitoring instrumentation is inoperable. However, a portion of the radiation monitoring instrumentation is also utilized for RCS leakage detection. CTS 3.3.3.1 Action c states that the provisions of Specification 3.0.3 are not applicable. Yet, CTS Table 3.3-6 Action 14 (Unit 1) and Action 23 (Unit 2) require complying with Specification 3.4.6.1. CTS 3.4.6.1 Action d requires entry into Specification 3.0.3 when all required leakage detection monitors, including the containment gaseous and particulate activity RCS leakage detection instrumentation, are inoperable. Therefore, the requirements of CTS 3.3.3.1 and

CTS 3.4.6.1 appear to conflict with regard to CTS 3.0.3 compliance. This change eliminates conflicting statements regarding LCO 3.0.3 compliance by removing the Specification 3.0.3 waiver for the containment gaseous and particulate activity RCS leakage detection instrumentation and preserves the intent of the CTS requirement to apply Specification 3.0.3 when all required leakage detection monitors, including the containment gaseous and particulate activity RCS leakage detection instruments, are inoperable. This change is designated as administrative and is acceptable because it does not result in a technical change to the CTS.

A06 CTS 3.3.3.1 Table 3.3-6 requires a minimum of one channel to be OPERABLE for the containment gaseous activity RCS leakage detection monitor (Instrument 2.a.i) and the containment particulate activity RCS leakage detection monitor (Instrument 2.a.ii). The associated CTS Table 3.3-6 Action requires action to be taken pursuant to Specification 3.4.6.1. CTS 3.4.6.1.b requires either one gaseous channel or one particulate channel of the containment atmosphere radioactivity monitor to be OPERABLE and provides actions when one "required" containment atmosphere radioactivity monitor is inoperable. Consistent with CTS 3.4.6.1, ITS LCO 3.4.15.b also requires one channel of the containment atmosphere radioactivity monitor (gaseous or particulate) to be OPERABLE and ACTIONS when one "required" channel is inoperable. This changes the CTS presentation by eliminating potential confusion of the existing requirements by clarifying the intent that one channel of either the gaseous or particulate activity RCS leakage detection instrument must be OPERABLE. This change is acceptable as it represents a change in the format and presentation of the CTS to more accurately reflect the intent of the existing requirements as specified in CTS 3.4.6.1. As the proposed change is the result of changes in the format and presentation of the CTS requirements, it is designated administrative.

REMOVED DETAIL CHANGES

LA01 (*Type 1 - Removing Details of System Design and System Description, Including Design Limits*) CTS 3.3.3.1 Table 3.3-6 for radiation monitoring instrumentation has a column specifying the Measurement Range and a specific measurement range for the containment gaseous and particulate activity RCS leakage detection instrumentation. ITS 3.4.15 does not retain the measurement range of the containment gaseous and particulate activity RCS leakage detection instrumentation. This changes the CTS by moving the instrument measurement range to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.15, RCS LEAKAGE DETECTION INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.15 RCS Leakage Detection Instrumentation

BASES

BACKGROUND

GDC 30 of Appendix A to 10 CFR 50 (Ref. 1) requires means for detecting and, to the extent practical, identifying the location of the source of RCS LEAKAGE. Regulatory Guide 1.45, Revision 0, (Ref. 2) describes acceptable methods for selecting leakage detection systems.

Leakage detection systems must have the capability to detect significant reactor coolant pressure boundary (RCPB) degradation as soon after occurrence as practical to minimize the potential for propagation to a gross failure. Thus, an early indication or warning signal is necessary to permit proper evaluation of all unidentified LEAKAGE. ~~[In addition to meeting the OPERABILITY requirements, the monitors are typically set to provide the most sensitive response without causing an excessive number of spurious alarms.]~~ 2

reactor cavity

The ~~containment~~ sump used to collect unidentified LEAKAGE ~~[~~is~~]~~ ~~[(or) and the containment air cooler condensate flow rate monitor] [are]~~ instrumented to alarm for increases above in the normal flow rates. 1 2

The reactor coolant contains radioactivity that, when released to the containment, may be detected by radiation monitoring instrumentation. Radioactivity detection systems are included for monitoring both particulate and gaseous activities, because of their sensitivities and rapid responses to RCS LEAKAGE. 1

The measurement range of the containment particulate and gaseous radioactivity monitoring instruments is 10 to 10^6 cpm.

~~Other indications may be used to detect an increase in unidentified LEAKAGE; however, they are not required to be OPERABLE by this LCO. An increase in humidity of the containment atmosphere would indicate release of water vapor to the containment. Dew point temperature measurements can thus be used to monitor humidity levels of the containment atmosphere as an indicator of potential RCS LEAKAGE.~~ 1

~~Since the humidity level is influenced by several factors, a quantitative evaluation of an indicated leakage rate by this means may be questionable and should be compared to observed increases in liquid flow into or from the containment sump [and condensate flow from air coolers]. Humidity level monitoring is considered most useful as an indirect alarm or indication to alert the operator to a potential problem. Humidity monitors are not required by this LCO.~~ 1

BASES

BACKGROUND (continued)

Air temperature and pressure monitoring methods may also be used to infer unidentified LEAKAGE to the containment. Containment temperature and pressure fluctuate slightly during plant operation, but a rise above the normally indicated range of values may indicate RCS LEAKAGE into the containment. The relevance of temperature and pressure measurements is affected by containment free volume and, for temperature, detector location. Alarm signals from these instruments can be valuable in recognizing rapid and sizable leakage to the containment. Temperature and pressure monitors are not required by this LCO.

The above-mentioned LEAKAGE detection methods or systems differ in sensitivity and response time. ~~[Some of these systems could serve as early alarm systems signaling the operators that closer examination of other detection systems is necessary to determine the extent of any corrective action that may be required.]~~ 2

APPLICABLE SAFETY ANALYSES

The need to evaluate the severity of an alarm or an indication is important to the operators, and the ability to compare and verify with indications from other systems is necessary.

The safety significance of RCS LEAKAGE varies widely depending on its source, rate, and duration. Therefore, detecting and monitoring RCS LEAKAGE into the containment area are necessary. Quickly separating the identified LEAKAGE from the unidentified LEAKAGE provides quantitative information to the operators, allowing them to take corrective action should leakage occur detrimental to the safety of the facility and the public.

RCS leakage detection instrumentation satisfies Criterion 1 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires instruments of diverse monitoring principles to be OPERABLE to provide confidence that small amounts of unidentified LEAKAGE are detected in time to allow actions to place the plant in a safe condition when RCS LEAKAGE indicates possible RCPB degradation.

two

The LCO requires ~~[three]~~ instruments to be OPERABLE. 2

reactor cavity

The ~~containment~~ sump is used to collect unidentified LEAKAGE. ~~[The containment sump consists of the normal sump and the emergency sump.~~ The LCO requirements apply to the total amount of unidentified LEAKAGE collected in ~~[~~the~~][both]~~ sump~~[s].]~~ The monitor on the ~~containment~~ sump detects ~~[level or~~ flow rate ~~or the operating frequency of a pump]~~ and is instrumented to detect when there is ~~[leakage of] [~~an 1 2

reactor cavity

BASES

LCO (continued)

increase above the normal value by] 1 gpm. The identification of [an increase in] unidentified LEAKAGE will be delayed by the time required for the unidentified LEAKAGE to travel to the containment sump and it may take longer than one hour to detect a 1 gpm increase in unidentified LEAKAGE, depending on the origin and magnitude of the LEAKAGE. This sensitivity is acceptable for containment sump monitor OPERABILITY.

reactor cavity

reactor cavity

inlet flow

1

1

The reactor coolant contains radioactivity that, when released to the containment, can be detected by the gaseous or particulate containment atmosphere radioactivity monitor. Only one of the two detectors is required to be OPERABLE. Radioactivity detection systems are included for monitoring both particulate and gaseous activities because of their sensitivities and rapid responses to RCS LEAKAGE, but have recognized limitations. Reactor coolant radioactivity levels will be low during initial reactor startup and for a few weeks thereafter, until activated corrosion products have been formed and fission products appear from fuel element cladding contamination or cladding defects. If there are few fuel element cladding defects and low levels of activation products, it may not be possible for the gaseous or particulate containment atmosphere radioactivity monitors to detect a 1 gpm increase within 1 hour during normal operation. However, the gaseous or particulate containment atmosphere radioactivity monitor is OPERABLE when it is capable of detecting a 1 gpm increase in unidentified LEAKAGE within 1 hour given an RCS activity equivalent to that assumed in the design calculations for the monitors (Reference 3).

[An increase in humidity of the containment atmosphere could indicate the release of water vapor to the containment. Condensate flow from air coolers is instrumented to detect when there is an increase above the normal value by 1 gpm. The time required to detect a 1 gpm increase above the normal value varies based on environmental and system conditions and may take longer than 1 hour. This sensitivity is acceptable for containment air cooler condensate flow rate monitor OPERABILITY.]

2

The LCO is satisfied when monitors of diverse measurement means are available. Thus, the containment sump monitor, in combination with a particulate or gaseous radioactivity monitor [and a containment air cooler condensate flow rate monitor], provides an acceptable minimum.

inlet flow

reactor cavity

1

2

APPLICABILITY Because of elevated RCS temperature and pressure in MODES 1, 2, 3, and 4, RCS leakage detection instrumentation is required to be OPERABLE.

1

BASES

APPLICABILITY (continued)

In MODE 5 or 6, the temperature is ≤ 200°F and pressure is maintained low or at atmospheric pressure. Since the temperatures and pressures are far lower than those for MODES 1, 2, 3, and 4, the likelihood of leakage and crack propagation is much smaller. Therefore, the requirements of this LCO are not applicable in MODES 5 and 6.

ACTIONS

A.1 and A.2

reactor cavity

inlet flow

If the ~~containment~~ sump monitor is inoperable, no other form of sampling can provide the equivalent information. 1

However, the containment atmosphere radioactivity monitor will provide indications of changes in leakage. Together with the containment atmosphere radioactivity monitor, the periodic surveillance for RCS water inventory balance, SR 3.4.13.1, must be performed at an increased frequency of 24 hours to provide information that is adequate to detect leakage. A Note is added allowing that SR 3.4.13.1 is not required to be performed until 12 hours after establishing steady state operation (stable temperature, power level, pressurizer and makeup tank levels, makeup and letdown~~, and [RCP seal injection and return flows]~~). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established. 2

Restoration of the sump monitor to OPERABLE status is required to regain the function in a Completion Time of 30 days after the monitor's failure. This time is acceptable considering the frequency and adequacy of the RCS water inventory balance required by Required Action A.1.

B.1.1, B.1.2, ~~B.2.1,~~ and B.2~~.2~~ 1

With both gaseous and particulate containment atmosphere radioactivity monitoring instrumentation channels inoperable, alternative action is required. Either grab samples of the containment atmosphere must be taken and analyzed, or water inventory balances, in accordance with SR 3.4.13.1, must be performed to provide alternate periodic information. With a sample obtained and analyzed or an inventory balance performed every 24 hours, the reactor may be operated for up to 30 days to allow restoration of at least one of the radioactivity monitors.

~~[Alternatively, continued operation is allowed if the air cooler condensate flow rate monitoring system is OPERABLE, provided grab samples are taken or water inventory balance performed every 24 hours.]~~ 2

BASES

ACTIONS (continued)

The 24 hour interval provides periodic information that is adequate to detect leakage. A Note is added allowing that SR 3.4.13.1 is not required to be performed until 12 hours after establishing steady state operation (stable temperature, power level, pressurizer and makeup tank levels, makeup and letdown~~, and [RCP seal injection and return flows]~~). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established. The 30 day Completion Time recognizes at least one other form of leakage detection is available. 2

~~[C.1 and C.2~~

~~If the containment air cooler condensate flow rate monitor is inoperable, alternative action is again required. Either SR 3.4.15.1 must be performed, or water inventory balances, in accordance with SR 3.4.13.1, must be performed to provide alternate periodic information. Provided a CHANNEL CHECK is performed every 8 hours or an inventory balance is performed every 24 hours, reactor operation may continue while awaiting restoration of the containment air cooler condensate flow rate monitor to OPERABLE status.~~ 2

~~The 24 hour interval provides periodic information that is adequate to detect RCS LEAKAGE. A Note is added allowing that SR 3.4.13.1 is not required to be performed until 12 hours after establishing steady state operation (stable temperature, power level, pressurizer and makeup tank levels, makeup and letdown, and [RCP seal injection and return flows]). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established.]~~ 2

C.1 and C.2

~~D.1, D.2.1, and D.2.2~~ 1

reactor cavity

inlet flow

With the ~~containment~~ sump monitor~~, [and the containment air cooler condensate flow rate monitor]~~ inoperable, the only means of detecting LEAKAGE is the required containment atmosphere radiation monitor. A Note clarifies that this Condition is only applicable when the only OPERABLE monitor is the required containment atmosphere gaseous radiation monitor. The containment atmosphere gaseous radioactivity monitor typically cannot detect a 1 gpm leak within one hour when RCS activity is low. In addition, this configuration does not provide the required diverse means of leakage detection. Indirect methods of monitoring RCS leakage must be implemented. Grab samples of the containment atmosphere must be taken and analyzed every 12 hours to provide 2

BASES

ACTIONS (continued)

alternate periodic information. The 12 hour interval is sufficient to detect increasing RCS leakage. The Required Action provides 7 days to restore another RCS leakage monitor to OPERABLE status to regain the intended leakage detection diversity. The 7 day Completion Time ensures that the plant will not be operated in a degraded configuration for a lengthy time period.

The Note assumes the containment particulate radioactivity monitor is inoperable. If the containment particulate radioactivity monitor is restored to OPERABLE status within the 7 day Completion Time to restore the reactor cavity sump inlet flow monitor to OPERABLE status, the Condition may be exited.

1

~~E.1 and E.2~~

~~If the required containment atmosphere radioactivity monitor [and the containment air cooler condensate flow rate monitor] are inoperable, the only means of detecting leakage is the containment sump monitor. This Condition does not provide the required diverse means of leakage detection. The Required Action is to restore either of the inoperable monitors to OPERABLE status within 30 days to regain the intended leakage detection diversity. The 30 day Completion Times ensure that the plant will not be operated in a reduced configuration for a lengthy time period.~~

1

D D

~~F~~.1 and ~~F~~.2

1

or

If any Required Action of Condition A, B, ~~[~~C~~], [D] or [E]~~ cannot be met within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

1

E

~~G~~.1

1

If all required monitors are inoperable, no automatic means of monitoring leakage are available and immediate plant shutdown in accordance with LCO 3.0.3 is required.

1

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.15.1

SR 3.4.15.1 requires the performance of a CHANNEL CHECK of the required containment atmosphere radioactivity monitors. The check gives reasonable confidence the channel is operating properly. ~~[The Frequency of [12] hours is based on instrument reliability and is reasonable for detecting off normal conditions.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~]~~

SR 3.4.15.2

SR 3.4.15.2 requires the performance of a CHANNEL FUNCTIONAL TEST of the required containment atmosphere radioactivity monitors. The test ensures that the monitor can perform its function in the desired manner. The test verifies the alarm setpoint and relative accuracy of the instrument string. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other

BASES

SURVEILLANCE REQUIREMENTS (continued)

Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. ~~[The Frequency of 92 days considers instrument reliability, and operating experience has shown it proper for detecting degradation.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~]~~

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

and

SR 3.4.15.3~~,~~ SR 3.4.15.4~~, and [SR 3.4.15.5]~~ 1

These SRs require the performance of a CHANNEL CALIBRATION for each of the RCS leakage detection instrumentation channels. The calibration verifies the accuracy of the instrument string, including the instruments located inside containment. [~~ The Frequency of [18] months is a typical refueling cycle and considers channel reliability. Operating experience has shown this Frequency is acceptable.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

B 3.4.15 RCS Leakage Detection Instrumentation

BASES

BACKGROUND

GDC 30 of Appendix A to 10 CFR 50 (Ref. 1) requires means for detecting and, to the extent practical, identifying the location of the source of RCS LEAKAGE. Regulatory Guide 1.45, Revision 0, (Ref. 2) describes acceptable methods for selecting leakage detection systems.

Leakage detection systems must have the capability to detect significant reactor coolant pressure boundary (RCPB) degradation as soon after occurrence as practical to minimize the potential for propagation to a gross failure. Thus, an early indication or warning signal is necessary to permit proper evaluation of all unidentified LEAKAGE. ~~[In addition to meeting the OPERABILITY requirements, the monitors are typically set to provide the most sensitive response without causing an excessive number of spurious alarms.]~~ 2

reactor cavity

The ~~containment~~ sump used to collect unidentified LEAKAGE ~~[~~is~~]~~ ~~[(or) and the containment air cooler condensate flow rate monitor] [are]~~ instrumented to alarm for increases above in the normal flow rates. 1 2

The reactor coolant contains radioactivity that, when released to the containment, may be detected by radiation monitoring instrumentation. Radioactivity detection systems are included for monitoring both particulate and gaseous activities, because of their sensitivities and rapid responses to RCS LEAKAGE. 1

The measurement range of the containment particulate radioactivity monitoring instrument is 10 to 10^7 cpm. The measurement range of the containment gaseous radioactivity monitoring instrument is 10^{-7} to 10^{-2} µCi/cc.

~~Other indications may be used to detect an increase in unidentified LEAKAGE; however, they are not required to be OPERABLE by this LCO. An increase in humidity of the containment atmosphere would indicate release of water vapor to the containment. Dew point temperature measurements can thus be used to monitor humidity levels of the containment atmosphere as an indicator of potential RCS LEAKAGE.~~ 1

~~Since the humidity level is influenced by several factors, a quantitative evaluation of an indicated leakage rate by this means may be questionable and should be compared to observed increases in liquid flow into or from the containment sump [and condensate flow from air coolers]. Humidity level monitoring is considered most useful as an indirect alarm or indication to alert the operator to a potential problem. Humidity monitors are not required by this LCO.~~ 1

BASES

BACKGROUND (continued)

Air temperature and pressure monitoring methods may also be used to infer unidentified LEAKAGE to the containment. Containment temperature and pressure fluctuate slightly during plant operation, but a rise above the normally indicated range of values may indicate RCS LEAKAGE into the containment. The relevance of temperature and pressure measurements is affected by containment free volume and, for temperature, detector location. Alarm signals from these instruments can be valuable in recognizing rapid and sizable leakage to the containment. Temperature and pressure monitors are not required by this LCO.

The above-mentioned LEAKAGE detection methods or systems differ in sensitivity and response time. ~~[Some of these systems could serve as early alarm systems signaling the operators that closer examination of other detection systems is necessary to determine the extent of any corrective action that may be required.]~~ 2

APPLICABLE SAFETY ANALYSES

The need to evaluate the severity of an alarm or an indication is important to the operators, and the ability to compare and verify with indications from other systems is necessary.

The safety significance of RCS LEAKAGE varies widely depending on its source, rate, and duration. Therefore, detecting and monitoring RCS LEAKAGE into the containment area are necessary. Quickly separating the identified LEAKAGE from the unidentified LEAKAGE provides quantitative information to the operators, allowing them to take corrective action should leakage occur detrimental to the safety of the facility and the public.

RCS leakage detection instrumentation satisfies Criterion 1 of 10 CFR 50.36(c)(2)(ii).

LCO

This LCO requires instruments of diverse monitoring principles to be OPERABLE to provide confidence that small amounts of unidentified LEAKAGE are detected in time to allow actions to place the plant in a safe condition when RCS LEAKAGE indicates possible RCPB degradation.

two

The LCO requires ~~[three]~~ instruments to be OPERABLE. 2

reactor cavity

The ~~containment~~ sump is used to collect unidentified LEAKAGE. ~~[The containment sump consists of the normal sump and the emergency sump.~~ The LCO requirements apply to the total amount of unidentified LEAKAGE collected in ~~[~~the~~][both]~~ sump~~[s].]~~ The monitor on the ~~containment~~ sump detects ~~[level or~~ flow rate ~~or the operating frequency of a pump]~~ and is instrumented to detect when there is ~~[leakage of]~~ [an 1 2

reactor cavity

BASES

LCO (continued)

increase above the normal value by] 1 gpm. The identification of [an increase in] unidentified LEAKAGE will be delayed by the time required for the unidentified LEAKAGE to travel to the containment sump and it may take longer than one hour to detect a 1 gpm increase in unidentified LEAKAGE, depending on the origin and magnitude of the LEAKAGE. This sensitivity is acceptable for containment sump monitor OPERABILITY.

reactor cavity

reactor cavity

inlet flow

1

1

The reactor coolant contains radioactivity that, when released to the containment, can be detected by the gaseous or particulate containment atmosphere radioactivity monitor. Only one of the two detectors is required to be OPERABLE. Radioactivity detection systems are included for monitoring both particulate and gaseous activities because of their sensitivities and rapid responses to RCS LEAKAGE, but have recognized limitations. Reactor coolant radioactivity levels will be low during initial reactor startup and for a few weeks thereafter, until activated corrosion products have been formed and fission products appear from fuel element cladding contamination or cladding defects. If there are few fuel element cladding defects and low levels of activation products, it may not be possible for the gaseous or particulate containment atmosphere radioactivity monitors to detect a 1 gpm increase within 1 hour during normal operation. However, the gaseous or particulate containment atmosphere radioactivity monitor is OPERABLE when it is capable of detecting a 1 gpm increase in unidentified LEAKAGE within 1 hour given an RCS activity equivalent to that assumed in the design calculations for the monitors (Reference 3).

[An increase in humidity of the containment atmosphere could indicate the release of water vapor to the containment. Condensate flow from air coolers is instrumented to detect when there is an increase above the normal value by 1 gpm. The time required to detect a 1 gpm increase above the normal value varies based on environmental and system conditions and may take longer than 1 hour. This sensitivity is acceptable for containment air cooler condensate flow rate monitor OPERABILITY.]

2

The LCO is satisfied when monitors of diverse measurement means are available. Thus, the containment sump monitor, in combination with a particulate or gaseous radioactivity monitor [and a containment air cooler condensate flow rate monitor], provides an acceptable minimum.

inlet flow

reactor cavity

1

2

APPLICABILITY Because of elevated RCS temperature and pressure in MODES 1, 2, 3, and 4, RCS leakage detection instrumentation is required to be OPERABLE.

BASES

APPLICABILITY (continued)

In MODE 5 or 6, the temperature is ≤ 200°F and pressure is maintained low or at atmospheric pressure. Since the temperatures and pressures are far lower than those for MODES 1, 2, 3, and 4, the likelihood of leakage and crack propagation is much smaller. Therefore, the requirements of this LCO are not applicable in MODES 5 and 6.

ACTIONS

A.1 and A.2

reactor cavity

inlet flow

If the ~~containment~~ sump monitor is inoperable, no other form of sampling can provide the equivalent information. 1

However, the containment atmosphere radioactivity monitor will provide indications of changes in leakage. Together with the containment atmosphere radioactivity monitor, the periodic surveillance for RCS water inventory balance, SR 3.4.13.1, must be performed at an increased frequency of 24 hours to provide information that is adequate to detect leakage. A Note is added allowing that SR 3.4.13.1 is not required to be performed until 12 hours after establishing steady state operation (stable temperature, power level, pressurizer and makeup tank levels, makeup and letdown~~, and [RCP seal injection and return flows]~~). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established. 2

Restoration of the sump monitor to OPERABLE status is required to regain the function in a Completion Time of 30 days after the monitor's failure. This time is acceptable considering the frequency and adequacy of the RCS water inventory balance required by Required Action A.1.

B.1.1, B.1.2, ~~B.2.1,~~ and B.2~~.2~~ 1

With both gaseous and particulate containment atmosphere radioactivity monitoring instrumentation channels inoperable, alternative action is required. Either grab samples of the containment atmosphere must be taken and analyzed, or water inventory balances, in accordance with SR 3.4.13.1, must be performed to provide alternate periodic information. With a sample obtained and analyzed or an inventory balance performed every 24 hours, the reactor may be operated for up to 30 days to allow restoration of at least one of the radioactivity monitors.

~~[Alternatively, continued operation is allowed if the air cooler condensate flow rate monitoring system is OPERABLE, provided grab samples are taken or water inventory balance performed every 24 hours.]~~ 2

BASES

ACTIONS (continued)

The 24 hour interval provides periodic information that is adequate to detect leakage. A Note is added allowing that SR 3.4.13.1 is not required to be performed until 12 hours after establishing steady state operation (stable temperature, power level, pressurizer and makeup tank levels, makeup and letdown~~, and [RCP seal injection and return flows]~~). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established. The 30 day Completion Time recognizes at least one other form of leakage detection is available. 2

~~[C.1 and C.2~~

~~If the containment air cooler condensate flow rate monitor is inoperable, alternative action is again required. Either SR 3.4.15.1 must be performed, or water inventory balances, in accordance with SR 3.4.13.1, must be performed to provide alternate periodic information. Provided a CHANNEL CHECK is performed every 8 hours or an inventory balance is performed every 24 hours, reactor operation may continue while awaiting restoration of the containment air cooler condensate flow rate monitor to OPERABLE status.~~ 2

~~The 24 hour interval provides periodic information that is adequate to detect RCS LEAKAGE. A Note is added allowing that SR 3.4.13.1 is not required to be performed until 12 hours after establishing steady state operation (stable temperature, power level, pressurizer and makeup tank levels, makeup and letdown, and [RCP seal injection and return flows]). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established.]~~ 2

C.1 and C.2

~~D.1, D.2.1, and D.2.2~~ 1

reactor cavity

inlet flow

With the ~~containment~~ sump monitor~~, [and the containment air cooler condensate flow rate monitor]~~ inoperable, the only means of detecting LEAKAGE is the required containment atmosphere radiation monitor. A Note clarifies that this Condition is only applicable when the only OPERABLE monitor is the required containment atmosphere gaseous radiation monitor. The containment atmosphere gaseous radioactivity monitor typically cannot detect a 1 gpm leak within one hour when RCS activity is low. In addition, this configuration does not provide the required diverse means of leakage detection. Indirect methods of monitoring RCS leakage must be implemented. Grab samples of the containment atmosphere must be taken and analyzed every 12 hours to provide 2

BASES

ACTIONS (continued)

alternate periodic information. The 12 hour interval is sufficient to detect increasing RCS leakage. The Required Action provides 7 days to restore another RCS leakage monitor to OPERABLE status to regain the intended leakage detection diversity. The 7 day Completion Time ensures that the plant will not be operated in a degraded configuration for a lengthy time period.

The Note assumes the containment particulate radioactivity monitor is inoperable. If the containment particulate radioactivity monitor is restored to OPERABLE status within the 7 day Completion Time to restore the reactor cavity sump inlet flow monitor to OPERABLE status, the Condition may be exited.

1

~~E.1 and E.2~~

~~If the required containment atmosphere radioactivity monitor [and the containment air cooler condensate flow rate monitor] are inoperable, the only means of detecting leakage is the containment sump monitor. This Condition does not provide the required diverse means of leakage detection. The Required Action is to restore either of the inoperable monitors to OPERABLE status within 30 days to regain the intended leakage detection diversity. The 30 day Completion Times ensure that the plant will not be operated in a reduced configuration for a lengthy time period.~~

1

D D

~~F~~.1 and ~~F~~.2

1

or

If any Required Action of Condition A, B, ~~[~~C~~], [D] or [E]~~ cannot be met within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

1

E

~~G~~.1

1

If all required monitors are inoperable, no automatic means of monitoring leakage are available and immediate plant shutdown in accordance with LCO 3.0.3 is required.

1

BASES

SURVEILLANCE REQUIREMENTS

SR 3.4.15.1

SR 3.4.15.1 requires the performance of a CHANNEL CHECK of the required containment atmosphere radioactivity monitors. The check gives reasonable confidence the channel is operating properly. ~~[The Frequency of [12] hours is based on instrument reliability and is reasonable for detecting off normal conditions.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~----------]~~

SR 3.4.15.2

SR 3.4.15.2 requires the performance of a CHANNEL FUNCTIONAL TEST of the required containment atmosphere radioactivity monitors. The test ensures that the monitor can perform its function in the desired manner. The test verifies the alarm setpoint and relative accuracy of the instrument string. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other

BASES

SURVEILLANCE REQUIREMENTS (continued)

Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. ~~[The Frequency of 92 days considers instrument reliability, and operating experience has shown it proper for detecting degradation.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~]~~

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

and

SR 3.4.15.3~~,~~ SR 3.4.15.4~~, and [SR 3.4.15.5]~~ 1

These SRs require the performance of a CHANNEL CALIBRATION for each of the RCS leakage detection instrumentation channels. The calibration verifies the accuracy of the instrument string, including the instruments located inside containment. [~~ The Frequency of [18] months is a typical refueling cycle and considers channel reliability. Operating experience has shown this Frequency is acceptable.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.15, BASES, RCS LEAKAGE DETECTION INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

REACTOR COOLANT SYSTEM

SPECIFIC ACTIVITY

LIMITING CONDITION FOR OPERATION

LCO 3.4.16 ~~3.4.8~~ ~~The~~ specific activity ~~of the primary coolant~~ shall be ~~limited~~ ~~to:~~

RCS DOSE EQUIVALENT I-131 and DOSE EQUIVALENT XE-133

within limits.

SR 3.4.16.2 ~~a.~~ ≤ 1.0 μCi/gram DOSE EQUIVALENT I-131, and

SR 3.4.16.1 ~~b.~~ ≤ 518.9 μCi/gram DOSE EQUIVALENT XE-133.

Applicability **APPLICABILITY:** MODES 1, 2, 3, and 4.

ACTION:

Condition A
Required Action A.1

~~a.~~ ~~With the specific activity of the primary coolant >1.0 μCi/gram~~ DOSE EQUIVALENT I-131, verify DOSE EQUIVALENT I-131 is ≤ 60.0 μCi/gram once per four hours.

not within limits

~~b.~~ With the specific activity of the primary coolant > 1.0 μCi/gram DOSE EQUIVALENT I-131, but ≤ 60.0 μCi/gram DOSE EQUIVALENT I-131, operation may continue for up to 48 hours ~~while efforts are made to~~ restore DOSE EQUIVALENT I-131 to within ~~the 1.0 μCi/gram~~ limit.

Required Action A.2

LCO 3.0.4.c is applicable.

Required Action A.1 and A.2 Note

Condition C

~~c.~~ With the specific activity of the primary coolant > 1.0 μCi/gram DOSE EQUIVALENT I-131 for greater than 48 hours during one continuous time interval, or > 60.0 μCi/gram DOSE EQUIVALENT I-131,

Required Action C.1 and C.2

be in ~~HOT STANDBY~~ within 6 hours and ~~COLD SHUTDOWN~~ within ~~the following~~ ~~30~~ hours.

MODE 3

MODE 5

36

~~d.~~ With the specific activity of the primary coolant > 518.9 μCi/gram DOSE EQUIVALENT XE-133, operation may continue for up to 48 hours ~~while efforts are made to~~ restore DOSE EQUIVALENT XE-133 to within ~~the 518.9 μCi/gram DOSE EQUIVALENT XE-133~~ limit.

Required Action B.1

LCO 3.0.4.c is applicable.

Required Action B.1 Note

Condition C

~~e.~~ With the specific activity of the primary coolant > 518.9 μCi/gram DOSE EQUIVALENT XE-133 for greater than 48 hours during one continuous time interval,

Required Action C.1 and C.2

be in ~~HOT STANDBY~~ within 6 hours and ~~COLD SHUTDOWN~~ within ~~the following~~ ~~30~~ hours.

DISCUSSION OF CHANGES
ITS 3.4.16, RCS SPECIFIC ACTIVITY

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.4.8 (MODES 1, 2, 3, and 4), ACTION a, requires Table 4.4-4, Sampling Test 3.a, Isotopic Analysis for Iodine, to be performed every 4 hours until the specific activity of the primary coolant is restored to within its limits. This is also restated in CTS Table 4.4-4, Footnote #. ITS 3.4.16 Required Action A.1 essentially requires the same analysis; however, the explicit statement to perform the isotopic analysis for iodine "until restored to within limits" is not included. This changes the CTS by deleting the explicit statement to perform the isotopic analysis for iodine until the limits are met.

The purpose of the statement "until the specific activity of the primary coolant is restored to within its limits," in CTS 3.4.8 (MODES 1, 2, 3, and 4) ACTION a., Table 4.4-4 Item 3.a, and footnote #, is to ensure the Surveillance is performed until the limit is met. In ITS, stating that the analysis is required until the specific activity is within limits is unnecessary. ITS LCO 3.0.2 requires the Required Actions of the entered Condition(s) to be performed upon discovery of failure to meet the LCO, until the LCO is met. If the LCO is met or is no longer applicable prior to the expiration of the specified Completion Time(s), completion of the Required Action(s) is not required unless otherwise stated. This change is acceptable since ITS LCO 3.0.2 will require the Required Action to be performed until the LCO is met. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 CTS Table 4.4-4 Item 3.b Frequency requires, that one sample between 2 and 6 hours following a THERMAL POWER change exceeding (i.e., >) 15% of the RATED THERMAL POWER within a one hour period. ITS SR 3.4.16.2 Frequency requires, one sample between 2 and 6 hours after a THERMAL POWER change of greater than or equal to (i.e., ≥) 15% RTP within 1 hour. This changes the CTS by requiring one sample to be taken between 2 and 6 hours after a THERMAL POWER change of greater than or equal to (i.e., ≥) 15% RTP within 1 hour.

The purpose of CTS Table 4.4-4 Item 3.b Frequency is to ensure one sample is taken between 2 and 6 hours following a THERMAL POWER change exceeding 15 percent of the RATED THERMAL POWER within a one hour period. This change is acceptable because ITS SR 3.4.16.2 requires essentially the same Frequency with a sample between 2 and 6 hours after a THERMAL POWER change of greater than or equal to 15% RTP within 1 hour. This change is designated as administrative because it does not result in technical changes to CTS.

DISCUSSION OF CHANGES
ITS 3.4.16, RCS SPECIFIC ACTIVITY

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS Table 4.4-4, Item 2 requires an isotopic analysis to determine whether DOSE EQUIVALENT I-131 concentration is within limit. CTS Table 4.4-4, Item 3 requires an isotopic analysis for iodine including I-131, I-132, I-133, I-134 and I-135. ITS SR 3.4.16.2 requires the verification that reactor coolant DOSE EQUIVALENT I-131 specific activity is within limit. ITS 3.4.16 Required Action A.1 requires the verification that DOSE EQUIVALENT I-131 is within the acceptable region. This changes the CTS by moving the detail that an isotopic analysis must be performed to satisfy the requirements of the Surveillances to the Bases.

The removal of these details for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS SR 3.4.16.2 and ITS 3.4.16 Required Action A.1 still retain the requirements to verify reactor coolant DOSE EQUIVALENT I-131 is within limit. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.16, RCS SPECIFIC ACTIVITY

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. ISTS SR 3.4.16 Note is deleted. PSL retains the current licensing basis that samples DOSE EQUIVALENT XE-133 in the applicable Modes.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.16 RCS Specific Activity

BASES

BACKGROUND

The maximum dose that an individual at the exclusion area boundary can receive for 2 hours following an accident, or at the low population zone outer boundary for the radiological release duration, is specified in [10 CFR 100.11][10 CFR 50.67] (Ref. 1). Doses to control room operators must be limited per GDC 19. The limits on specific activity ensure that the offsite and control room doses are appropriately limited during analyzed transients and accidents. 2

The RCS specific activity LCO limits the allowable concentration level of radionuclides in the reactor coolant. The LCO limits are established to minimize the dose consequences in the event of a steam line break (SLB) or steam generator tube rupture (SGTR) accident.

The LCO contains specific activity limits for both DOSE EQUIVALENT I-131 and DOSE EQUIVALENT XE-133. The allowable levels are intended to ensure that offsite and control room doses meet the appropriate acceptance criteria in the Standard Review Plan (SR) (Ref. 2).

APPLICABLE SAFETY ANALYSES

The LCO limits on the specific activity of the reactor coolant ensure that the resulting offsite and control room doses meet the appropriate SRP acceptance criteria following a SLB or SGTR accident. The safety analyses (Refs. 3 and 4) assume the specific activity of the reactor coolant is at the LCO limits, and an existing reactor coolant steam generator (SG) tube leakage rate of [1 gpm] exists. The safety analyses assume the specific activity of the secondary coolant is at its limit of [0.1] μCi/gm DOSE EQUIVALENT I-131 from LCO 3.7.19, "Secondary Specific Activity." 2

0.25 gpm per SG; 0.5 gpm total

2

The analyses for the SLB and SGTR accidents establish the acceptance limits for RCS specific activity. Reference to these analyses is used to assess changes to the unit that could affect RCS specific activity, as they relate to the acceptance limits.

The safety analyses consider two cases of reactor coolant iodine specific activity. One case assumes specific activity at [1.0] μCi/gm DOSE EQUIVALENT I-131 with a concurrent large iodine spike that increases the rate of release of iodine from the fuel rods containing cladding defects to the primary coolant immediately after a SLB (by a factor of 500), or SGTR (by a factor of 335), respectively. The second case assumes the initial reactor coolant iodine activity at [60.0] μCi/gm DOSE EQUIVALENT 2

2

BASES

APPLICABLE SAFETY ANALYSES (continued)

Fuel damage is assumed for the SLB event and the activity released exceeds that released by the two iodine spike cases; therefore, the two iodine spike cases are not analyzed for the SLB event.

I-131 due to an iodine spike caused by a reactor or an RCS transient prior to the accident. In both cases, the noble gas specific activity is assumed to be ~~[280]~~ µCi/gm DOSE EQUIVALENT XE-133. 518.9 1 2

The SGTR analysis assumes a rise in pressure in the ruptured SG causes radioactively contaminated steam to discharge to the atmosphere through the atmospheric dump valves or the main steam safety valves. The atmospheric discharge stops when the turbine bypass to the condenser removes the excess energy to rapidly reduce the RCS pressure and close the valves. The unaffected SG removes core decay heat by venting steam until the cooldown ends and the Shutdown Cooling (SDC) System is placed in service.

The SLB radiological analysis assumes that offsite power is lost at the same time as the pipe break occurs outside containment. The affected SG blows down completely and steam is vented directly to the atmosphere. The unaffected SG removes core decay heat by venting steam to the atmosphere until the cooldown ends and the SDC System is placed in service.

Operation with iodine specific activity levels greater than the LCO limit is permissible, if the activity levels do not exceed ~~[~~60.0~~]~~ µCi/gm for more than 48 hours. 2

The limits on RCS specific activity are also used for establishing standardization in radiation shielding and plant personnel radiation protection practices.

RCS specific activity satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The iodine specific activity in the reactor coolant is limited to ~~[~~1.0~~]~~ µCi/gm DOSE EQUIVALENT I-131, and the noble gas specific activity in the reactor coolant is limited to ~~[280]~~ µCi/gm DOSE EQUIVALENT XE-133. 518.9 2 2

The limits on specific activity ensure that offsite and control room doses will meet the appropriate SRP acceptance criteria (Ref. 2).

The SLB and SGTR accident analyses (Refs. 3 and 4) show that the calculated doses are within acceptable limits. Violation of the LCO may result in reactor coolant radioactivity levels that could, in the event of a SLB or SGTR, lead to doses that exceed the SRP acceptance criteria (Ref. 2).

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, operation within the LCO limits for DOSE EQUIVALENT I-131 and DOSE EQUIVALENT XE-133 is necessary to limit the potential consequences of a SLB or SGTR to within the SRP acceptance criteria (Ref. 2).

In MODES 5 and 6, the steam generators are not being used for decay heat removal, the RCS and steam generators are depressurized, and primary to secondary leakage is minimal. Therefore, the monitoring of RCS specific activity is not required.

ACTIONS

A.1 and A.2

With the DOSE EQUIVALENT I-131 greater than the LCO limit, samples at intervals of 4 hours must be taken to demonstrate that the specific activity is ≤ ~~[~~60.0~~]~~ µCi/gm. The Completion Time of 4 hours is required to obtain and analyze a sample. Sampling is continued every 4 hours to provide a trend. 2

The DOSE EQUIVALENT I-131 must be restored to within limit within 48 hours. The Completion Time of 48 hours is acceptable since it is expected that, if there were an iodine spike, the normal coolant iodine concentration would be restored within this time period. Also, there is a low probability of a SLB or SGTR occurring during this time period.

A Note permits the use of the provisions of LCO 3.0.4.c. This allowance permits entry into the applicable MODE(S), relying on Required Actions A.1 and A.2 while the DOSE EQUIVALENT I-131 LCO limit is not met. This allowance is acceptable due to the significant conservatism incorporated into the specific activity limit, the low probability of an event which is limiting due to exceeding this limit, and the ability to restore transient-specific activity excursions while the plant remains at, or proceeds to, power operation.

B.1

With the DOSE EQUIVALENT XE-133 greater than the LCO limit, DOSE EQUIVALENT XE-133 must be restored to within limit within 48 hours. The allowed Completion Time of 48 hours is acceptable since it is expected that, if there were a noble gas spike, the normal coolant noble gas concentration would be restored within this time period. Also, there is a low probability of a SLB or SGTR occurring during this time period.

BASES

ACTIONS (continued)

A Note permits the use of the provisions of LCO 3.0.4.c. This allowance permits entry into the applicable MODES(S), relying on Required Action B.1 while the DOSE EQUIVALENT XE-133 LCO limit is not met. This allowance is acceptable due to the significant conservatism incorporated into the specific activity limit, the low probability of an event which is limiting due to exceeding this limit, and the ability to restore transient-specific activity excursions while the plant remains at, or proceeds to, power operation.

C.1 and C.2

If the Required Action and associated Completion Time of Condition A or B is not met, or if the DOSE EQUIVALENT I-131 is > ~~[~~60.0~~]~~ µCi/gm, the reactor must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

2

SURVEILLANCE REQUIREMENTS

SR 3.4.16.1

SR 3.4.16.1 requires performing a gamma isotopic analysis as a measure of the noble gas specific activity of the reactor coolant ~~at least once every 7 days~~. This measurement is the sum of the degassed gamma activities and the gaseous gamma activities in the sample taken. This Surveillance provides an indication of any increase in the noble gas specific activity.

1

1

The periodic Surveillance Frequency is controlled under the Surveillance Frequency Control. Program, and

Trending the results of this Surveillance allows proper remedial action to be taken before reaching the LCO limit under normal operating conditions. ~~The 7 day Frequency considers the low probability of a gross fuel failure during this time.~~

1

Due to the inherent difficulty in detecting Kr-85 in a reactor coolant sample due to masking from radioisotopes with similar decay energies, such as F-18 and I-134, it is acceptable to include the minimum detectable activity for Kr-85 in the SR 3.4.16.1 calculation. If a specific noble gas nuclide listed in the definition of DOSE EQUIVALENT XE-133 is not detected, it should be assumed to be present at the minimum detectable activity.

~~A Note modifies the SR to allow entry into and operation in MODE 4, MODE 3, and MODE 2 prior to performing the SR. This allows the Surveillance to be performed in those MODES, prior to entering MODE 1.~~

3

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.4.16.2

This Surveillance is performed to ensure iodine specific activity remains within the LCO limit during normal operation and following fast power changes when iodine spiking is more apt to occur. The ~~14 day Frequency~~ is adequate to trend changes in the iodine activity level~~, considering noble gas activity is monitored every 7 days~~. The Frequency, between 2 and 6 hours after a power change ≥ 15% RTP within a 1 hour period, is established because the iodine levels peak during this time following iodine spike initiation; samples at other times would provide inaccurate results.

periodic Surveillance Frequency is controlled under the Surveillance Frequency Control Program, and

1

The Note modifies this SR to allow entry into and operation in MODE 4, MODE 3, and MODE 2 prior to performing the SR. This allows the Surveillance to be performed in those MODES, prior to entering MODE 1.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.16 RCS Specific Activity

BASES

BACKGROUND

The maximum dose that an individual at the exclusion area boundary can receive for 2 hours following an accident, or at the low population zone outer boundary for the radiological release duration, is specified in [10 CFR 100.11][10 CFR 50.67] (Ref. 1). Doses to control room operators must be limited per GDC 19. The limits on specific activity ensure that the offsite and control room doses are appropriately limited during analyzed transients and accidents. 2

The RCS specific activity LCO limits the allowable concentration level of radionuclides in the reactor coolant. The LCO limits are established to minimize the dose consequences in the event of a steam line break (SLB) or steam generator tube rupture (SGTR) accident.

The LCO contains specific activity limits for both DOSE EQUIVALENT I-131 and DOSE EQUIVALENT XE-133. The allowable levels are intended to ensure that offsite and control room doses meet the appropriate acceptance criteria in the Standard Review Plan (SR) (Ref. 2).

APPLICABLE SAFETY ANALYSES

The LCO limits on the specific activity of the reactor coolant ensure that the resulting offsite and control room doses meet the appropriate SRP acceptance criteria following a SLB or SGTR accident. The safety analyses (Refs. 3 and 4) assume the specific activity of the reactor coolant is at the LCO limits, and an existing reactor coolant steam generator (SG) tube leakage rate of [1 gpm] exists. The safety analyses assume the specific activity of the secondary coolant is at its limit of [0.1] µCi/gm DOSE EQUIVALENT I-131 from LCO 3.7.19, "Secondary Specific Activity." 2

0.25 gpm per SG; 0.5 gpm total

2

The analyses for the SLB and SGTR accidents establish the acceptance limits for RCS specific activity. Reference to these analyses is used to assess changes to the unit that could affect RCS specific activity, as they relate to the acceptance limits.

The safety analyses consider two cases of reactor coolant iodine specific activity. One case assumes specific activity at [1.0] µCi/gm DOSE EQUIVALENT I-131 with a concurrent large iodine spike that increases the rate of release of iodine from the fuel rods containing cladding defects to the primary coolant immediately after a SLB (by a factor of 500), or SGTR (by a factor of 335), respectively. The second case assumes the initial reactor coolant iodine activity at [60.0] µCi/gm DOSE EQUIVALENT 2

2

1

BASES

APPLICABLE SAFETY ANALYSES (continued)

Fuel damage is assumed for the SLB event and the activity released exceeds that released by the two iodine spike cases; therefore, the two iodine spike cases are not analyzed for the SLB event.

I-131 due to an iodine spike caused by a reactor or an RCS transient prior to the accident. In both cases, the noble gas specific activity is assumed to be ~~[280]~~ µCi/gm DOSE EQUIVALENT XE-133. 518.9 1 2

The SGTR analysis assumes a rise in pressure in the ruptured SG causes radioactively contaminated steam to discharge to the atmosphere through the atmospheric dump valves or the main steam safety valves. The atmospheric discharge stops when the turbine bypass to the condenser removes the excess energy to rapidly reduce the RCS pressure and close the valves. The unaffected SG removes core decay heat by venting steam until the cooldown ends and the Shutdown Cooling (SDC) System is placed in service.

The SLB radiological analysis assumes that offsite power is lost at the same time as the pipe break occurs outside containment. The affected SG blows down completely and steam is vented directly to the atmosphere. The unaffected SG removes core decay heat by venting steam to the atmosphere until the cooldown ends and the SDC System is placed in service.

Operation with iodine specific activity levels greater than the LCO limit is permissible, if the activity levels do not exceed ~~[~~60.0~~]~~ µCi/gm for more than 48 hours. 2

The limits on RCS specific activity are also used for establishing standardization in radiation shielding and plant personnel radiation protection practices.

RCS specific activity satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The iodine specific activity in the reactor coolant is limited to ~~[~~1.0~~]~~ µCi/gm DOSE EQUIVALENT I-131, and the noble gas specific activity in the reactor coolant is limited to ~~[280]~~ µCi/gm DOSE EQUIVALENT XE-133. 518.9 2 2
The limits on specific activity ensure that offsite and control room doses will meet the appropriate SRP acceptance criteria (Ref. 2).

The SLB and SGTR accident analyses (Refs. 3 and 4) show that the calculated doses are within acceptable limits. Violation of the LCO may result in reactor coolant radioactivity levels that could, in the event of a SLB or SGTR, lead to doses that exceed the SRP acceptance criteria (Ref. 2).

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, operation within the LCO limits for DOSE EQUIVALENT I-131 and DOSE EQUIVALENT XE-133 is necessary to limit the potential consequences of a SLB or SGTR to within the SRP acceptance criteria (Ref. 2).

In MODES 5 and 6, the steam generators are not being used for decay heat removal, the RCS and steam generators are depressurized, and primary to secondary leakage is minimal. Therefore, the monitoring of RCS specific activity is not required.

ACTIONS

A.1 and A.2

With the DOSE EQUIVALENT I-131 greater than the LCO limit, samples at intervals of 4 hours must be taken to demonstrate that the specific activity is ≤ ~~[~~60.0~~]~~ µCi/gm. The Completion Time of 4 hours is required to obtain and analyze a sample. Sampling is continued every 4 hours to provide a trend. 2

The DOSE EQUIVALENT I-131 must be restored to within limit within 48 hours. The Completion Time of 48 hours is acceptable since it is expected that, if there were an iodine spike, the normal coolant iodine concentration would be restored within this time period. Also, there is a low probability of a SLB or SGTR occurring during this time period.

A Note permits the use of the provisions of LCO 3.0.4.c. This allowance permits entry into the applicable MODE(S), relying on Required Actions A.1 and A.2 while the DOSE EQUIVALENT I-131 LCO limit is not met. This allowance is acceptable due to the significant conservatism incorporated into the specific activity limit, the low probability of an event which is limiting due to exceeding this limit, and the ability to restore transient-specific activity excursions while the plant remains at, or proceeds to, power operation.

B.1

With the DOSE EQUIVALENT XE-133 greater than the LCO limit, DOSE EQUIVALENT XE-133 must be restored to within limit within 48 hours. The allowed Completion Time of 48 hours is acceptable since it is expected that, if there were a noble gas spike, the normal coolant noble gas concentration would be restored within this time period. Also, there is a low probability of a SLB or SGTR occurring during this time period.

BASES

ACTIONS (continued)

A Note permits the use of the provisions of LCO 3.0.4.c. This allowance permits entry into the applicable MODES(S), relying on Required Action B.1 while the DOSE EQUIVALENT XE-133 LCO limit is not met. This allowance is acceptable due to the significant conservatism incorporated into the specific activity limit, the low probability of an event which is limiting due to exceeding this limit, and the ability to restore transient-specific activity excursions while the plant remains at, or proceeds to, power operation.

C.1 and C.2

If the Required Action and associated Completion Time of Condition A or B is not met, or if the DOSE EQUIVALENT I-131 is > ~~[~~60.0~~]~~ µCi/gm, the reactor must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

DISCUSSION OF CHANGES
ITS 3.4.17, STEAM GENERATOR (SG) TUBE INTEGRITY

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 2 only:** CTS 3.4.5 LCO, Action a., and 4.4.5.2 state, in part, that SG repair applies only to the original SGs. Unit 2 contains two AREVA Model 86/19Ti replacement Steam Generators (containing Alloy 690TT Tubing) which were installed at RFO-17 in 2007 (EC 235453, Rev. 0. “PCM-05137 Replacement Steam Generators 2A & 2B). Therefore, the details associated with repairing of SG tubes rather than plugging of SG tubes are deleted from CTS 3.4.5.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.17, STEAM GENERATOR (SG) TUBE INTEGRITY

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. ISTS 3.4.17, “Special Test Exception (STE)-RCS Loops,” has not been adopted. Therefore, ISTS 3.4.18, “Steam Generator (SG) Tube Integrity,” is renumbered as ITS 3.4.17, “Steam Generator (SG) Tube Integrity.”

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.~~18~~ 17 Steam Generator (SG) Tube Integrity 3

BASES

BACKGROUND

Steam generator (SG) tubes are small diameter, thin walled tubes that carry primary coolant through the primary to secondary heat exchangers. The SG tubes have a number of important safety functions. Steam generator tubes are an integral part of the reactor coolant pressure boundary (RCPB) and, as such, are relied on to maintain the primary system's pressure and inventory. The SG tubes isolate the radioactive fission products in the primary coolant from the secondary system. In addition, as part of the RCPB, the SG tubes are unique in that they act as the heat transfer surface between the primary and secondary systems to remove heat from the primary system. This Specification addresses only the RCPB integrity function of the SG. The SG heat removal function is addressed by LCO 3.4.4, "RCS Loops – MODES 1 and 2," LCO 3.4.5, "RCS Loops – MODE 3," LCO 3.4.6, "RCS Loops – MODE 4," and LCO 3.4.7, "RCS Loops – MODE 5, Loops Filled.

SG tube integrity means that the tubes are capable of performing their intended RCPB safety function consistent with the licensing basis, including applicable regulatory requirements.

Steam generator tubing is subject to a variety of degradation mechanisms. Steam generator tubes may experience tube degradation related to corrosion phenomena, such as wastage, pitting, intergranular attack, and stress corrosion cracking, along with other mechanically induced phenomena such as denting and wear. These degradation mechanisms can impair tube integrity if they are not managed effectively. The SG performance criteria are used to manage SG tube degradation.

5.5.6

Specification ~~5.5.8~~, "Steam Generator (SG) Program," requires that a program be established and implemented to ensure that SG tube integrity is maintained. Pursuant to Specification ~~5.5.8~~, tube integrity is maintained when the SG performance criteria are met. There are three SG performance criteria: structural integrity, accident induced leakage, and operational LEAKAGE. The SG performance criteria are described in Specification ~~5.5.8~~. Meeting the SG performance criteria provides reasonable assurance of maintaining tube integrity at normal and accident conditions. 1

The processes used to meet the SG performance criteria are defined by the Steam Generator Program Guidelines (Ref. 1).

BASES

APPLICABLE SAFETY ANALYSES

The steam generator tube rupture (SGTR) accident is the limiting design basis event for SG tubes and avoiding an SGTR is the basis for this Specification. The analysis of a SGTR event assumes a bounding primary to secondary LEAKAGE rate equal to the operational LEAKAGE rate limits in LCO 3.4.13, "RCS Operational LEAKAGE," plus the leakage rate associated with a double-ended rupture of a single tube. The accident analysis for a SGTR assumes the contaminated secondary fluid is only briefly released to the atmosphere via safety valves and the majority is discharged to the main condenser.

The analysis for design basis accidents and transients other than a SGTR assume the SG tubes retain their structural integrity (i.e., they are assumed not to rupture.) In these analyses, the steam discharge to the atmosphere is based on the total primary to secondary LEAKAGE from all SGs of ~~[1~~ gallon per minute~~] or is assumed to increase to [1 gallon per minute] as a result of accident induced conditions~~. For accidents that do not involve fuel damage, the primary coolant activity level of DOSE EQUIVALENT I-131 is assumed to be equal to the LCO 3.4.16, "RCS Specific Activity," limits. For accidents that assume fuel damage, the primary coolant activity is a function of the amount of activity released from the damaged fuel. The dose consequences of these events are within the limits of GDC 19 (Ref. 2), 10 CFR 100 (Ref. ~~3~~) or the NRC approved licensing basis (e.g., a small fraction of these limits).

0.5 2

10 CFR 50.67 (Ref. 3), 4 1

Steam generator tube integrity satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires that SG tube integrity be maintained. The LCO also requires that all SG tubes that satisfy the plugging ~~[or repair]~~ criteria be plugged ~~[or repaired]~~ in accordance with the Steam Generator Program.

During an SG inspection, any inspected tube that satisfies the Steam Generator Program plugging ~~[or repair]~~ criteria is ~~[repaired or]~~ removed from service by plugging. If a tube was determined to satisfy the plugging ~~[or repair]~~ criteria but was not plugged ~~[or repaired]~~, the tube may still have tube integrity. 2

In the context of this Specification, a SG tube is defined as the entire length of the tube, including the tube wall ~~[and any repairs made to it]~~, between the tube-to-tubesheet weld at the tube inlet and the tube-to-tubesheet weld at the tube outlet. The tube-to-tubesheet weld is not considered part of the tube. 2

A SG tube has tube integrity when it satisfies the SG performance criteria. The SG performance criteria are defined in Specification ~~5.5.8~~, "Steam Generator Program," and describe acceptable SG tube performance. The Steam Generator Program also provides the evaluation process for determining conformance with the SG performance criteria. 1

5.5.6

BASES

LCO (continued)

There are three SG performance criteria: structural integrity, accident induced leakage, and operational LEAKAGE. Failure to meet any one of these criteria is considered failure to meet the LCO.

The structural integrity performance criterion provides a margin of safety against tube burst or collapse under normal and accident conditions, and ensures structural integrity of the SG tubes under all anticipated transients included in the design specification. Tube burst is defined as, "The gross structural failure of the tube wall. The condition typically corresponds to an unstable opening displacement (e.g., opening area increased in response to constant pressure) accompanied by ductile (plastic) tearing of the tube material at the ends of the degradation." Tube collapse is defined as, "For the load displacement curve for a given structure, collapse occurs at the top of the load versus displacement curve where the slope of the curve becomes zero." The structural integrity performance criterion provides guidance on assessing loads that have a significant effect on burst or collapse. In that context, the term "significant" is defined as "An accident loading condition other than differential pressure is considered significant when the addition of such loads in the assessment of the structural integrity performance criterion could cause a lower structural limit or limiting burst/collapse condition to be established." For tube integrity evaluations, except for circumferential degradation, axial thermal loads are classified as secondary loads. For circumferential degradation, the classification of axial thermal loads as primary or secondary loads will be evaluated on a case-by-case basis. The division between primary and secondary classifications will be based on detailed analysis and/or testing.

Structural integrity requires that the primary membrane stress intensity in a tube not exceed the yield strength for all ASME Code, Section III, Service Level A (normal operating conditions) and Service Level B (upset or abnormal conditions) transients included in the design specification. This includes safety factors and applicable design basis loads based on ASME Code, Section III, Subsection NB (Ref. ~~4~~ 5) and Draft Regulatory Guide 1.121 (Ref. ~~5~~ 6). 1

The accident induced leakage performance criterion ensures that the primary to secondary LEAKAGE caused by a design basis accident, other than a SGTR, is within the accident analysis assumptions. The accident analysis assumes that accident induced leakage does not exceed ~~[1 gpm per SG, except for specific types of degradation at specific locations where the NRC has approved greater accident induced leakage.]~~ 0.5 gpm total through all SGs and 0.25 gpm through any one SG. 2 The accident induced leakage rate includes any primary to secondary LEAKAGE existing prior to the accident in addition to primary to secondary LEAKAGE induced during the accident.

BASES

LCO (continued)

The operational LEAKAGE performance criterion provides an observable indication of SG tube conditions during plant operation. The limit on operational LEAKAGE is contained in LCO 3.4.13, "RCS Operational LEAKAGE," and limits primary to secondary LEAKAGE through any one SG to 150 gallons per day. This limit is based on the assumption that a single crack leaking this amount would not propagate to a SGTR under the stress conditions of a LOCA or a main steam line break. If this amount of LEAKAGE is due to more than one crack, the cracks are very small, and the above assumption is conservative.

APPLICABILITY

Steam generator tube integrity is challenged when the pressure differential across the tubes is large. Large differential pressures across SG tubes can only be experienced in MODE 1, 2, 3, or 4.

RCS conditions are far less challenging in MODES 5 and 6 than during MODES 1, 2, 3, and 4. In MODES 5 and 6, primary to secondary differential pressure is low, resulting in lower stresses and reduced potential for LEAKAGE.

ACTIONS

The ACTIONS are modified by a Note clarifying that the Conditions may be entered independently for each SG tube. This is acceptable because the Required Actions provide appropriate compensatory actions for each affected SG tube. Complying with the Required Actions may allow for continued operation, and subsequent affected SG tubes are governed by subsequent Condition entry and application of associated Required Actions.

A.1 and A.2

Condition A applies if it is discovered that one or more SG tubes examined in an inservice inspection satisfy the tube plugging ~~[or repair]~~ criteria but were not plugged ~~[or repaired]~~ in accordance with the Steam Generator Program as required by SR 3.4.~~18~~.2. An evaluation of SG tube integrity of the affected tube(s) must be made. Steam generator tube integrity is based on meeting the SG performance criteria described in the Steam Generator Program. The SG plugging ~~[or repair]~~ criteria define limits on SG tube degradation that allow for flaw growth between inspections while still providing assurance that the SG performance criteria will continue to be met. In order to determine if a SG tube that should have been plugged ~~[or repaired]~~ has tube integrity, an evaluation must be completed that demonstrates that the SG performance criteria will continue to be met until the next refueling outage or SG tube inspection. The tube integrity determination is based on the estimated condition of the tube at the time the situation is discovered and the

17 2 3 2 2

BASES

ACTIONS (continued)

estimated growth of the degradation prior to the next SG tube inspection. If it is determined that tube integrity is not being maintained, Condition B applies.

A Completion Time of 7 days is sufficient to complete the evaluation while minimizing the risk of plant operation with a SG tube that may not have tube integrity.

If the evaluation determines that the affected tube(s) have tube integrity, Required Action A.2 allows plant operation to continue until the next refueling outage or SG inspection provided the inspection interval continues to be supported by an operational assessment that reflects the affected tubes. However, the affected tube(s) must be plugged ~~[or repaired]~~ prior to entering MODE 4 following the next refueling outage or SG inspection. This Completion Time is acceptable since operation until the next inspection is supported by the operational assessment. 2

B.1 and B.2

If the Required Actions and associated Completion Times of Condition A are not met or if SG tube integrity is not being maintained, the reactor must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the desired plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.4.~~18~~ 17.1 3

During shutdown periods the SGs are inspected as required by this SR and the Steam Generator Program. NEI 97-06, Steam Generator Program Guidelines (Ref. 1), and its referenced EPRI Guidelines, establish the content of the Steam Generator Program. Use of the Steam Generator Program ensures that the inspection is appropriate and consistent with accepted industry practices.

During SG inspections a condition monitoring assessment of the SG tubes is performed. The condition monitoring assessment determines the "as found" condition of the SG tubes. The purpose of the condition monitoring assessment is to ensure that the SG performance criteria have been met for the previous operating period.

The Steam Generator Program determines the scope of the inspection and the methods used to determine whether the tubes contain flaws satisfying the tube plugging ~~[or repair]~~ criteria. Inspection scope (i.e., 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

which tubes or areas of tubing within the SG are to be inspected) is a function of existing and potential degradation locations. The Steam Generator Program also specifies the inspection methods to be used to find potential degradation. Inspection methods are a function of degradation morphology, non-destructive examination (NDE) technique capabilities, and inspection locations.

The Steam Generator Program defines the Frequency of SR 3.4.~~18~~.1. The Frequency is determined by the operational assessment and other limits in the SG examination guidelines (Ref. ~~6~~). The Steam Generator Program uses information on existing degradations and growth rates to determine an inspection Frequency that provides reasonable assurance that the tubing will meet the SG performance criteria at the next scheduled inspection. In addition, Specification ~~5.5.8~~ contains prescriptive requirements concerning inspection intervals to provide added assurance that the SG performance criteria will be met between scheduled inspections. If crack indications are found in any SG tube, the maximum inspection interval for all affected and potentially affected SGs is restricted by Specification ~~5.5.8~~ until subsequent inspections support extending the inspection interval.

SR 3.4.~~18~~.2

During an SG inspection, any inspected tube that satisfies the Steam Generator Program plugging ~~[or repair]~~ criteria is ~~[repaired or]~~ removed from service by plugging. The tube plugging ~~[or repair]~~ criteria delineated in Specification ~~5.5.8~~ are intended to ensure that tubes accepted for continued service satisfy the SG performance criteria with allowance for error in the flaw size measurement and for future flaw growth. In addition, the tube plugging ~~[or repair]~~ criteria, in conjunction with other elements of the Steam Generator Program, ensure that the SG performance criteria will continue to be met until the next inspection of the subject tube(s). Reference 1 provides guidance for performing operational assessments to verify that the tubes remaining in service will continue to meet the SG performance criteria.

~~[Steam generator tube repairs are only performed using approved repair methods as described in the Steam Generator Program.]~~

The Frequency of prior to entering MODE 4 following a SG inspection ensures that the Surveillance has been completed and all tubes meeting the plugging ~~[or repair]~~ criteria are plugged ~~[or repaired]~~ prior to subjecting the SG tubes to significant primary to secondary pressure differential.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.~~18~~ 17 Steam Generator (SG) Tube Integrity 3

BASES

BACKGROUND

Steam generator (SG) tubes are small diameter, thin walled tubes that carry primary coolant through the primary to secondary heat exchangers. The SG tubes have a number of important safety functions. Steam generator tubes are an integral part of the reactor coolant pressure boundary (RCPB) and, as such, are relied on to maintain the primary system's pressure and inventory. The SG tubes isolate the radioactive fission products in the primary coolant from the secondary system. In addition, as part of the RCPB, the SG tubes are unique in that they act as the heat transfer surface between the primary and secondary systems to remove heat from the primary system. This Specification addresses only the RCPB integrity function of the SG. The SG heat removal function is addressed by LCO 3.4.4, "RCS Loops – MODES 1 and 2," LCO 3.4.5, "RCS Loops – MODE 3," LCO 3.4.6, "RCS Loops – MODE 4," and LCO 3.4.7, "RCS Loops – MODE 5, Loops Filled.

SG tube integrity means that the tubes are capable of performing their intended RCPB safety function consistent with the licensing basis, including applicable regulatory requirements.

Steam generator tubing is subject to a variety of degradation mechanisms. Steam generator tubes may experience tube degradation related to corrosion phenomena, such as wastage, pitting, intergranular attack, and stress corrosion cracking, along with other mechanically induced phenomena such as denting and wear. These degradation mechanisms can impair tube integrity if they are not managed effectively. The SG performance criteria are used to manage SG tube degradation.

5.5.6

Specification ~~5.5.8~~, "Steam Generator (SG) Program," requires that a program be established and implemented to ensure that SG tube integrity is maintained. Pursuant to Specification ~~5.5.8~~, tube integrity is maintained when the SG performance criteria are met. There are three SG performance criteria: structural integrity, accident induced leakage, and operational LEAKAGE. The SG performance criteria are described in Specification ~~5.5.8~~. Meeting the SG performance criteria provides reasonable assurance of maintaining tube integrity at normal and accident conditions. 1

The processes used to meet the SG performance criteria are defined by the Steam Generator Program Guidelines (Ref. 1).

BASES

APPLICABLE SAFETY ANALYSES

The steam generator tube rupture (SGTR) accident is the limiting design basis event for SG tubes and avoiding an SGTR is the basis for this Specification. The analysis of a SGTR event assumes a bounding primary to secondary LEAKAGE rate equal to the operational LEAKAGE rate limits in LCO 3.4.13, "RCS Operational LEAKAGE," plus the leakage rate associated with a double-ended rupture of a single tube. The accident analysis for a SGTR assumes the contaminated secondary fluid is only briefly released to the atmosphere via safety valves and the majority is discharged to the main condenser.

The analysis for design basis accidents and transients other than a SGTR assume the SG tubes retain their structural integrity (i.e., they are assumed not to rupture.) In these analysis, the steam discharge to the atmosphere is based on the total primary to secondary LEAKAGE from all SGs of ~~[1~~ gallon per minute~~] or is assumed to increase to [1 gallon per minute]~~ as a result of accident induced conditions. For accidents that do not involve fuel damage, the primary coolant activity level of DOSE EQUIVALENT I-131 is assumed to be equal to the LCO 3.4. 16, "RCS Specific Activity," limits. For accidents that assume fuel damage, the primary coolant activity is a function of the amount of activity released from the damaged fuel. The dose consequences of these events are within the limits of GDC 19 (Ref. 2), 10 CFR 100 (Ref. ~~3~~) or the NRC approved licensing basis (e.g., a small fraction of these limits).

0.5 2 1 10 CFR 50.67 (Ref. 3), 4

Steam generator tube integrity satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires that SG tube integrity be maintained. The LCO also requires that all SG tubes that satisfy the plugging ~~[or repair]~~ criteria be plugged ~~[or repaired]~~ in accordance with the Steam Generator Program. 2

During an SG inspection, any inspected tube that satisfies the Steam Generator Program plugging ~~[or repair]~~ criteria is ~~[repaired or]~~ removed from service by plugging. If a tube was determined to satisfy the plugging ~~[or repair]~~ criteria but was not plugged ~~[or repaired]~~, the tube may still have tube integrity. 2

In the context of this Specification, a SG tube is defined as the entire length of the tube, including the tube wall ~~[~~and any repairs made to it~~]~~, between the tube-to-tubesheet weld at the tube inlet and the tube-to-tubesheet weld at the tube outlet. The tube-to-tubesheet weld is not considered part of the tube. 2

A SG tube has tube integrity when it satisfies the SG performance criteria. The SG performance criteria are defined in Specification ~~5.5.8~~, "Steam Generator Program," and describe acceptable SG tube performance. The Steam Generator Program also provides the evaluation process for determining conformance with the SG performance criteria. 1

5.5.6

BASES

LCO (continued)

There are three SG performance criteria: structural integrity, accident induced leakage, and operational LEAKAGE. Failure to meet any one of these criteria is considered failure to meet the LCO.

The structural integrity performance criterion provides a margin of safety against tube burst or collapse under normal and accident conditions, and ensures structural integrity of the SG tubes under all anticipated transients included in the design specification. Tube burst is defined as, "The gross structural failure of the tube wall. The condition typically corresponds to an unstable opening displacement (e.g., opening area increased in response to constant pressure) accompanied by ductile (plastic) tearing of the tube material at the ends of the degradation." Tube collapse is defined as, "For the load displacement curve for a given structure, collapse occurs at the top of the load versus displacement curve where the slope of the curve becomes zero." The structural integrity performance criterion provides guidance on assessing loads that have a significant effect on burst or collapse. In that context, the term "significant" is defined as "An accident loading condition other than differential pressure is considered significant when the addition of such loads in the assessment of the structural integrity performance criterion could cause a lower structural limit or limiting burst/collapse condition to be established." For tube integrity evaluations, except for circumferential degradation, axial thermal loads are classified as secondary loads. For circumferential degradation, the classification of axial thermal loads as primary or secondary loads will be evaluated on a case-by-case basis. The division between primary and secondary classifications will be based on detailed analysis and/or testing.

Structural integrity requires that the primary membrane stress intensity in a tube not exceed the yield strength for all ASME Code, Section III, Service Level A (normal operating conditions) and Service Level B (upset or abnormal conditions) transients included in the design specification. This includes safety factors and applicable design basis loads based on ASME Code, Section III, Subsection NB (Ref. ~~4~~ 5) and Draft Regulatory Guide 1.121 (Ref. ~~5~~ 6). 1

The accident induced leakage performance criterion ensures that the primary to secondary LEAKAGE caused by a design basis accident, other than a SGTR, is within the accident analysis assumptions. The accident analysis assumes that accident induced leakage does not exceed ~~[1 gpm per SG, except for specific types of degradation at specific locations where the NRC has approved greater accident induced leakage.]~~ The accident induced leakage rate includes any primary to secondary LEAKAGE existing prior to the accident in addition to primary to secondary LEAKAGE induced during the accident. 2

0.5 gpm total through all SGs and 0.25 gpm through any one SG.

BASES

LCO (continued)

The operational LEAKAGE performance criterion provides an observable indication of SG tube conditions during plant operation. The limit on operational LEAKAGE is contained in LCO 3.4.13, "RCS Operational LEAKAGE," and limits primary to secondary LEAKAGE through any one SG to 150 gallons per day. This limit is based on the assumption that a single crack leaking this amount would not propagate to a SGTR under the stress conditions of a LOCA or a main steam line break. If this amount of LEAKAGE is due to more than one crack, the cracks are very small, and the above assumption is conservative.

APPLICABILITY

Steam generator tube integrity is challenged when the pressure differential across the tubes is large. Large differential pressures across SG tubes can only be experienced in MODE 1, 2, 3, or 4.

RCS conditions are far less challenging in MODES 5 and 6 than during MODES 1, 2, 3, and 4. In MODES 5 and 6, primary to secondary differential pressure is low, resulting in lower stresses and reduced potential for LEAKAGE.

ACTIONS

The ACTIONS are modified by a Note clarifying that the Conditions may be entered independently for each SG tube. This is acceptable because the Required Actions provide appropriate compensatory actions for each affected SG tube. Complying with the Required Actions may allow for continued operation, and subsequent affected SG tubes are governed by subsequent Condition entry and application of associated Required Actions.

A.1 and A.2

Condition A applies if it is discovered that one or more SG tubes examined in an inservice inspection satisfy the tube plugging ~~[or repair]~~ criteria but were not plugged ~~[or repaired]~~ in accordance with the Steam Generator Program as required by SR 3.4.~~18~~.2. An evaluation of SG tube integrity of the affected tube(s) must be made. Steam generator tube integrity is based on meeting the SG performance criteria described in the Steam Generator Program. The SG plugging ~~[or repair]~~ criteria define limits on SG tube degradation that allow for flaw growth between inspections while still providing assurance that the SG performance criteria will continue to be met. In order to determine if a SG tube that should have been plugged ~~[or repaired]~~ has tube integrity, an evaluation must be completed that demonstrates that the SG performance criteria will continue to be met until the next refueling outage or SG tube inspection. The tube integrity determination is based on the estimated condition of the tube at the time the situation is discovered and the

17
2
3
2
2

BASES

ACTIONS (continued)

estimated growth of the degradation prior to the next SG tube inspection. If it is determined that tube integrity is not being maintained, Condition B applies.

A Completion Time of 7 days is sufficient to complete the evaluation while minimizing the risk of plant operation with a SG tube that may not have tube integrity.

If the evaluation determines that the affected tube(s) have tube integrity, Required Action A.2 allows plant operation to continue until the next refueling outage or SG inspection provided the inspection interval continues to be supported by an operational assessment that reflects the affected tubes. However, the affected tube(s) must be plugged ~~[or repaired]~~ prior to entering MODE 4 following the next refueling outage or SG inspection. This Completion Time is acceptable since operation until the next inspection is supported by the operational assessment. 2

B.1 and B.2

If the Required Actions and associated Completion Times of Condition A are not met or if SG tube integrity is not being maintained, the reactor must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the desired plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.4.~~18~~ 17.1 3

During shutdown periods the SGs are inspected as required by this SR and the Steam Generator Program. NEI 97-06, Steam Generator Program Guidelines (Ref. 1), and its referenced EPRI Guidelines, establish the content of the Steam Generator Program. Use of the Steam Generator Program ensures that the inspection is appropriate and consistent with accepted industry practices.

During SG inspections a condition monitoring assessment of the SG tubes is performed. The condition monitoring assessment determines the "as found" condition of the SG tubes. The purpose of the condition monitoring assessment is to ensure that the SG performance criteria have been met for the previous operating period.

The Steam Generator Program determines the scope of the inspection and the methods used to determine whether the tubes contain flaws satisfying the tube plugging ~~[or repair]~~ criteria. Inspection scope (i.e., 2

BASES

SURVEILLANCE REQUIREMENTS (continued)

which tubes or areas of tubing within the SG are to be inspected) is a function of existing and potential degradation locations. The Steam Generator Program also specifies the inspection methods to be used to find potential degradation. Inspection methods are a function of degradation morphology, non-destructive examination (NDE) technique capabilities, and inspection locations.

The Steam Generator Program defines the Frequency of SR 3.4.~~18~~.1. The Frequency is determined by the operational assessment and other limits in the SG examination guidelines (Ref. ~~6~~). The Steam Generator Program uses information on existing degradations and growth rates to determine an inspection Frequency that provides reasonable assurance that the tubing will meet the SG performance criteria at the next scheduled inspection. In addition, Specification ~~5.5.8~~ contains prescriptive requirements concerning inspection intervals to provide added assurance that the SG performance criteria will be met between scheduled inspections. If crack indications are found in any SG tube, the maximum inspection interval for all affected and potentially affected SGs is restricted by Specification ~~5.5.8~~ until subsequent inspections support extending the inspection in~~v~~erval.

SR 3.4.~~18~~.2

During an SG inspection, any inspected tube that satisfies the Steam Generator Program plugging ~~[or repair]~~ criteria is ~~[repaired or]~~ removed from service by plugging. The tube plugging ~~[or repair]~~ criteria delineated in Specification ~~5.5.8~~ are intended to ensure that tubes accepted for continued service satisfy the SG performance criteria with allowance for error in the flaw size measurement and for future flaw growth. In addition, the tube plugging ~~[or repair]~~ criteria, in conjunction with other elements of the Steam Generator Program, ensure that the SG performance criteria will continue to be met until the next inspection of the subject tube(s). Reference 1 provides guidance for performing operational assessments to verify that the tubes remaining in service will continue to meet the SG performance criteria.

~~[Steam generator tube repairs are only performed using approved repair methods as described in the Steam Generator Program.]~~

The Frequency of prior to entering MODE 4 following a SG inspection ensures that the Surveillance has been completed and all tubes meeting the plugging ~~[or repair]~~ criteria are plugged ~~[or repaired]~~ prior to subjecting the SG tubes to significant primary to secondary pressure differential.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.17, BASES, STEAM GENERATOR (SG) TUBE INTEGRITY

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. ISTS 3.4.17, “Special Test Exception (STE)-RCS Loops,” has not been adopted. Therefore, ISTS 3.4.18, “Steam Generator (SG) Tube Integrity,” is renumbered as ITS 3.4.17, “Steam Generator (SG) Tube Integrity.”

Unit 2 CTS 3/4.4.9.2, Pressurizer Heatup/Cooldown Limits

Current Technical Specifications (CTS) Markup and Discussion of Changes (DOCs)

REACTOR COOLANT SYSTEM

PRESSURIZER

LIMITING CONDITION FOR OPERATION

R01

3.4.9.2 The pressurizer temperature shall be limited to:

a. A maximum heatup of 100°F in any one hour period,

b. A maximum cooldown of 200°F in any one hour period, and

c. A maximum Reactor Coolant System spray water temperature differential of 350°F.

APPLICABILITY: At all times.

ACTION:

With the pressurizer temperature limits in excess of any of the above limits, restore the temperature to within the limits within 30 minutes; perform an analysis to determine the effects of the out-of-limit condition on the fracture toughness properties of the pressurizer; determine that the pressurizer remains acceptable for continued operation or be in at least HOT STANDBY within the next 6 hours and reduce the pressurizer pressure to less than 500 psia within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.4.9.2 The pressurizer temperatures shall be determined to be within the limits in accordance with the Surveillance Frequency Control Program during system heatup or cooldown. The spray water temperature differential shall be determined to be within the limit in accordance with the Surveillance Frequency Control Program during steady state operation.

REACTOR COOLANT SYSTEM

PRESSURIZER HEATUP/COOLDOWN LIMITS

LIMITING CONDITION FOR OPERATION R01

3.4.9.2 The pressurizer temperature shall be limited to:

a. A maximum heatup of 100°F in any 1-hour period, and

b. A maximum cooldown of 200°F in any 1-hour period.

APPLICABILITY: At all times.

ACTION:

With the pressurizer temperature limits in excess of any of the above limits, restore the temperature to within the limits within 30 minutes; perform an engineering evaluation to determine the effects of the out-of-limit condition on the structural integrity of the pressurizer; determine that the pressurizer remains acceptable for continued operation or be in at least HOT STANDBY within the next 6 hours and reduce the pressurizer pressure to less than 500 psig within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.4.9.2 The pressurizer temperatures shall be determined to be within the limits in accordance with the Surveillance Frequency Control Program during system heatup or cooldown.

ADMINISTRATIVE CHANGES

None

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

R01 The limitation on the pressurizer pressure and temperature (P/T) ensures that the pressurizer is operated within the design criteria assumed for the fatigue analysis performed in accordance with the ASME Code requirements. As such, the Technical Specification places limits on variables consistent with structural analysis results. These limits do not represent an initial condition assumption of a DBA or transient. Although the limits represent operating restrictions, and Criterion 2 includes operating restrictions, the Criterion 2 discussion of the Final Policy Statement specified that only those operating restrictions required to preclude unanalyzed accidents and transients be included in Technical Specifications.

The ITS does not include these Specifications. This changes the CTS by relocating these Specification to the Technical Requirements Manual (TRM). This change is acceptable because the Pressurizer Temperature Specification does not meet the 10 CFR 50.36(c)(2)(ii) criteria for inclusion into the ITS.

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. Pressurizer P/T limits are not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. Pressurizer P/T limits do not represent a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. Pressurizer P/T limits are not part of a primary success path in the mitigation of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. Pressurizer P/T limits are not addressed in the PSL PSA and do not represent a structure, system, or component which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

Since 10 CFR 50.36(c)(2)(ii) criteria have not been satisfied, the Unit 1 Pressurizer Specification, which specifies pressurizer heatup and cooldown limits, and Unit 2 Pressurizer Heatup and Cooldown Limits Specification may be

relocated to a licensee controlled document outside the Technical Specifications. Pressure and temperature limits associated with the limiting RCS pressure boundary components are retained in separate Technical Specifications. ASME code requirements associated with the limits on pressurizer heatup and cooldown will continue to be controlled pursuant 10 CFR 50.55a. Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as relocation because the Specification does not meet the criteria in 10 CFR 50.36(c)(2)(ii) and has been relocated to the TRM.

ADMINISTRATIVE CHANGES

None

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

R01 Reactor Coolant System (RCS) vents are provided to exhaust noncondensible gases and/or steam from the primary system that could inhibit natural circulation core cooling. The function, capabilities, and testing requirements of the RCS vent system are consistent with the requirements of Item II.b.1 of NUREG-0737, "Clarification of TMI Action Plan Requirements," November 1980.

The purpose of the pressurizer safety valves is to provide primary relief capability to exhaust noncondensible gases and steam from the RCS during a DBA or transient at power and the pressurizer power operated relief valves (PORVs) provide vent capability during RCS low temperature and pressure conditions.

The ITS does not include these Specifications. This changes the CTS by relocating these Specifications to the Technical Requirements Manual (TRM). This change is acceptable because the Reactor Coolant System Vent Specification does not meet the 10 CFR 50.36(c)(2)(ii) criteria for inclusion into the ITS.

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. The RCS vents do not function as installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary.

2. The RCS vents are not process variables, design features, or operating restrictions that represents an initial condition of a DBA or transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. The RCS vents are not a structures, systems or components that are part of the primary success path and which function or actuate to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The RCS vents are not specifically addressed in the PSL PSA and do not represent components which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

Since 10 CFR 50.36(c)(2)(ii) criteri have not been satisfied, the Reactor Coolant System Vents Specification may be relocated to a licensee controlled document

outside Technical Specifications. Pressure relief requirements are retained in separate Technical Specifications and ensure relief capability is provided to exhaust noncondensible gases and steam from the primary system. In addition, this NUREG-0737 requirement is required pursuant to 10 CFR 50.34(f)(2)(vi). Compliance with applicable portions of 10 CFR 50.34(f)(2) is required by the operating licenses of PSL Units 1 and 2. Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as relocation because the Specification does not meet the criteria in 10 CFR 50.36(c)(2)(ii) and has been relocated to the TRM.

SPECIAL TEST EXCEPTIONS

3/4.10.3 REACTOR COOLANT LOOPS

LIMITING CONDITION FOR OPERATION

3.10.3 The limitations of Specification 3.4.1 and noted requirements of Tables 2.2-1 and 3.3-1 may be suspended during the performance of startup and PHYSICS TESTS, provided:

a. The THERMAL POWER does not exceed 5% of RATED THERMAL POWER, and

b. The reactor trip setpoints of the OPERABLE power level channels are set at less than or equal to 20% of RATED THERMAL POWER.

APPLICABILITY: During startup and PHYSICS TESTS.

ACTION:

With the THERMAL POWER greater then 5% of RATED THERMAL POWER, immediately trip the reactor.

SURVEILLANCE REQUIREMENTS

4.10.3.1 The THERMAL POWER shall be determined to be less than or equal to 5% of RATED THERMAL POWER in accordance with the Surveillance Frequency Control Program during startup and PHYSICS TESTS.

4.10.3.2 Each wide range logarithmic and power level neutron flux monitoring channel shall be subjected to a CHANNEL FUNCTIONAL TEST within 12 hours prior to initiating startup and PHYSICS TESTS.

DISCUSSION OF CHANGES
CTS 3/4.10.3, REACTOR COOLANT LOOPS – UNIT 2 ONLY

ADMINISTRATIVE CHANGES

None

MORE RESTRICTIVE CHANGES

M01 Current Technical Specifications (CTS) 3/4.10.3 provides an exception to the limitations of CTS 3.4.1 and the noted requirements of CTS Tables 2.2-1 and 3.3-1. This special test exception permits reactor criticality under reduced flow conditions and is required to perform certain startup and PHYSICS TESTS while at low THERMAL POWER levels. The Improved Technical Specifications (ITS) do not contain this special test exception. This changes the CTS by eliminating a special test exception.

This change is acceptable because this type of PHYSICS TEST is no longer performed. Reactor Coolant System (RCS) flow will be maintained in accordance with the requirements of LCO 3.4.4, "RCS Loops - MODES 1 and 2," during PHYSICS TESTS in MODES 1 and 2. As a result, this CTS Special test exception is not needed. This change is designated as more restrictive because an exception to the CTS is being deleted.

JUSTIFICATION FOR DEVIATIONS
ITS 3.4.17, SPECIAL TEST EXCEPTION (STE) - RCS LOOPS

1. This Reactor Coolant System Loops - Test Exceptions Specification is not included in the PSL Unit 1 and Unit 2 ITS because the exception is not needed to perform any required startup or PHYSICS TESTS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.17 Special Test Exception (STE) RCS Loops

1

BASES

BACKGROUND

This special test exception to LCO 3.4.4, "RCS Loops - MODES 1 and 2," and LCO 3.3.1, "RPS Instrumentation," permits reactor criticality under no flow conditions during PHYSICS TESTS (natural circulation demonstration, station blackout, and loss of offsite power) while at low THERMAL POWER levels. Section XI of 10 CFR Part 50, Appendix B (Ref. 1), requires that a test program be established to ensure that structures, systems, and components will perform satisfactorily in service. All functions necessary to ensure that the specified design conditions are not exceeded during normal operation and anticipated operational occurrences must be tested. This testing is an integral part of the design, construction, and operation of the power plant as specified in 10 CFR 50, Appendix A, GDC 1 (Ref. 2).

The key objectives of a test program are to provide assurance that the facility has been adequately designed to validate the analytical models used in the design and analysis, to verify the assumptions used to predict plant response, to provide assurance that installation of equipment at the facility has been accomplished in accordance with the design, and to verify that the operating and emergency procedures are adequate. Testing is performed prior to initial criticality, during startup, and following low power operations.

The tests will include verifying the ability to establish and maintain natural circulation following a plant trip between 10% and 20% RTP, performing natural circulation cooldown on emergency power, and during the cooldown, showing that adequate boron mixing occurs and that pressure can be controlled using auxiliary spray and pressurizer heaters powered from the emergency power sources.

APPLICABLE SAFETY ANALYSES

As described in LCO 3.0.7, compliance with Special Test Exception LCOs is optional, and therefore no criteria of 10 CFR 50.36(c)(2)(ii) apply. Special Test Exception LCOs provide flexibility to perform certain operations by appropriately modifying requirements of other LCOs. A discussion of the criteria satisfied for the other LCOs is provided in their respective Bases.

BASES

LCO

This LCO is provided to allow for the performance of PHYSICS TESTS in MODE 2 (after a refueling), where the core cooling requirements are significantly different than after the core has been operating. Without this LCO, plant operations would be held bound to the normal operating LCOs for reactor coolant loops and circulation (MODES 1 and 2), and the appropriate tests could not be performed. 1

In MODE 2, where core power level is considerably lower and the associated PHYSICS TESTS must be performed, operation is allowed under no flow conditions provided THERMAL POWER is < 5% RTP and the reactor trip setpoints of the OPERABLE power level channels are set ≤ 20% RTP. These limits ensure no Safety Limits or fuel design limits will be violated.

The exception is allowed even though there are no bounding safety analyses. These tests are allowed since they are performed under close supervision during the test program and provide valuable information on the plant's capability to cool down without offsite power available to the reactor coolant pumps.

APPLICABILITY

This LCO ensures that the plant will not be operated in MODE 1 without forced circulation. It only allows testing under these conditions while in MODE 2. This testing establishes that heat input from nuclear heat does not exceed the natural circulation heat removal capabilities. Therefore, no safety or fuel design limits will be violated as a result of the associated tests.

ACTIONS

A.1

If THERMAL POWER increases to > 5% RTP, the reactor must be tripped immediately. This ensures the plant is not placed in an unanalyzed condition and prevents exceeding the specified acceptable fuel design limits.

SURVEILLANCE REQUIREMENTS

SR 3.4.17.1

THERMAL POWER must be verified to be within limits to ensure that the fuel design criteria are not violated during the performance of the PHYSICS TESTS. [The hourly Frequency has been shown by operating practice to be sufficient to regularly assess conditions for potential degradation and verify operation is within the LCO limits. Plant operations are conducted slowly during the performance of PHYSICS TESTS, and monitoring the power level once per hour is sufficient to ensure that the power level does not exceed the limit.

BASES

SURVEILLANCE REQUIREMENTS (continued)

1

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

----------REVIEWER'S NOTE----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

SR 3.4.17.2

Within 12 hours of initiating startup or PHYSICS TESTS, a CHANNEL FUNCTIONAL TEST must be performed on each logarithmic power level and linear power level neutron flux monitoring channel to verify OPERABILITY and adjust setpoints to proper values. This will ensure that the Reactor Protection System is properly aligned to provide the required degree of core protection during startup or the performance of the PHYSICS TESTS. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. The interval is adequate to ensure that the appropriate equipment is OPERABLE prior to the tests to aid the monitoring and protection of the plant during these tests.

With all four safety injection tanks OPERABLE, each tank shall have a minimum pressure of 235 psig and a maximum pressure of 650 psig and a contained water volume of between 833 and 1556 cubic feet with a boron concentration of between 1900 and 2200 ppm of boron.~~

LA03

Applicability **APPLICABILITY:** MODES 1, 2 and 3 with pressurizer pressure ≥ 1750 psia.

ACTION:

Condition A ~~a.~~ ~~With~~ one SIT inoperable ~~due~~ to level boron concentration not within limits, or one SIT inoperable due to ~~an~~ inability to verify ~~the required~~ water volume or ~~nitrogen cover-~~pressure, restore ~~the inoperable~~ SIT to OPERABLE status with 72 hours; otherwise, be in ~~at least HOT~~ STANDBY within ~~the next~~ 6 hours and ~~in HOT SHUTDOWN~~ within ~~the following~~ 6 hours.

Required Action A.1 MODE 3

Required Action C .1, C.2 12

Reduce pressurizer pressure to < 1750 psia — A02

Condition B ~~b.~~ ~~With~~ one SIT inoperable ~~due to~~ for reasons other than ~~those stated in~~ ACTION-a, restore ~~the inoperable~~ SIT to OPERABLE status within 24 hours; otherwise, be in ~~at least HOT STANDBY~~ within ~~the next~~ 6 hours and ~~in HOT SHUTDOWN~~ within ~~the following~~ 6 hours.

Required Action B.1 MODE 3

Required Action C .1, C.2 12

Reduce pressurizer pressure to < 1750 psia — A02

Add proposed Action D — A03

SURVEILLANCE REQUIREMENTS

~~4.5.1.1~~ ~~Each safety injection tank shall be demonstrated OPERABLE:~~

SR 3.5.1.1, SR 3.5.1.2, SR 3.5.1.3 ~~a.~~ In accordance with the Surveillance Frequency Control Program ~~by:~~

SR 3.5.1.2 SR 3.5.1.3 ~~1.~~ Verify~~ing that the~~ borated water volume and nitrogen cover-pressure in each SIT is ~~in the tanks are~~ within ~~their~~ limits~~, and~~

SR 3.5.1.1 ~~2.~~ Verify~~ing that~~ each safety injection tank isolation valve is open.

A01

MERGENCY CORE COOLING SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

NOTE Only required to be performed for affected SIT. — A03

SR 3.5.1.4

~~b.~~ In accordance with the Surveillance Frequency Control Program and once within 6 hours after each solution volume increase of ~~greater than or equal to~~ 1% of tank volume ~~by~~ verify~~ing the~~ boron concentration ≥ in each SIT is ≥ 1900 ppm and ≤ 2200 ppm. ~~of the safety injection tank solution~~. that is not the result of addition from the RWT. ~~This latter surveillance is not required when the volume increase makeup source is the RWT and the RWT has not been diluted since verifying that the RWT boron concentration is equal to or greater than the safety injection tank boron concentration limit~~.

LA01

SR 3.5.1.5

~~c.~~ In accordance with the Surveillance Frequency Control Program ~~when the RCS pressure is above 700 psia, by~~ verify~~ing that~~ power ~~to the~~ isolation valve operator ~~is disconnected~~ removed from each SIT ~~by maintaining the breaker open by administrative controls~~.

LA05

LA02

~~d. In accordance with the Surveillance Frequency Control Program by verifying that each safety injection tank isolation valve opens automatically under each of the following conditions:~~

~~1. When an actual or simulated RCS pressure signal exceeds 515 psia, and~~

~~2. Upon receipt of a safety injection test signal.~~

LA04

DISCUSSION OF CHANGES
ITS 3.5.1, SAFETY INJECTION TANKS (SITs)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.5.1 Actions a. and b. require in part, “otherwise, be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours” when a SIT cannot be restored to OPERABLE status within the required time. ITS 3.5.1 Required Action C.2 requires, when the Required Actions and associated Completion Times are not met, reducing pressurizer pressure to < 1750 psia. This changes the end state in CTS 3.5.1 Actions a. and b. from MODE 4 to MODE 3 with pressurizer pressure < 1750 psia.

The purpose of CTS 3.5.1 Action a. and b. is to place the plant in a condition in which the equipment is no longer required. CTS 3.5.1 Action a. and b. provide appropriate actions to take for an inoperable SIT when the unit is in MODE 1, 2, or 3 with pressurizer pressure is ≥ 1750 psia. The SIT is not required to be OPERABLE when pressurizer pressure is < 1750 psia. Below 1750 psia, the rate of RCS blowdown is such that the ECCS pumps can provide adequate injection to ensure that peak clad temperature remains below 10 CFR 50.46 limit of 2200°F. Therefore, in accordance with CTS 3.0.2 (ITS LCO 3.0.2), when pressurizer pressure is < 1750 psia, the requirements to be in MODE 4 in CTS 3.5.1 Action a. and b. are no longer required to be completed. The SITs, with pressurizer pressure below 1750 psia, are no longer required to be OPERABLE.

These changes are designated as administrative changes and are acceptable because they maintain the current requirement to place the unit in a condition in which the SITs are no longer required consistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2) and, therefore, do not result in a technical change to the CTS.

A03 CTS 3.5.1 does not contain a specific ACTION for two or more SITs inoperable. With two or more SITs inoperable, CTS 3.0.3 would be entered. ITS 3.5.1 ACTION D directs entry into LCO 3.0.3 when two or more SITs are inoperable. This changes the CTS by specifically stating to enter LCO 3.0.3 in this System Specification.

This change is acceptable because the action taken with two or more SITs inoperable is unchanged. Adding this ACTION is consistent with the ITS convention of directing entry into LCO 3.0.3 when multiple ACTIONS are presented in the ITS, and entry into these multiple ACTIONS could result in a loss of safety function. This change is designated as administrative because it does not result in a technical change to the CTS.

A04 Unit 1 CTS 4.5.1.b, and Unit 2 CTS 4.5.1.1.b state, in part, that verification of the boron concentration of the SIT solution is required once within 6 hours after each solution volume increase of ≥ 1% of tank volume; however, this surveillance is not required when the volume increase makeup source is the RWT and the RWT has not been diluted since verifying that the RWT boron concentration is equal to or greater than the SIT boron concentration limit.

The purpose of the Unit 1 CTS 4.5.1.b, and Unit 2 CTS 4.5.1.1.b Surveillance Frequency is to designate the Frequency, as well as certain requirements or special conditions. ITS SR 3.5.1.4 adds a Note to the Surveillance Frequency that states, "Only required to be performed for affected SIT." The CTS Surveillance Frequency is implicit that the Surveillance be performed for only the affected SIT, that being the SIT subject to the solution volume increase. CTS does not contain this Note. This changes the CTS by adding the ITS SR 3.5.1.4 Note to clarify that the Surveillance is only required to be performed for the affected SIT. This change is acceptable because ITS SR 3.5.1.4 Note clarifies that the Surveillance is only required to be performed for the affected SIT. This change is designated as administrative because it does not result in technical changes to CTS.

A05 **Unit 1 only:** Unit 1 CTS 4.5.1.c requires verification that power be removed from each SIT isolation valve operator when RCS pressure is above 1750 psia. ITS SR 3.5.1.5 requires verification that power be removed from each SIT isolation valve operator when pressurizer pressure is greater than or equal to a specific pressure. This changes the CTS by deleting the specific pressure at which power be removed from the SIT isolation valve operators.

The purpose of the CTS requirement is to ensure power is removed from each SIT isolation valve operator when RCS pressure is above a specific value to further ensure that an active failure could not result in the undetected closure of an SIT motor operated isolation valve. This pressure value is typically above the pressure the SITs are required to be OPERABLE. For instance, the ISTS 3.5.1 Applicability is, in part, with pressurizer pressure ≥ 700 psia and ISTS SR 3.5.1.5 requires power to be removed from the isolation valve operator ≥ 2000 psia. Per the requirements of CTS 4.0.1 (ITS SR 3.0.1) and CTS 4.0.4 (ITS SR 3.0.4), SRs must be met prior to entry into the Applicability, which in the case of CTS 3.5.1 (ITS LCO 3.5.1) is MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia. Conversely, as stated in the ITS Bases of SR 3.0.1, Surveillances do not have to be performed when the unit is in a MODE or other specified condition for which the requirements of the associated LCO are not applicable. Therefore, it is unnecessary to specifically require power to the valve operator be removed "when in MODE 3 with pressure ≥ 1750 psia" and this additional wording has been removed from Unit 1 ITS SR 3.5.1.5. As such, this additional wording has been removed from Unit 2 ITS SR 3.5.1.5.

This change is acceptable because ITS SR 3.5.1.5 requires essentially the same verification by requiring that power be removed from each SIT isolation valve operator when the SITs are required to be OPERABLE (i.e., when pressurizer pressure is greater than or equal to 1750 psia for Unit 1. This change is designated as administrative because it does not result in technical changes to CTS because the Surveillance requirement will continue to require power to the

SIT isolation valve operator to be removed when the SITs are required to be OPERABLE (i.e., in MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia).

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS 3.5.1.c requires a minimum SIT boron concentration of 1900 ppm but does not require a maximum boron concentration. ITS SR 3.5.1.4 requires verification that SIT boron concentration is within both a minimum and maximum limit. Similarly, Unit 2 CTS 3.5.1.c requires boron concentration within a minimum 1900 ppm and a maximum 2200 ppm. This changes the Unit 1 CTS by adding a SIT boron concentration maximum limit of 2200 ppm.

The purpose of CTS 3.5.1.c is to provide a SIT minimum boron concentration limit to ensure that, following a LOCA with a minimum level in the SIT, the reactor will remain subcritical in the cold condition following mixing of the SIT and RCS water volumes. The SIT maximum boron concentration limit is based on boron precipitation in the core following a LOCA which could result in reduced heat removal capability between the fuel cladding and the reactor coolant. This change is acceptable, because the maximum boron concentration limit provides assurance that the SIT is capable of performing its function when required. This change is designated as more restrictive because it adds a SIT maximum boron concentration limit to the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* PSL Unit 1 CTS 4.5.1.b, and PSL Unit 2 CTS 4.5.1.1.b state that verification of boron concentration of the SIT solution is required once within 6 hours after each solution volume increase of ≥ 1% of tank volume, and that the Surveillance is not required when the volume increase makeup source is the RWT and the RWT has not been diluted since verifying that the RWT boron concentration is equal to or greater than the SIT boron concentration limit. ITS SR 3.5.1.4 states that verification of boron concentration of each SIT is required once within 6 hours after each solution volume increase of ≥ 1% of tank volume that is not the result of addition from the refueling water tank. ITS does not include a Surveillance Frequency requirement that retains the statement that the RWT has not been diluted since verifying that the RWT boron concentration is equal to or greater than the SIT boron concentration limit. This changes the CTS by relocation of the CTS requirement to the ITS Bases. The ITS 3.5.1.4 Bases will include that it is not necessary to verify boron concentration if the added water is from the RWT, because the boron concentration of the water contained in the RWT is within the SIT boron concentration requirements.

The removal of these details for performing surveillance requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS SR 3.5.1.4 retains the CTS PSL Unit 1 CTS 4.5.1.b, and PSL Unit 2 CTS 4.5.1.1.b, requirement by stating that verification of boron concentration of the SIT solution is required once within 6 hours after each solution volume increase of ≥ 1% of tank volume that is not the result of addition from the refueling water tank. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications. | R1

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* PSL Unit 1 CTS 4.5.1.c, and PSL Unit 2 CTS 4.5.1.1.c require verifying that power to the (SIT) isolation valve operator is removed / disconnected by maintaining the breaker open under administrative control. ITS SR 3.5.1.5 states verify power is removed from each SIT isolation valve operator. ITS does not include the detailed requirement that the breaker to the isolation valve operator be maintained open under administrative control. This changes the CTS by relocation of the administrative control details to the ITS Bases. The ITS 3.5.1.5 Bases will include that removal of power to the SIT isolation valve operators is conducted under administrative control.

The removal of these details for performing surveillance requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS SR 3.5.1.5 retains the requirement to ensure power is removed from the SIT isolation valve operator. ITS SR 3.5.1.5 states verify power is removed from each SIT isolation valve operator. This change is acceptable because these types of procedural details will continue to be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA03 **Unit 2 only:** *(Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program, or Surveillance Frequency Control Program)* CTS 3.5.1 LCO Note states “When in MODE 3 with pressurizer pressure less than 1750 psia, at least three safety injection tanks shall be OPERABLE, each with a minimum pressure of 235 psig and a maximum pressure of 650 psig and a contained water volume of between 1250 and 1556 cubic feet with a boron concentration of between 1900 and 2200 ppm of boron. With all four safety injection tanks OPERABLE, each tank shall have a minimum pressure of 235 psig and a maximum pressure of 650 psig and a contained water volume of between 833 and 1556 cubic feet with a boron

concentration of between 1900 and 2200 ppm of boron." ITS 3.5.1 does not include this requirement. PSL Unit 2 CTS 3.5.1 Applicability is MODES 1, 2, and 3 with pressurizer pressure ≥ 1750 psia. The SIT is not required to be OPERABLE when pressurizer pressure is < 1750 psia. Therefore, in accordance with CTS 3.0.2 (ITS LCO 3.0.2), when pressurizer pressure is < 1750 psia, the requirements in the Note are no longer required. Similarly, DOC A02 changes the end state in CTS 3.5.1 Actions a. and b. from MODE 4 to MODE 3 with pressurizer pressure < 1750 psia. This changes the CTS by relocating the requirements in the Note to the Technical Requirements Manual.

The removal of SIT requirements when in MODE 3 with pressurizer pressure < 1750 psia is acceptable because this type of information is not necessary to be included in the Technical Specifications in order to provide adequate protection of public health and safety. The ITS retains the requirements for SITs to be OPERABLE when in MODES 1, 2, and 3 with pressurizer pressure ≥ 1750 psia. When pressurizer pressure is below 1750 psia the ECCS pumps can provide adequate injection to ensure that peak clad temperature remains below the 10 CFR 50.46 limit of 2200°F. Therefore, the SITs are not required to be OPERABLE, and the SIT motor operated isolation valves may be closed to isolate the SITs from the RCS during plant shutdown or startup. Also, this change is acceptable because these types of procedural details will continue to be controlled in the TRM. Changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because these SIT requirements are not required by the CTS 3.5.1 and ITS 3.5.1 Applicability, that being MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia. | R1

LA04 *(Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program, or Surveillance Frequency Control Program)* PSL Unit 1 CTS 4.5.1.d states "In accordance with the Surveillance Frequency Control Program by verifying that each safety injection tank isolation valve opens automatically under each of the following conditions: When the RCS pressure exceeds 350 psia, and Upon receipt of a safety injection test signal." PSL Unit 2 CTS 4.5.1.1.d states "In accordance with the Surveillance Frequency Control Program by verifying that each safety injection tank isolation valve opens automatically under each of the following conditions: When an actual or simulated RCS pressure signal exceeds 515 psia, and Upon receipt of a safety injection test signal.

ITS 3.5.1 does not include this requirement. ITS SR 3.5.1.1 requires verification that each SIT isolation valve is fully open when in MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia. Additionally, ITS SR 3.5.1.5 requires verification that power is removed from each SIT isolation valve operator when pressurizer pressure is ≥ 1750 psia. ITS SR 3.5.1.1 and SR 3.5.1.5 provide assurance each SIT isolation valve is open and remains open (power removed from its valve operator) when in MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia. | R1

The SITs are not required to be OPERABLE when pressurizer pressure is < 1750 psia. Therefore, in accordance with CTS 3.0.2 (ITS LCO 3.0.2), when pressurizer pressure is < 1750 psia, the requirements in PSL Unit 1 CTS 4.5.1.d

and PSL Unit 2 CTS 4.5.1.1.d are no longer required. Similarly, DOC A02 changes the end state in CTS 3.5.1 Actions a. and b. from MODE 4 to MODE 3 with pressurizer pressure < 1750 psia. This changes the CTS by relocating the requirements in the PSL Unit 1 CTS 4.5.1.d and PSL Unit 2 CTS 4.5.1.1.d.

The removal of SIT requirements when in MODE 3 with pressurizer pressure < 1750 psia is acceptable because this type of information is not necessary to be included in the Technical Specifications in order to provide adequate protection of public health and safety. The ITS retains the requirements for SITs to be OPERABLE when in MODES 1, 2, and 3 with pressurizer pressure ≥ 1750 psia. Also, this change is acceptable because these types of procedural details will be adequately controlled in the TRM. Changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because these SIT requirements are not required by the CTS 3.5.1 and ITS 3.5.1 Applicability, that being MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia. | R1

LA05 **Unit 2 only:** *(Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program, or Surveillance Frequency Control Program)* Unit 2 CTS 4.5.1.1.c requires verification that the power be removed from each SIT isolation valve operator when RCS pressure is above 700 psia. ITS SR 3.5.1.5 requires verification that power be removed from each SIT isolation valve operator. This changes the CTS by deleting the specific pressure at which power be removed from the SIT isolation valve operators. | R1

The purpose of the CTS requirement is to ensure power is removed from each SIT isolation valve operator when RCS pressure is above a specific value to further ensure that an active failure could not result in the undetected closure of an SIT motor operated isolation valve. This pressure value is typically above the pressure the SITs are required to be OPERABLE. For instance, the ISTS 3.5.1 Applicability is, in part, with pressurizer pressure ≥ 700 psia and ISTS SR 3.5.1.5 requires power to be removed from the isolation valve operator ≥ 2000 psia. Per the requirements of CTS 4.0.1 (ITS SR 3.0.1) and CTS 4.0.4 (ITS SR 3.0.4), SRs must be met prior to entry into the Applicability, which in the case of CTS 3.5.1 (ITS LCO 3.5.1) is MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia. Conversely, as stated in the ITS Bases of SR 3.0.1, Surveillances do not have to be performed when the unit is in a MODE or other specified condition for which the requirements of the associated LCO are not applicable. Therefore, it is unnecessary to specifically require power to the valve operator be removed in MODE 3 with RCS pressure ≥ 700 psia. Unit 2 CTS 3.5.1 Applicability does not require the SITs to be OPERABLE until in at least MODE 3 with pressurizer pressure ≥ 1750 psia. As such, this additional wording has been removed from Unit 2 ITS SR 3.5.1.5. This changes the CTS by relocating this requirement in CTS 3.5.1 to the Technical Requirements Manual.

The removal of this SIT requirement when in MODE 3 with pressurizer pressure < 1750 psia is acceptable because this type of information is not necessary to be included in the Technical Specifications in order to provide adequate protection of public health and safety. The ITS retains the requirements for SITs to be OPERABLE when in MODES 1, 2, and 3 with pressurizer pressure ≥ 1750 psia.

When pressurizer pressure is below 1750 psia the ECCS pumps can provide adequate injection to ensure that peak clad temperature remains below the 10 CFR 50.46 limit of 2200°F. Therefore, the SITs are not required to be OPERABLE, and the SIT motor operated isolation valves may be closed to isolate the SITs from the RCS during plant shutdown or startup. Also, this change is acceptable because these types of procedural details will continue to be controlled in the TRM. Changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because these SIT requirements are not required by the CTS 3.5.1 and ITS 3.5.1 Applicability, that being MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia. | R1

JUSTIFICATION FOR DEVIATIONS
ITS 3.5.1, SAFETY INJECTION TANKS (SITs)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The purpose ISTS 3.5.1.5 is to ensure power is removed from each SIT isolation valve operator when RCS pressure is above a specified value to further ensure that an active failure could not result in the undetected closure of an SIT motor operated isolation valve. This pressure value is intended to be above the pressure the SITs are required to be OPERABLE. However, the CTS Applicability is MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia and the equivalent Surveillances (Unit 1 CTS 4.5.1.c and Unit 2 CTS 4.5.1.1.c) require power to be removed to the isolation valve operators above 1750 psia or less. Per the requirements of ISTS SR 3.0.1 and ISTS SR 3.0.4, SRs must be met prior to entry into the Applicability, which in the case of ITS LCO 3.5.1 is MODES 1 and 2, and MODE 3 with pressurizer pressure ≥ 1750 psia. Conversely, as stated in the ITS Bases of SR 3.0.1, Surveillances do not have to be performed when the unit is in a MODE or other specified condition for which the requirements of the associated LCO are not applicable. Therefore, it is unnecessary to specifically require power to the valve operator be removed "when in MODE 3 with pressure ≥ 1750 psia" and this additional wording has been removed.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.1 Safety Injection Tanks (SITs)

BASES

BACKGROUND

The functions of the ~~[~~four~~]~~ SITs are to supply water to the reactor vessel during the blowdown phase of a loss of coolant accident (LOCA), to provide inventory to help accomplish the refill phase that follows thereafter, and to provide Reactor Coolant System (RCS) makeup for a small break LOCA. 2

The blowdown phase of a large break LOCA is the initial period of the transient during which the RCS departs from equilibrium conditions, and heat from fission product decay, hot internals, and the vessel continues to be transferred to the reactor coolant. The blowdown phase of the transient ends when the RCS pressure falls to a value approaching that of the containment atmosphere.

The refill phase of a LOCA follows immediately where reactor coolant inventory has vacated the core through steam flashing and ejection out through the break. The core is essentially in adiabatic heatup. The balance of the SITs' inventory is then available to help fill voids in the lower plenum and reactor vessel downcomer to establish a recovery level at the bottom of the core and ongoing reflood of the core with the addition of safety injection (SI) water.

The SITs are pressure vessels partially filled with borated water and pressurized with nitrogen gas. The SITs are passive components, since no operator or control action is required for them to perform their function. Internal tank pressure is sufficient to discharge the contents to the RCS, if RCS pressure decreases below the SIT pressure.

Each SIT is piped into one RCS cold leg via the injection lines utilized by the High Pressure Safety Injection and Low Pressure Safety Injection (HPSI and LPSI) systems. Each SIT is isolated from the RCS by a motor operated isolation valve and ~~two~~ check valve~~s in series~~. The motor operated isolation valves are normally open, with power removed from the valve motor to prevent inadvertent closure prior to or during an accident. 1 | R1

The SIT gas and water volumes, gas pressure, and outlet pipe size are selected to allow three of the four SITs to partially recover the core before significant clad melting or zirconium water reaction can occur following a LOCA. The need to ensure that three SITs are adequate for this function is consistent with the LOCA assumption that the entire contents of one SIT will be lost via the break during the blowdown phase of a LOCA.

BASES

APPLICABLE SAFETY ANALYSES

The SITs are taken credit for in both the large and small break LOCA analyses at full power (Ref. 1). These are the Design Basis Accidents (DBAs) that establish the acceptance limits for the SITs. Reference to the analyses for these DBAs is used to assess changes to the SITs as they relate to the acceptance limits.

In performing the LOCA calculations, conservative assumptions are made concerning the availability of SI flow. These assumptions include signal generation time, equipment starting times, and delivery time due to system piping. In the early stages of a LOCA with a loss of offsite power, the SITs provide the sole source of makeup water to the RCS. (The assumption of a loss of offsite power is required by regulations.) This is because the LPSI pumps, HPSI pumps, and charging pumps cannot deliver flow until the diesel generators (DGs) start, come to rated speed, and go through their timed loading sequence. In cold leg breaks, the entire contents of one SIT are assumed to be lost through the break during the blowdown and reflood phases.

The limiting large break LOCA is a double ended guillotine cold leg break at the discharge of the reactor coolant pump.

During this event, the SITs discharge to the RCS as soon as RCS pressure decreases to below SIT pressure. As a conservative estimate, no credit is taken for SI pump flow until the SITs are empty. This results in a minimum effective delay of over 60 seconds, during which the SITs must provide the core cooling function. The actual delay time does not exceed 30 seconds. No operator action is assumed during the blowdown stage of a large break LOCA.

The worst case small break LOCA also assumes a time delay before pumped flow reaches the core. For the larger range of small breaks, the rate of blowdown is such that the increase in fuel clad temperature is terminated solely by the SITs, with pumped flow then providing continued cooling. As break size decreases, the SITs and HPSI pumps both play a part in terminating the rise in clad temperature. As break size continues to decrease, the role of the SITs continues to decrease until they are not required, and the HPSI pumps become solely responsible for terminating the temperature increase.

This LCO helps to ensure that the following acceptance criteria, established by 10 CFR 50.46 (Ref. 2) for the ECCS, will be met following a LOCA:

BASES

APPLICABLE SAFETY ANALYSES (continued)

a. Maximum fuel element cladding temperature is ≤ 2200°F,

b. Maximum cladding oxidation is ≤ 0.17 times the total cladding thickness before oxidation,

c. Maximum hydrogen generation from a zirconium water reaction is ≤ 0.01 times the hypothetical amount that would be generated if all of the metal in the cladding cylinders surrounding the fuel, excluding the cladding surrounding the plenum volume, were to react, and

d. The core is maintained in a coolable geometry.

Since the SITs discharge during the blowdown phase of a LOCA, they do not contribute to the long term cooling requirements of 10 CFR 50.46.

Since the SITs are passive components, single active failures are not applicable to their operation. The SIT isolation valves, however, are not single failure proof; therefore, whenever the valves are open, power is removed from their operators and the switch is key locked open.

These precautions ensure that the SITs are available during an accident (Ref. 3). With power supplied to the valves, a single active failure could result in a valve closure, which would render one SIT unavailable for injection. If a second SIT is lost through the break, only two SITs would reach the core. Since the only active failure that could affect the SITs would be the closure of a motor operated outlet valve, the requirement to remove power from these eliminates this failure mode.

The minimum volume requirement for the SITs ensures that three SITs can provide adequate inventory to reflood the core and downcomer following a LOCA. The downcomer then remains flooded until the HPSI and LPSI systems start to deliver flow.

The maximum volume limit is based on maintaining an adequate gas volume to ensure proper injection and the ability of the SITs to fully discharge, as well as limiting the maximum amount of boron inventory in the SITs.

BASES

APPLICABLE SAFETY ANALYSES (continued)

A minimum of ~~25% narrow range level, corresponding to [1790]~~ 1090 cubic feet of borated water, and a maximum of ~~75% narrow range level, corresponding to [1927]~~ cubic feet of borated water, are used in the safety analyses as the volume in the SITs. ~~To allow for instrument inaccuracy, a [28]% narrow range (corresponding to [1802] cubic feet) and a [72]% narrow range (corresponding to [1914] cubic feet) are specified. The analyses are based upon the cubic feet requirements; the percentage figures are provided for operator use because the level indicator provided in the control room is marked in percentages, not in cubic feet.~~ 1170 2 3 2 2 3

The minimum nitrogen cover pressure requirement ensures that the contained gas volume will generate discharge flow rates during injection that are consistent with those assumed in the safety analyses.

The maximum nitrogen cover pressure limit ensures that excessive amounts of gas will not be injected into the RCS after the SITs have emptied.

A minimum pressure of ~~[593]~~ 230 psig and a maximum pressure of ~~[632]~~ 280 psig are used in the analyses. ~~To allow for instrument accuracy, a [615] psig minimum and [655] psig maximum are specified.~~ The maximum allowable boron concentration of ~~[2800]~~ 2200 ppm is based upon boron precipitation limits in the core following a LOCA. Establishing a maximum limit for boron is necessary since the time at which boron precipitation would occur in the core following a LOCA is a function of break location, break size, the amount of boron injected into the core, and the point of ECCS injection. Post LOCA emergency procedures directing the operator to establish simultaneous hot and cold leg injection are based on the worst case minimum boron precipitation time. Maintaining the maximum SIT boron concentration within the upper limit ensures that the SITs do not invalidate this calculation. An excessive boron concentration in any of the borated water sources used for injection during a LOCA could result in boron precipitation earlier than predicted. 4 2

The minimum boron requirements of ~~[1500]~~ 1900 ppm are based on beginning of life reactivity values and are selected to ensure that the reactor will remain subcritical during the reflood stage of a large break LOCA. During a large break LOCA, all control element assemblies (CEAs) are assumed not to insert into the core, and the initial reactor shutdown is 2

BASES

APPLICABLE SAFETY ANALYSES (continued)

accomplished by void formation during blowdown. Sufficient boron concentration must be maintained in the SITs to prevent a return to criticality during reflood. ~~Although this requirement is similar to the basis for the minimum boron concentration of the refueling water tank (RWT), the minimum SIT concentration is lower than that of the RWT since the SITs need not account for dilution by the RCS.~~ 1

The SITs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO establishes the minimum conditions required to ensure that the SITs are available to accomplish their core cooling safety function following a LOCA. ~~[~~Four~~]~~ SITs are required to be OPERABLE to ensure that 100% of the contents of ~~[~~three~~]~~ of the SITs will reach the core during a LOCA. 2

This is consistent with the assumption that the contents of one tank spill through the break. If the contents of fewer than three tanks are injected during the blowdown phase of a LOCA, the ECCS acceptance criteria of 10 CFR 50.46 (Ref. 2) could be violated.

For an SIT to be considered OPERABLE, the isolation valve must be fully open, power removed above ~~[2000]~~ ~~psig~~, and the limits established in the SR for contained volume, boron concentration, and nitrogen cover pressure must be met. 2

1750 psia

APPLICABILITY

In MODES 1 and 2, and MODE 3 with RCS pressure ≥ ~~700~~ psia, the SIT OPERABILITY requirements are based on an assumption of full power operation. Although cooling requirements decrease as power decreases, the SITs are still required to provide core cooling as long as elevated RCS pressures and temperatures exist. 2

1750

This LCO is only applicable at pressures ≥ ~~700~~ psia. Below ~~700~~ psia, the rate of RCS blowdown is such that the ECCS pumps can provide adequate injection to ensure that peak clad temperature remains below the 10 CFR 50.46 (Ref. 2) limit of 2200°F. 2

1750

1750

In MODE 3, at pressures < ~~700~~ psia, and in MODES 4, 5, and 6, the SIT motor operated isolation valves are closed to isolate the SITs from the RCS. ~~This allows RCS cooldown and depressurization without discharging the SITs into the RCS or requiring depressurization of the SITs.~~ 5

during unit shutdown and startup

BASES

ACTIONS

A.1

If the boron concentration of one SIT is not within limits, it must be returned to within the limits within 72 hours. In this condition, ability to maintain subcriticality or minimum boron precipitation time may be reduced, but the reduced concentration effects on core subcriticality during reflood are minor. Boiling of the ECCS water in the core during reflood concentrates the boron in the saturated liquid that remains in the core. In addition, the volume of the SIT is still available for injection. Since the boron requirements are based on the average boron concentration of the total volume of three SITs, the consequences are less severe than they would be if an SIT were not available for injection. Thus, 72 hours is allowed to return the boron concentration to within limits.

The combination of redundant level and pressure instrumentation for any single SIT provides sufficient information so that it is not worthwhile to always attempt to correct drift associated with one instrument, with the resulting radiation exposures during entry into containment, as there is sufficient time to repair one in the event that a second one became inoperable. Because these instruments do not initiate a safety action, it is reasonable to extend the allowable outage time for them. While technically inoperable, the SIT will be available to fulfill its safety function during this time and, thus, this Completion Time results in a negligible increase in risk.

B.1

If one SIT is inoperable, for reasons other than boron concentration or the inability to verify level or pressure, the SIT must be returned to OPERABLE status within 24 hours. In this Condition, the required contents of three SITs cannot be assumed to reach the core during a LOCA as is assumed in Appendix K (Ref. 5).

CE NPSD-994 (Ref. 6) provides a series of deterministic and probabilistic findings that support the 24 hour Completion Time as having no affect on risk as compared to shorter periods for restoring the SIT to OPERABLE status.

BASES

ACTIONS (continued)

C.1 and C.2

If the SIT cannot be restored to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and pressurizer pressure reduced to < ~~700~~ 1750 psia within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. 2

D.1

If more than one SIT is inoperable, the unit is in a condition outside the accident analyses. Therefore, LCO 3.0.3 must be entered immediately.

SURVEILLANCE REQUIREMENTS

SR 3.5.1.1

Verification that each SIT isolation valve is fully open, before power is removed from its valve operator, as indicated in the control room, ensures that SITs are available for injection and ensures timely discovery if a valve should be partially closed. If an isolation valve is not fully open, the rate of injection to the RCS would be reduced. Although a motor operated valve should not change position with power removed, a closed valve could result in not meeting accident analysis assumptions. ~~[A 12 hour Frequency is considered reasonable in view of other administrative controls that ensure the unlikelihood of a mispositioned isolation valve.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.1.2 and SR 3.5.1.3

SIT borated water volume and nitrogen cover pressure should be verified to be within specified limits in order to ensure adequate injection during a LOCA. [Due to the static design of the SITs, a 12 hour Frequency usually allows the operator sufficient time to identify changes before the limits are reached. Operating experience has shown this Frequency to be appropriate for early detection and correction of off normal trends. 2

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement. 2
----------]

SR 3.5.1.4

Thirty-one days is reasonable for verification to determine that each SIT's boron concentration is within the required limits, because the static design of the SITs limits the ways in which the concentration can be changed. [The 31 day Frequency is adequate to identify changes that could occur from mechanisms such as stratification or inleakage. 2
Sampling the affected SIT within 6 hours after a 1% volume increase will identify whether inleakage has caused a reduction in boron concentration to below the required limit. It is not necessary to verify boron concentration if the added water is from the RWT, because the water contained in the RWT is within the SIT boron concentration requirements. This is consistent with the recommendations of NUREG-1366 (Ref. 4). 6

the boron concentration of

and assumes the RWT has not been diluted since the last time the RWT boron concentration was verified to be within limits.

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.1 Safety Injection Tanks (SITs)

BASES

BACKGROUND

The functions of the ~~[~~four~~]~~ SITs are to supply water to the reactor vessel during the blowdown phase of a loss of coolant accident (LOCA), to provide inventory to help accomplish the refill phase that follows thereafter, and to provide Reactor Coolant System (RCS) makeup for a small break LOCA. 2

The blowdown phase of a large break LOCA is the initial period of the transient during which the RCS departs from equilibrium conditions, and heat from fission product decay, hot internals, and the vessel continues to be transferred to the reactor coolant. The blowdown phase of the transient ends when the RCS pressure falls to a value approaching that of the containment atmosphere.

The refill phase of a LOCA follows immediately where reactor coolant inventory has vacated the core through steam flashing and ejection out through the break. The core is essentially in adiabatic heatup. The balance of the SITs' inventory is then available to help fill voids in the lower plenum and reactor vessel downcomer to establish a recovery level at the bottom of the core and ongoing reflood of the core with the addition of safety injection (SI) water.

The SITs are pressure vessels partially filled with borated water and pressurized with nitrogen gas. The SITs are passive components, since no operator or control action is required for them to perform their function. Internal tank pressure is sufficient to discharge the contents to the RCS, if RCS pressure decreases below the SIT pressure.

Each SIT is piped into one RCS cold leg via the injection lines utilized by the High Pressure Safety Injection and Low Pressure Safety Injection (HPSI and LPSI) systems. Each SIT is isolated from the RCS by a motor operated isolation valve and ~~two~~ check valve~~s in series~~. The motor operated isolation valves are normally open, with power removed from the valve motor to prevent inadvertent closure prior to or during an accident. 1 | R1

The SIT gas and water volumes, gas pressure, and outlet pipe size are selected to allow three of the four SITs to partially recover the core before significant clad melting or zirconium water reaction can occur following a LOCA. The need to ensure that three SITs are adequate for this function is consistent with the LOCA assumption that the entire contents of one SIT will be lost via the break during the blowdown phase of a LOCA.

BASES

APPLICABLE SAFETY ANALYSES

The SITs are taken credit for in both the large and small break LOCA analyses at full power (Ref. 1). These are the Design Basis Accidents (DBAs) that establish the acceptance limits for the SITs. Reference to the analyses for these DBAs is used to assess changes to the SITs as they relate to the acceptance limits.

In performing the LOCA calculations, conservative assumptions are made concerning the availability of SI flow. These assumptions include signal generation time, equipment starting times, and delivery time due to system piping. In the early stages of a LOCA with a loss of offsite power, the SITs provide the sole source of makeup water to the RCS. (The assumption of a loss of offsite power is required by regulations.) This is because the LPSI pumps, HPSI pumps, and charging pumps cannot deliver flow until the diesel generators (DGs) start, come to rated speed, and go through their timed loading sequence. In cold leg breaks, the entire contents of one SIT are assumed to be lost through the break during the blowdown and reflood phases.

The limiting large break LOCA is a double ended guillotine cold leg break at the discharge of the reactor coolant pump.

During this event, the SITs discharge to the RCS as soon as RCS pressure decreases to below SIT pressure. As a conservative estimate, no credit is taken for SI pump flow until the SITs are empty. This results in a minimum effective delay of over 60 seconds, during which the SITs must provide the core cooling function. The actual delay time does not exceed 30 seconds. No operator action is assumed during the blowdown stage of a large break LOCA.

The worst case small break LOCA also assumes a time delay before pumped flow reaches the core. For the larger range of small breaks, the rate of blowdown is such that the increase in fuel clad temperature is terminated solely by the SITs, with pumped flow then providing continued cooling. As break size decreases, the SITs and HPSI pumps both play a part in terminating the rise in clad temperature. As break size continues to decrease, the role of the SITs continues to decrease until they are not required, and the HPSI pumps become solely responsible for terminating the temperature increase.

This LCO helps to ensure that the following acceptance criteria, established by 10 CFR 50.46 (Ref. 2) for the ECCS, will be met following a LOCA:

BASES

APPLICABLE SAFETY ANALYSES (continued)

a. Maximum fuel element cladding temperature is ≤ 2200°F,

b. Maximum cladding oxidation is ≤ 0.17 times the total cladding thickness before oxidation,

c. Maximum hydrogen generation from a zirconium water reaction is ≤ 0.01 times the hypothetical amount that would be generated if all of the metal in the cladding cylinders surrounding the fuel, excluding the cladding surrounding the plenum volume, were to react, and

d. The core is maintained in a coolable geometry.

Since the SITs discharge during the blowdown phase of a LOCA, they do not contribute to the long term cooling requirements of 10 CFR 50.46.

Since the SITs are passive components, single active failures are not applicable to their operation. The SIT isolation valves, however, are not single failure proof; therefore, whenever the valves are open, power is removed from their operators and the switch is key locked open.

These precautions ensure that the SITs are available during an accident (Ref. 3). With power supplied to the valves, a single active failure could result in a valve closure, which would render one SIT unavailable for injection. If a second SIT is lost through the break, only two SITs would reach the core. Since the only active failure that could affect the SITs would be the closure of a motor operated outlet valve, the requirement to remove power from these eliminates this failure mode.

The minimum volume requirement for the SITs ensures that three SITs can provide adequate inventory to reflood the core and downcomer following a LOCA. The downcomer then remains flooded until the HPSI and LPSI systems start to deliver flow.

The maximum volume limit is based on maintaining an adequate gas volume to ensure proper injection and the ability of the SITs to fully discharge, as well as limiting the maximum amount of boron inventory in the SITs.

BASES

APPLICABLE SAFETY ANALYSES (continued)

A minimum of ~~25% narrow range level, corresponding to [1790]~~ 1420 cubic feet of borated water, and a maximum of ~~75% narrow range level, corresponding to [1927]~~ cubic feet of borated water, are used in the safety analyses as the volume in the SITs. ~~To allow for instrument inaccuracy, a [28]% narrow range (corresponding to [1802] cubic feet) and a [72]% narrow range (corresponding to [1914] cubic feet) are specified. The analyses are based upon the cubic feet requirements; the percentage figures are provided for operator use because the level indicator provided in the control room is marked in percentages, not in cubic feet.~~ 1556 2 3 2 2 3

The minimum nitrogen cover pressure requirement ensures that the contained gas volume will generate discharge flow rates during injection that are consistent with those assumed in the safety analyses.

The maximum nitrogen cover pressure limit ensures that excessive amounts of gas will not be injected into the RCS after the SITs have emptied.

A minimum pressure of ~~[593]~~ 500 psig and a maximum pressure of ~~[632]~~ 650 psig are used in the analyses. ~~To allow for instrument accuracy, a [615] psig minimum and [655] psig maximum are specified.~~ 4 The maximum allowable boron concentration of ~~[2800]~~ 2200 ppm is based upon boron precipitation limits in the core following a LOCA. 2 Establishing a maximum limit for boron is necessary since the time at which boron precipitation would occur in the core following a LOCA is a function of break location, break size, the amount of boron injected into the core, and the point of ECCS injection. Post LOCA emergency procedures directing the operator to establish simultaneous hot and cold leg injection are based on the worst case minimum boron precipitation time. Maintaining the maximum SIT boron concentration within the upper limit ensures that the SITs do not invalidate this calculation. An excessive boron concentration in any of the borated water sources used for injection during a LOCA could result in boron precipitation earlier than predicted.

The minimum boron requirements of ~~[1500]~~ 1900 ppm are based on beginning of life reactivity values and are selected to ensure that the reactor will remain subcritical during the reflood stage of a large break LOCA. 2 During a large break LOCA, all control element assemblies (CEAs) are assumed not to insert into the core, and the initial reactor shutdown is

BASES

APPLICABLE SAFETY ANALYSES (continued)

accomplished by void formation during blowdown. Sufficient boron concentration must be maintained in the SITs to prevent a return to criticality during reflood. ~~Although this requirement is similar to the basis for the minimum boron concentration of the refueling water tank (RWT), the minimum SIT concentration is lower than that of the RWT since the SITs need not account for dilution by the RCS.~~ 1

The SITs satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO establishes the minimum conditions required to ensure that the SITs are available to accomplish their core cooling safety function following a LOCA. ~~[~~Four~~]~~ SITs are required to be OPERABLE to ensure that 100% of the contents of ~~[~~three~~]~~ of the SITs will reach the core during a LOCA. 2

This is consistent with the assumption that the contents of one tank spill through the break. If the contents of fewer than three tanks are injected during the blowdown phase of a LOCA, the ECCS acceptance criteria of 10 CFR 50.46 (Ref. 2) could be violated.

For an SIT to be considered OPERABLE, the isolation valve must be fully open, power removed above ~~[2000]~~ ~~psig~~, and the limits established in the SR for contained volume, boron concentration, and nitrogen cover pressure must be met. 2

1750 psia

APPLICABILITY

In MODES 1 and 2, and MODE 3 with RCS pressure ≥ ~~700~~ psia, the SIT OPERABILITY requirements are based on an assumption of full power operation. Although cooling requirements decrease as power decreases, the SITs are still required to provide core cooling as long as elevated RCS pressures and temperatures exist. 2

1750

This LCO is only applicable at pressures ≥ ~~700~~ psia. Below ~~700~~ psia, the rate of RCS blowdown is such that the ECCS pumps can provide adequate injection to ensure that peak clad temperature remains below the 10 CFR 50.46 (Ref. 2) limit of 2200°F. 2

1750 1750

In MODE 3, at pressures < ~~700~~ psia, and in MODES 4, 5, and 6, the SIT motor operated isolation valves are closed to isolate the SITs from the RCS. ~~This allows RCS cooldown and depressurization without discharging the SITs into the RCS or requiring depressurization of the SITs.~~ 5

1750

during unit shutdown and startup

BASES

ACTIONS

A.1

If the boron concentration of one SIT is not within limits, it must be returned to within the limits within 72 hours. In this condition, ability to maintain subcriticality or minimum boron precipitation time may be reduced, but the reduced concentration effects on core subcriticality during reflood are minor. Boiling of the ECCS water in the core during reflood concentrates the boron in the saturated liquid that remains in the core. In addition, the volume of the SIT is still available for injection. Since the boron requirements are based on the average boron concentration of the total volume of three SITs, the consequences are less severe than they would be if an SIT were not available for injection. Thus, 72 hours is allowed to return the boron concentration to within limits.

The combination of redundant level and pressure instrumentation for any single SIT provides sufficient information so that it is not worthwhile to always attempt to correct drift associated with one instrument, with the resulting radiation exposures during entry into containment, as there is sufficient time to repair one in the event that a second one became inoperable. Because these instruments do not initiate a safety action, it is reasonable to extend the allowable outage time for them. While technically inoperable, the SIT will be available to fulfill its safety function during this time and, thus, this Completion Time results in a negligible increase in risk.

B.1

If one SIT is inoperable, for reasons other than boron concentration or the inability to verify level or pressure, the SIT must be returned to OPERABLE status within 24 hours. In this Condition, the required contents of three SITs cannot be assumed to reach the core during a LOCA as is assumed in Appendix K (Ref. 5).

CE NPSD-994 (Ref. 6) provides a series of deterministic and probabilistic findings that support the 24 hour Completion Time as having no affect on risk as compared to shorter periods for restoring the SIT to OPERABLE status.

BASES

ACTIONS (continued)

C.1 and C.2

If the SIT cannot be restored to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and pressurizer pressure reduced to < ~~700~~ 1750 psia within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. 2

D.1

If more than one SIT is inoperable, the unit is in a condition outside the accident analyses. Therefore, LCO 3.0.3 must be entered immediately.

SURVEILLANCE REQUIREMENTS

SR 3.5.1.1

Verification that each SIT isolation valve is fully open, as indicated in the control room before power is removed from its valve operator, ensures that SITs are available for injection and ensures timely discovery if a valve should be partially closed. If an isolation valve is not fully open, the rate of injection to the RCS would be reduced. Although a motor operated valve should not change position with power removed, a closed valve could result in not meeting accident analysis assumptions. ~~[A 12 hour Frequency is considered reasonable in view of other administrative controls that ensure the unlikelihood of a mispositioned isolation valve.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.1.2 and SR 3.5.1.3

SIT borated water volume and nitrogen cover pressure should be verified to be within specified limits in order to ensure adequate injection during a LOCA. [Due to the static design of the SITs, a 12 hour Frequency usually allows the operator sufficient time to identify changes before the limits are reached. Operating experience has shown this Frequency to be appropriate for early detection and correction of off normal trends. 2

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement. 2
----------]

SR 3.5.1.4

Thirty-one days is reasonable for verification to determine that each SIT's boron concentration is within the required limits, because the static design of the SITs limits the ways in which the concentration can be changed. [The 31 day Frequency is adequate to identify changes that could occur from mechanisms such as stratification or inleakage. 2
Sampling the affected SIT within 6 hours after a 1% volume increase will identify whether inleakage has caused a reduction in boron concentration to below the required limit. It is not necessary to verify boron concentration if the added water is from the RWT, because the water contained in the RWT is within the SIT boron concentration requirements. This is consistent with the recommendations of NUREG-1366 (Ref. 4). 6

the boron concentration of

and assumes the RWT has not been diluted since the last time the RWT boron concentration was verified to be within limits.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

2

SR 3.5.1.5

Verification that power is removed from each SIT isolation valve operator ~~when the pressurizer pressure is ≥ 2000 psia~~ ensures that an active failure could not result in the undetected closure of an SIT motor operated isolation valve. If this were to occur, only two SITs would be available for injection, given a single failure coincident with a LOCA~~. [Since installation and~~ removal of power to the SIT isolation valve operators is conducted under administrative control~~, the 31 day Frequency was chosen to provide additional assurance that power is removed~~.

2

JUSTIFICATION FOR DEVIATIONS
ITS 3.5.1, BASES, SAFETY INJECTION TANKS (SITs)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The SIT instrument range percentage values, with and without allowance for instrument inaccuracy, that correspond to the minimum and maximum SIT volumes in cubic feet of borated water are deleted. The analyses are based upon the cubic feet requirements; the percentage values are provided for operator use. Plant procedures implement ITS SR 3.5.1.2 to verify borated water volume in each SIT and include appropriate unit of measurement and instrument accuracy allowances. Therefore, the instrument values and associated description for operator use are unnecessary. The SIT volume values retained in ITS 3.5.1.2 reflect the SIT volume values assumed in the PSL safety analysis.

4. The SIT instrument range values with allowance for instrument inaccuracy, correspond to the minimum and maximum SIT nitrogen pressures are deleted. The analyses are based upon the actual pressures; the instrument accuracy values are provided for operator use. Plant procedures implement ITS SR 3.51.3 to verify nitrogen cover pressure in each SIT and include appropriate unit of measurement and instrument accuracy allowances. Therefore, the instrument accuracy range in the ITS Bases is unnecessary. The SIT nitrogen cover pressure values retained in ITS 3.5.1.3 reflect the SIT pressure values assumed in the PSL safety analysis.

5. The ISTS Bases statement regarding why an SIT is isolated when not within the ITS Applicability is changed to state that the SIT isolation valves are closed to isolate the SITs from the RCS during unit shutdown and startup. Plant procedures implement shutdown and startup requirements including when the SITs may and may not be isolated from the RCS. This change is consistent with the ITS SR 3.5.1.5 description.

6. Additional clarification is added from the CTS to the Bases of ITS 3.5.1.4 to state that the SIT boron concentration verification is unnecessary because the boron concentration of the water contained in the RWT is within the SIT boron concentration requirements. This assumes the RWT has not been diluted since the last time the RWT boron concentration was verified to be within limits.

DISCUSSION OF CHANGES
ITS 3.5.2, ECCS - OPERATING

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.5.2 Actions a.1 and a.2 require in part, “or be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours.” when one ECCS subsystem cannot be restored to OPERABLE status within the required time. ITS 3.5.2 Required Action C.2 requires, when the Required Actions and associated Completion Times are not met, reducing pressurizer pressure to < 1750 psia within 12 hours (i.e., within the following 6 hours). This changes the end state in CTS 3.5.2 Actions a.1 and a.2 from HOT SHUTDOWN (MODE 4) to MODE 3 with pressurizer pressure < 1750 psia.

The purpose of CTS 3.5.2 Action a.1 and a.2 is to place the plant in a condition in which the equipment is no longer required. CTS 3.5.2 Action a.1 and a.2 provide appropriate actions to take for an inoperable ECCS subsystem when the unit is in MODE 1, 2, or 3 with pressurizer pressure is ≥ 1750 psia. The ECCS subsystems are not required to be OPERABLE when pressurizer pressure is < 1750 psia, as stated in CTS 3.5.2. Therefore, in accordance with CTS 3.0.2 (ITS LCO 3.0.2), when pressurizer pressure is < 1750 psia, the requirements to be in MODE 4 in CTS 3.5.1 Action a.1 and a.2 are no longer required to be completed. The ECCS subsystems, with pressurizer pressure below 1750 psia, are no longer required to be OPERABLE.

These changes are designated as administrative changes and are acceptable because they maintain the current requirement to place the unit in a condition in which the ECCS subsystems are no longer required consistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2) and, therefore, do not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.5.2 requires an OPERABLE charging pump. Unit 1 CTS 4.5.2.e.2 and f., and Unit 2 4.5.2.f.2 and g., require performance testing of the ECCS subsystems. CTS does not include a Surveillance Requirement for performance testing of the charging pumps. ITS SR 3.5.2.5 requires verification that the charging pumps develop a minimum required flow. ITS SR 3.5.2.5 requires this SR to be conducted in accordance with the INSERVICE TESTING PROGRAM. This changes the CTS by adding the ITS requirement to verify each charging pump develops a minimum required flow.

The purpose of ITS SR 3.5.2.5 is to verify charging flow within a testing Frequency required in accordance with the INSERVICE TESTING PROGRAM. This change is acceptable because it provides additional assurance that each charging pump will be capable of performing its function. This change is designated as more restrictive because it adds an SR to the CTS.

M02 CTS 4.5.2 does not contain surveillances for boric acid makeup tank (BAMT) volume and the BAMT concentration for the charging pump ECCS function. Similarly, ISTS 3.5.2 does not contain a surveillance for the BAMT volume and the boron concentration for the charging pump ECCS function. The ISTS 3.5.2 assumes the RWT as the ECCS water source for LPSI, HPSI, and charging ECCS subsystems. The PSL design connects the ECCS charging subsystem to the BAMTs. Though the charging subsystem can be aligned to the RWT, and the charging pump suction automatically aligns to the RWT on Volume Control Tank low level, the RWT to charging pump suction valve gets a close signal on a safety injection actuation signal. This changes the CTS by adding Surveillance Requirements for the BAMTs.

The Note to CTS 3.5.2.d refers to CTS 3.1.2.2 for charging subsystem flow path requirements and CTS 3.1.2.2 refers to CTS 3.1.2.8 for BAMT requirements including volume and boron concentration, respectively. However, these boration requirements are not related to the ECCS OPERABILITY but, rather, provide boration requirements to ensure the capability to restore shutdown margin during normal operations. The boration related Specifications, including CTS 3.1.2.2 and 3.1.2.8, are relocated to a licensee controlled document (e.g, Technical Requirements Manual). See DOC LA02 for a discussion of changes related to the relocation of the CTS 3.1.2.2 and 3.1.2.8 references in CTS 3.5.2.d Note.

The new ITS SR 3.5.2.10 and ITS SR 3.5.2.11 require verification that each BAMT volume is greater than or equal to the specified minimum required volume, and that each BAMT boron concentration is greater than or equal to the specified minimum required boron concentration. These Surveillances are necessary to periodically verify that a sufficient usable BAMT water volume level and boron concentration are available to the charging pump for injection during a small break LOCA (SBLOCA). PSL performed an engineering evaluation for the SBLOCA Analysis and determined that a minimum BAMT water volume of 3675 gallons for each tank provides adequate volume to meet the charging pump flow requirement credited in the SBLOCA analysis. A minimum BAMT water volume of 4000 gallons was selected to provide additional margin for future variations in the analysis. Additionally, although boron concentration from the charging flow is not directly credited in the SBLOCA analysis to maintain subcriticality, a minimum boron concentration that is equivalent to the minimum RWT boron concentration (i.e., ≥ 1900 ppm) is used for the charging pump flow.

The minimum boron concentration in the BAMT is important for the post-LOCA return to criticality analysis. This analysis determines the minimum sump boron concentration at the time of simultaneous hot/cold leg injection to confirm return to criticality does not occur. This analysis uses the minimum boron from the available sources, which includes the BAMTs. Currently, the analysis is strictly based on the RCS boron and minimum RWT boron concentration. With the

BAMT boron requirement being added to ITS 3.5.2, ECCS -Operating, the minimum BAMT boron concentration must be at least equal to the RWT minimum boron concentration. The maximum BAMT boron concentration is used in the post-LOCA long term boron precipitation analysis. The current analysis considers the volume of two full BAMTs (9975 gallons/tank) at a boron concentration that bounds the current maximum specified BAMT boron concentration parameters (volume and boron concentration). Thus, there is no need to specify a maximum boron concentration in ITS 3.5.2, ECCS – Operating.

PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, SR 3.5.2.10 and SR 3.5.2.11 will be performed at a Frequency in accordance with the Surveillance Frequency Control Program with an initial Frequency of 7 days consistent with the ISTS SR 3.5.4.2 Frequency for the RWT, and consistent with the CTS 4.1.2.8.a Frequency for the BAMT volume and boron concentration. The initial Frequency considers that the BAMT volume and boron concentration are normally stable. This changes the CTS by adding a Surveillance Requirement to verify that each BAMT volume is greater than or equal to the specified minimum required volume in accordance with the Surveillance Frequency Control Program and by adding a Surveillance Requirement to verify that each BAMT boron concentration is greater than or equal to the specified minimum required boron concentration in accordance with the Surveillance Frequency Control Program.

The purpose of this Surveillance is to assure that the necessary quality of systems and components is maintained. The Frequency is proposed to be specified in accordance with the Surveillance Frequency Control Program and is acceptable because the periodic Frequency is placed under licensee control pursuant to the methodology described in NEI 04-10, which is specified in ITS Section 5.5. The SFCP provides the necessary administrative controls to require that surveillances related to testing, calibration and inspection are conducted at a frequency to assure that the necessary quality of systems and components is maintained, that facility operation will be within safety limits, and that the limiting conditions for operation will be met. Florida Power & Light Company (FPL) has determined that the control of the periodic Frequency in accordance with the SFCP is consistent with the intent of TSTF-425, Revision 3, and with the NRC's model SE dated July 6, 2009 (*74 FR 32001*). The proposed Frequency of SR 3.5.2.10 is a periodic frequency and does not meet the scope exclusion criteria identified in Section 1.0, "Introduction," of the TSTF-425 model SE.

The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) “Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program” (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066). This change is designated as more restrictive because it adds additional requirements to the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.5.2 states, in part, that two independent ECCS subsystems shall be OPERABLE with each subsystem comprised of: (a) one OPERABLE high pressure safety injection (HPSI) pump, (b) one OPERABLE low pressure safety injection pump, (c) an independent OPERABLE flow path capable of taking suction from the refueling water tank on a safety injection actuation signal and automatically transferring suction to the containment sump on a recirculation actuation signal, and (d) one OPERABLE charging pump. Similarly, Unit 1 CTS 4.5.2.e.2 and f, and Unit 2 CTS 4.5.2.f.2 and g, state, in part, the ECCS pumps (i.e., HPSI, LPSI, Charging) to be tested that are part of an OPERABLE ECCS train. ITS 3.5.2 does not contain this level of detail of what constitutes OPERABILITY. This changes the CTS by moving details concerning what constitutes an OPERABLE ECCS train, and that the two systems must be "independent" to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for two ECCS trains to be OPERABLE and is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 3.5.2.d Note states “One ECCS subsystem charging pump shall satisfy the flow path requirements of Specification 3.1.2.2.a or 3.1.2.2.d. The second ECCS subsystem charging pump shall satisfy the flow path requirements of Specification 3.1.2.2.b or 3.1.2.2.e”. ITS LCO 3.5.2 does not include details associated with the flow path requirements necessary to support a ECCS charging subsystem. This changes the CTS by removing details related to a ECCS charging subsystem and relocating required details to the ITS Bases.

As stated in the NRC safety evaluation (SE) associated with the Unit 2 extended power uprate (See NRC to FPL letter dated July 9, 2012; NRC ADAMS Accession No. ML12268A167), the purpose of the CTS Note is to assure that ECCS sources credited in the LOCA analysis are available to support the charging subsystems. ITS LCO 3.5.2 states that two ECCS trains shall be OPERABLE. The details of the OPERABILITY requirements associated with the

ECCS trains are addressed by the Surveillance Requirements and the ITS Bases.

The purpose of CTS 3.1.2.2 requirements (referenced in CTS 3.5.2.d Note) is to ensure a means to control the chemical neutron absorber (boron) concentration in the Reactor Coolant System (RCS) is available and to provide adequate requirements to restore shutdown margin during normal operations. These boration requirements are not related to the ECCS OPERABILITY requirements. Referencing reactivity control Specifications for compliance with ECCS is inappropriate and could result in requirements inconsistent with the LOCA analysis. In addition, the boration-related Specifications, including the Specifications referenced in the CTS 3.5.2.d Note are relocated to a licensee controlled document (e.g., Technical Requirements Manual) - see ITS 3.1 Deleted - Relocated Specifications. Therefore, to avoid confusion between boration requirements, as specified in CTS 3.1.2.2, and the charging subsystem requirements to support ECCS OPERABILITY, the ITS Bases relocates sufficient detail to the ITS Bases to assure that ECCS sources (e.g., charging subsystems) credited in the LOCA analysis are available. The proposed ITS Bases states, in part:

> "Charging pump flow paths take suction from OPERABLE BAMTs (e.g., volume within required limit) and supplies the RCS via the normal charging lines.
>
> One charging pump flow path taking suction from either a single BAMT via the associated boric acid makeup pump, or both BAMTs via both boric acid makeup pumps. A second charging pump flow path taking suction from either a single BAMT via gravity feed valves, or both BAMTs via gravity feed valves."

The removal of these details for charging pump flow paths to meet operability requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS LCO 3.5.2 and the associated Surveillance Requirements retain sufficient requirements to assure two OPERABLE ECCS trains, which includes two OPERABLE charging subsystems. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA03 *(Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program, or Surveillance Frequency Control Program)* Unit 1 CTS 4.5.2.c and Unit 2 4.5.2.d state "By a visual inspection which verifies that no loose debris (rags, trash, clothing, etc.) is present in the containment which could be transported to the containment sump and cause restriction of the pump suctions during LOCA conditions. This visual inspection shall be performed: For all accessible areas of the containment prior

to establishing CONTAINMENT INTEGRITY, and at least once daily of the areas affected within containment by the containment entry and during the final entry when CONTAINMENT INTEGRITY is established." ITS 3.5.2 does not include these Surveillances. This changes the CTS by removing the Surveillance for visual inspections inside Containment and relocating them to the Technical Requirements Manual.

The removal of these visual inspections from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications in order to provide adequate protection of public health and safety. The ITS retains the Surveillance to perform a visual inspection of each ECCS train containment sump suction inlet to ensure that it is not restricted by debris and the suction inlet trash racks and screens show no evidence of structural distress or abnormal corrosion. Periodic inspections of each ECCS train containment sump suction inlet ensure that it is unrestricted and stays in proper operating condition. Also, this change is acceptable because these types of procedural details will be adequately controlled in the TRM. Changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because visual inspections inside Containment are being removed from the Technical Specifications. | R1

LA04 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS 4.5.2.e.3 and Unit 2 4.5.2.f.3 each state "Verifying that upon receipt of an actual or simulated Recirculation Actuation Signal: each low-pressure safety injection pump stops, each containment sump isolation valve opens, each refueling water tank outlet valve closes, and each safety injection system recirculation valve to the refueling water tank closes." ITS does not contain details for automatic valve positioning in response to an actuation signal. ITS SR 3.5.2.6 and ITS SR 3.5.2.8 demonstrate that each automatic ECCS valve actuates to the required position on an actual or simulated SIAS and on an RAS, and that the LPSI pumps stop on receipt of an actual or simulated RAS. This changes the CTS by deleting the details that state, in part, that upon receipt of an actual or simulated Recirculation Actuation Signal, each containment sump isolation valve opens, each refueling water tank outlet valve closes, and each safety injection system recirculation valve to the refueling water tank closes.

The removal of these details for performing surveillance requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the Surveillance Requirements to demonstrate that each automatic ECCS valve actuates to the required position on an actual or simulated SIAS and on an RAS. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 - Relaxation of Required Action)* CTS 3.5.2 Action a.2 states that with one ECCS subsystem inoperable for reasons other than condition a.1 (i.e., one LPSI subsystem inoperable), restore the inoperable subsystem to OPERABLE status within 72 hours or in accordance with the Risk Informed Completion Time. ITS 3.5.2 Action B states, with "one or more" trains inoperable for reasons other than Condition A, restore the train(s) to OPERABLE status within 72 hours or in accordance with the Risk Informed Completion Time. Additionally, ITS 3.5.2 Action D states that with less than 100% of the ECCS flow equivalent to a single OPERABLE ECCS train available, enter LCO 3.0.3 immediately. CTS does not provide an action for the condition with less than 100% of the ECCS flow equivalent to a single OPERABLE ECCS subsystem.

This changes the CTS by allowing combinations of equipment in each train to be credited with meeting the ECCS safety function provided 100% of the ECCS flow equivalent to a single OPERABLE ECCS train is available. For example, under the CTS an inoperable HPSI pump in one train and an inoperable LPSI pump in the other train would require an immediate entry into CTS 3.0.3. Under the ITS, the same condition would allow 72 hours before requiring a shutdown because the remaining OPERABLE HPSI pump and LPSI pump are capable of producing flow equivalent to a single OPERABLE ECCS train.

The purpose of CTS 3.5.2 Action a.2 is to limit the period of time the plant can operate without redundant ECCS trains. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to degraded conditions in order to minimize risk associated with continued plant operation while providing time to repair inoperable equipment. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABILITY status of the remaining ECCS equipment, a reasonable time for repairs or replacement of required equipment, and the low probability of a design basis accident occurring during the time period. ITS 3.5.2 Action B continues to ensure that the capability of the equivalent of an ECCS train is available and limits the time in this condition to 72 hours. The ECCS in this condition can still perform its safety function, assuming no single failure occurs. ITS 3.5.2 Action D continues to ensure that there are necessary actions to place the plant in a safe condition outside of the Mode of Applicability since the ECCS safety function for 100% ECCS flow equivalent to a single ECCS train is no longer available. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 9 – Deletion of Reporting Requirements)* Unit 1 CTS 3.5.2 Action b. states "In the event the ECCS is actuated and injects water into the Reactor Coolant System, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days describing the circumstances of the actuation and the total accumulated actuation cycles to date." Unit 2 CTS 3.5.2 Action b. states "In the event the ECCS is actuated and injects water into the Reactor Coolant System, a Special Report shall be

prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days describing the circumstances of the actuation and the total accumulated actuation cycles to date. The current value of the usage factor for each affected safety injection nozzle shall be provided in this Special Report whenever its value exceeds 0.70." ITS 3.5.2 does not contain this CTS 90-day Special Report requirement in the event the ECCS is actuated and injects water into the RCS. ITS 3.5.2 retains the ACTIONS for inoperable ECCS trains. This changes the CTS by deleting this 90-day Special Report.

The removal of these details for making reports from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the LCO for two ECCS trains to be OPERABLE and ACTIONS when one or more ECCS trains are inoperable. Deletion of the ECCS reporting requirement is acceptable since 10 CFR 50.72(b)(2)(iv) requires a 4 hour notification in the event of an unplanned ECCS actuation and injection into the RCS. Additionally, 10 CFR 50.73(2)(iv)(A) also requires submission of a licensee event report for any unplanned event or condition that resulted in manual or automatic actuation of ECCS. PSL Unit 1 and Unit 2 operating licenses require compliance with 10 CFR 50.72 and 50.73. Therefore, the CTS requirement is unnecessary. Requirements continue to be provided in ITS to mitigate a DBA while in MODES 1, 2 and 3 with pressurizer pressure ≥ 1750 psia. This change is designated as less restrictive because reports that would be submitted under the CTS will not be required under the ITS.

L03 *(Category 8 – Deletion of Surveillance Requirement Shutdown Performance Requirements)* Unit 1 CTS 4.5.2.e and Unit 2 CTS 4.5.2.f contain the requirement to perform the test "during shutdown." ITS SR 3.5.2.6, SR 3.5.2.7, and SR 3.5.2.8 do not specify conduct of the test to occur during shutdown. This changes the CTS by deleting the requirement to perform these Surveillances during shutdown. | R1

The purpose of Unit 1 CTS 4.5.2.e and Unit 2 CTS 4.5.2.f is to demonstrate that each automatic ECCS valve actuates to the required position on an actual or simulated SIAS and on an RAS, that each ECCS pump starts on receipt of an actual or simulated SIAS, and that the LPSI pumps stop and each automatic containment sump, RWT outlet, and SI recirc valve actuates to the required position on receipt of an actual or simulated RAS.

The proposed Surveillance does not include the restriction that it be performed during shutdown. The control of unit conditions appropriate to perform the test is an issue for procedures and scheduling and has been determined by the NRC Staff to be unnecessary as a Technical Specification restriction. As indicated in Generic Letter 91-04, removal of this specific restriction is consistent with the vast majority of other Technical Specification Surveillances that do not dictate unit conditions for the Surveillance. This change is designated as less restrictive because the Surveillance may be performed during plant conditions other than shutdown.

L04 *(Category 5 – Deletion of Surveillance Requirement)* Unit 1 CTS 4.5.2.e.1 and Unit 2 CTS 4.5.2.f.1 require verification that each automatic ECCS valve in the

flow path actuates to its correct position. ITS SR 3.5.2.6 requires verification that each automatic ECCS valve in the flow path "that is not locked, sealed, or otherwise secured in position" actuates to the correct position. This changes the CTS by deleting the Surveillance Requirement for those valves that are locked, sealed, or otherwise secured in position.

The purpose of Unit 1 CTS 4.5.2.e.1 and Unit 2 CTS 4.5.2.f.1 is to provide assurance that if an event occurred requiring ECCS valves to be in their correct position, then those requiring automatic actuation would actuate to their correct position. This change is acceptable because the deleted Surveillance is not necessary to verify that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to provide confidence that the equipment can perform its assumed safety function. Those automatic valves that are locked, sealed, or otherwise secured in position are not required to actuate on a safety injection actuation signal or a recirculation actuation signal in order to perform their safety function because they are already in the required position. Testing such valves would not provide any additional assurance of OPERABILITY. Valves that are required to actuate will continue to be tested. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L05 *(Category 6 – Relaxation Of Surveillance Requirement Acceptance Criteria)* Unit 1 CTS 4.5.2.e.1 and e.2 and Unit 2 4.5.2.f.1 and f.2 state, in part, that automatic valve actuations (e.1, f.1) and automatic pump actuations (e.2, f.2) occur upon receipt of a Safety Injection Actuation Signal. ITS SR 3.5.2.6 and SR 3.5.2.7 allow the use of a simulated or actual signal when performing these tests. This changes the CTS by allowing the use of unplanned actuations to perform the Surveillance based on the collection of sufficient information to satisfy the surveillance test requirements.

The purpose of CTS is to demonstrate that each automatic ECCS valve actuates to the required position on an SIAS and on an RAS, that each ECCS pump starts on receipt of an SIAS, and that the LPSI pumps stop on receipt of an RAS. This change is acceptable because the channel itself cannot discriminate between an "actual" or "simulated" signal. Therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change is designated as less restrictive because it allows an actual signal to be credited for Surveillance where only a simulated signal was previously allowed in the CTS.

L06 **Unit 2 Only:** *(Category 7 - Relaxation of Surveillance Frequency)* CTS 4.5.2.h.1 states, in part, that verification of the correct position of each electrical and/or mechanical position stop for ECCS throttle valves is required “during valve stroking operation or following maintenance on the valve and prior to declaring the valve OPERABLE when the ECCS subsystems are required to be OPERABLE.” ISTS SR 3.5.2.1 states “Verify, for each ECCS throttle valve listed below, each position stop is in the correct position.” The ITS Surveillance does not require the valve position stop verification during valve stroking operation or following maintenance on the valve. This changes the CTS by deleting the Surveillance frequency requirement “during valve stroking operation or following

maintenance on the valve and prior to declaring the valve OPERABLE when the ECCS subsystems are required to be OPERABLE."

The purpose of CTS 4.5.h.1 is verification of the correct position of each electrical and/or mechanical position stop for ECCS throttle valves. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a frequency necessary to give confidence that the equipment can perform its assumed safety function. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

L07 **Unit 2 Only:** *(Category 5 – Deletion of Surveillance Requirement)* CTS 4.5.2.a states in part, that each ECCS subsystem shall be demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program by verifying that the following valves are in the indicated positions with power to the valve operators removed. These valves include Safety Injection Tank (SIT) Vent Valves V3733, V3734, V3735, V3736, V3737, V3738, V3739, V3740. CTS 3.5.2 (ITS LCO 3.5.2) requires two ECCS subsystems to be OPERABLE with each subsystem comprised of one high-pressure safety injection (HPSI) pump, one low-pressure safety injection pump, flow path taking suction from the refueling water tank, and one charging pump. CTS 3.5.2 does not include the SITs as components of an ECCS subsystem. The SIT ECCS function is addressed in CTS 3.5.1 (ITS LCO 3.5.1). Neither ITS 3.5.1 nor 3.5.2 contains a Surveillance to verify the SIT vent valves are locked closed with power to the valve operators removed. This changes the CTS by deleting the Surveillance of verifying SIT vent valves are locked closed with power to the valve operators removed.

The purpose of CTS 4.5.2.a is to verify SIT vent valves are locked in the correct position with power to the valve operators removed to ensure a valve mispositioning event cannot occur, rendering the ECCS inoperable. The basis for this Surveillance, as described in the Bases of ISTS SR 3.5.2.1, is to ensure an inadvertent valve misalignment or active failure, similar to those described in IE Information Notice No. 87-01, does not result in disabling the function of both ECCS trains (subsystems) and invalidate the accident analysis. The SIT vent valves are not required to meet the LCO of CTS 3.5.2 and do not support the OPERABILITY of the ECCS subsystems. The SIT vent valves support OPERABILITY of the SITs by maintaining the integrity of the SIT pressure boundary. This change is acceptable because during a plant startup, the SIT vent valves must be closed to pressurize the SITs and meet the nitrogen cover pressure requirements of CTS 3.5.1.d and 4.5.1.1.a.1. This ensures the SITs are pressurized and available to inject its contents in the event of a LOCA. Thus, appropriate equipment continues to be tested in a manner and at a frequency necessary to give confidence that the equipment can perform its assumed safety function. Additionally, the SIT vent valves are designed to fail close on loss of power and a vent valve misposition will only affect one SIT. Therefore, an inadvertent valve misalignment or active failure, similar to those described in IE Information Notice No. 87-01, will not result in disabling the SIT ECCS function. Any SIT vent valve misposition will also result in a decrease of nitrogen cover pressure below the CTS 3.5.1.d (ITS SR 3.5.1.3) requirement requiring the associated SIT to be declared inoperable and appropriate actions

performed. Therefore, the deleted Surveillance Requirement is not necessary to support OPERABILITY of the ECCS subsystems and is not necessary to ensure that the SITs can perform their required ECCS function~~s~~.

This change is designated as less restrictive because a Surveillance~~s~~ which is required in the CTS will not be required in the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.5.2, ECCS - OPERATING

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal. The adoption of this Condition is contingent upon implementation of a program to perform a contemporaneous assessment of the overall impact on safety of proposed plant configurations prior to performing and during performance of maintenance activities that remove equipment from service. St. Lucie Plant Unit 1 and Unit 2 Current Technical Specifications (CTS) were revised in Amendments 247 and 199, for Unit 1 and Unit 2 respectively, are revised to adopt a Risk Informed Completion Time (RICT) Program on July 2, 2019 (ADAMS Accession No. ML19113A099).

4. ISTS does not provide a Surveillance Requirement for visual inspection of the ECCS containment sump suction inlets for debris and the suction inlet trash racks and screens for evidence of structural distress or abnormal corrosion. Unit 1 CTS 4.5.2.d.2 and Unit 2 CTS 4.5.2.e.2 Surveillances requiring a containment sump visual inspection of ECCS pump suction inlets, are similar to the visual inspection required by ISTS SR 3.6.13.1. However, FPL is not adopting the ISTS 3.6.13 requirements but rather is retaining the current Surveillance. The ISTS is changed by adding ITS SR 3.2.5.9 for Unit 1 and SR 3.5.2.1 for Unit 2. ISTS SR 3.5.2.9 does not apply to PSL Unit 1 since mechanical stops are not required in the Unit 1 licensing basis. The Unit 1 ECCS design includes flow limiting orifices. Therefore, the ISTS SR 3.5.2.9 text is replaced with the proposed Surveillance Requirement in Unit 1 ITS. ISTS SR 3.5.2.1 does not apply for PSL Unit 2 since there is no single valve that could be mispositioned that would result in a loss of both ECCS trains as described in the ISTS Bases of SR 3.5.2.1. Therefore, the ISTS SR 3.5.2.1 text is replaced with the proposed Surveillance Requirement in the Unit 2 ITS.

5. ISTS 3.5.2 does not contain surveillances for the boric acid makeup tank (BAMT) volume and boron concentration for the charging pump ECCS function. The ISTS 3.5.2 assumes the refueling water tank (RWT) as the ECCS water source for low pressure safety injection, high pressure safety injection, and charging ECCS subsystems. The PSL design connects the ECCS charging subsystem to the BAMTs. Though the charging subsystem can be aligned to the RWT, and the charging pump suction automatically aligns to the RWT on Volume Control Tank low level, the RWT to charging pump suction valve gets a close signal on a safety injection actuation signal. This change adds SR 3.5.2.10 to verify that each BAMT volume is greater than or equal to the specified minimum required volume in accordance with the Surveillance Frequency Control Program and adds SR 3.5.2.11 to verify that each BAMT minimum concentration is greater than or equal to the specified minimum required boron concentration in accordance with the Surveillance Frequency Control Program. These new Surveillances are necessary to periodically verify that a sufficient usable BAMT water volume and boron concentration are available to the charging pump for injection during a small break LOCA. DOC M02

provides additional discussion of change for adding SR 3.5.2.10 and its Frequency and adding SR 3.5.2.11 and its Frequency.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.2 ECCS - Operating

BASES

BACKGROUND

The function of the ECCS is to provide core cooling and negative reactivity to ensure that the reactor core is protected after any of the following accidents:

a. Loss of coolant accident (LOCA),

b. Control Element Assembly (CEA) ejection accident,

c. Loss of secondary coolant accident, including uncontrolled steam release or loss of feedwater, and

d. Steam generator tube rupture (SGTR).

The addition of negative reactivity is designed primarily for the loss of secondary coolant accident where primary cooldown could add enough positive reactivity to achieve criticality and return to significant power.

There are two phases of ECCS operation: injection and recirculation. In the injection phase, all injection is initially added to the Reactor Coolant System (RCS) via the cold legs. ~~After the blowdown stage of the LOCA stabilizes, injection flow is split equally between the hot and cold legs.~~ After the refueling water tank (RWT) has been depleted, the ECCS recirculation phase is entered as the ECCS suction is automatically transferred to the containment sump.

1

Two redundant, 100% capacity trains are provided. In MODES 1, 2, and 3, with pressurizer pressure ≥ ~~1700~~ 1750 psia, each train consists of high pressure safety injection (HPSI), low pressure safety injection (LPSI), and charging subsystems. In MODES 1, 2, and 3, with pressurizer pressure ≥ ~~1700~~ 1750 psia, both trains must be OPERABLE. This ensures that 100% of the core cooling requirements can be provided in the event of a single active failure.

1

1

A suction header supplies water from the RWT or the containment sump to the ECCS pumps. Separate piping supplies each train. The discharge headers from each HPSI pump divide into four supply lines. Both HPSI trains feed into each of the four injection lines. The discharge header from each LPSI pump ~~divides into two supply lines~~ combine to a common header, then divide into four injection lines, each feeding ~~the~~ one ~~injection line to two~~ RCS cold leg~~s~~. Control valves or orifices are set to balance the flow to the RCS. This flow balance directs sufficient flow to the core to meet the analysis assumptions following a LOCA in one of the RCS cold legs.

1

1

BASES

BACKGROUND (continued)

For LOCAs that are too small to initially depressurize the RCS below the shutoff head of the HPSI pumps, the charging pumps supply water to maintain inventory until the RCS pressure decreases below the HPSI pump shutoff head. During this period, the steam generators (SGs) must provide the core cooling function. The charging pumps take suction from the ~~RWT~~ on a safety injection actuation signal (SIAS) and discharge directly to the RCS through a common header. ~~The normal supply source for the charging pumps is isolated on an SIAS to prevent noncondensible gas (e.g., air, nitrogen, or hydrogen) from being entrained in the charging pumps.~~

boric acid makeup tanks (BAMTs) via gravity feed valves or boric acid makeup pump discharge valves

1 4

During low temperature conditions in the RCS, limitations are placed on the maximum number of HPSI pumps that may be OPERABLE. Refer to the Bases for LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System," for the basis of these requirements.

During a large break LOCA, RCS pressure will decrease to < 200 psia in < 20 seconds. The safety injection (SI) systems are actuated upon receipt of an SIAS. The actuation of safeguard loads is accomplished in a programmed time sequence. If offsite power is available, the safeguard loads start immediately in the programmed sequence. If offsite power is not available, the Engineered Safety Feature (ESF) buses shed normal operating loads and are connected to the diesel generators (DGs). Safeguard loads are then actuated in the programmed time sequence. The time delay associated with diesel starting, sequenced loading, and pump starting determines the time required before pumped flow is available to the core following a LOCA.

1

E

emergency

1

and

The active ECCS components, along with the passive safety injection tanks (SITs)~~,~~ the RWT~~, and the containment sump, are~~ covered in LCO 3.5.1, "Safety Injection Tanks (SITs)," LCO 3.5.4, "Refueling Water Tank (RWT)," ~~and LCO 3.8.13, "Containment Sump,"~~ provide the cooling water necessary to meet GDC 35 (Ref. 1).

1

3

and

APPLICABLE SAFETY ANALYSES

The LCO helps to ensure that the following acceptance criteria, established by 10 CFR 50.46 (Ref. 2) for ECCSs, will be met following a LOCA:

a. Maximum fuel element cladding temperature is ≤ 2200°F,

b. Maximum cladding oxidation is ≤ 0.17 times the total cladding thickness before oxidation,

1

BASES

APPLICABLE SAFETY ANALYSES (continued)

c. Maximum hydrogen generation from a zirconium water reaction is ≤ 0.01 times the hypothetical amount generated if all of the metal in the cladding cylinders surrounding the fuel, excluding the cladding surrounding the plenum volume, were to react,

d. Core is maintained in a coolable geometry, and

e. Adequate long term core cooling capability is maintained.

The LCO also limits the potential for a post trip return to power following a steam line break (SLB) and ensures that containment temperature limits are met.

Both HPSI and LPSI subsystems are assumed to be OPERABLE in the large break LOCA analysis at full power (Ref. 3). This analysis establishes a minimum required runout flow for the HPSI and LPSI pumps, as well as the maximum required response time for their actuation. The HPSI pumps and charging pumps are credited in the small break LOCA analysis. This analysis establishes the flow and discharge head requirements at the design point for the HPSI pump. The SGTR and SLB analyses also credit the HPSI pumps, but are not limiting in their design.

The large break LOCA event with a loss of offsite power and a single failure (disabling one ECCS train) establishes the OPERABILITY requirements for the ECCS. During the blowdown stage of a LOCA, the RCS depressurizes as primary coolant is ejected through the break into the containment. The nuclear reaction is terminated either by moderator voiding during large breaks or control element assembly (CEA) insertion during small breaks. Following depressurization, emergency cooling water is injected into the cold legs, flows into the downcomer, fills the lower plenum, and refloods the core.

On smaller breaks, RCS pressure will stabilize at a value dependent upon break size, heat load, and injection flow. The smaller the break, the higher this equilibrium pressure. In ~~all~~ LOCA analyses, injection flow is not credited until RCS pressure drops below the shutoff head of the HPSI pumps. 1

BASES

APPLICABLE SAFETY ANALYSES (continued)

The LCO ensures that an ECCS train will deliver sufficient water to match decay heat boiloff rates soon enough to minimize core uncovery for a large LOCA. It also ensures that the HPSI pump will deliver sufficient water during a small break LOCA and provide sufficient boron to maintain the core subcritical following an SLB. For smaller LOCAs, the charging pumps deliver sufficient fluid to maintain RCS inventory until the RCS can be depressurized below the HPSI pumps' shutoff head. During this period of a small break LOCA, the SGs continue to serve as the heat sink providing core cooling.

ECCS - Operating satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

In MODES 1, 2, and 3, with pressurizer pressure ≥ ~~1700~~ 1750 psia, two independent (and redundant) ECCS trains are required to ensure that sufficient ECCS flow is available, assuming there is a single failure affecting either train. Additionally, individual components within the ECCS trains may be called upon to mitigate the consequences of other transients and accidents. 1

In MODES 1 and 2, and in MODE 3 with pressurizer pressure ≥ ~~1700~~ 1750 psia, an ECCS train consists of an HPSI subsystem, an LPSI subsystem, and a charging pump. 1

Each ~~train~~ HPSI and LPSI subsystem includes the piping, instruments, and controls to ensure the availability of an OPERABLE flow path capable of taking suction from the RWT on an SIAS and automatically transferring suction to the containment sump upon a recirculation actuation signal (RAS). Management of gas voids is important to ECCS OPERABILITY. 1

During an event requiring ECCS actuation, a flow path is provided to ensure an abundant supply of water from the RWT to the RCS, via the HPSI and LPSI pumps and their respective supply headers, to each of the four cold leg injection nozzles. In the long term, this flow path may be switched to take its supply from the containment sump and to supply part of its flow to the RCS hot legs via the shutdown cooling (SDC) suction nozzles. ~~The~~ charging pump flow path take~~s~~ s suction from the ~~RWT~~ BAMT(s) and supplies the RCS via the normal charging lines. 1

The flow path for each train must maintain its designed independence to ensure that no single failure can disable both ECCS trains.

One charging pump flow path taking suction from either a single BAMT via the associated boric acid makeup pump, or both BAMTs via both boric acid makeup pumps. A second charging pump flow path taking suction from either a single BAMT via gravity feed valves, or both BAMTs via gravity feed valves. 4

BASES

APPLICABILITY

In MODES 1 and 2, and in MODE 3 with RCS pressure ≥ ~~1700~~ 1750 psia, the ECCS OPERABILITY requirements for the limiting Design Basis Accident (DBA) large break LOCA are based on full power operation. Although reduced power would not require the same level of performance, the accident analysis does not provide for reduced cooling requirements in the lower MODES. The HPSI pump performance is based on the small break LOCA, which establishes the pump performance curve and has less dependence on power. The charging pump performance requirements are based on a small break LOCA. The requirements of MODES 2 and 3, with RCS pressure ≥ ~~1700~~ 1750 psia, are bounded by the MODE 1 analysis. 1

The ECCS functional requirements of MODE 3, with RCS pressure < ~~1700~~ 1750 psia, and MODE 4 are described in LCO 3.5.3, "ECCS - Shutdown." 1

In MODES 5 and 6, unit conditions are such that the probability of an event requiring ECCS injection is extremely low. Core cooling requirements in MODE 5 are addressed by LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," and LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled." MODE 6 core cooling requirements are addressed by LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level," and LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level."

ACTIONS

A.1

With one LPSI subsystem inoperable, action must be taken to restore OPERABLE status within 7 days ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. In this condition, the remaining OPERABLE ECCS train is adequate to perform the heat removal function. However, the overall reliability is reduced because a single failure to the remaining LPSI subsystem could result in loss of ECCS function. The 7 day Completion Time is reasonable to perform corrective maintenance on the inoperable LPSI subsystem. The 7 day Completion Time is based on the findings of the deterministic and probabilistic analysis in Reference 6. Reference 6 concluded that extending the Completion Time to 7 days for an inoperable LPSI train provides plant operational flexibility while simultaneously reducing overall plant risk. This is because the risks incurred by having the LPSI train unavailable for a longer time at power will be substantially offset by the benefits associated with avoiding unnecessary plant transitions and by reducing risk during plant shutdown operations. 2

BASES

ACTIONS (continued)

B.1

If one or more trains are inoperable except for reasons other than Condition A (one LPSI subsystem inoperable) and at least 100% of the ECCS flow equivalent to a single OPERABLE ECCS train is available, the inoperable components must be returned to OPERABLE status within 72 hours [or in accordance with the Risk Informed Completion Time Program]. The 72 hour Completion Time is based on an NRC study (Ref. 4) using a reliability evaluation and is a reasonable amount of time to effect many repairs. 2

An ECCS train is inoperable if it is not capable of delivering the design flow to the RCS. The individual components are inoperable if they are not capable of performing their design function, or if supporting systems are not available.

The LCO requires the OPERABILITY of a number of independent subsystems. Due to the redundancy of trains and the diversity of subsystems, the inoperability of one component in a train does not render the ECCS incapable of performing its function. Neither does the inoperability of two different components, each in a different train, necessarily result in a loss of function for the ECCS. This allows increased flexibility in plant operations when components in opposite trains are inoperable.

An event accompanied by a loss of offsite power and the failure of an emergency DG can disable one ECCS train until power is restored. A reliability analysis (Ref. 4) has shown that the impact with one full ECCS train inoperable is sufficiently small to justify continued operation for 72 hours.

Reference 5 describes situations in which one component, such as a shutdown cooling total flow control valve, can disable both ECCS trains. With one or more components inoperable, such that 100% of the equivalent flow to a single OPERABLE ECCS train is not available, the facility is in a condition outside the accident analyses. Therefore, LCO 3.0.3 must be immediately entered.

BASES

ACTIONS (continued)

C.1 and C.2

If the inoperable train cannot be restored to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and pressurizer pressure reduced to <~~1700~~ psia within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power in an orderly manner and without challenging unit systems.

1750

1

D.1

D is applicable with less than 100% of the ECCS flow equivalent to a single OPERABLE train available.

Condition ~~B is applicable with one or more trains inoperable~~. The allowed Completion Time is based on the assumption that at least 100% of the ECCS flow equivalent to a single OPERABLE ECCS train is available. With less than 100% of the ECCS flow equivalent to a single OPERABLE ECCS train available, the facility is in a condition outside of the accident analyses. Therefore, LCO 3.0.3 must be entered immediately.

of Condition B

5

SURVEILLANCE REQUIREMENTS

SR 3.5.2.1

Verification of proper valve position ensures that the flow path from the ECCS pumps to the RCS is maintained. Misalignment of these valves could render both ECCS trains inoperable. Securing these valves in position by removing power ~~or by key locking the control in the correct position~~ ensures that the valves cannot be inadvertently misaligned or change position as the result of an active failure. These valves are of the type described in Reference 5, which can disable the function of both ECCS trains and invalidate the accident analysis. ~~[A 12 hour Frequency is considered reasonable in view of other administrative controls ensuring that a mispositioned valve is an unlikely possibility.~~

The two series minimum flow isolation valves are common to the HPSI, LPSI, and containment spray pumps. Therefore, it is critical that these valves must be maintained open during the initial phase of a LOCA to prevent ECCS pump damage as a result of the pumps operating at shutoff head.

1

1

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

2

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.2.2

Verifying the correct alignment for manual, power operated, and automatic valves in the ECCS flow paths provides assurance that the proper flow paths will exist for ECCS operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these valves were verified to be in the correct position prior to locking, sealing, or securing. A valve that receives an actuation signal is allowed to be in a nonaccident position provided the valve automatically repositions within the proper stroke time. This Surveillance does not require any testing or valve manipulation. Rather, it involves verification that those valves capable of being mispositioned are in the correct position.

[The 31 day Frequency is appropriate because the valves are operated under procedural control and an improper valve position would only affect a single train. This Frequency has been shown to be acceptable through operating experience.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

2

2

The Surveillance is modified by a Note which exempts system vent flow paths opened under administrative control. The administrative control should be proceduralized and include stationing a dedicated individual at the system vent flow path who is in continuous communication with the operators in the control room. This individual will have a method to rapidly close the system vent flow path if directed.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.2.3

ECCS piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the ECCS and may also prevent water hammer, pump cavitation, and pumping of noncondensible gas into the reactor vessel.

Selection of ECCS locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

The ECCS is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. If accumulated gas is discovered that exceeds the acceptance criteria for the susceptible location (or the volume of accumulated gas at one or more susceptible locations exceeds an acceptance criteria for gas volume at the suction or discharge of a pump), the Surveillance is not met. If the accumulated gas is eliminated or brought within the acceptance criteria limits during performance of the Surveillance, the Surveillance is met and past system OPERABILITY is evaluated under the Corrective Action Program. If it is determined by subsequent evaluation that the ECCS is not rendered inoperable by the accumulated gas (i.e., the system is sufficiently filled with water), the Surveillance may be declared met. Accumulated gas should be eliminated or brought within the acceptance criteria limits. | R1

ECCS locations susceptible to gas accumulation are monitored and, if gas is found, the gas volume is compared to the acceptance criteria for the location. Susceptible locations in the same system flow path which are subject to the same gas intrusion mechanisms may be verified by monitoring a representative sub-set of susceptible locations. Monitoring may not be practical for locations that are inaccessible due to radiological or environmental conditions, the plant configuration, or personnel safety. For these locations alternative methods (e.g., operating parameters, remote monitoring) may be used to monitor the susceptible location. Monitoring is not required for susceptible locations where the maximum potential accumulated gas void volume has been evaluated and

BASES

SURVEILLANCE REQUIREMENTS (continued)

determined to not challenge system OPERABILITY. The accuracy of the method used for monitoring the susceptible locations and trending of the results should be sufficient to assure system OPERABILITY during the Surveillance interval.

~~[The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the ECCS piping and the adequacy of the procedural controls governing system operation.~~
~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. The Surveillance Frequency may vary by location susceptible to gas accumulation.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

SR 3.5.2.4

Periodic surveillance testing of ECCS pumps to detect gross degradation caused by impeller structural damage or other hydraulic component problems is required by the ASME Code. This type of testing may be accomplished by measuring the pump developed head at only one point of the pump characteristic curve. This verifies both that the measured performance is within an acceptable tolerance of the original pump baseline performance and that the performance at the test flow is greater than or equal to the performance assumed in the unit safety analysis. SRs are specified in the INSERVICE TESTING PROGRAM of the ASME Code. The ASME Code provides the activities and Frequencies necessary to satisfy the requirements.

SR 3.5.2.5

~~Discharge head at~~ design flow is a normal test of charging pump performance required by the ASME Code and the INSERVICE TESTING PROGRAM. A quarterly Frequency for such tests is a Code requirement. Such inservice ~~inspections~~ tests detect component degradation and incipient failures.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.2.6, SR 3.5.2.7, and SR 3.5.2.8

These SRs demonstrate that each automatic ECCS valve actuates to the required position on an actual or simulated SIAS and on an RAS, that each ECCS pump starts on receipt of an actual or simulated SIAS, and that the LPSI pumps stop on receipt of an actual or simulated RAS. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. [The 18 month Frequency is based on the need to perform these Surveillances under the conditions that apply during a plant outage and the potential for unplanned transients if the Surveillances were performed with the reactor at power. The 18 month Frequency is also acceptable based on consideration of the design reliability (and confirming operating experience) of the equipment.

and each automatic containment sump, RWT outlet, and SI recirc valve to the RWT actuates to the required position

6

2

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

2

The actuation logic is tested as part of the Engineered Safety Feature Actuation System (ESFAS) testing, and equipment performance is monitored as part of the INSERVICE TESTING PROGRAM.

SR 3.5.2.9

7

Realignment of valves in the flow path on an SIAS is necessary for proper ECCS performance. The safety injection valves have stops to position them properly so that flow is restricted to a ruptured cold leg, ensuring that the other cold legs receive at least the required minimum flow. This SR is not required for units with flow limiting orifices. [The 18 month Frequency is based on the same factors as those stated above for SR 3.5.2.6, SR 3.5.2.7, and SR 3.5.2.8.

7

Periodic inspections of ECCS train containment sump suction inlets ensure they are unrestricted and stay in proper operating condition.

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.2 ECCS - Operating

BASES

BACKGROUND

The function of the ECCS is to provide core cooling and negative reactivity to ensure that the reactor core is protected after any of the following accidents:

a. Loss of coolant accident (LOCA),

b. Control Element Assembly (CEA) ejection accident,

c. Loss of secondary coolant accident, including uncontrolled steam release or loss of feedwater, and

d. Steam generator tube rupture (SGTR).

The addition of negative reactivity is designed primarily for the loss of secondary coolant accident where primary cooldown could add enough positive reactivity to achieve criticality and return to significant power.

There are two phases of ECCS operation: injection and recirculation. In the injection phase, all injection is initially added to the Reactor Coolant System (RCS) via the cold legs. ~~After the blowdown stage of the LOCA stabilizes, injection flow is split equally between the hot and cold legs.~~ After the refueling water tank (RWT) has been depleted, the ECCS recirculation phase is entered as the ECCS suction is automatically transferred to the containment sump. 1

1750

Two redundant, 100% capacity trains are provided. In MODES 1, 2, and 3, with pressurizer pressure ≥ ~~1700~~ psia, each train consists of high pressure safety injection (HPSI), low pressure safety injection (LPSI), and charging subsystems. In MODES 1, 2, and 3, with pressurizer pressure ≥ ~~1700~~ psia, both trains must be OPERABLE. This ensures that 100% of the core cooling requirements can be provided in the event of a single active failure. 1 1

1750

A suction header supplies water from the RWT or the containment sump to the ECCS pumps. Separate piping supplies each train. The discharge headers from each HPSI pump divide into four supply lines. Both HPSI trains feed into each of the four injection lines. The discharge header from each LPSI pump divides into two supply lines, each feeding the injection line to two RCS cold legs. Control valves or orifices are set to balance the flow to the RCS. This flow balance directs sufficient flow to the core to meet the analysis assumptions following a LOCA in one of the RCS cold legs.

BASES

BACKGROUND (continued)

For LOCAs that are too small to initially depressurize the RCS below the shutoff head of the HPSI pumps, the charging pumps supply water to maintain inventory until the RCS pressure decreases below the HPSI pump shutoff head. During this period, the steam generators (SGs) must provide the core cooling function. The charging pumps take suction from the ~~RWT~~ on a safety injection actuation signal (SIAS) and discharge directly to the RCS through a common header. ~~The normal supply source for the charging pumps is isolated on an SIAS to prevent noncondensible gas (e.g., air, nitrogen, or hydrogen) from being entrained in the charging pumps.~~

boric acid makeup tanks (BAMTs) via gravity feed valves or boric acid makeup pump discharge valves

1 4

During low temperature conditions in the RCS, limitations are placed on the maximum number of HPSI pumps that may be OPERABLE. Refer to the Bases for LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System," for the basis of these requirements.

During a large break LOCA, RCS pressure will decrease to < 200 psia in < 20 seconds. The safety injection (SI) systems are actuated upon receipt of an SIAS. The actuation of safeguard loads is accomplished in a programmed time sequence. If offsite power is available, the safeguard loads start immediately in the programmed sequence. If offsite power is not available, the Engineered Safety Feature (ESF) buses shed normal operating loads and are connected to the diesel generators (DGs). Safeguard loads are then actuated in the programmed time sequence. The time delay associated with diesel starting, sequenced loading, and pump starting determines the time required before pumped flow is available to the core following a LOCA.

1

emergency

E

1

and

The active ECCS components, along with the passive safety injection tanks (SITs)~~,~~ the RWT~~, and the containment sump, are~~ covered in LCO 3.5.1, "Safety Injection Tanks (SITs)," LCO 3.5.4, "Refueling Water Tank (RWT)," ~~and LCO 3.8.13, "Containment Sump,"~~ provide the cooling water necessary to meet GDC 35 (Ref. 1).

1

3

and

APPLICABLE SAFETY ANALYSES

The LCO helps to ensure that the following acceptance criteria, established by 10 CFR 50.46 (Ref. 2) for ECCSs, will be met following a LOCA:

a. Maximum fuel element cladding temperature is ≤ 2200°F,

b. Maximum cladding oxidation is ≤ 0.17 times the total cladding thickness before oxidation,

BASES

APPLICABLE SAFETY ANALYSES (continued)

c. Maximum hydrogen generation from a zirconium water reaction is ≤ 0.01 times the hypothetical amount generated if all of the metal in the cladding cylinders surrounding the fuel, excluding the cladding surrounding the plenum volume, were to react,

d. Core is maintained in a coolable geometry, and

e. Adequate long term core cooling capability is maintained.

The LCO also limits the potential for a post trip return to power following a steam line break (SLB) and ensures that containment temperature limits are met.

Both HPSI and LPSI subsystems are assumed to be OPERABLE in the large break LOCA analysis at full power (Ref. 3). This analysis establishes a minimum required runout flow for the HPSI and LPSI pumps, as well as the maximum required response time for their actuation. The HPSI pumps and charging pumps are credited in the small break LOCA analysis. This analysis establishes the flow and discharge head requirements at the design point for the HPSI pump. The SGTR and SLB analyses also credit the HPSI pumps, but are not limiting in their design.

The large break LOCA event with a loss of offsite power and a single failure (disabling one ECCS train) establishes the OPERABILITY requirements for the ECCS. During the blowdown stage of a LOCA, the RCS depressurizes as primary coolant is ejected through the break into the containment. The nuclear reaction is terminated either by moderator voiding during large breaks or control element assembly (CEA) insertion during small breaks. Following depressurization, emergency cooling water is injected into the cold legs, flows into the downcomer, fills the lower plenum, and refloods the core.

On smaller breaks, RCS pressure will stabilize at a value dependent upon break size, heat load, and injection flow. The smaller the break, the higher this equilibrium pressure. In ~~all~~ LOCA analyses, injection flow is not credited until RCS pressure drops below the shutoff head of the HPSI pumps. 1

BASES

APPLICABLE SAFETY ANALYSES (continued)

The LCO ensures that an ECCS train will deliver sufficient water to match decay heat boiloff rates soon enough to minimize core uncovery for a large LOCA. It also ensures that the HPSI pump will deliver sufficient water during a small break LOCA and provide sufficient boron to maintain the core subcritical following an SLB. For smaller LOCAs, the charging pumps deliver sufficient fluid to maintain RCS inventory until the RCS can be depressurized below the HPSI pumps' shutoff head. During this period of a small break LOCA, the SGs continue to serve as the heat sink providing core cooling.

ECCS - Operating satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

1750

In MODES 1, 2, and 3, with pressurizer pressure ≥ ~~1700~~ psia, two independent (and redundant) ECCS trains are required to ensure that sufficient ECCS flow is available, assuming there is a single failure affecting either train. Additionally, individual components within the ECCS trains may be called upon to mitigate the consequences of other transients and accidents.

1

1750

In MODES 1 and 2, and in MODE 3 with pressurizer pressure ≥ ~~1700~~ psia, an ECCS train consists of an HPSI subsystem, an LPSI subsystem, and a charging pump.

1

HPSI and LPSI subsystem

Each ~~train~~ includes the piping, instruments, and controls to ensure the availability of an OPERABLE flow path capable of taking suction from the RWT on an SIAS and automatically transferring suction to the containment sump upon a recirculation actuation signal (RAS). Management of gas voids is important to ECCS OPERABILITY.

1

During an event requiring ECCS actuation, a flow path is provided to ensure an abundant supply of water from the RWT to the RCS, via the HPSI and LPSI pumps and their respective supply headers, to each of the four cold leg injection nozzles. In the long term, this flow path may be switched to take its supply from the containment sump and to supply part of its flow to the RCS hot legs via the shutdown cooling (SDC) suction nozzles. ~~The~~ charging pump flow path take~~s~~ suction from the ~~RWT~~ and supplies the RCS via the normal charging line~~s~~.

BAMT(s)

The flow path for each train must maintain its designed independence to ensure that no single failure can disable both ECCS trains.

One charging pump flow path taking suction from either a single BAMT via the associated boric acid makeup pump, or both BAMTs via both boric acid makeup pumps. A second charging pump flow path taking suction from either a single BAMT via gravity feed valves, or both BAMTs via gravity feed valves.

4

1

BASES

APPLICABILITY

In MODES 1 and 2, and in MODE 3 with RCS pressure ≥ ~~1700~~ 1750 psia, the ECCS OPERABILITY requirements for the limiting Design Basis Accident (DBA) large break LOCA are based on full power operation. Although reduced power would not require the same level of performance, the accident analysis does not provide for reduced cooling requirements in the lower MODES. The HPSI pump performance is based on the small break LOCA, which establishes the pump performance curve and has less dependence on power. The charging pump performance requirements are based on a small break LOCA. The requirements of MODES 2 and 3, with RCS pressure ≥ ~~1700~~ 1750 psia, are bounded by the MODE 1 analysis. 1

The ECCS functional requirements of MODE 3, with RCS pressure < ~~1700~~ 1750 psia, and MODE 4 are described in LCO 3.5.3, "ECCS - Shutdown." 1

In MODES 5 and 6, unit conditions are such that the probability of an event requiring ECCS injection is extremely low. Core cooling requirements in MODE 5 are addressed by LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," and LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled." MODE 6 core cooling requirements are addressed by LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level," and LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level."

ACTIONS

A.1

With one LPSI subsystem inoperable, action must be taken to restore OPERABLE status within 7 days ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. In this condition, the remaining OPERABLE ECCS train is adequate to perform the heat removal function. However, the overall reliability is reduced because a single failure to the remaining LPSI subsystem could result in loss of ECCS function. The 7 day Completion Time is reasonable to perform corrective maintenance on the inoperable LPSI subsystem. The 7 day Completion Time is based on the findings of the deterministic and probabilistic analysis in Reference 6. Reference 6 concluded that extending the Completion Time to 7 days for an inoperable LPSI train provides plant operational flexibility while simultaneously reducing overall plant risk. This is because the risks incurred by having the LPSI train unavailable for a longer time at power will be substantially offset by the benefits associated with avoiding unnecessary plant transitions and by reducing risk during plant shutdown operations. 2

BASES

ACTIONS (continued)

B.1

If one or more trains are inoperable except for reasons other than Condition A (one LPSI subsystem inoperable) and at least 100% of the ECCS flow equivalent to a single OPERABLE ECCS train is available, the inoperable components must be returned to OPERABLE status within 72 hours [or in accordance with the Risk Informed Completion Time Program]. The 72 hour Completion Time is based on an NRC study (Ref. 4) using a reliability evaluation and is a reasonable amount of time to effect many repairs. 2

An ECCS train is inoperable if it is not capable of delivering the design flow to the RCS. The individual components are inoperable if they are not capable of performing their design function, or if supporting systems are not available.

The LCO requires the OPERABILITY of a number of independent subsystems. Due to the redundancy of trains and the diversity of subsystems, the inoperability of one component in a train does not render the ECCS incapable of performing its function. Neither does the inoperability of two different components, each in a different train, necessarily result in a loss of function for the ECCS. This allows increased flexibility in plant operations when components in opposite trains are inoperable.

An event accompanied by a loss of offsite power and the failure of an emergency DG can disable one ECCS train until power is restored. A reliability analysis (Ref. 4) has shown that the impact with one full ECCS train inoperable is sufficiently small to justify continued operation for 72 hours.

Reference 5 describes situations in which one component, such as a shutdown cooling total flow control valve, can disable both ECCS trains. With one or more components inoperable, such that 100% of the equivalent flow to a single OPERABLE ECCS train is not available, the facility is in a condition outside the accident analyses. Therefore, LCO 3.0.3 must be immediately entered.

BASES

ACTIONS (continued)

C.1 and C.2

If the inoperable train cannot be restored to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and pressurizer pressure reduced to < ~~1700~~ psia within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power in an orderly manner and without challenging unit systems.

1750

1

D.1

D is applicable with less than 100% of the ECCS flow equivalent to a single OPERABLE train available.

Condition ~~B is applicable with one or more trains inoperable~~. The allowed Completion Time is based on the assumption that at least 100% of the ECCS flow equivalent to a single OPERABLE ECCS train is available. With less than 100% of the ECCS flow equivalent to a single OPERABLE ECCS train available, the facility is in a condition outside of the accident analyses. Therefore, LCO 3.0.3 must be entered immediately.

5

of Condition B

SURVEILLANCE REQUIREMENTS

SR 3.5.2.1

~~Verification of proper valve position ensures that the flow path from the ECCS pumps to the RCS is maintained. Misalignment of these valves could render both ECCS trains inoperable. Securing these valves in position by removing power or by key locking the control in the correct position ensures that the valves cannot be inadvertently misaligned or change position as the result of an active failure. These valves are of the type described in Reference 5, which can disable the function of both ECCS trains and invalidate the accident analysis. [A 12 hour Frequency is considered reasonable in view of other administrative controls ensuring that a mispositioned valve is an unlikely possibility.~~

7

~~OR~~ Periodic inspections of ECCS train containment sump suction inlets ensure they are unrestricted and stay in proper operating condition.

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.2.2

Verifying the correct alignment for manual, power operated, and automatic valves in the ECCS flow paths provides assurance that the proper flow paths will exist for ECCS operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these valves were verified to be in the correct position prior to locking, sealing, or securing. A valve that receives an actuation signal is allowed to be in a nonaccident position provided the valve automatically repositions within the proper stroke time. This Surveillance does not require any testing or valve manipulation. Rather, it involves verification that those valves capable of being mispositioned are in the correct position.

[The 31 day Frequency is appropriate because the valves are operated under procedural control and an improper valve position would only affect a single train. This Frequency has been shown to be acceptable through operating experience.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

The Surveillance is modified by a Note which exempts system vent flow paths opened under administrative control. The administrative control should be proceduralized and include stationing a dedicated individual at the system vent flow path who is in continuous communication with the operators in the control room. This individual will have a method to rapidly close the system vent flow path if directed.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.2.3

ECCS piping and components have the potential to develop voids and pockets of entrained gases. Preventing and managing gas intrusion and accumulation is necessary for proper operation of the ECCS and may also prevent water hammer, pump cavitation, and pumping of noncondensible gas into the reactor vessel.

Selection of ECCS locations susceptible to gas accumulation is based on a review of system design information, including piping and instrumentation drawings, isometric drawings, plan and elevation drawings, and calculations. The design review is supplemented by system walk downs to validate the system high points and to confirm the location and orientation of important components that can become sources of gas or could otherwise cause gas to be trapped or difficult to remove during system maintenance or restoration. Susceptible locations depend on plant and system configuration, such as stand-by versus operating conditions.

The ECCS is OPERABLE when it is sufficiently filled with water. Acceptance criteria are established for the volume of accumulated gas at susceptible locations. If accumulated gas is discovered that exceeds the acceptance criteria for the susceptible location (or the volume of accumulated gas at one or more susceptible locations exceeds an acceptance criteria for gas volume at the suction or discharge of a pump), the Surveillance is not met. If the accumulated gas is eliminated or brought within the acceptance criteria limits during performance of the Surveillance, the Surveillance is met, and past system OPERABILITY is evaluated under the Corrective Action Program. If it is determined by subsequent evaluation that the ECCS is not rendered inoperable by the accumulated gas (i.e., the system is sufficiently filled with water), the Surveillance may be declared met. Accumulated gas should be eliminated or brought within the acceptance criteria limits. | R1

ECCS locations susceptible to gas accumulation are monitored and, if gas is found, the gas volume is compared to the acceptance criteria for the location. Susceptible locations in the same system flow path which are subject to the same gas intrusion mechanisms may be verified by monitoring a representative sub-set of susceptible locations. Monitoring may not be practical for locations that are inaccessible due to radiological or environmental conditions, the plant configuration, or personnel safety. For these locations alternative methods (e.g., operating parameters, remote monitoring) may be used to monitor the susceptible location. Monitoring is not required for susceptible locations where the maximum potential accumulated gas void volume has been evaluated and

BASES

SURVEILLANCE REQUIREMENTS (continued)

determined to not challenge system OPERABILITY. The accuracy of the method used for monitoring the susceptible locations and trending of the results should be sufficient to assure system OPERABILITY during the Surveillance interval.

~~[The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the ECCS piping and the adequacy of the procedural controls governing system operation.~~
~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. The Surveillance Frequency may vary by location susceptible to gas accumulation.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

SR 3.5.2.4

Periodic surveillance testing of ECCS pumps to detect gross degradation caused by impeller structural damage or other hydraulic component problems is required by the ASME Code. This type of testing may be accomplished by measuring the pump developed head at only one point of the pump characteristic curve. This verifies both that the measured performance is within an acceptable tolerance of the original pump baseline performance and that the performance at the test flow is greater than or equal to the performance assumed in the unit safety analysis. SRs are specified in the INSERVICE TESTING PROGRAM of the ASME Code. The ASME Code provides the activities and Frequencies necessary to satisfy the requirements.

SR 3.5.2.5

~~Discharge head at~~ design flow is a normal test of charging pump performance required by the ASME Code and the INSERVICE TESTING PROGRAM. A quarterly Frequency for such tests is a Code requirement. Such inservice ~~inspections~~ tests detect component degradation and incipient failures.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.5.2.6, SR 3.5.2.7, and SR 3.5.2.8

These SRs demonstrate that each automatic ECCS valve actuates to the required position on an actual or simulated SIAS and on an RAS, that each ECCS pump starts on receipt of an actual or simulated SIAS, and that the LPSI pumps stop on receipt of an actual or simulated RAS. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. [The 18 month Frequency is based on the need to perform these Surveillances under the conditions that apply during a plant outage and the potential for unplanned transients if the Surveillances were performed with the reactor at power. The 18 month Frequency is also acceptable based on consideration of the design reliability (and confirming operating experience) of the equipment.

and each automatic containment sump, RWT outlet, and SI recirc valve to the RWT actuates to the required position

6

2

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

REVIEWER'S NOTE

Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

]

2

The actuation logic is tested as part of the Engineered Safety Feature Actuation System (ESFAS) testing, and equipment performance is monitored as part of the INSERVICE TESTING PROGRAM.

SR 3.5.2.9

Realignment of valves in the flow path on an SIAS is necessary for proper ECCS performance. The safety injection valves have stops to position them properly so that flow is restricted to a ruptured cold leg, ensuring that the other cold legs receive at least the required minimum flow. This SR is not required for units with flow limiting orifices. [The 18 month Frequency is based on the same factors as those stated above for SR 3.5.2.6, SR 3.5.2.7, and SR 3.5.2.8.

The HPSI header injection valves are throttled to prevent HPSI pump runout.

SR 3.5.2.10

This Surveillance verifies that the water volume in the BAMT is above the minimum usable volume plus additional margin to ensure that a sufficient water supply is available to the charging pump for injection during a small break LOCA. The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. 8

SR 3.5.2.11

This Surveillance verifies that the boron concentration in the BAMT is above the minimum BAMT boron concentration to ensure that a sufficient borated water supply is available to the charging pump for injection during a small break LOCA. The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. 8

JUSTIFICATION FOR DEVIATIONS
ITS 3.5.2, BASES, ECCS - OPERATING

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. ISTS 3.6.13, "Containment Sump" is not being adopted and St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) does not have a separate containment sump Specification. The Containment Sump function ensures debris is not transported to the ECCS and containment spray pump suction inlets during a LOCA, which could inhibit operation of these mitigation systems. Requirements associated with this function are provided in ITS 3.5.2, "ECCS – Operating", and ITS 3.5.3, "ECCS – Shutdown" for PSL Unit 1 and Unit 2. Therefore, ISTS 3.6.13 is not included in the PSL Unit 1 and Unit 2 ITS. The reference to a containment sump Specification is deleted.

4. ISTS Background and LCO descriptions include charging pump details. These details are enhanced to include charging pump flow paths that maintain the required independence of ECCS trains. These details for the charging pump flow paths are relocated from the CTS and are added to the ITS Bases.

5. Editorial change made to the Bases of Condition D to reflect the wording of Condition D in ISTS 3.5.2 (ITS 3.5.2) and further clarify the distinction between Conditions B and D.

6. ISTS SR 3.5.5.6, SR 3.5.2.7, and SR 3.5.2.8 description contains that each automatic ECCS valve actuates and each ECCS pump starts on an actual or simulated SIAS and on an RAS, and that the LPSI pump stops on receipt of an actual or simulated RAS. Unit 1 CTS 4.5.2.e.3 and Unit 2 4.5.2.f.3 each provide details that upon receipt of an actual or simulated RAS, that in addition to each LPSI pump stops, each containment sump isolation valve opens, each refueling water tank outlet valve closes, and each safety injection system recirculation valve to the refueling water tank closes. These details for automatic valves design actuation in response to an RAS are relocated from the CTS and are added to the ISTS Bases to recognize these design features.

7. The CTS Surveillance requiring a containment sump visual inspection of ECCS pump suction inlets is added to ITS SR 3.2.5.9 for Unit 1 and SR 3.5.2.1 for Unit 2. The ISTS Bases are revised to reflect the change to the ISTS SRs. The Bases discussion added is similar to the discussion provided for the Bases of ISTS SR 3.5.2.10 in Revision 4 of NUREG-1432.

8. ISTS 3.5.2 does not contain surveillances for the boric acid makeup tank (BAMT) volume and boron concentration for the charging pump ECCS function. This ISTS Bases change reflects the change to the Specification, which adds SR 3.5.2.10 to verify that each BAMT volume is greater than or equal to the specified minimum volume in accordance with the Surveillance Frequency Control Program and SR 3.5.2.11 to verify that each BAMT minimum boron concentration is greater than or

equal to the specified minimum required boron concentration in accordance with the Surveillance Frequency Control Program. The added Bases discussion is similar to the Bases discussion provided for the refueling water tank (RWT) volume verification of ISTS SR 3.5.4.2 and the RWT boron concentration verification of ISTS SR 3.5.4.3.

ECCS SUBSYSTEMS - SHUTDOWN

LIMITING CONDITION FOR OPERATION

In MODE 4, only the safety injection actuation and recirculation actuation manual channels and associated actuation logic are required. — L01

high pressure safety injection (HPSI) train

LCO 3.5.3

~~3.5.3~~ ~~As a minimum,~~ one ~~ECCS subsystem comprised of the following~~ shall be OPERABLE:

~~a. In MODES 3* and 4#, one ECCS subsystem composed of one OPERABLE high pressure safety injection pump and one OPERABLE flow path capable of taking suction from the refueling water storage tank on a safety injection actuation signal and automatically transferring suction to the containment sump on a sump recirculation actuation signal.~~ — LA01

b. Prior to decreasing the reactor coolant system temperature below 270°F a maximum of only one high pressure safety injection pump shall be OPERABLE with its associated header stop valve open. — See ITS 3.4.12

c. Prior to decreasing the reactor coolant system temperature below 236°F all high pressure safety injection pumps shall be disabled and their associated header stop valves closed except as allowed by Specifications 3.1.2.1 and 3.1.2.3.

Applicability

APPLICABILITY: MODES 3* and 4~~.~~ with RCS cold leg temperature > 250°F — A03

MODES 5 and 6 when the Pressurizer manway cover is in place and the reactor vessel head is on. — See ITS 3.4.12

ACTION:

Required HPSI train inoperable — required HPSI train — within 1 hour — L02

ACTION A

~~a. With no ECCS subsystems OPERABLE in MODES 3* and 4#, immediately~~ restore ~~one ECCS subsystem~~ to OPERABLE status or be in ~~COLD SHUTDOWN~~ within ~~20~~ 24 hours. — L03

ACTION B

MODE 4 with RCS cold leg temperature ≤ 250°F — A03

b. With RCS temperature below 270°F and with more than the allowed high pressure safety injection pump OPERABLE or injection valves and header isolation valves open, immediately disable the high pressure safety injection pump(s) or close the header isolation valves. — See ITS 3.4.12

~~c. In the event the ECCS is actuated and injects water into the Reactor Coolant System, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days describing the circumstances of the actuation and the total accumulated actuation cycles to date.~~ — L04

ACTIONS Note

~~d.~~ LCO 3.0.4.b is not applicable to ECCS High Pressure Safety Injection subsystem when entering MODE 4.

SURVEILLANCE REQUIREMENTS

For required, HPSI train, applicable portions of the following SRs are applicable: SR 3.5.2.1 SR 3.5.2.2 SR 3.5.2.4 SR 3.5.2.7 SR 3.5.2.3 SR 3.5.2.6 SR 3.5.2.9 — A02

SR 3.5.3.1

~~4.5.3.1 The ECCS subsystem shall be demonstrated OPERABLE per the applicable Surveillance Requirements of 4.5.2.~~

4.5.3.2 The high pressure safety injection pumps shall be verified inoperable and the associated header stop valves closed prior to decreasing below the above specified Reactor Coolant System temperature and once per month when the Reactor Coolant System is at refueling temperatures. — See ITS 3.4.12

Applicability * With pressurizer pressure < 1750 psia.

Applicability # REACTOR COOLANT SYSTEM cold leg temperature above 250°F.

A02

* With pressurizer pressure less than 1750 psia.

\# One HPSI shall be rendered inoperable prior to entering MODE 5. — See ITS 3.4.12

DISCUSSION OF CHANGES
ITS 3.5.3, ECCS - SHUTDOWN

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 4.5.3.1, and Unit 2 CTS 4.5.3, state that the ECCS subsystem shall be demonstrated OPERABLE per the applicable Surveillance Requirements of 4.5.2, but do not specify the applicable Surveillance Requirements. Similarly, ITS SR 3.5.3.1 specifies the applicable ITS 3.5.2 Surveillance Requirements.

The purpose of this SR is to ensure the required HPSI train is OPERABLE. Per the definition of OPERABILITY, the required HPSI train is OPERABLE or has OPERABILITY when it is capable of performing its specified safety function and when all necessary attendant equipment required for the HPSI train to perform its specified safety function are also capable of performing their related support function(s). Thus, only the SRs required to verify the HPSI train can perform its intended safety function are required. SR 3.5.2.5 and SR 3.5.2.8 verify charging pump and LPSI pump features, respectively, and are not part of the required HPSI train. Therefore, these SRs are not specified in the ITS.

This change is designated as administrative and is acceptable because it only clarifies the current requirement and does not result in a technical change to the CTS.

A03 **Unit 1 only**: CTS 3.5.3 Applicability requires, in part, at least one ECCS subsystem to be OPERABLE in MODE 4. CTS 3.5.3.a describes an ECCS subsystem in MODE 4 as consisting of one OPERABLE HPSI pump with the proper flowpath. The MODE 4 requirement in CTS 3.5.3.a is modified by # footnote, which states Reactor Coolant System cold leg temperature above 250°F. In MODE 4 with RCS cold leg temperature above 250°F (per # footnote), CTS 3.5.3 Action a requires the plant to be in Cold Shutdown (i.e., MODE 5) within the required completion time if the required ECCS subsystem cannot be restored immediately. ITS 3.5.3 requires one HPSI train to be OPERABLE in MODE 3 with pressurizer pressure < 1750 psia and in MODE 4 with RCS cold leg temperature > 250°F. When the required HPSI train (i.e., required ECCS subsystem) cannot be restored to OPERABLE status within the required Completion Time, ITS 3.5.3 Required Action B.1 requires the unit to be in MODE 4 with RCS cold leg temperature ≤ 250°F. This changes the Applicability from MODE 4 to MODE 4 with RCS cold leg temperature > 250°F and the action end state from MODE 4 to MODE 4 with RCS cold leg temperature ≤ 250°F.

The CTS 3.5.3 Applicability has a dual purpose: to provide applicability for the ECCS shutdown requirements and the low temperature overpressure protection (LTOP) requirements. ITS 3.5.3 provides ECCS shutdown requirements and ITS

3.4.12 provides LTOP requirements. The purpose of the ECCS shutdown requirements is to ensure adequate core cooling systems are available in the event of a loss of RCS inventory when the reactor is shutdown and the RCS is hot and pressurized. The purpose of CTS 3.5.3 Action a is to restore the required ECCS subsystem to OPERABLE status in a timely manner or place the plant in a condition in which the equipment is no longer required. CTS 3.5.3.a and Action a address the requirement for one ECCS subsystem when in MODE 3 with pressurizer pressure < 1750 psia and in MODE 4 with RCS cold leg temperature > 250°F. In MODE 4 below 250°F there is no CTS requirement or action related to ECCS. CTS 3.5.3.b and c and the associated action support the LTOP analysis and are not related to the ECCS function. Specifically, CTS 3.5.3.b limits HPSI to a maximum of only one with its associated header stop valve open when RCS temperature is ≤ 270°F and CTS 3.5.3.c requires all HPSI pumps to be disabled and their header stop valves closed (i.e., incapable of injecting into the RCS) when RCS temperature is ≤ 236°F in MODE 4. As a result, no ECCS is required to be OPERABLE in MODE 4 with RCS cold leg temperature ≤ 250°F. Therefore, the ITS ECCS Shutdown Applicability is modified from MODE 4 to MODE 4 with RCS cold leg temperature ≤ 250°F consistent with the CTS intent and the end state action is modified to require exiting the Applicability consistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2).

These changes are designated as administrative changes and are acceptable because they maintain the current requirement that one HPSI train be OPERABLE in MODE 4 with RCS cold leg temperature > 250°F and to place the unit in a condition in which the required HPSI train is no longer required consistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2) and, therefore, do not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Unit 1 CTS 3.5.3.a and Unit 2 CTS 3.5.3.a and 3.5.3.b, state, in part, that as a minimum, one ECCS subsystem composed of one OPERABLE high pressure safety injection pump and one OPERABLE flow path capable of taking suction from the refueling water storage tank on a safety injection actuation signal and automatically transferring suction to the containment sump on a sump recirculation actuation signal. Additionally, Discussion of Change L01 changes the CTS 3.5.3 LCO to only require manual channel actuation in MODE 4. ITS 3.5.3 retains the requirement that one high pressure safety

injection (HPSI) train shall be OPERABLE. This changes the CTS by moving the details of what composes an OPERABLE ECCS subsystem, including flowpath and actuation functions, to the Bases.

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement that one high pressure safety injection (HPSI) train shall be OPERABLE. Also this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specifications Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 1 – Relaxation of LCO Requirements)* CTS 3.5.3 states, in part, that one OPERABLE flow path capable of taking suction from the refueling water tank on a safety injection actuation signal and automatically transferring suction to the containment sump on a sump recirculation actuation signal is required to be OPERABLE in MODE 3 with pressurizer pressure < 1750 psia and MODE 4. This changes the CTS 3.5.3 LCO to only require manual channel actuation in MODE 4. CTS 3.3.2.1 and Table 3.3-3 only require automatic SIAS and RAS in MODES 1, 2, and 3, and manual channel actuation is required in MODE 4. Furthermore, Discussion of Change LA01 changes the CTS by moving the details of what composes an OPERABLE ECCS subsystem, including flowpath and actuation functions, to the Bases.

The purpose of CTS 3.5.3 is to state the limiting conditions for operation. This change is acceptable because the LCO requirements continue to ensure that the required HPSI train is maintained consistent with the safety analyses and licensing basis. This change is designated as less restrictive because less stringent LCO requirements are being applied in the ITS than were applied in the CTS.

L02 **Unit 1 Only:** *(Category 3 – Relaxation of Completion Time)* CTS 3.5.3 Action a. states, in part, “immediately restore one ECCS subsystem to OPERABLE status or be in COLD SHUTDOWN within 20 hours.” With the required HPSI train inoperable, ITS 3.5.3 Required Action A.1 allows 1 hour to restore the required HPSI train to OPERABLE status. This changes the CTS by relaxing the Completion Time from “immediately” to 1 hour.

The purpose of CTS 3.5.3 Action a. is to take action with no HPSI train OPERABLE. With no HPSI train OPERABLE, the unit is not prepared to respond to a loss of coolant accident. The ITS 1 hour Completion Time to restore at least one HPSI train to OPERABLE status ensures that prompt action is taken to restore the required cooling capacity or to initiate actions to place the unit in a condition where an ECCS train is not required. This change is acceptable

because the Completion Time is consistent with the Completion Time in the ISTS and continues to provide safe operation under the specific Condition, considering the low probability of a DBA occurring during the allowed Completion Time.

This change is designated as less restrictive because additional time is allowed to restore the required HPSI train to OPERABLE status than was allowed in the CTS.

L03 *(Category 3 – Relaxation of Completion Time)* Unit 1 CTS 3.5.3 Action a. states, in part, "immediately restore one ECCS subsystem to OPERABLE status or be in COLD SHUTDOWN within 20 hours." Unit 2 CTS 3.5.3 Action a. states, in part, "restore at least one ECCS subsystem to OPERABLE status within 1 hour or be in COLD SHUTDOWN within the next 20 hours." With the Required Action and associated Completion Time not met, that being the required HPSI train is not restored to OPERABLE status within the associated Completion Time, ITS 3.5.3 Required Action B.1 allows 24 hours to be in a condition where an ECCS train is not required. This changes the CTS by relaxing the Completion Time from "within the next 20 hours" to 24 hours.

The purpose of CTS 3.5.3 Action a. is to take action with no HPSI train OPERABLE. With no HPSI train OPERABLE, the unit is not prepared to respond to a loss of coolant accident. The ITS 24 hour Completion Time for ITS 3.5.3 Required Action B.1 is reasonable, based on operating experience, to reach the condition in an orderly manner and without challenging plant systems. This change is acceptable because the Completion Time is consistent with the time in the ISTS to reach the required plant condition to provide safe operation under the specific Condition, considering the low probability of a DBA occurring during the allowed Completion Time.

This change is designated as less restrictive because additional time is allowed to place the unit in a MODE or specified condition where an ECCS train is not required than was allowed in the CTS.

L04 *(Category 9 – Deletion of Reporting Requirements)* Unit 1 CTS 3.5.3 Action c. states "In the event the ECCS is actuated and injects water into the Reactor Coolant System, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days describing the circumstances of the actuation and the total accumulated actuation cycles to date." Unit 2 CTS 3.5.3 Action b. states "In the event the ECCS is actuated and injects water into the Reactor Coolant System, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days describing the circumstances of the actuation and the total accumulated actuation cycles to date. The current value of the usage factor for each affected safety injection nozzle shall be provided in this Special Report whenever its value exceeds 0.70." ITS 3.5.3 does not contain this CTS 90-day Special Report requirement in the event the ECCS is actuated and injects water into the RCS. ITS 3.5.3 retains the ACTIONS for the required HPSI train inoperable. This changes the CTS by deleting this 90-day Special Report.

The removal of these details for making reports from the Technical Specifications is acceptable because this type of information is not necessary to be included in

the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the LCO for one required HPSI train OPERABLE and the ACTIONS for the required HPSI train inoperable. Deletion of the ECCS reporting requirement is acceptable since 10 CFR 50.72(b)(2)(iv) requires a 4 hour notification in the event of an unplanned ECCS actuation and injection into the RCS. Additionally, 10 CFR 50.73(2)(iv)(A) also requires submission of a licensee event report for any unplanned event or condition that resulted in manual or automatic actuation of ECCS. PSL Unit 1 and Unit 2 operating licenses require compliance with 10 CFR 50.72 and 50.73. Therefore, the CTS requirement is unnecessary. Requirements continue to be provided in ITS to mitigate a DBA while Mode 3 with pressurizer pressure < 1750 psia and in Hot Standby (MODE 4) conditions. This change is designated as less restrictive because reports that would be submitted under the CTS will not be required under the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.5.3, ECCS - SHUTDOWN

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Clarification is added to ISTS SR 3.5.3.1. The change clarifies the intent that only the required HPSI train portions of the listed SRs are applicable. This change is similar to the SR wording of SR 3.5.3.1 of ISTS NUREGs 1430 (Babcock and Wilcox) and 1431 (Westinghouse).

4. **Unit 1 only**: To support the Unit 1 low temperature overpressure protection (LTOP) analysis, all HPSI pumps must be incapable of injecting into the Reactor Coolant System (RCS) when RCS cold leg temperature is ≤ 236°F in MODE 4. Therefore, the change to the Applicability in the ITS to MODE 4 with RCS cold leg temperature > 250°F is made consistent with the # footnote in CTS to ensure both HPSI subsystems are blocked prior to RCS cold leg temperature dropping below 236°F. Core cooling requirements in MODE 4 when RCS cold leg temperature is ≤ 250°F are addressed by LCO 3.4.6, “RCS Loops – MODE 4.” Required Action B.1 is modified in the ITS to require action to exit the Applicability consistent with the change to the Applicability.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.3 ECCS - Shutdown

Thus, only the SI and recirculation actuation manual channels and associated actuation logic to the required HPSI train are required in MODE 3 with pressurizer pressure < 1750 psia and MODE 4 with RCS cold leg temperature > 250°F.

BASES

BACKGROUND

, as it describes the design of the ECCS,

The Background section for Bases B 3.5.2, "ECCS - Operating," is applicable to these Bases, with the following modifications.

1750 when RCS cold leg temperature is > 250°F

In MODE 3 with pressurizer pressure < ~~1700~~ psia and in MODE 4, an ECCS train is defined as one high pressure safety injection (HPSI) subsystem. The HPSI ~~flow path~~ consists of piping, valves, and pumps that enable water from the refueling water tank (RWT) and the containment sump to be injected into the Reactor Coolant System (RCS) following the accidents described in Bases 3.5.2.

train

APPLICABLE SAFETY ANALYSES

~~The Applicable Safety Analyses section of Bases 3.5.2 is applicable to these Bases.~~

Due to the stable conditions associated with operation in MODE 4, and the reduced probability of a Design Basis Accident (DBA), the ECCS operational requirements are reduced. Included in these reductions is that certain automatic safety injection (SI) actuation signals are not available. ~~In this MODE, sufficient time exists for manual actuation of the required ECCS to mitigate the consequences of a DBA.~~

Only one train of ECCS is required for ~~MODE 4~~. Protection against single failures is not relied on for this MODE of operation.

MODE 3 with pressurizer pressure < 1750 psia and MODE 4 with RCS cold leg temperature > 250°F.

ECCS - Shutdown satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

1750

In MODE 3 with pressurizer pressure < ~~1700~~ psia, an ECCS subsystem is composed of a single HPSI subsystem. Each HPSI subsystem includes the piping, instruments, and controls to ensure an OPERABLE flow path capable of taking suction from the RWT and transferring suction to the containment sump.

and MODE 4 when RCS cold leg temperature is > 250°F

During an event requiring ECCS actuation, a flow path is required to supply water from the RWT to the RCS via the HPSI pumps and their respective supply headers to each of the four cold leg injection nozzles. In the long term, this flow path may be switched to take its supply from the containment sump and to deliver its flow to the RCS hot and cold legs. Management of gas voids is important to ECCS OPERABILITY.

Plant licensing basis does not require an analysis to determine the effects of a loss of coolant accident (LOCA) or demonstration of ECCS equipment capability to mitigate a LOCA in MODE 3 with pressurizer pressure < 1750 psia or MODE 4 when RCS cold leg temperature is > 250°F. However, one HPSI subsystem is required to be OPERABLE in MODE 3 with pressurizer pressure < 1750 psia and MODE 4 with RCS cold leg temperature > 250°F to ensure sufficient ECCS flow is available to the core and adequate core cooling is maintained following a loss of RCS inventory.

BASES

when RCS cold leg temperature is ≤ 300°F

LCO (continued)

1750

With RCS pressure < ~~1700~~ psia, one HPSI pump is acceptable without single failure consideration, based on the stable reactivity condition of the reactor and the limited core cooling requirements. The low pressure safety injection (LPSI) pumps may therefore be released from the ECCS train for use in shutdown cooling (SDC). In MODE 4 ~~with RCS cold leg temperature less than or equal to the LTOP enable temperature specified in the PTLR~~, a maximum of one HPSI pump is allowed to be OPERABLE in accordance with LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System."

In addition, no HPSI pump can be OPERABLE when RCS cold leg temperature is ≤ 236°F in accordance with LCO 3.4.12.

3

3

3

APPLICABILITY

1750

In MODES 1, 2, and 3 with RCS pressure ≥ ~~1700~~ psia, the OPERABILITY requirements for ECCS are covered by LCO 3.5.2.

1750

with RCS cold leg temperature > 250°F

In MODE 3 with RCS pressure < ~~1700~~ psia and in MODE 4, one OPERABLE ECCS train is acceptable without single failure consideration, based on the stable reactivity condition of the reactor and the limited core cooling requirements.

3

3

MODE 4 when RCS cold leg temperature is ≤ 250°F and in

MODE 4 when RCS cold leg temperature is ≤ 250°F are addressed by LCO 3.4.6, "RCS Loops – MODE 4. Core cooling requirements in

In MODES 5 and 6, unit conditions are such that the probability of an event requiring ECCS injection is extremely low. Core cooling requirements in MODE 5 are addressed by LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," and LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled." MODE 6 core cooling requirements are addressed by LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level," and LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level."

1

ACTIONS

A Note prohibits the application of LCO 3.0.4.b to an inoperable ECCS High Pressure Safety Injection subsystem. There is an increased risk associated with entering MODE 4 from MODE 5 with an inoperable ECCS High Pressure Safety Injection subsystem and the provisions of LCO 3.0.4.b, which allow entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, should not be applied in this circumstance.

A.1

With no HPSI pump OPERABLE, the unit is not prepared to respond to a loss of coolant accident. The 1 hour Completion Time to restore at least one HPSI train to OPERABLE status ensures that prompt action is taken to restore the required cooling capacity or to initiate actions to place the unit in ~~MODE 5,~~ where an ECCS train is not required.

a condition

1

BASES

ACTIONS (continued)

B.1

MODE 4 with RCS cold leg temperature ≤ 250°F

When the Required Action cannot be completed within the required Completion Time, a controlled shutdown should be initiated. Twenty-four hours is reasonable, based on operating experience, to reach ~~MODE 5~~ in an orderly manner and without challenging plant systems.

BASES

BACKGROUND

, as it describes the design of the ECCS,

The Background section for Bases B 3.5.2, "ECCS - Operating," is applicable to these Bases, with the following modifications.

1750

In MODE 3 with pressurizer pressure < ~~1700~~ psia and in MODE 4, an ECCS train is defined as one high pressure safety injection (HPSI) subsystem. The HPSI ~~flow path~~ consists of piping, valves, and pumps that enable water from the refueling water tank (RWT) and the containment sump to be injected into the Reactor Coolant System (RCS) following the accidents described in Bases 3.5.2.

train

APPLICABLE SAFETY ANALYSES

~~The Applicable Safety Analyses section of Bases 3.5.2 is applicable to these Bases.~~

Due to the stable conditions associated with operation in MODE 4, and the reduced probability of a Design Basis Accident (DBA), the ECCS operational requirements are reduced. Included in these reductions is that certain automatic safety injection (SI) actuation signals are not available. ~~In this MODE, sufficient time exists for manual actuation of the required ECCS to mitigate the consequences of a DBA.~~

Only one train of ECCS is required for ~~MODE 4~~. Protection against single failures is not relied on for this MODE of operation.

MODE 3 with pressurizer pressure < 1750 psia and MODE 4.

ECCS - Shutdown satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

1750

and MODE 4

LCO

In MODE 3 with pressurizer pressure < ~~1700~~ psia, an ECCS subsystem is composed of a single HPSI subsystem. Each HPSI subsystem includes the piping, instruments, and controls to ensure an OPERABLE flow path capable of taking suction from the RWT and transferring suction to the containment sump.

During an event requiring ECCS actuation, a flow path is required to supply water from the RWT to the RCS via the HPSI pumps and their respective supply headers to each of the four cold leg injection nozzles. In the long term, this flow path may be switched to take its supply from the containment sump and to deliver its flow to the RCS hot and cold legs. Management of gas voids is important to ECCS OPERABILITY.

Plant licensing basis does not require an analysis to determine the effects of a loss of coolant accident (LOCA) or demonstration of ECCS equipment capability to mitigate a LOCA in MODE 3 with pressurizer pressure < 1750 psia or MODE 4. However, one HPSI subsystem is required to be OPERABLE in MODE 3 with pressurizer pressure < 1750 psia and MODE 4 to ensure sufficient ECCS flow is available to the core and adequate core cooling is maintained following a loss of RCS inventory.

BASES

when any RCS cold leg temperature is ≤ 240°F following entry from MODE 3 and when any RCS cold leg temperature is ≤ 252°F following entry from MODE 5, 3

LCO (continued)

1750

With RCS pressure < ~~1700~~ psia, one HPSI pump is acceptable without single failure consideration, based on the stable reactivity condition of the reactor and the limited core cooling requirements. The low pressure safety injection (LPSI) pumps may therefore be released from the ECCS train for use in shutdown cooling (SDC). In MODE 4 ~~with RCS cold leg temperature less than or equal to the LTOP enable temperature specified in the PTLR~~, a maximum of one HPSI pump is allowed to be OPERABLE in accordance with LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System." 3

APPLICABILITY

1750

In MODES 1, 2, and 3 with RCS pressure ≥ ~~1700~~ psia, the OPERABILITY requirements for ECCS are covered by LCO 3.5.2. 3

1750

In MODE 3 with RCS pressure < ~~1700~~ psia and in MODE 4, one OPERABLE ECCS train is acceptable without single failure consideration, based on the stable reactivity condition of the reactor and the limited core cooling requirements. 3

In MODES 5 and 6, unit conditions are such that the probability of an event requiring ECCS injection is extremely low. Core cooling requirements in MODE 5 are addressed by LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," and LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled." MODE 6 core cooling requirements are addressed by LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level," and LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level."

ACTIONS

A Note prohibits the application of LCO 3.0.4.b to an inoperable ECCS High Pressure Safety Injection subsystem. There is an increased risk associated with entering MODE 4 from MODE 5 with an inoperable ECCS High Pressure Safety Injection subsystem and the provisions of LCO 3.0.4.b, which allow entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, should not be applied in this circumstance.

A.1

With no HPSI pump OPERABLE, the unit is not prepared to respond to a loss of coolant accident. The 1 hour Completion Time to restore at least one HPSI train to OPERABLE status ensures that prompt action is taken to restore the required cooling capacity or to initiate actions to place the unit in MODE 5, where an ECCS train is not required.

BASES

ACTIONS (continued)

DISCUSSION OF CHANGES
ITS 3.5.4, REFUELING WATER TANK(RWT)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 **Unit 1 only:** CTS 3.5.4.b requires a minimum RWT boron concentration of 1900 ppm but does not require a maximum boron concentration. ITS SR 3.5.4.3 requires verification that RWT boron concentration is within a minimum and maximum limit. Similarly, Unit 2 CTS 3.5.4.b requires boron concentration within a minimum 1900 ppm and a maximum 2200 ppm. This changes the Unit 1 CTS by adding a RWT boron concentration maximum limit of 2200 ppm.

The purpose of CTS 3.5.4.b is to provide a RWT minimum boron concentration limit to ensure that, following a LOCA with a minimum level in the RWT, the reactor will remain subcritical in the cold condition following mixing of the RWT and RCS water volumes. The RWT maximum boron concentration limit is based on boron precipitation in the core following a LOCA which could result in reduced heat removal capability between the fuel cladding and the reactor coolant. This change is acceptable, because the maximum boron concentration limit provides additional assurance that the RWT is capable of performing its function and not impeding other mitigation systems from performing their safety functions.

This change is designated as more restrictive because it adds a RWT maximum boron concentration limit to the CTS.

M02 **Unit 1 only:** CTS 3.5.4.d requires a minimum RWT water temperature of 55°F when in MODES 1 and 2. CTS 3.5.4.e requires a minimum RWT water temperature of 40°F when in MODES 3 and 4. ITS SR 3.5.4.1 requires verification that RWT boron concentration is within a minimum and maximum limit, with the minimum limit the same for MODES 1, 2, 3, and 4. Similarly, Unit 2 CTS 3.5.4.c requires water temperature of between 55°F and 100°F in MODES 1, 2, 3 and 4. This changes the Unit 1 CTS by changing the RWT minimum water temperature to 55°F in MODES 3 and 4.

The purpose of CTS 3.5.4.e is to provide a RWT minimum water temperature in MODES 3 and 4 to ensure that the RWT is capable of performing its function when required. This change is acceptable because raising the minimum required water temperature from 40°F to 55°F in MODES 3 and 4 provides additional margin to the low temperature design limit and provides assurance that the RWT will be capable of performing its function. In addition, raising the minimum temperature of the RWT will further minimize the reactivity impact as a result of

an inadvertent ECCS injection while shutdown. This change is designated as more restrictive because it changes the RWT minimum water temperature in MODES 3 and 4 to a higher temperature than required in CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 **Unit 2 only:** (*Type 6 – Removal of SR Frequency to the Surveillance Frequency Control Program*) CTS 4.5.4.b requires verification that RWT borated water temperature is within limits at least once per 24 hours when the outside (i.e., ambient) air temperature is less than 55°F or greater than 100°F. ITS SR 3.5.4.1 requires a similar Surveillance and specifies a periodic Frequency of, "In accordance with the Surveillance Frequency Control Program." This changes the CTS by moving the specified periodic Frequency to the Surveillance Frequency Control Program.

The removal of periodic Surveillance Requirement Frequencies is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement to periodically verify RWT borated water temperature is within limits. The existing Surveillance Frequency is removed from Technical Specifications and placed under licensee control pursuant to the methodology described in NEI 04-10. The control of changes to periodic Surveillance Frequencies is in accordance with the Surveillance Frequency Control Program requirements specified in CTS 6.8.4 (ITS 5.5.16). This program ensures that Surveillance Requirements specified in the Technical Specifications are performed at intervals sufficient to assure the associated Limiting Conditions for Operation are met. This change is designated as a less restrictive removal of detail change because Surveillance Frequencies are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 3 – Relaxation of Completion Time)* CTS 3.5.4 ACTION allows 1 hour to restore an inoperable RWT. ITS 3.5.4 ACTION A allows 8 hours to restore the RWT to OPERABLE status if the inoperability is due to the RWT boron concentration not within limits. ITS 3.5.4 ACTION C allows 8 hours to restore the RWT to OPERABLE status if the inoperability is due to the RWT borated water temperature not within limits. ITS 3.5.4 ACTION D requires the restoration of the RWT to an OPERABLE status within 1 hour for reasons other than Condition A or Condition C (e.g., RWT water volume not within limits). This changes the CTS by expanding the Completion Time for restoration of an inoperable RWT due to boron concentration or borated water temperature not within limits from 1 hour to 8 hours.

The purpose of CTS 3.5.4 Action is to require prompt action to restore the RWT to OPERABLE status. This change is acceptable because the Completion Time is consistent with safe operation under the specified Condition, considering a reasonable time to restore RWT parameters and the low probability of a DBA occurring during the allowed Completion Time. The primary function of the RWT is to contain sufficient borated water volume to support the ECCS during the injection phase following a LOCA. This RWT water volume continues to be available while in the Condition with the RWT boron concentration or the RWT borated water temperature not within limits. As a result, the most important safety function of the RWT can still be provided. The allowed Completion Time of 8 hours to restore the RWT to within limits was developed considering the time required to change the boron concentration or water temperature and that the contents of the tank are still available for injection. Given the remaining abilities of the RWT, requiring a plant shutdown after one hour is not warranted. This change is designated as less restrictive because additional time is allowed to restore parameters to within the LCO limits than was allowed in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.5.4 ACTION, states, "With the refueling water tank inoperable, restore the tank to OPERABLE status within 1 hour or be in at least HOT STANDBY within 6 hours and in COLD SHUTDOWN within the following 30 hours."

ITS 3.5.4 ACTION A allows 8 hours to restore the RWT to OPERABLE status if the inoperability is due to the RWT boron concentration not within limits. ITS 3.5.4 ACTION C allows 8 hours to restore the RWT to OPERABLE status if the inoperability is due to the RWT borated water temperature not within limits. ITS 3.5.4 ACTION D requires the restoration of the RWT to an OPERABLE status within 1 hour for reasons other than Condition A or Condition C (e.g., RWT water volume not within limits). ITS ACTION E requires that with the Required Action and associated Completion Time of Condition C (borated water temperature) or D (borated water volume) not met, then be in MODE 3 within 6 hours and MODE 5 within 36 hours consistent with CTS. In addition, the end state of ITS 3.5.4 is MODE 5 consistent with CTS.

ITS ACTION B requires that with the Required Action and associated Completion Time of Condition A (boron concentration) not met, then be in MODE 3 within 6 hours and includes a NOTE modifying Required Action B.1 that states, “LCO 3.0.4.a is not applicable when entering MODE 3 or MODE 4.” This changes CTS by changing the end state of CTS 3.5.4.b, RWT boron concentration, from MODE 5 (Cold Shutdown) to MODE 3 (Hot Standby).

This change is acceptable because the modification of the end state from MODE 5 to MODE 3, with respect to RWT boron concentration, is consistent with CE NPSD-1186-A, Revision 00, “Technical Justification for the Risk-Informed Modification to Selected Required Action End States for CEOG Member PWRs,” dated October 2001 (ADAMS Accession No. ML110410539) and Technical Specifications Task Force (TSTF) traveler TSTF- 422, Revision 2, “Change in Technical Specifications End States, (CE NPSD-1186),“ dated December 22, 2009 (ADAMS Accession No. ML103270197) allowances.

Florida Power & Light Company provided the regulatory commitments regarding the implementation of TSTF-422, Revision 2, in License Amendment Request for Adoption of Technical Specifications Task Force (TSTF) Traveler TSTF-422, Revision 2, "Change in Technical Specifications End States, (CE NPSD-1186)," Using the Consolidated Line Item Improvement Process (ADAMS Accession No. ML16118A272). The NRC issued Amendment Nos. 234 and 184 to Renewed Facility Operating License Nos. DPR-67 and NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2, respectively (ADAMS Accession No. ML16210A374).

This change is designated as less restrictive because instead of requiring the plant to achieve COLD SHUTDOWN (MODE 5) with the RWT boron concentration not restored to within limits, the ITS end state is HOT STANDBY (MODE 3) with the Note that LCO 3.0.4.a not applicable when entering MODE 3 or MODE 4.

L03 **Unit 1 only:** (*Category 7 – Relaxation of Surveillance Frequency)* CTS 4.5.4.b states that the RWT be demonstrated OPERABLE by verifying the RWT water temperature within limits in accordance with the Surveillance Frequency Control Program. ITS SR 3.5.4.1 also states that the RWT be demonstrated OPERABLE by verifying the RWT water temperature within limits in accordance with the Surveillance Frequency Control Program. ITS SR 3.5.4.1 is modified by a Note that eliminates the requirement to perform this Surveillance when ambient air temperatures are within the operating temperature limits of the RWT. This changes the CTS by adopting the ITS SR 3.5.4.1 Note that eliminates the requirement to perform this Surveillance when ambient air temperatures are within the operating temperature limits of the RWT.

The purpose of CTS 4.5.4.b and ITS SR 3.5.4.1 is to verify RWT water temperature within limits. This change is acceptable because with ambient temperatures within the RWT operating temperature limits, the RWT temperature should not exceed the limits since the RWT is exposed to ambient temperature and is not insulated. Because of the RWT design, tank temperature tracks closely with outside ambient temperature. Thus, periodic verification of the RWT temperature is unnecessary while ambient temperature is between 55°F and 100°F. This change is designated as less restrictive because Surveillances will be performed less frequently under the ITS than under the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.5.4, REFUELING WATER TANK (RWT)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.4 Refueling Water Tank (RWT)

BASES

BACKGROUND

The RWT supports the ECCS and the Containment Spray System by providing a source of borated water for Engineered Safety Feature (ESF) pump operation.

The RWT supplies two ECCS trains by separate, redundant supply headers. Each header also supplies one train of the Containment Spray System. A motor operated isolation valve is provided in each header to allow the operator to isolate the usable volume of the RWT from the ECCS after the ESF pump suction has been transferred to the containment sump following depletion of the RWT during a loss of coolant accident (LOCA). A separate header is used to supply the Chemical and Volume Control System (CVCS) from the RWT. Use of a single RWT to supply both trains of the ECCS is acceptable since the RWT is a passive component, and passive failures are not assumed to occur coincidently with the Design Basis Event during the injection phase of an accident. Not all the water stored in the RWT is available for injection following a LOCA; the location of the ECCS suction piping in the RWT will result in some portion of the stored volume being unavailable.

The high pressure safety injection (HPSI), low pressure safety injection (LPSI), and containment spray pumps are provided with recirculation lines that ensure each pump can maintain minimum flow requirements when operating at shutoff head conditions. These lines discharge back to the RWT, which vents to the atmosphere. When the suction for the HPSI and containment spray pumps is transferred to the containment sump, this flow path must be isolated to prevent a release of the containment sump contents to the RWT. If not isolated, this flow path could result in a release of contaminants to the atmosphere and the eventual loss of suction head for the ESF pumps.

This LCO ensures that:

a. The RWT contains sufficient borated water to support the ECCS during the injection phase,

b. Sufficient water volume exists in the containment sump to support continued operation of the ESF pumps at the time of transfer to the recirculation mode of cooling, and

c. The reactor remains subcritical following a LOCA.

BASES

BACKGROUND (continued)

Insufficient water inventory in the RWT could result in insufficient cooling capacity of the ECCS when the transfer to the recirculation mode occurs. Improper boron concentrations could result in a reduction of SDM or excessive boric acid precipitation in the core following a LOCA, as well as excessive caustic stress corrosion of mechanical components and systems inside containment.

APPLICABLE SAFETY ANALYSES

During accident conditions, the RWT provides a source of borated water to the HPSI, LPSI, containment spray, and charging pumps. As such, it provides containment cooling and depressurization, core cooling, and replacement inventory and is a source of negative reactivity for reactor shutdown (Ref. 1). The design basis transients and applicable safety analyses concerning each of these systems are discussed in the Applicable Safety Analyses section of Bases B 3.5.2, "ECCS - Operating," and B 3.6.6, "Containment Spray and Cooling Systems." These analyses are used to assess changes to the RWT in order to evaluate their effects in relation to the acceptance limits.

The volume limit of ~~[362,800]~~ 477,360 gallons is based on two factors: 2

a. Sufficient deliverable volume must be available to provide at least 20 minutes ~~(plus a 10% margin)~~ of full flow from all ESF pumps prior to reaching a low level switchover to the containment sump for recirculation and 1

b. The containment sump water volume must be sufficient to support continued ESF pump operation after the switchover to recirculation occurs. This sump volume water inventory is supplied by the RWT borated water inventory.

Twenty minutes is the point at which 75% of the design flow of one HPSI pump is capable of meeting or exceeding the decay heat boiloff rate.

When ESF pump suction is transferred to the sump, there must be sufficient water in the sump to ensure adequate net positive suction head (NPSH) for the HPSI and containment spray pumps. The RWT capacity must be sufficient to supply this amount of water without considering the inventory added from the safety injection tanks or Reactor Coolant System (RCS), but accounting for loss of inventory to containment subcompartments and reservoirs due to containment spray operation and to areas outside containment due to leakage from ECCS injection and recirculation equipment.

BASES

APPLICABLE SAFETY ANALYSES (continued)

1900

The ~~[1720]~~ ppm limit for minimum boron concentration was established to ensure that, following a LOCA with a minimum level in the RWT, the reactor will remain subcritical in the cold condition following mixing of the RWT and RCS water volumes. Small break LOCAs assume that all control rods are inserted, except for the control element assembly (CEA) of highest worth, which is withdrawn from the core. Large break LOCAs assume that all CEAs remain withdrawn from the core. The most limiting case occurs at beginning of core life. 2

2200

The maximum boron limit of ~~[2500]~~ ppm in the RWT is based on boron precipitation in the core following a LOCA. With the reactor vessel at saturated conditions, the core dissipates heat by pool nucleate boiling. Because of this boiling phenomenon in the core, the boric acid concentration will increase in this region. If allowed to proceed in this manner, a point will be reached where boron precipitation will occur in the core. Post LOCA emergency procedures direct the operator to establish simultaneous hot and cold leg injection to prevent this condition by establishing a forced flow path through the core regardless of break location. These procedures are based on the minimum time in which precipitation could occur, assuming that maximum boron concentrations exist in the borated water sources used for injection following a LOCA. Boron concentrations in the RWT in excess of the limit could result in precipitation earlier than assumed in the analysis. 2

55

The upper limit of ~~[~~100~~]~~°F and the lower limit of ~~[40]~~°F on RWT temperature are the limits assumed in the accident analysis. Although RWT temperature affects the outcome of several analyses, the upper and lower limits established by the LCO are not limited by any of these analyses. 2

The RWT satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The RWT ensures that an adequate supply of borated water is available to cool and depressurize the containment in the event of a Design Basis Accident (DBA) and to cool and cover the core in the event of a LOCA, that the reactor remains subcritical following a DBA, and that an adequate level exists in the containment sump to support ESF pump operation in the recirculation mode.

To be considered OPERABLE, the RWT must meet the limits established in the SRs for water volume, boron concentration, and temperature.

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, the RWT OPERABILITY requirements are dictated by the ECCS and Containment Spray System OPERABILITY requirements. Since ~~both~~ the ECCS ~~and the Containment Spray System~~ must be OPERABLE in MODES 1, 2, 3, and 4, the RWT must be OPERABLE to support ~~their~~ its operation. 1 1

Core cooling requirements in MODE 5 are addressed by LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," and LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled." MODE 6 core cooling requirements are addressed by LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level," and LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level."

ACTIONS

A.1

With RWT boron concentration not within limits, it must be returned to within limits within 8 hours. In this condition neither the ECCS nor the Containment Spray System can perform their design functions; therefore, prompt action must be taken to restore the tank to OPERABLE condition. The allowed Completion Time of 8 hours to restore the RWT to within limits was developed considering the time required to change boron concentration and that the contents of the tank are still available for injection.

B.1

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~

~~1. [LICENSEE] will follow the guidance established in Section 11 of NUMARC 93-01, "Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," Nuclear Management and Resource Council, Revision [4F].~~

~~2. [LICENSEE] will follow the guidance established in Revision 2 of WCAP-16364-NP, "Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422)," Westinghouse, May 2010.~~ 3

If the RWT boron concentration is not restored to within limits within the associated Completion Time, the plant must be brought to MODE 3 within 6 hours. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant

BASES

ACTIONS (continued)

systems. Reference 2 demonstrated that is it acceptable to remain in MODE 3 in this condition because the boron concentration limit is based on MODE 1 events which are unlikely in MODE 3, such as a LOCA, and conditions which do not exist in MODE 3, such as a critical core with all rods out. Since the anticipated deviations from the RWT boron concentration requirements are expected to be small and the ability to correct the deficiency is expected to be readily available, entry into MODE 4 or 5 is not necessary.

Required Action B.1 is modified by a Note that states that LCO 3.0.4.a is not applicable when entering MODE 3 or MODE 4. This Note prohibits the use of LCO 3.0.4.a to enter MODE 3 or MODE 4 during startup with the LCO not met. However, there is no restriction on the use of LCO 3.0.4.b, if applicable, because LCO 3.0.4.b requires performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering MODE 4, and establishment of risk management actions, if appropriate. LCO 3.0.4 is not applicable to, and the Note does not preclude, changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

C.1

With RWT water temperature not within limits, it must be returned to within limits within 8 hours. In this condition neither the ECCS nor the Containment Spray System can perform their design functions; therefore, prompt action must be taken to restore the tank to OPERABLE condition. The allowed Completion Time of 8 hours to restore the RWT to within limits was developed considering the time required to change water temperature and that the contents of the tank are still available for injection.

D.1 or RWT inoperable for reasons other than boron concentration, borated water temperature, or borated water volume, 1

With RWT borated water volume not within limits, it must be returned to within limits within 1 hour. In this condition, neither the ECCS nor Containment Spray System can perform their design functions; therefore, prompt action must be taken to restore the tank to OPERABLE status or to place the unit in a MODE in which these systems are not required. The allowed Completion Time of 1 hour to restore the RWT to OPERABLE status is based on this condition simultaneously affecting multiple redundant trains.

BASES

ACTIONS (continued)

E.1 and E.2

If the RWT temperature or water volume cannot be restored to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.5.4.1

RWT borated water temperature shall be verified to be within the limits assumed in the accident analysis. ~~[This Frequency of 24 hours has been shown to be sufficient to identify temperature changes that approach either acceptable limit.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~]~~

The SR is modified by a Note that eliminates the requirement to perform this Surveillance when ambient air temperatures are within the operating temperature limits of the RWT. With ambient temperatures within this range, the RWT temperature should not exceed the limits.

SR 3.5.4.2

Above minimum RWT water volume level shall be verified. This Frequency ensures that a sufficient initial water supply is available for injection and to support continued ESF pump operation on recirculation. ~~[Since the RWT volume is normally stable and is provided with a Low Level Alarm, a 7 day Frequency is appropriate and has been shown to be acceptable through operating experience.~~ 2

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

SR 3.5.4.3

Boron concentration of the RWT shall be verified to be within the required range. This Frequency ensures that the reactor will remain subcritical following a LOCA. Further, it ensures that the resulting sump pH will be maintained in an acceptable range such that boron precipitation in the core will not occur earlier than predicted and the effect of chloride and caustic stress corrosion on mechanical systems and components will be minimized. ~~[Since the RWT volume is normally stable, a 7 day sampling Frequency is appropriate and has been shown through operating experience to be acceptable.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.4 Refueling Water Tank (RWT)

BASES

BACKGROUND

The RWT supports the ECCS and the Containment Spray System by providing a source of borated water for Engineered Safety Feature (ESF) pump operation.

The RWT supplies two ECCS trains by separate, redundant supply headers. Each header also supplies one train of the Containment Spray System. A motor operated isolation valve is provided in each header to allow the operator to isolate the usable volume of the RWT from the ECCS after the ESF pump suction has been transferred to the containment sump following depletion of the RWT during a loss of coolant accident (LOCA). A separate header is used to supply the Chemical and Volume Control System (CVCS) from the RWT. Use of a single RWT to supply both trains of the ECCS is acceptable since the RWT is a passive component, and passive failures are not assumed to occur coincidently with the Design Basis Event during the injection phase of an accident. Not all the water stored in the RWT is available for injection following a LOCA; the location of the ECCS suction piping in the RWT will result in some portion of the stored volume being unavailable.

The high pressure safety injection (HPSI), low pressure safety injection (LPSI), and containment spray pumps are provided with recirculation lines that ensure each pump can maintain minimum flow requirements when operating at shutoff head conditions. These lines discharge back to the RWT, which vents to the atmosphere. When the suction for the HPSI and containment spray pumps is transferred to the containment sump, this flow path must be isolated to prevent a release of the containment sump contents to the RWT. If not isolated, this flow path could result in a release of contaminants to the atmosphere and the eventual loss of suction head for the ESF pumps.

This LCO ensures that:

a. The RWT contains sufficient borated water to support the ECCS during the injection phase,

b. Sufficient water volume exists in the containment sump to support continued operation of the ESF pumps at the time of transfer to the recirculation mode of cooling, and

c. The reactor remains subcritical following a LOCA.

BASES

BACKGROUND (continued)

Insufficient water inventory in the RWT could result in insufficient cooling capacity of the ECCS when the transfer to the recirculation mode occurs. Improper boron concentrations could result in a reduction of SDM or excessive boric acid precipitation in the core following a LOCA, as well as excessive caustic stress corrosion of mechanical components and systems inside containment.

APPLICABLE SAFETY ANALYSES

During accident conditions, the RWT provides a source of borated water to the HPSI, LPSI, containment spray, and charging pumps. As such, it provides containment cooling and depressurization, core cooling, and replacement inventory and is a source of negative reactivity for reactor shutdown (Ref. 1). The design basis transients and applicable safety analyses concerning each of these systems are discussed in the Applicable Safety Analyses section of Bases B 3.5.2, "ECCS - Operating," and B 3.6.6, "Containment Spray and Cooling Systems." These analyses are used to assess changes to the RWT in order to evaluate their effects in relation to the acceptance limits.

The volume limit of ~~[362,800]~~ 477,360 gallons is based on two factors: 2

a. Sufficient deliverable volume must be available to provide at least 20 minutes ~~(plus a 10% margin)~~ of full flow from all ESF pumps prior to reaching a low level switchover to the containment sump for recirculation and 1

b. The containment sump water volume must be sufficient to support continued ESF pump operation after the switchover to recirculation occurs. This sump volume water inventory is supplied by the RWT borated water inventory.

Twenty minutes is the point at which 75% of the design flow of one HPSI pump is capable of meeting or exceeding the decay heat boiloff rate.

When ESF pump suction is transferred to the sump, there must be sufficient water in the sump to ensure adequate net positive suction head (NPSH) for the HPSI and containment spray pumps. The RWT capacity must be sufficient to supply this amount of water without considering the inventory added from the safety injection tanks or Reactor Coolant System (RCS), but accounting for loss of inventory to containment subcompartments and reservoirs due to containment spray operation and to areas outside containment due to leakage from ECCS injection and recirculation equipment.

BASES

APPLICABLE SAFETY ANALYSES (continued)

1900

The ~~[1720]~~ ppm limit for minimum boron concentration was established to ensure that, following a LOCA with a minimum level in the RWT, the reactor will remain subcritical in the cold condition following mixing of the RWT and RCS water volumes. Small break LOCAs assume that all control rods are inserted, except for the control element assembly (CEA) of highest worth, which is withdrawn from the core. Large break LOCAs assume that all CEAs remain withdrawn from the core. The most limiting case occurs at beginning of core life. 2

2200

The maximum boron limit of ~~[2500]~~ ppm in the RWT is based on boron precipitation in the core following a LOCA. With the reactor vessel at saturated conditions, the core dissipates heat by pool nucleate boiling. Because of this boiling phenomenon in the core, the boric acid concentration will increase in this region. If allowed to proceed in this manner, a point will be reached where boron precipitation will occur in the core. Post LOCA emergency procedures direct the operator to establish simultaneous hot and cold leg injection to prevent this condition by establishing a forced flow path through the core regardless of break location. These procedures are based on the minimum time in which precipitation could occur, assuming that maximum boron concentrations exist in the borated water sources used for injection following a LOCA. Boron concentrations in the RWT in excess of the limit could result in precipitation earlier than assumed in the analysis. 2

55

The upper limit of ~~[~~100~~]~~°F and the lower limit of ~~[40]~~°F on RWT temperature are the limits assumed in the accident analysis. Although RWT temperature affects the outcome of several analyses, the upper and lower limits established by the LCO are not limited by any of these analyses. 2

The RWT satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The RWT ensures that an adequate supply of borated water is available to cool and depressurize the containment in the event of a Design Basis Accident (DBA) and to cool and cover the core in the event of a LOCA, that the reactor remains subcritical following a DBA, and that an adequate level exists in the containment sump to support ESF pump operation in the recirculation mode.

To be considered OPERABLE, the RWT must meet the limits established in the SRs for water volume, boron concentration, and temperature.

BASES

APPLICABILITY

In MODES 1, 2, 3, and 4, the RWT OPERABILITY requirements are dictated by the ECCS and Containment Spray System OPERABILITY requirements. Since ~~both~~ the ECCS ~~and the Containment Spray System~~ must be OPERABLE in MODES 1, 2, 3, and 4, the RWT must be OPERABLE to support ~~their~~ its operation. 1 1

Core cooling requirements in MODE 5 are addressed by LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," and LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled." MODE 6 core cooling requirements are addressed by LCO 3.9.4, "Shutdown Cooling (SDC) and Coolant Circulation - High Water Level," and LCO 3.9.5, "Shutdown Cooling (SDC) and Coolant Circulation - Low Water Level."

ACTIONS

A.1

With RWT boron concentration not within limits, it must be returned to within limits within 8 hours. In this condition neither the ECCS nor the Containment Spray System can perform their design functions; therefore, prompt action must be taken to restore the tank to OPERABLE condition. The allowed Completion Time of 8 hours to restore the RWT to within limits was developed considering the time required to change boron concentration and that the contents of the tank are still available for injection.

B.1

~~REVIEWER'S NOTE~~

~~Adoption of a MODE 4 end state requires the licensee to make the following commitments:~~
