6. FPL Letter L-2022-009 dated January 19, 2022, License Amendment Request for the Technical Specifications Conversion to NUREG-1432 Revision 5 – Request for Supplemental Information (RSI) Response (ADAMS Accession No. ML22019A069)
7. NRC Letter dated February 23, 2022, St. Lucie Nuclear Plant, Unit Nos. 1 And 2 – Acceptance of Licensing Amendment Request for The Technical Specification Conversion to NUREG-1432, Revision 5 (EPID L-2021-LLI-0000) (ADAMS Accession Nos. ML22049A553)

FPL, licensee for St. Lucie Plant (PSL), Units 1 and 2, has submitted an Improved Technical Specifications (ITS) conversion License Amendment Request (LAR) for the Facility Operating Licenses for PSL Units 1 and 2 (References 1 and 2). On November 17, 2021, the NRC held a public meeting (References 3) with FPL to discuss review topics of interest (Reference 4) for the ITS conversion LAR submittals. Based on this meeting, the NRC subsequently issued to FPL its request for supplemental information (RSI) for the PSL ITS conversion LAR (Reference 5). FPL responded to the RSI on January 19, 2022 (Reference 6). On February 23, 2022, the NRC issued to FPL the St. Lucie Nuclear Plant, Units 1 and 2 - Acceptance of License Amendment Request for the Technical Specifications Conversion to NUREG-1432, Revision 5 (EPID L-2021-LLI-0000).

This submittal incorporates the changes as identified in Reference 6 and other enhancements. Enhancements include self-identified editorial and typographical corrections and as identified by the

NRC in Enclosure 2 of Reference 5. These enhancements support the goal of conforming, to the extent practical, to Revision 5 of NUREG-1432.

There are six enclosures to this letter. Enclosures 2 and 4 contain content changes. There are no changes to Enclosures 1, 3, 5, and 6. Revisions in Enclosures 2 and 4 revisions are denoted by revision bars. Enclosures 1, 3, 5, and 6 are included in Revision 1 for completeness.

In addition to the enclosures, the letter contains one attachment. Attachment 1 provides a discussion of the LAR Revision 1 content and includes a description of the additional pages added to the ITS Conversion LAR and FPL responses to NRC recommended editorial changes not incorporated.

For ease of reference, the index of enclosed Revision 1 information is provided on page 3 of this letter.

Based on the information provided in Enclosure 2, FPL determined that the proposed license amendment does not involve a significant hazards consideration pursuant to 10 CFR 50.92(c) and that the changes are exempt from environmental review pursuant to the provisions of 10 CFR 51.22(c)(9).

Should you have any questions regarding this submittal, please contact me at (561) 304-6256 or William.Maher@fpl.com.

I declare under penalty of perjury that the foregoing is true and correct.

Executed on the 3rd day of June 2022.

Sincerely,

William Maher

CONTENTS OF THE ST. LUCIE PLANT, UNITS 1 AND 2, IMPROVED TECHNICAL SPECIFICATIONS (ITS) REVISION 1 SUBMITTAL

Summary of LAR Changes

By letter dated September 15, 2021 (Reference 1), Florida Power & Light Company (FPL) requested a license amendment to convert St. Lucie Plant Units 1 and 2 (PSL) current Technical Specifications (CTS) to a version based on U.S. NRC NUREG 1432, "Standard Technical Specifications – Combustion Engineering Plants," Revision 5.0 (ISTS) designated as PSL's improved Technical Specifications (ITS). On December 21, 2021 (Reference 2), the NRC provided a request for supplemental information (RSI) to support the NRC staff's acceptance review. The supplemental information requested by the NRC was provided by FPL by letter dated January 19, 2022 (Reference 3). To support the NRC with the formal review of the PSL ITS Conversion license amendment request (LAR), the PSL ITS LAR has been revised to incorporate changes as identified in the FPL response to the NRC RSI during LAR acceptance review.

Revision 1 to the PSL ITS LAR includes:

1. Editorial and typographical corrections self-identified post ITS LAR submittal and as identified by the NRC staff during acceptance review of the ITS application (Reference 3);
2. Incorporation of changes, as applicable, identified in the responses to the NRC RSI (Reference 3);
3. Incorporation of recently revised Unit 1 CTS 3.8.2.1 and Unit 2 CTS 3.8.3.1 pages to reflect PSL Amendments 252 (Unit 1) and 207 (Unit 2) associated with the addition of Risk Informed Completion Times for the Inverters and 120 V AC instrument buses (Reference 4);
4. Modification of noted allowance in ITS 3.4.8, “RCS Loops - MODE 5, Loops Not Filled,” to restore PSL current licensing basis of 1 hour to remove shutdown cooling (SDC) pumps from operation instead of the more restrictive ITS requirement of 15 minutes to remove SDC pumps from operation when switching from one loop to another; and
5. Added Discussion of Change (DOC) L07 to ITS 3.3.1 to address Unit 2 CTS Table 4.3-1, Functional Unit 15 Channel Functional Test Frequency change from “in accordance with the Surveillance Frequency Control Program” to “Once within 7 days prior to each reactor startup” to be consistent with Unit 1 CTS and the ISTS.

Revision to Enclosures 2 and 4 of the original ITS submittal is provided with revision bars annotating the changes. Enclosures 1, 3, 5, and 6 of the original ITS submittal did not require revision but are provided in LAR Revision 1 for completeness.

NRC Recommended Editorials Not Incorporated

In the NRC to FPL letter dated December 21, 2021 (Reference 2), Enclosure 2 provides a list of editorial issues identified by the NRC staff. As stated in the letter, the items in Enclosure 2 were included for FPL’s information only. These editorial issues have been incorporated into Revision 1 of the ITS Conversion LAR except for the following:

Volume 8 – Section 3.3 (ADAMS Accession No. ML21265A293)

1. On pages 68, 69, 80, and 81/450, Both Units – The ITS say to insert figure 2.2-1, but there does not appear to be adequate space on the page. If another page is added the page

numbering will be incorrect. Also figure 3.3.1-3 on ITS page 3.3.1-12 (taken from CTS figure 2.2-2) is labeled page 1 of 1, but it appears to be page 2 of 2. Figure 2.2-1 appears to be page 1 of 2.

FPL Response

No change is made to the submittal. The CTS Figure inserts listed herein correlate the CTS Figures to the ITS Figure 3.3.1-1, ITS Figure 3.3.1-2, and ITS Figure 3.3.1-3, as applicable. ITS Figure 3.3.1-3, as indicated, will contain two pages.

- CTS Figure 2.2-3 will be ITS Figure 3.3.1-1 (Page 1 of 1),
- CTS Figure 2.2-4 will be ITS Figure 3.3.1-2 (Page 1 of 1),
- CTS Figure 2.2-1 will be ITS Figure 3.3.1-3 (Page 1 of 2), and
- CTS Figure 2.2-2 will be ITS Figure 3.3.1-3 (Page 2 of 2).

Additionally, the ITS page numbering is updated in the clean typed ITS that will be provided prior to issuance of the license amendment and based on the changes identified in the ISTS markups. Repagination is not shown in any ISTS markup.

2. On pages 88 and 128/450 and others, Affects Both Units – The bases refer to Variable Power Level – High Trip as the VPHT. Also, the term is written as Variable Power Level Trip – High. The TS Table 3.3.1-1 does not include the term “Trip.” The bases should be consistent with the TS and the acronym should be reflective of the name of the trip or be deleted. This issue shows up multiple times in the bases.

FPL Response

No change is made to the VHPT acronym as it relates to the Reactor Protection System Instrument Function 1, Variable Power Level – High. The VHPT acronym is consistent with PSL terminology for this Function as shown in the Updated Final Safety Analysis Report (UFSAR).

Additional LAR Content

Revision 1 of the ITS LAR contains a total of 14 additional pages not included in Revision 0. The following provides a list of the additional LAR pages and a discussion of the contents of the additional pages:

Volume 6, ITS Section 3.1 (NRC ADAMS Accession No. ML21265A291)

- Added 1 page - Added cover page for Attachment 9, Relocated/Deleted Current Technical Specifications.”

Volume 10, ITS Section 3.5 (NRC ADAMS Accession No. ML21265A295)

- Added 12 pages - Added Attachment 6, ISTS Not Adopted, which indicates ISTS 3.5.5, “Trisodium Phosphate (TSP),” is not adopted for the PSL Unit 1 ITS. TSP is not included in the PSL Unit 1 design and licensing basis for removal of iodine fission product inventory and control of pH in the containment sump during accident conditions. PSL Unit 1 utilizes the Spray Additive System to remove iodine fission product inventory and control pH in the containment sump during accident conditions.

Volume 12, ITS Section 3.7 (NRC ADAMS Accession No. ML21265A297) - Attachment 18, Relocated/Deleted Current Technical Specifications

- Deleted 26 pages – Removed pages that were partial duplicate of ITS 3.7.11.

- Added 15 pages - 8 pages added for relocation of Unit 1 and Unit 2 CTS 3/4.7.2, Steam Generator Pressure/Temperature and 7 pages added for relocation of Unit 2 CTS 3/4.7.6, Flood Protection.
- Total reduction of 11 pages in Section 3.7 from Volume 12 of Enclosure 2 of the ITS LAR Rev. 0.

Volume 13, ITS Section 3.8 (NRC ADAMS Accession No. ML21265A298)

- ITS 3.8.5 - Discussion of Changes – Added 1 page. Added DOC L05 to ITS 3.8.5, DC Sources, Discussion of Changes which changes the number of pages from 4 pages to 5 pages.

Volume 14, ITS Section 3.9 (NRC ADAMS Accession No. ML21265A299)

- Added Attachment 7, Relocated/Deleted Current Technical Specifications which added 9 pages for relocation of Unit 1 and Unit 2 CTS 3/4.9.3, Decay Time.

Volume 16, ITS Chapter 5.0 (NRC ADAMS Accession No. ML21265A301)

- ITS Section 5.2 - Discussion of Changes - Added 1 page. Added DOC A06 to ITS 5.2, Organization, which changes the number of pages from 4 pages to 5 pages.

- ITS Section 5.5 - Discussion of Changes - Added 1 page. Added DOC M04 and DOC LA08 to ITS 5.5, Programs and Manuals, Discussion of Changes which changes the number of pages from 11 pages to 12 pages.

CONTENTS OF THE ST. LUCIE PLANT IMPROVED TECHNICAL SPECIFICATIONS (ITS) SUBMITTAL

Executive Summary

The proposed changes from the St. Lucie Plant (PSL) Unit 1 and Unit 2 current Technical Specifications (CTS) to the Improved Technical Specifications (ITS) are based on Revision 5.0 of NUREG 1432, “Standard Technical Specifications – Combustion Engineering Plants.” There are no additional NRC approved generic changes (Technical Specification Task Force (TSTF) change travelers) since approval of NUREG-1432, Revision 5, to address in this license amendment request as of September 15, 2021. Additionally, there are no linked PSL submittals associated with this ITS license amendment request. Technical Specification Task Force (TSTF)-GG-13-01, “Improved Technical Specifications Conversion Guidance,” Revision 0, was used to prepare the content of the license amendment request.

- The Battery Monitoring and Maintenance Program is included to provide for battery restoration and maintenance per the guidance of IEEE 450-2010, “IEEE Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications.” The Notice of Availability for TSTF-500, Revision 2, "DC Electrical Rewrite - Update to TSTF-360," (76FR54510) references the model application and safety evaluation for plant-specific adoption of TSTF–500, Revision 2 (NRC ADAMS Accession No. ML111751792). PSL has verified the applicable information specified in Section 2.2 of the TSTF-500 model application, including applicable UFSAR information. FPL has verified the following information in support of PSL adoption of TSTF-500, Revision 2:

- A letter has been obtained from the manufacturer of the batteries used at PSL Units 1 and 2 verifying the acceptability of using float current monitoring instead of specific gravity monitoring as a reliable and accurate indication of the state-of-charge of the battery and that this will hold true over the life of the battery.

- Measurement equipment used to monitor float current has the necessary accuracy and capability to measure electrical currents in the expected range.

- Spare battery chargers are available and appropriately sized to support each battery. Each 125 VDC battery charger is a full capacity charger. Typically, two battery chargers are operated in parallel to supply the battery and carry the DC loads. However, either connected battery charger can meet full DC bus load demand and recharge its associated battery. In addition, an additional full capacity swing battery charger can be connected to either DC bus.

- Maintaining battery connection resistances below the battery manufacturer specifications keeps the battery bounded by the battery performance data that was used to qualify the cells. The connection resistance readings are maintained within

20% of the baseline resistance values determined during installation for optimum performance of the battery system. IEEE 450-2010 supports this methodology.

Commitments associated with TSTF-500 are provided in Enclosure 5. A description of the UFSAR changes associated with TSTF-500 are provided in Enclosure 6. Commitments and UFSAR revision packages associated with TSTF-500 will be completed prior to implementation of the ITS Amendment.

Several risk informed initiatives incorporated into the Improved Standard Technical Specifications (ISTS) and associated Bases specified in NUREG-1432, Rev. 5.0, have been previously approved and incorporated into the PSL Unit 1 and Unit 2 Technical Specifications. Therefore, information related to the NRC reviewer notes provided in the ISTS and ISTS Bases associated with these risk informed initiatives are provided in the LAR submittals, FPL responses to NRC staff requests for additional information, and accompanying safety evaluations associated with these risk informed license amendments.

PSL adopted a Surveillance Frequency Control Program (SFCP) on June 22, 2015, in License Amendments 223 and 173, for Unit 1 and Unit 2 respectively (NRC ADAMS Accession No. ML15127A066). In the NRC safety evaluation accompanying the SFCP amendments, the NRC concluded that the adoption of TSTF-425, Revision 3, and risk-informed methodology of NEI 04-10, "Risk-Informed Method for Control of Surveillance Frequencies," Revision 1, as referenced in the Administrative Controls section of the Technical Specifications, satisfies the key principles of risk-informed decisionmaking applied to the relocated Surveillance frequencies as delineated in Regulatory Guide 1.177, Revision 1, and Regulatory Guide 1.174, Revision 2. Changes to Surveillance frequencies listed in the SFCP are made in accordance with NEI 04-10, Revision 1, as specified in CTS Chapter 6 (ITS Chapter 5).

PSL adopted TSTF-422, "Change in Technical Specifications End States (CE NPSD-1186)," Revision 2, with application of site-specific variations and deviations from TSTF-422, on August 30, 2016, in License Amendments 234 and 184, for Unit 1 and Unit 2 respectively (NRC ADAMS Accession No. ML16210A374). As stated in several NRC reviewer notes in the ISTS Bases, the adoption of a MODE 4 end state requires the licensee to make commitments to follow the guidance established in Section 11 of NUMARC 93-01, “Industry Guidance for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants,” Nuclear Management and Resource Council, Revision [4F] and in Revision 2 of WCAP-16364-NP, “Implementation Guidance for Risk Informed Modification to Selected Required Action End States at Combustion Engineering NSSS Plants (TSTF-422).” FPL conducts risk assessments using the procedures and guidance endorsed by Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants." Regulatory Guide 1.160 endorses the guidance in Section 11 of NUMARC 93-01, Revision 4A. As stated in the safety evaluation accompanying the TSTF-422 End-State amendments, FPL also reviewed the supporting Topical Report WCAP-16364-NP, Revision 2. The NRC staff concluded that PSL's commitment to Regulatory Guide 1.160 guidance is acceptable for application of TSTF-422.

PSL adopted TSTF -505, Revision 1, "Provide Risk-Informed Extended Completion Times - RITSTF Initiative 4b" to include Risk Informed Completion Times (RICTs) for

selected Technical Specification systems. License Amendments 247 and 199, were issued on July 2, 2019, for Unit 1 and Unit 2 respectively, to incorporate the RICTs and an associated administrative program (NRC ADAMS Accession No. ML19113A099). In the NRC safety evaluation accompanying the RICT amendment, the NRC found that the PSL PRA maintenance and change process ensures that the configuration risk management program models used in the RICT calculations will continue to use PRA methods acceptable to the NRC and that the PRA model will be updated as necessary to reflect the as-built and as-operated plant. The NRC also found that appropriate programmatic and procedural controls for the RICT Program are consistent with the guidance of NEI 06-09, Revision 0-A. Controls to calculate Risk Informed Completion Times (RICTs) are provided in the CTS Chapter 6 (ITS Chapter 5) and implemented in accordance with NEI 06-09-A, Revision 0, "Risk-Managed Technical Specifications (RMTS) Guidelines." The LAR submittal, FPL responses to NRC staff requests for additional information, and safety evaluation accompanying the RICT amendment address the implementation of the RICT program to perform a contemporaneous assessment of the overall impact on safety of proposed plant configurations prior to performing and during performance of maintenance activities that remove equipment from service as stated in several NRC reviewer notes in the ISTS Bases.

Enclosure 2 of the submittal for the conversion of the PSL Unit 1 and Unit 2 CTS to the ITS provides the proposed changes to the CTS, discussion of changes for the proposed CTS changes, the PSL Unit 1 and Unit 2 ITS and ITS Bases, as marked up utilizing NUREG-1432, and justification for deviations from the NUREG. Enclosure 2 consists of the following sixteen volumes:

Volume Titles

1. Application of Selection Criteria to the St. Lucie Plant Technical Specifications
2. Generic Determination of No Significant Hazards Considerations and Environmental Assessment
3. ITS Chapter 1.0, Use and Application
4. ITS Chapter 2.0, Safety Limits
5. ITS Section 3.0, Limiting Condition for Operation (LCO) Applicability and Surveillance Requirement (SR) Applicability
6. ITS Section 3.1, Reactivity Control Systems
7. ITS Section 3.2, Power Distribution Limits
8. ITS Section 3.3, Instrumentation
9. ITS Section 3.4, Reactor Coolant System
10. ITS Section 3.5, Emergency Core Cooling Systems (ECCS)
11. ITS Section 3.6, Containment Systems
12. ITS Section 3.7, Plant Systems
13. ITS Section 3.8, Electrical Power Systems
14. ITS Section 3.9, Refueling Operations
15. ITS Chapter 4.0, Design Features
16. ITS Chapter 5.0, Administrative Controls

Volume 1 is provided to assist the Nuclear Regulatory Commission (NRC) in the review and approval of Volumes 2 through 16. Below is a brief description of the content of each of the volumes in this submittal.

Volume 1

Volume 1 provides details concerning the application of the selection criteria to the individual PSL Unit 1 and Unit 2 CTS. Each CTS Specification is evaluated, and a determination is made as to whether the CTS Specification meets the criteria in 10 CFR 50.36(c)(2)(ii) for retention in the proposed ITS.

Volume 2

Volume 2 contains generic evaluations required by 10 CFR 50.91(a), which support a finding of No Significant Hazards Consideration (NSHC). Based on the inherent similarities in the NSHC evaluations, generic evaluations for a finding of NSHC have been provided for the following categories of CTS changes:

- Administrative Changes
- More Restrictive Changes
- Relocated Specifications
- Removed Detail Changes
- Less Restrictive Changes - Category 1 - Relaxation of LCO Requirements
- Less Restrictive Changes - Category 2 - Relaxation of Applicability
- Less Restrictive Changes - Category 3 - Relaxation of Completion Time
- Less Restrictive Changes - Category 4 - Relaxation of Required Action
- Less Restrictive Changes - Category 5 - Deletion of Surveillance Requirement
- Less Restrictive Changes - Category 6 - Relaxation of Surveillance Requirement Acceptance Criteria
- Less Restrictive Changes - Category 7 - Relaxation of Surveillance Frequency
- Less Restrictive Changes - Category 8 - Deletion of Surveillance Requirement Shutdown Performance Requirements
- Less Restrictive Changes - Category 9 - Deletion of Reporting Requirements

For less restrictive changes not covered by a generic Less Restrictive Change category, specific NSHC evaluations have been provided in the applicable Chapter, Section, or Specification in Volumes 3 through 16. Additionally, specific NSHC evaluations have been provided for changes that have been identified beyond the CTS and the ISTS consistent with the guidance of TSTF-GG-13-01.

In addition, Volume 2 contains an evaluation of environmental consideration in accordance with 10 CFR 51.21. It has been determined that the proposed license amendment meets the eligibility criteria for categorical exclusion set forth in 10 CFR 51.22(b), and no environmental impact statement or environmental assessment need be prepared in connection with the proposed license amendment.

Volumes 3 through 16

Volumes 3 through 16 provide the details and justification to support the proposed changes. Each volume corresponds to a Chapter, Section, or Specification of NUREG-1432. Volumes 3, 4, and 15 are arranged by ITS Chapter. Volumes 5 and 16 are arranged by ITS Section. Volumes 6 through 14 are arranged by ITS Specification. Each volume contains the required information to review the conversion to ITS, and include the following:

- Individual Chapter, Section, or Specification, as applicable, in ITS order.
- Relocated/Deleted CTS Specifications (if applicable); and
- ISTS Specifications not adopted in the PSL Unit 1 and Unit 2 ITS (if applicable).

The information for each Chapter, Section, and Specification, as applicable, is organized as follows:

CTS Markup and Discussion of Changes (DOCs)

This section contains a markup of the CTS pages, either for CTS pages associated with an Individual ITS Specification or for Relocated/Deleted CTS Specifications, and the DOCs from the CTS. Other CTS license amendment requests under NRC review, as described in Enclosure 4 of this submittal, are not linked to this license amendment request and have not been incorporated in the proposed change.

The CTS markup pages for each ITS Specification are normally in numerical order. However, more than one CTS Specification is sometimes used in the generation of an ITS Specification. In this case, the CTS pages that are the major contributor to the ITS Specification are shown first, followed by the remaining associated CTS pages in numerical order.

The left-hand margin of the CTS markup pages includes a cross-reference to the equivalent ITS requirement. The upper right-hand corner of the CTS markup pages is annotated with the ITS Specification number to which it applies. Items on the CTS markup pages that are addressed in other proposed ITS Chapters, Sections, or Specifications are annotated with the appropriate reference.

The CTS markup pages are annotated with an alphanumeric designator to identify the differences between the CTS and the proposed ITS. The designator corresponds to a DOC, which provides the description and justification of the change to the CTS. The DOCs are located directly following the associated CTS markup for each Chapter, Section, or Specification, as applicable.

Each proposed change to the CTS is designated as one of the following DOC categories:

Designator	**Category**
A	ADMINISTRATIVE CHANGES – Changes to the CTS that do not result in new requirements or change operational restrictions or flexibility. These changes are supported in aggregate by a single generic NSHC.
M	MORE RESTRICTIVE CHANGES - Changes to the CTS that result in added restrictions or reduced flexibility. These changes are supported in aggregate by a single generic NSHC.
R	RELOCATED SPECIFICATIONS - Changes to the CTS that relocate specifications that do not meet the selection criteria of

10 CFR 50.36(c)(2)(ii). These changes are supported in aggregate by a single generic NSHC.

LA REMOVED DETAIL CHANGES - Changes to the CTS that eliminate detail and relocate the detail to a licensee controlled document. Typically, this involves details of system design and function, or procedural detail on methods of conducting a Surveillance Requirement. These changes are supported in aggregate by a single generic NSHC. In addition, the generic type of removed detail change is identified in italics at the beginning of the DOC.

L LESS RESTRICTIVE CHANGES - Changes to the CTS that result in reduced restrictions or added flexibility. These changes are supported either in aggregate by a generic NSHC that addresses a particular category of less restrictive change, or by a specific NSHC if the change is not covered by one of the generic categories of less restrictive changes. If the less restrictive change is covered by a generic NSHC, the category of the change is identified in italics at the beginning of the DOC.

The DOCs are numbered sequentially within each letter designator for each ITS Chapter, Section, or Specification. Where a proposed change is applicable to only Unit 1 or Unit 2, it is identified as such at the beginning of the DOC in bold text.

The CTS Bases pages are replaced in their entirety by the proposed PSL Unit 1 and Unit 2 ITS Bases. Therefore, the CTS Bases markup pages are not provided in the ITS submittal.

ISTS Markup and Justification for Deviations (JFDs)

This section contains a markup of the NUREG-1432, Volume 1, ISTS pages, either for ISTS pages associated with an Individual ITS Specification or ISTS Specifications not adopted in the PSL ITS, and JFDs from the ISTS. The ISTS pages are annotated with a numeric designator to identify the differences between the ISTS and the proposed ITS. The designator corresponds to a JFD, which provides the justification for the difference. Where a JFD is applicable to only Unit 1 or Unit 2, it is identified as such at the beginning of the JFD in bold text. The JFDs are located directly following the associated ISTS markup for each Chapter, Section, or Specification, as applicable.

The left-hand margin of the ISTS markup pages includes a cross-reference to the equivalent CTS requirement.

ISTS Bases Markup and JFDs

This section contains a markup of the NUREG-1432, Volume 2, ISTS Bases pages, either for ISTS Bases pages associated with an Individual ITS Specification or ISTS Specifications not adopted in the PSL Unit 1 and 2 ITS, and JFDs from the ISTS Bases. The ISTS Bases pages are annotated with a numeric designator to identify the differences between the ISTS Bases and the proposed ITS Bases. The designator corresponds to a JFD, which provides the justification for the difference. Where a JFD is applicable to only Unit 1 or Unit 2, it is identified as such at the beginning of the JFD

in bold text. The Bases JFDs are located directly following the associated ISTS Bases markup for each Chapter, Section, or Specification, as applicable. The volumes for ITS Chapters 1.0, 4.0, and 5.0 do not include this section, because NUREG-1432 does not include any Bases for these Chapters.

Determination of NSHC

This section contains the determination in accordance with 10 CFR 50.91(a)(1) using the criteria of 10 CFR 50.92(c) to support a finding of NSHC. For changes covered by a generic NSHC, the generic NSHCs are in Volume 2. For less restrictive changes not covered by a generic less restrictive category or have been determined to be a change beyond the CTS and the ITS, a specific NSHC evaluation has been performed. Each evaluation is annotated to correspond to the DOC discussed in the specific NSHC evaluation. For ITS Chapters, Sections, or Specifications for which the changes are covered by a generic NSHC evaluation, a statement that there are no specific NSHCs is provided.

APPENDIX

A. JUSTIFICATION FOR SPECIFICATION RELOCATION

APPLICATION OF SELECTION CRITERIA
TO THE ST LUCIE PLANT UNIT 1 AND UNIT 2
TECHNICAL SPECIFICATIONS

1. INTRODUCTION

The purpose of this document is to confirm the results of the Combustion Engineering (C-E) Owners Group application of the Technical Specification selection criteria on a plant specific basis for the St. Lucie Nuclear Plant (PSL) Unit 1 and Unit 2. Florida Power & Light Company (hereinafter FPL) has reviewed the application and confirmed the applicability of the selection criteria to each of the Technical Specifications utilized in report CEN-355, "C-E Owners Group Restructured Standard Technical Specifications Volume 1 Criteria Application," (Reference 1), NRC Staff Review of nuclear steam supply system (NSSS) Vendor Owners Groups Application of The Commission's Interim Policy Statement Criteria To Standard Technical Specifications, Wilgus/Murley letter dated May 9, 1988 (Reference 2), and as revised in NUREG-1432, Revision 5.0 "Standard Technical Specifications, Combustion Engineering Plants" (Reference 3) and applied the criteria to each of the current PSL Technical Specifications. Additionally, in accordance with the NRC Final Policy Statement (Reference 4), this confirmation of the application of selection criteria includes confirming the risk insights from Probabilistic Risk Assessment (PRA) evaluations, provided in Reference 1, as applicable to the PSL.

2. SELECTION CRITERIA

FPL has utilized the selection criteria provided in Section 36 of Part 50 of Title 10 of the Code of Federal Regulations (10 CFR 50.36), dated July 19, 1995 (Reference 5), which were codified following issuance of the Final Commission Policy Statement on Technical Specifications Improvements for Nuclear Power Reactors, dated July 22, 1993 (Reference 4) to develop the results contained in the attached matrix. PRA insights as used in the C-E Owners Group submittal were utilized, confirmed by FPL, and are discussed in the next section of this report. The selection criteria and discussion provided in Reference 4 are as follows:

Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary:

Discussion of Criterion 1: A basic concept in the adequate protection of the public health and safety is the prevention of accidents. Instrumentation is installed to detect significant abnormal degradation of the reactor coolant pressure boundary so as to allow operator actions to either correct the condition or to shut down the plant safely, thus reducing the likelihood of a loss-of-coolant accident.

This criterion is intended to ensure that Technical Specifications control those instruments specifically installed to detect excessive reactor coolant system leakage. This criterion should not, however, be interpreted to include instrumentation to detect precursors to reactor coolant pressure boundary leakage or instrumentation to identify the source of actual leakage (e.g., loose parts monitor, seismic instrumentation, valve position indicators).

Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a design basis accident (DBA) or transient analyses that either assumes the failure of or presents a challenge to the integrity of a fission product barrier:

Discussion of Criterion 2: Another basic concept in the adequate protection of the public health and safety is that the plant shall be operated within the bounds of the initial conditions assumed in the existing DBA and transient analyses and that the plant will be operated to preclude unanalyzed transients and accidents. These analyses consist of postulated events, analyzed in

the Final Safety Analysis Report (FSAR), for which a structure, system, or component must meet specified functional goals. These analyses are contained in Chapters 6 and 15 of the FSAR (or equivalent chapters) and are identified as Condition II, III, or IV events (ANSI N18.2) (or equivalent) that either assume the failure of or present a challenge to the integrity of a fission product barrier.

As used in Criterion 2, process variables are only those parameters for which specific values or ranges of values have been chosen as reference bounds in the DBA or transient analyses and which are monitored and controlled during power operation such that process values remain within the analysis bounds. Process variables captured by Criterion 2 are not, however, limited to only those directly monitored and controlled from the control room.

These could also include other features or characteristics that are specifically assumed in DBA and transient analyses even if they cannot be directly observed in the control room (e.g, moderator temperature coefficient and hot channel factors).

The purpose of this criterion is to capture those process variables that have initial values assumed in the DBA and transient analyses, and which are monitored and controlled during power operation. If these variables are maintained within the established values, risk to the public safety is presumed to be acceptably low. This criterion also includes active design features (e.g., high pressure/low pressure system valves and interlocks) and operating restrictions (pressure/temperature limits) needed to preclude unanalyzed accidents and transients.

Criterion 3: A structure, system, or component that is part of the primary success path and which functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier:

Discussion of Criterion 3: A third concept in the adequate protection of the public health and safety is that in the event that a postulated DBA or transient should occur, structures, systems, and components are available to function or to actuate in order to mitigate the consequences of the DBA or transient. Safety sequence analyses or their equivalent have been performed in

recent years and provide a method of presenting the plant response to an accident. These can be used to define the primary success paths.

A safety sequence analysis is a systematic examination of the actions required to mitigate the consequences of events considered in the plant's DBA and transient analyses, as presented in Chapters 6 and 15 of the plant's Final Safety Analysis Report (or equivalent chapters). Such a safety sequence analysis considers all applicable events, whether explicitly or implicitly presented. The primary success path of a safety sequence analysis consists of the combination and sequences of equipment needed to operate (including consideration of the single failure criteria), so that the plant response to DBAs and transients limits the consequences of these events to within the appropriate acceptance criteria.

It is the intent of this criterion to capture into Technical Specifications only those structures, systems, and components that are part of the primary success path of a safety sequence analysis. Also captured by this criterion are those support and actuation systems that are necessary for items in the primary success path to successfully function. The primary success path for a particular mode of operation does not include backup and diverse equipment (e.g., rod withdrawal block which is a backup to the average power range monitor high flux trip in the startup mode, safety valves which are backup to low temperature overpressure relief valves during cold shutdown).

Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety:

Discussion of Criterion 4: It is the Commission policy that pressurized water reactor (PWR) licensees retain in their Technical Specifications LCOs, action statements and Surveillance Requirements for the Residual Heat Removal System, which operating experience and PRA have generally shown to be significant to public health and safety, and any other structures, systems, or components that meet this criterion.

The Commission recognizes that other structures, systems, or components may meet this criterion. Plant and design-specific PRA's have yielded valuable insight to unique plant vulnerabilities not fully recognized in the safety analysis report DBA or transient analyses. It is

the intent of this criterion that those requirements that PRA or operating experience exposes as significant to public health and safety, consistent with the Commission's Safety Goal and Severe Accident Policies, be retained or included in Technical Specifications.

The Commission expects that licensees, in preparing their Technical Specification related submittals, will utilize any plant specific PRA or risk survey and any available literature on risk insights and PRAs. This material should be employed to strengthen the technical bases for those requirements that remain in Technical Specifications, when applicable, and to verify that none of the requirements to be relocated contain constraints of prime importance in limiting the likelihood or severity of the accident sequences that are commonly found to dominate risk.

Similarly, the NRC staff will also employ risk insights and PRAs in evaluating Technical Specifications related submittals. Further, as a part of the Commission's ongoing program of improving Technical Specifications, it will continue to consider methods to make better use of risk and reliability information for defining future generic Technical Specification requirements.

3. PRA INSIGHTS

Introduction and Objectives

Reference 4 includes a statement that NRC expects licensees to utilize any plant specific PRA or risk survey and any available literature on risk insights and PRAs to strengthen the technical bases for these requirements that remain in Technical Specifications and to verify that none of the requirements to be relocated contain constraints of prime importance in limiting the likelihood or severity of the accident sequences that are commonly found to dominate risk.

Those Technical Specifications proposed as being relocated to other plant controlled documents will be maintained under programs subject to the 10 CFR 50.59 review process. These Relocated Specifications have been compared to a variety of PRA material with two purposes: 1) to identify if a Specification component or topic is addressed by PRA; and 2) if addressed, to judge if the Relocated Specification component or topic is risk-important. The intent of the PRA review was to provide an additional screen to the deterministic criteria. This review was accomplished in the generic C-E Owners Group submittal CEN-355 (Reference 1). The results

of this generic review have been confirmed by FPL for the applicable PSL Specifications to be relocated.

Assumptions and Approach

The results of the generic criteria application documented in CEN-355 were reviewed to identify systems and components to be relocated from the Technical Specifications to other means of control. This list was compared to the findings from several PRAs to determine if any of the items proposed to be removed from the Technical Specifications were risk significant.

At the time CEN-355 was issued, the only published PRA for a C-E designed NSSS was the Calvert Cliffs Unit 1 Interim Reliability Evaluation Program (IREP) (NUREG/CR-3511, “Interim Reliability Evaluation Program: Analysis of the Calvert Cliffs Unit 1 Nuclear Power Plant," dated August 1984). This IREP was examined to identify the systems and components in the risk dominant event sequences. Event sequences with lower frequency of occurrence than the cutoff of 1.0 E-6 per year were also reviewed to ensure that systems of prime importance were not overlooked. Tables 3-1 and 3-2 of CEN-355 summarized the results of the examination of the risk significant event sequences. As noted in CEN-355, Calvert Cliffs Unit 1 is of the same design as PSL Units 1 and 2.

Table 3-1 represented those systems and components found to be risk significant; i.e., systems and components required to terminate or mitigate the event sequences leading to core melt having a frequency of occurrence of at least 1.0 E-6 per year.

Table 3-2 identified the dominant accident sequences identified as leading to core melt which have a frequency greater than E-6 per year.

To ensure an adequate representation of plants with a C-E designed NSSS, several partial PRAs for plants with a C-E NSSS were examined. These included:

- CEN-239, “Probabilistic Risk Assessment of the Effect of PORVs on Depressurization and Decay Heat Removal,” Supplements 1, 2, and 3, June 1983;
- PRA evaluations of Palisades main steam line break events; and

- PSL Shutdown Decay Heat Removal Analysis NUREG/CR-4710, “Shutdown Decay Heat Removal Analysis, Combustion Engineering 2-Loop PWR Case Study,” 1987.

Also, full PRAs on PWRs with other NSSS designs were examined. These included:

- Oconee, a two loop Babcock and Wilcox PWR, and
- Seabrook, a four loop Westinghouse PWR.

To ensure that no risk-significant systems were overlooked, a listing of the requirements not meeting criteria for retention as technical specifications was reviewed and documented in Table 3-3 of CEN-355, Appendix B.

Appendix C of CEN-355 includes safety sequence diagrams for identified types of initiating events considered in formal risk assessments. Table C 1 in Appendix C, CEN-355 tabulated the events for which the safety sequence analysis (SSA) were performed. The results of the SSA are summarized in the sequence of events diagrams provided in Table C.1 of Appendix C, CEN-355.

4. RESULTS OF APPLICATION OF SELECTION CRITERIA

The selection criteria from Section 2 herein were applied to the PSL Unit 1 and Unit 2 Technical Specifications. The following Summary Disposition Matrix for St. Lucie Unit 1 and Unit 2 is a summary of that application indicating which Specifications are being retained or relocated, the criteria for inclusion, if applicable, the NRC results of the criteria application as expressed in the NRC Staff Review of NSSS Vendor Owners Groups Application of The Commission's Interim Policy Statement Criteria To Standard Technical Specifications, Wilgus/Murley letter dated May 9, 1988 (Reference 2), and any necessary explanatory notes. Discussions that document the rationale for the relocation of each Specification which failed to meet the selection criteria are provided in Appendix A, except as noted in the Summary Disposition Matrix.

SUMMARY DISPOSITION MATRIX FOR ST. LUCIE PLANT (PSL) UNIT 1 AND UNIT 2

U1 Current TS (CTS) Number	U2 CTS Number (if different)	CTS Specification Title	New TS (ITS) Reference	Retained/ Criterion For Inclusion (1)	Notes
1.0		**DEFINITIONS**	1.1	Yes	This section provides definitions for several defined terms used throughout the remainder of Technical Specifications. They are provided to improve the meaning of certain terms. As such, direct application of the Technical Specification selection criteria is not appropriate. However, only those definitions for defined terms that remain because of application of the selection criteria, will remain as definitions in this section of Technical Specifications.
2.1		**SAFETY LIMITS**			
2.1.1		Reactor Core	2.1.1	Yes	Application of Technical Specification selection criteria is not appropriate. However, Safety Limits will be included in Technical Specifications as required by 10 CFR 50.36.
2.1.2		Reactor Coolant System Pressure	2.1.2	Yes	Same as above.

(1) The Applicable Safety Analysis section of the Bases for the individual Technical Specifications describes the reason specific Technical Specification selection criteria are met.

APPENDIX A

JUSTIFICATION FOR SPECIFICATION RELOCATION

APPLICATION OF SELECTION CRITERIA
TO THE ST LUCIE PLANT UNIT 1 AND UNIT 2
TECHNICAL SPECIFICATIONS

Appendix A – Justification for Specification Relocation

Unit 2 CTS Tables 3.3-1 and 4.3-1, Reactor Protective System Instrumentation, Functional Unit 10
Unit 2 CTS Table 2.2-1, Reactor Protective System Instrumentation Trip Setpoint Limits, Functional Unit 10 | R1

DISCUSSION:

The Reactor Protective System (RPS) initiates a reactor trip to protect against violating the core specified acceptable fuel design limits and breaching the reactor coolant pressure boundary (RCPB) during anticipated operational occurrences (AOOs). By tripping the reactor, the RPS also assists the Engineered Safety Features (ESF) systems in mitigating accidents. The protection and monitoring systems have been designed to ensure safe operation of the reactor. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the RPS, as well as Limiting Conditions for Operation on other reactor system parameters and equipment performance. Technical Specifications are required by 10 CFR 50.36 to include LSSS for variables that have significant safety functions.

The NRC position on application of the screening criteria to RPS instrumentation is documented in a letter dated May 9, 1988 from T.E. Murley (NRC) to the Owners Groups (Reference 2). The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function specified in CTS Table 2.2-1, 3.3-1 and 4.3-1 is provided as a plant specific reactor trip as an equipment protective feature required as a stipulation by NRC staff in justifying acceptance of the Reactor Coolant Water Component Cooling Water piping design. This reactor trip is not required for reactor protection and is not assumed in any accident or transient analysis. In addition, this automatic reactor trip feature on a loss of component cooling water (CCW) flow to the reactor coolant pumps (RCPs) is not required to protect against violating the core specified acceptable fuel design limits or breaching the RCPB during AOOs and is not considered an LSSS for a variable that has a significant safety function. | R1

COMPARISON TO SELECTION CRITERIA:

1. The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function is not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function is not a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier.

3. The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function is not a structure, system, or component that is part of the primary success path or which functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The loss of CCW flow to the RCPs is addressed in the PSL PRA with respect to requiring operator action to recover the CCW flow or remove the RCPs from service. The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function is not a significant risk contributor to core damage frequency and offsite releases in the PSL PRA. Therefore, the Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function does not

represent a structure, system, or component which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the selection criteria have not been satisfied for Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function, the requirements of this reactor trip instrument may be relocated to a licensee controlled document outside the Technical Specifications. Other reactor trip functions that are necessary to protect against violating the core specified acceptable fuel design limits or breaching the RCPB during AOOs are retained in the Technical Specifications (e.g., Reactor Coolant Flow – Low reactor trip and manual reactor trip functions).

Current Technical Specification (CTS) 3/4.1.1.3, Boron Dilution

DISCUSSION:

CTS 3/4.1.1.3 establishes a minimum flow rate to the reactor pressure vessel (RPV) of at least 3000 gpm whenever a reduction in Reactor Coolant System (RCS) boron concentration is being made. This minimum flowrate provides adequate mixing, prevents stratification, and ensures that reactivity changes will be gradual during boron concentration changes in the RCS.

A minimum boron dilution flow rate to the RPV is not assumed as an initial condition of a design basis accident (DBA) or transient analysis nor is it an assumed value to mitigate a DBA or transient (e.g., a boron dilution event).

COMPARISON TO SELECTION CRITERIA:

1. The minimum boron dilution flow rate to the RPV is not an instrumentation system. Therefore, this Specification does not constitute an instrumentation system that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary.

2. The minimum boron dilution flow rate to the RPV is not a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier. This Specification specifies a minimum flowrate value that provides adequate mixing, prevents stratification, and ensures that reactivity changes in the core are gradual during boron concentration changes in the RCS. These limits, however, do not reflect initial condition assumptions in a DBA or transient.

3. The minimum boron dilution flow rate to the RPV is a parameter and not a structure, system, or component that is part of the primary success path and which functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The minimum boron dilution flow rate to the RPV is a parameter requirement and is not a structure, system, or component which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the selection criteria have not been satisfied, the Boron Dilution Specification may be relocated to a licensee controlled document outside the Technical Specifications. Control element assembly insertion limits during power operation, shutdown margin requirements during shutdown, and boration concentration requirements during refueling are retained in separate Technical Specifications and ensure adequate excess negative core reactivity is available in the event of an inadvertent boron dilution event. Additionally, RCS circulation requirements to provide mixing and prevent stratification are retained in separate Technical Specifications (i.e., shutdown cooling specifications).

CTS 3/4.1.2.1, Flow Paths – Shutdown; CTS 3/4.1.2.2, Flow Paths – Operating;
CTS 3/4.1.2.3, Charging Pumps – Shutdown; CTS 3/4.1.2.4, Charging Pumps – Operating;
CTS 3/4.1.2.5, Boric Acid Pumps – Shutdown; CTS 3/4.1.2.6, Boric Acid Pumps – Operating;
CTS 3/4.1.2.7, Borated Water Sources – Shutdown; CTS 3/4.1.2.8, Borated Water Sources – Operating

DISCUSSION:

The components associated with the boration system Technical Specifications provide the means to control the chemical neutron absorber (boron) concentration in the RCS and to help maintain the shutdown margin during normal operations. To accomplish this functional requirement, the current boration system technical specifications require a source of borated water, one or more flow paths to inject borated water into the RCS, and either a charging pump or high pressure safety injection pump to provide the necessary charging head.

The RCS boration management system functions to control boron concentration and maintain shutdown margin are not assumed to be OPERABLE to mitigate the consequences of a DBA or transient. In the case of a malfunction of a component in the boration systems which causes a boron dilution event, response by the operator is to close the appropriate valves in the reactor makeup system. The plant response to a boron dilution event also includes control rod assembly movement and reactor trip features to ensure shutdown margin is maintained. The boration capabilities of the boration systems are not assumed to mitigate the boron dilution event.

COMPARISON TO SELECTION CRITERIA:

1. The boration systems do not constitute instrumentation systems that are used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary.

2. The boration systems are not process variables, design features, or operating restrictions that represent an initial condition of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier.

3. The RCS boration management system functions to control boron concentration and maintain shutdown margin do not represent a structure, system, or component that is part of the primary success path and which functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The PSL at-power PRA has shown that the RCS boration management system functions are not significant risk contributors to core damage frequency and offsite releases. PSL does not have shutdown PRA model. However, operational experience has shown that the boration management system is not a constraint of prime importance in the mitigation of any accident or transient that results in challenging public health and safety. Therefore, the RCS boration management system functions to control boron concentration and maintain shutdown margin do not represent structures, systems, or components which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the selection criteria have not been satisfied for the RCS boration management system functions to control boron concentration and maintain shutdown margin, the Boration System Specifications may be relocated to a licensee controlled document outside the Technical Specifications. RCS boration structures, systems, or components credited as the primary success path which function or actuate to mitigate a DBA or transient are retained in separate Technical Specifications (e.g., Emergency Core Cooling System). Additionally, shutdown margin requirements during shutdown, and boration concentration requirements during refueling are retained in separate Technical Specifications to ensure adequate excess negative core reactivity is available in the event of an inadvertent boron dilution event.

Unit 2 CTS 3/4.1.3.3, Position Indication Channels – Shutdown

DISCUSSION:

When the reactor is shutdown, one CEA position indication channel for each withdrawn CEA must be OPERABLE when the reactor trip breakers are closed and one or more CEAs are withdrawn. The purpose of this requirement is to provide the control room operator with indication of the position of a CEA when the CEA is not fully inserted and perform any related operations that are required. The CEA position indication channels do not provide any automatic function and no operator action assumed in accident or transient analyses (e.g., uncontrolled CEA withdrawal event) is initiated based on CEA position. Shutdown margin requirements ensure adequate excess negative reactivity is available to maintain the reactor subcritical when a CEA with the highest reactivity worth is withdrawn while the reactor is shutdown.

COMPARISON TO SELECTION CRITERIA:

1. The CEA position monitoring system when the reactor is shutdown is not an instrumentation system that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary.

2. The CEA position monitoring system when the reactor is shutdown is not a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier.

3. The CEA position monitoring system when the reactor is shutdown is not a structure, system, or component that is part of the primary success path or which functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The CEA position monitoring system when the reactor is shutdown and the reactor trip breakers are closed is not addressed in the PSL PRA and does not represent a system which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the selection criteria have not been satisfied for the CEA position monitoring system when the reactor trip breakers are closed and one or more CEAs are withdrawn, the requirements of the CEA Position Indication – Shutdown Specification may be relocated to a licensee controlled document outside the Unit 2 Technical Specifications. Shutdown Margin requirements during shutdown are retained in separate Technical Specifications and ensure adequate excess negative core reactivity is available in the event of a CEA system malfunction during shutdown (e.g., uncontrolled CEA withdrawal event from a subcritical condition).

Unit 1 CTS Table 3.3-11, Accident Monitoring Instrumentation, Instruments 2 through 6, and 8
Unit 2 CTS Table 3.3-10, Accident Monitoring Instrumentation, Instruments 6, 7, and 9 through 15

DISCUSSION:

Accident monitoring instrumentation ensures sufficient information is available following an accident to allow an operator to verify the response of automatic safety systems, and to take preplanned manual actions to accomplish a safe shutdown of the plant. The NRC position on application of the screening criteria to post-accident monitoring instrumentation is documented in a letter dated May 9, 1988 from T.E. Murley (NRC) to the Owners Groups (Reference 2). Regulatory Guide (RG) 1.97, Type A variables provide primary information; i.e., information that is essential for the direct accomplishment of the specified manual actions (including long term recovery actions) for which no automatic control is provided and that are required for safety systems to accomplish their safety functions for DBAs or transients. Additionally, it could not be confirmed that RG 1.97, non-Type A Category 1 variables are not of prime importance in limiting risk. Therefore, the NRC position is that the post-accident monitoring instrumentation list should contain Type A instruments and non-Type A Category 1 instruments specified in the plant's safety evaluation report (SER) on RG 1.97. Accordingly, this position has been applied to the PSL Units 1 and 2 RG 1.97 instruments. R1

A review of the PSL Units 1 and 2 UFSAR and the NRC Regulatory Guide 1.97 Safety Evaluation for PSL Units 1 and 2 shows that the following Unit 1 CTS Table 3.3-11 and Unit 2 CTS Table 3.3.10 Instruments do not meet Category 1 or Type A requirements:

Unit 1 CTS Table 3.3-11

Instrument 2	Auxiliary Feedwater Flow Rate
Instrument 3	RCS Subcooling Margin Monitor
Instrument 4	PORV Position Indicator – Acoustic Flow Monitor
Instrument 5	PORV Block Valve Position Indicator
Instrument 6	Safety Valve Position Indicator
Instrument 8	Containment Sump Level

Unit 2 CTS Table 3.3-10

Instrument 6	Steam Generator Pressure
Instrument 7	Steam Generator Water Level – Narrow Range
Instrument 9	Refueling Water Tank Water Level
Instrument 10	Auxiliary Feedwater Flow Rate
Instrument 11	RCS Subcooling Margin Monitor
Instrument 12	PORV Position/Flow Indicator
Instrument 13	PORV Block Valve Position Indicator
Instrument 14	Safety Valve Position/Flow Indicator
Instrument 15	Containment Sump Water Level (Narrow Range)

COMPARISON TO SELECTION CRITERIA:

1. These instruments are not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. The monitored parameters are not process variables, design features, or operating restrictions that are initial conditions of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier.

3. These instruments are not structures, systems, or components that are part of the primary success path or which function or actuate to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. These post-accident monitoring instrument functions are not addressed in the PSL PRA and do not represent a structure, system, or component which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the selection criteria have not been satisfied for instruments which do not meet RG 1.97 Type A or non-Type A, Category 1 variable requirements, the requirements of these instruments may be relocated to a licensee controlled document outside the Technical Specifications. Post-accident monitoring instruments that monitor RG 1.97 Type A variables and non-Type A, Category 1 variables are retained in the Technical Specifications.

Unit 1 CTS 3/4.4.9.2, Pressurizer
Unit 2 CTS 3/4.4.9.2, Pressurizer Heatup and Cooldown Limits

DISCUSSION:

The limitation on the pressurizer pressure and temperature (P/T) ensures that the pressurizer is operated within the design criteria assumed for the fatigue analysis performed in accordance with the ASME Code requirements. As such, the Technical Specification places limits on variables consistent with structural analysis results. These limits do not represent an initial condition assumption of a DBA or transient. Although the limits represent operating restrictions, and Criterion 2 includes operating restrictions, the Criterion 2 discussion of the Final Policy Statement specified that only those operating restrictions required to preclude unanalyzed accidents and transients be included in Technical Specifications.

COMPARISON TO SELECTION CRITERIA:

1. Pressurizer P/T limits are ASME Code parameter limits and are not instrumentation used for, or capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. Pressurizer P/T limits are ASME Code parameter limits and do not represent a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. Pressurizer P/T limits are ASME Code parameter limits and do not represent a structure, system or component that is part of a primary success path in the mitigation of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. Pressurizer P/T limits are ASME Code parameter limits and do not represent a structure, system, or component which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the selection criteria have not been satisfied, the Unit 1 Pressurizer Specification, which specifies pressurizer heatup and cooldown limits, and the Unit 2 Pressurizer Heatup and Cooldown Limits Specification may be relocated to a licensee controlled document outside the Technical Specifications. Pressure and temperature limits associated with the limiting RCS pressure boundary components are retained in separate Technical Specifications. ASME code requirements associated with the limits on pressurizer heatup and cooldown will continue to be controlled pursuant 10 CFR 50.55a.

Unit 1 CTS 3/4.4.15, Reactor Coolant System Vents
Unit 2 CTS 3/4.4.10, Reactor Coolant System Vents

DISCUSSION:

Reactor Coolant System (RCS) vents are provided to exhaust non-condensible gases and/or steam from the primary system that could inhibit natural circulation core cooling. The function, capabilities, and testing requirements of the RCS vent system are consistent with the requirements of Item II.b.1 of NUREG-0737, “Clarification of TMI [Three Mile island] Action Plan Requirements,” November 1980.

The pressurizer safety valves provide primary relief capability to exhaust non-condensible gases and steam from the RCS during a DBA or transient at power. The pressurizer power operated relief valves (PORVs) and other vent paths (e.g., pressurizer manway cover removed) provide vent capability during RCS low temperature and pressure conditions.

COMPARISON TO SCREENING CRITERIA:

1. The RCS vents do not function as installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary.

2. The RCS vents are not process variables, design features, or operating restrictions that represents an initial condition of a DBA or transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. The RCS vents are not a structures, systems or components that are part of the primary success path and which function or actuate to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The RCS vent function to preclude the inhibition of natural circulation core cooling is not a significant risk contributor to core damage frequency and offsite releases and this TMI function does not represent a structure, system, or component which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the screening criteria have not been satisfied for the RCS vent function that precludes the inhibition of natural circulation core cooling, the Reactor Coolant System Vents Specification may be relocated to a licensee controlled document outside Technical Specifications. Pressure relief requirements during power operation and during low temperature and pressure conditions are retained in separate Technical Specifications and ensure relief capability is provided to exhaust non-condensible gases and steam from the primary system. In addition, this NUREG-0737 requirement is required pursuant to 10 CFR 50.34(f)(2)(vi). Compliance with applicable portions of 10 CFR 50.34(f)(2) is required by the operating licenses of PSL Units 1 and 2.

CTS 3/4.7.2, Steam Generator Pressure/Temperature Limitation

DISCUSSION:

The limitation on steam generator pressure and temperature (P/T) ensures that pressure-induced stresses on the steam generators do not exceed the maximum allowable fracture toughness limits. These pressure and temperature limits are based on maintaining a steam generator reference temperature for Nil Ductility Transition (RT_{NDT}) sufficient to prevent brittle fracture. As such, the Technical Specification places limits on variables consistent with structural analysis results. These limits do not represent an initial condition assumption of a DBA or transient. Although the limits represent operating restrictions, and Criterion 2 includes operating restrictions, the Criterion 2 discussion of the Final Policy Statement specified that only those operating restrictions required to preclude unanalyzed accidents and transients be included in Technical Specifications.

COMPARISON TO SELECTION CRITERIA:

1. Steam generator P/T limits are ASME Code parameter limits and are not instrumentation used for, or capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. Steam generator P/T limits are ASME Code parameter limits and do not represent a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. Steam generator P/T limits are ASME Code parameter limits and not a structure, system, or component that is part of a primary success path in the mitigation of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. Steam generator P/T limits are ASME Code parameter limits and are not structures, systems, or components which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the selection criteria have not been satisfied, the Steam Generator Pressure/Temperature Limitation Specification may be relocated to a licensee controlled document outside the Technical Specifications. Pressure and temperature limits associated with the limiting RCS pressure boundary components are retained in separate Technical Specifications. ASME code requirements associated with the limits on steam generator heatup and cooldown will continue to be controlled pursuant 10 CFR 50.55a

Unit 2 CTS 3/4.7.6, Flood Protection

DISCUSSION:

External flooding during hurricane conditions is not designated as a PSL DBA or transient event. In addition, external flooding due to a hurricane is not postulated to occur during any DBA or transient, thus water level (as it pertains to wave run-up effects during a hurricane) is not credited in any safety analysis. The Flood Protection Technical Specification requirements ensure that facility protective actions will be taken in the event of flood conditions whenever a hurricane warning is issued. The installation of the stoplogs ensures adequate protection for wave run-up effects where no permanent adjacent structures exist and provides protection to safety-related equipment.

COMPARISON TO SCREENING CRITERIA:

1. Flood protection requirements are not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary prior to a DBA.

2. Flood protection requirements are not process variables that are initial conditions of a DBA or transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. Flood protection requirements are not part of the primary success path that functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The specific requirements specified in the Flood Protection Specification related to a hurricane are found to be non-significant risk contributors to core damage frequency and offsite releases and do not represent structures, systems, or components which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the screening criteria have not been satisfied, the Flood Protection Specification may be relocated to a licensee controlled document outside the Unit 2 Technical Specifications. A general requirement associated with hazard barriers (ITS LCO 3.0.9), which includes external flooding barriers, is added to ITS Section 3.0. A hazard barrier that cannot perform its related support function will be evaluated and managed under the Maintenance Rule plant configuration control requirement, 10 CFR 50.65(a)(4), and associated industry guidance, NUMARC 93-01, Revision 4A.

Unit 1 CTS 3/4.7.9, Sealed Source Contamination
Unit 2 CTS 3/4.7.10, Sealed Source Contamination

DISCUSSION:

The limitations on sealed source contamination are intended to ensure that the total body and individual organ irradiation doses do not exceed allowable limits in the event of ingestion or inhalation. This is done by imposing a maximum limitation of < 0.005 microcuries of removable contamination on each sealed source. This requirement and the associated surveillance requirements bear no relation to the conditions or limitations that are necessary to ensure safe reactor operation.

COMPARISON TO SELECTION CRITERIA:

1. The sealed source contamination limitation is not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. The sealed source contamination limitation is not a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

3. The sealed source contamination limitation is not part of a primary success path in the mitigation of a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The sealed source contamination limitation is not discussed in the PSL PRA and is not a structure, system, or component which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

CONCLUSION:

Since the selection criteria have not been satisfied, the Sealed Source Contamination Specification may be relocated to a licensee controlled document outside the Technical Specifications. Requirements associated with the sealed sources are governed by 10 CFR Part 70. Compliance with applicable portions of 10 CFR Part 70 is required by the operating licenses of PSL Units 1 and 2.

ST. LUCIE PLANT
UNIT 1 AND UNIT 2

IMPROVED TECHNICAL SPECIFICATIONS CONVERSION

GENERIC DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATION AND ENVIRONMENTAL ASSESSMENT

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
GENERIC CHANGES

10 CFR 50.92 EVALUATION
FOR
ADMINISTRATIVE CHANGES

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants" Some of the proposed changes involve reformatting, renumbering, and rewording of current technical specifications (CTS) with no change in intent. These changes, since they do not involve technical changes to the CTS, are administrative.

This type of change is connected with the movement of requirements within the current requirements, or with the modification of wording that does not affect the technical content of the CTS. These changes also include non-technical modifications of requirements to conform to TSTF-GG-05-01, "Writer's Guide for Plant-Specific Improved Standard Technical Specifications," or provide consistency with the Improved Standard Technical Specifications in NUREG-1432. Administrative changes are not intended to add, delete, or relocate any technical requirements of the CTS.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change involves reformatting, renumbering, and rewording the CTS. The reformatting, renumbering, and rewording process involves no technical changes to the CTS. As such, this change is administrative in nature and does not affect initiators of analyzed events or assumed mitigation of accident or transient events.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. **Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?**

   Response: No.

   The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or changes in methods governing normal plant operation. The proposed change will not impose any new or eliminate any old requirements.

   Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The proposed change will not reduce a margin of safety because it has no effect on any safety analyses assumptions. This change is administrative in nature.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
GENERIC CHANGES

10 CFR 50.92 EVALUATION
FOR
MORE RESTRICTIVE CHANGES

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve adding more restrictive requirements to the Current Technical Specifications by either making current requirements more stringent or by adding new requirements that currently do not exist.

These changes include additional requirements that decrease allowed outage times, increase the Frequency of Surveillances, impose additional Surveillances, increase the scope of Specifications to include additional plant equipment, increase the Applicability of Specifications, or provide additional Actions. These changes are made to conform to NUREG-1432 and have been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change provides more stringent Technical Specification requirements for the facility. These more stringent requirements do not result in operations that significantly increase the probability of initiating an analyzed event, and do not alter assumptions relative to mitigation of an accident or transient event. The more restrictive requirements continue to ensure process variables, structures, systems, and components are maintained consistent with the safety analyses and licensing basis.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. **Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?**

   Response: No.

   The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or changes in methods governing normal plant operation. The proposed change does impose different Technical Specification requirements. However, these changes are consistent with the assumptions in the safety analyses and licensing basis.

   Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The imposition of more restrictive requirements either has no effect on or increases the margin of plant safety. As provided in the discussion of change, each change in this category is, by definition, providing additional restrictions to enhance plant safety. The change maintains requirements within the safety analyses and licensing basis.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
GENERIC CHANGES

10 CFR 50.92 EVALUATION
FOR
RELOCATED SPECIFICATIONS

The Florida Power & Light Company (FPL) is converting St. Lucie Plant (PSL) to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve relocating Current Technical Specification (CTS) Limiting Conditions for Operations (LCOs) to licensee controlled documents.

FPL has evaluated the CTS using the criteria set forth in 10 CFR 50.36. Specifications identified by this evaluation that did not meet the retention requirements specified in the regulation are not included in the ITS. These specifications have been relocated from the CTS to a licensee controlled document (e.g., Technical Requirements Manual (TRM) or Updated Final Safety Analysis Report (UFSAR)).

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change relocates requirements and Surveillances for structures, systems, components, or variables that do not meet the criteria of 10 CFR 50.36(c)(2)(ii) for inclusion in Technical Specifications as identified in the Application of Selection Criteria to the PSL Technical Specifications. The affected structures, systems, components or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. The requirements and Surveillances for these affected structures, systems, components, or variables will be relocated from the CTS to a licensee controlled document that is maintained pursuant to 10 CFR 50.59. The UFSAR is subject to the change control provisions of 10 CFR 50.59 and 10 CFR 50.71(e). In addition, the affected structures, systems, components, or variables are addressed in existing surveillance procedures which are also controlled by 10 CFR 50.59, and are subject to the change control provisions imposed by plant administrative procedures, which endorse applicable regulations and standards.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. **Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?**

   Response: No.

   The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or change in the methods governing

normal plant operation. The proposed change will not impose or eliminate any requirements, and adequate control of existing requirements will be maintained.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The proposed change will not reduce a margin of safety because it has no significant effect on any safety analyses assumptions, as indicated by the fact that the requirements do not meet the 10 CFR 50.36 criteria for retention. In addition, the relocated requirements are moved without change, and any future changes to these requirements will be evaluated per 10 CFR 50.59.

NRC prior review and approval of changes to these relocated requirements, in accordance with 10 CFR 50.92, will no longer be required. This review and approval does not provide a specific margin of safety that can be evaluated. However, the proposed change is consistent with NUREG-1432, issued by the NRC, which allows revising the CTS to relocate these requirements and Surveillances to a licensee controlled document.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
GENERIC CHANGES

10 CFR 50.92 EVALUATION
FOR
REMOVED DETAIL CHANGES

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve moving details out of the Current Technical Specifications (CTS) and into the Technical Specifications Bases, the Updated Final Safety Analysis Report (UFSAR), the Containment Leakage Rate Testing Program, the Technical Requirements Manual (TRM), or other documents under regulatory control, such as the Offsite Dose Calculation Manual, the Quality Assurance Topical Report, the Inservice Testing Program, the Inservice Inspection Program, and the Surveillance Frequency Control Program. The removal of this information is considered to be less restrictive because it is no longer controlled by the Technical Specification change process. The removal of this information conforms to NUREG-1432 for format and content.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change relocates certain details from the CTS to other documents under regulatory control. The Technical Specification Bases and the TRM will be maintained in accordance with 10 CFR 50.59. In addition to 10 CFR 50.59 provisions, the Technical Specification Bases are subject to the change control provisions in the Administrative Controls Chapter of the ITS. The UFSAR is subject to the change control provisions of 10 CFR 50.59 and 10 CFR 50.71(e). Other documents are subject to controls imposed by the ITS or other regulations. Since any changes to these documents will be evaluated, no significant increase in the probability or consequences of an accident previously evaluated will be allowed.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. **Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?**

   Response: No.

   The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or changes in methods governing normal plant operation. The proposed change will not impose or eliminate any requirements, and adequate control of the information will be maintained.

   Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The proposed change will not reduce a margin of safety because it has no effect on any safety analyses assumptions. In addition, the details to be moved from the CTS to other documents are not being changed. Since any future changes to these details will be evaluated under the applicable regulatory change control mechanism, no significant reduction in a margin of safety will be allowed. A significant reduction in the margin of safety is not associated with the elimination of the 10 CFR 50.90 requirement for NRC review and approval of future changes to the relocated details. Not including these details in the Technical Specifications is consistent with NUREG-1432, issued by the NRC, which allows revising the Technical Specifications to relocate these requirements and Surveillances to a licensee controlled document controlled by 10 CFR 50.59, 10 CFR 50.71(e), or other Technical Specification controlled or regulation controlled documents.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
GENERIC CHANGES

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGES – CATEGORY 1
RELAXATION OF LCO REQUIREMENTS

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve relaxation of the Current Technical Specification (CTS) Limiting Conditions for Operation (LCOs) by the elimination of specific items from the LCO or Tables referenced in the LCO, or the addition of exceptions to the LCO.

These changes reflect the Standard Technical Specifications (ISTS) approach to provide LCO requirements that specify the protective conditions that are required to meet safety analysis assumptions for required features. These conditions replace the lists of specific devices used in the CTS to describe the requirements needed to meet the safety analysis assumptions. The ITS also includes LCO Notes which allow exceptions to the LCO for the performance of testing or other operational needs. The ITS provides the protection required by the safety analysis, and provides flexibility for meeting the conditions without adversely affecting operations since equivalent features are required to be OPERABLE. The ITS is also consistent with the plant current licensing basis, as may be modified in the discussion of individual changes. These changes are made to conform with NUREG-1432, and have been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change provides less restrictive LCO requirements for operation of the facility. These less restrictive LCO requirements do not result in operation that will significantly increase the probability of initiating an analyzed event and do not alter assumptions relative to mitigation of an accident or transient event in that the requirements continue to ensure process variables, structures, systems, and components are maintained consistent with the current safety analyses and licensing basis.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

Response: No.

The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or a change in the methods governing normal plant operation. The proposed change does impose different requirements. However, the change is consistent with the assumptions in the current safety analyses and licensing basis.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The imposition of less restrictive LCO requirements does not involve a significant reduction in the margin of safety. As provided in the discussion of change, this change has been evaluated to ensure that the current safety analyses and licensing basis requirements are maintained.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
GENERIC CHANGES

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGES – CATEGORY 2
RELAXATION OF APPLICABILITY

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve relaxation of the applicability of Current Technical Specification (CTS) Limiting Conditions for Operation (LCOs) by reducing the conditions under which the LCO requirements must be met.

CTS requirements are being eliminated during conditions for which the safety function of the specified safety system is met because the feature is performing its intended safety function. Deleting applicability requirements that are indeterminate or which are inconsistent with application of accident analyses assumptions is acceptable because when LCOs cannot be met, the ITS may be satisfied by exiting the applicability which takes the plant out of the conditions that require the safety system to be OPERABLE.

This change provides the protection required by the safety analyses, and provides flexibility for meeting limits by restricting the application of the limits to the conditions assumed in the safety analyses. The ITS is also consistent with the plant current licensing basis, as may be modified in the discussion of individual changes. The change is made to conform with NUREG-1432, and has been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change relaxes the conditions under which the LCO requirements for operation of the facility must be met. These less restrictive applicability requirements for the LCOs do not result in operation that will significantly increase the probability of initiating an analyzed event and do not alter assumptions relative to mitigation of an accident or transient event in that the requirements continue to ensure that process variables, structures, systems, and components are maintained in the MODES and other specified conditions assumed in the safety analyses and licensing basis.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

Response: No.

The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or a change in the methods governing normal plant operation. The proposed change does impose different requirements. However, the requirements are consistent with the assumptions in the safety analyses and licensing basis.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The relaxed applicability of LCO requirements does not involve a significant reduction in the margin of safety. As provided in the discussion of change, this change has been evaluated to ensure that the LCO requirements are applied in the MODES and specified conditions assumed in the safety analyses and licensing basis.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
GENERIC CHANGES

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGES – CATEGORY 3
RELAXATION OF COMPLETION TIME

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve relaxation of the Completion Times for Required Actions in the Current Technical Specifications.

Upon discovery of a failure to meet a Limiting Condition for Operation (LCO), the ITS specifies times for completing Required Actions of the associated Conditions. Required Actions of the associated Conditions are used to establish remedial measures that must be taken within specified Completion Times. These times define limits during which operation in a degraded condition is permitted. Adopting Completion Times from the ITS is acceptable because the Completion Times take into account the OPERABILITY status of the redundant systems of required features, the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of a Design Basis Accident (DBA) occurring during the repair period. In addition, the ITS provides consistent Completion Times for similar conditions. These changes are made to conform with NUREG-1432, and have been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change relaxes the Completion Time for a Required Action. Required Actions and their associated Completion Times are not initiating conditions for any accident previously evaluated, and the accident analyses do not assume that required equipment is out of service prior to the analyzed event. Consequently, the relaxed Completion Time does not significantly increase the probability of any accident previously evaluated. The consequences of an analyzed accident during the relaxed Completion Time are the same as the consequences during the existing Completion Time. As a result, the consequences of any accident previously evaluated are not significantly increased.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

Response: No.

The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or a change in the method governing normal plant operation. The Required Actions and associated Completion Times in the ITS have been evaluated to ensure that no new accident initiators are introduced.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The relaxed Completion Time for a Required Action does not involve a significant reduction in the margin of safety. As provided in the discussion of change, the change has been evaluated to ensure that the allowed Completion Time is consistent with safe operation under the specified Condition, considering the OPERABILITY status of the redundant systems of required features, the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of a DBA occurring during the repair period.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS

LESS RESTRICTIVE CHANGES – CATEGORY 4
RELAXATION OF REQUIRED ACTION

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve relaxation of the Required Actions in the Current Technical Specifications.

Upon discovery of a failure to meet a Limiting Condition for Operation (LCO), the ITS specifies Required Actions to complete for the associated Conditions. Required Actions of the associated Conditions are used to establish remedial measures that must be taken in response to the degraded conditions. These actions minimize the risk associated with continued operation while providing time to repair inoperable features. Some of the Required Actions are modified to place the plant in a MODE in which the LCO does not apply. Adopting Required Actions from NUREG-1432 is acceptable because the Required Actions take into account the OPERABILITY status of redundant systems of required features, the capacity and capability of the remaining features, and the compensatory attributes of the Required Actions as compared to the LCO requirements. These changes are made to conform with NUREG-1432, and have been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change relaxes Required Actions. Required Actions and their associated Completion Times are not initiating conditions for any accident previously evaluated, and the accident analyses do not assume that required equipment is out of service prior to the analyzed event. Consequently, the relaxed Required Actions do not significantly increase the probability of any accident previously evaluated. The Required Actions in the ITS have been developed to provide appropriate remedial actions to be taken in response to the degraded condition considering the OPERABILITY status of the redundant systems of required features, and the capacity and capability of remaining features while minimizing the risk associated with continued operation. As a result, the consequences of any accident previously evaluated are not significantly increased.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

Response: No.

The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or a change in the methods governing normal plant operation. The Required Actions and associated Completion Times in the ITS have been evaluated to ensure that no new accident initiators are introduced.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The relaxed Required Actions do not involve a significant reduction in the margin of safety. As provided in the discussion of change, this change has been evaluated to minimize the risk of continued operation under the specified Condition, considering the OPERABILITY status of the redundant systems of required features, the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of a Design Basis Accident (DBA) occurring during the repair period.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

LESS RESTRICTIVE CHANGES – CATEGORY 5
DELETION OF SURVEILLANCE REQUIREMENT

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve deletion of Surveillance Requirements in the Current Technical Specifications (CTS).

The CTS require safety systems to be tested and verified OPERABLE prior to entering applicable operating conditions. The ITS eliminates unnecessary CTS Surveillance Requirements that do not contribute to verification that the equipment used to meet the Limiting Condition for Operation (LCO) can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a frequency necessary to give confidence that the equipment can perform its assumed safety functions. These changes are made to conform with NUREG-1432, and have been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change deletes Surveillance Requirements. Surveillances are not initiators to any accident previously evaluated. Consequently, the probability of an accident previously evaluated is not significantly increased. The equipment being tested is still required to be OPERABLE and capable of performing the accident mitigation functions assumed in the accident analyses. As a result, the consequences of any accident previously evaluated are not significantly affected.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. **Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?**

   Response: No.

   The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or a change in the methods governing normal plant operation. The remaining Surveillance Requirements are consistent with industry practice, and are considered sufficient to prevent the removal of the subject Surveillances from creating a new or different type of accident.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The deleted Surveillance Requirements do not result in a significant reduction in the margin of safety. As provided in the discussion of change, the change has been evaluated to ensure that the deleted Surveillance Requirements are not necessary for verification that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a frequency necessary to give confidence that the equipment can perform its assumed safety function.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

LESS RESTRICTIVE CHANGES – CATEGORY 6
RELAXATION OF SURVEILLANCE REQUIREMENT ACCEPTANCE CRITERIA

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve the relaxation of Surveillance Requirements acceptance criteria in the Current Technical Specifications (CTS).

The CTS require safety systems to be tested and verified OPERABLE prior to entering applicable operating conditions. The ITS eliminates or relaxes the Surveillance Requirement acceptance criteria that do not contribute to verification that the equipment used to meet the Limiting Condition for Operation (LCO) can perform its required functions. For example, the ITS allows some Surveillance Requirements to verify OPERABILITY under actual or test conditions. Adopting the ITS allowance for "actual" conditions is acceptable because required features cannot distinguish between an "actual" signal or a "test" signal. Also included are changes to CTS requirements that are replaced in the ITS with separate and distinct testing requirements that when combined, include OPERABILITY verification of all components required in the LCO for the features specified in the CTS. Adopting this format preference in the ITS is acceptable because Surveillance Requirements that remain include testing of all previous features required to be verified OPERABLE. Changes that provide exceptions to Surveillance Requirements to provide for variations that do not affect the results of the test are also included in this category. These changes are made to conform with NUREG-1432, and have been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change relaxes the acceptance criteria of Surveillance Requirements. Surveillances are not initiators to any accident previously evaluated. Consequently, the probability of an accident previously evaluated is not significantly increased. The equipment being tested is still required to be OPERABLE and capable of performing the accident mitigation functions assumed in the accident analyses. As a result, the consequences of any accident previously evaluated are not significantly affected.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

Response: No.

The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or a change in the methods governing normal plant operation.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The relaxed acceptance criteria for Surveillance Requirements do not result in a significant reduction in the margin of safety. As provided in the discussion of change, the relaxed Surveillance Requirement acceptance criteria have been evaluated to ensure that they are sufficient to verify that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner that gives confidence that the equipment can perform its assumed safety function.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

FOR
LESS RESTRICTIVE CHANGES – CATEGORY 7
RELAXATION OF SURVEILLANCE FREQUENCY

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve the relaxation of Surveillance Frequencies in the Current Technical Specifications (CTS).

CTS and ITS Surveillance Frequencies specify time interval requirements for performing Surveillance tests. Increasing the time interval between Surveillance tests in the ITS results in decreased equipment unavailability due to testing which also increases equipment availability. In general, the ITS contain Surveillance Frequencies that are consistent with industry practice or industry standards for achieving acceptable levels of equipment reliability. Adopting testing practices specified in the ITS is acceptable based on similar design, like-component testing for the system application and the availability of other ITS requirements which provide regular checks to ensure limits are met. Relaxation of Surveillance Frequency can also include the addition of Surveillance Notes which allow testing to be delayed until appropriate unit conditions for the test are established, or exempt testing in certain MODES or specified conditions in which the testing cannot be performed.

Reduced testing can result in a safety enhancement because the unavailability due to testing is reduced, and reliability of the affected structure, system or component should remain constant or increase. Reduced testing is acceptable where operating experience, industry practice, or the industry standards such as manufacturers' recommendations have shown that these components usually pass the Surveillance when performed at the specified interval, thus the Surveillance Frequency is acceptable from a reliability standpoint. Surveillance Frequency changes to incorporate alternate train testing have been shown to be acceptable where other qualitative or quantitative test requirements are required that are established predictors of system performance. Surveillance Frequency extensions can be based on NRC-approved topical reports. The NRC staff has accepted topical report analyses that bound the plant-specific design and component reliability assumptions. These changes are made to conform with NUREG-1432, and have been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change relaxes Surveillance Frequencies. The relaxed Surveillance Frequencies have been established based on achieving acceptable levels of equipment reliability. Consequently, equipment that could initiate an accident previously evaluated will continue to operate as expected, and the probability of the

initiation of any accident previously evaluated will not be significantly increased. The equipment being tested is still required to be OPERABLE and capable of performing any accident mitigation functions assumed in the accident analyses. As a result, the consequences of any accident previously evaluated are not significantly affected.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

Response: No.

The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or a change in the methods governing normal plant operation.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The relaxed Surveillance Frequencies do not result in a significant reduction in the margin of safety. As provided in the discussion of change, the relaxation in the Surveillance Frequency has been evaluated to ensure that it provides an acceptable level of equipment reliability. Thus, appropriate equipment continues to be tested at a Frequency that gives confidence that the equipment can perform its assumed safety function when required.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DELETION OF SURVEILLANCE REQUIREMENT SHUTDOWN PERFORMANCE REQUIREMENTS

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve the deletion of the requirement to perform Surveillance Requirements while in a shutdown condition in the Current Technical Specifications (CTS).

The CTS require safety systems to be tested and verified OPERABLE periodically. The CTS requires these Surveillances to be performed with the unit in a specified condition, usually in a condition outside the Applicability of the Limiting Condition for Operation (LCO). The ITS Surveillance does not include the restriction on unit conditions. The control of the unit conditions appropriate to perform the test is an issue for procedures and scheduling, and has been determined by the NRC Staff to be unnecessary as an ITS restriction. As indicated in NRC Generic Letter No. 91-04, "Changes in Technical Specification Surveillance Intervals to Accommodate a 24-Month Fuel Cycle," dated April 2, 1991, allowing this control is consistent with the vast majority of other Technical Specification Surveillances that do not dictate unit conditions for the Surveillance. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to give confidence that the equipment can perform its assumed safety function. These changes are generally made to conform with NUREG-1432, and have been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change involves the deletion of the requirement to perform Surveillance Requirements while in a shutdown condition. Surveillances are not initiators to any accident previously evaluated. Consequently, the probability of an accident previously evaluated is not significantly increased. The appropriate plant conditions for performance of the Surveillance will continue to be controlled in plant procedures to assure the potential consequences are not significantly increased. This control method has been previously determined to be acceptable as indicated in NRC Generic Letter No. 91-04. The proposed change does not affect the availability of equipment or systems required to mitigate the consequences of an accident because of the availability of redundant systems or equipment.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

Response: No.

The proposed change involves the deletion of the requirement to perform Surveillance Requirements while in a shutdown condition, but does not change the method of performance. The appropriate plant conditions for performance of the Surveillance will continue to be controlled in plant procedures to assure the possibility of a new or different kind of accident is not created. The control method has been previously determined to be acceptable as indicated in NRC Generic Letter No. 91-04.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The proposed change involves the deletion of the requirement to perform Surveillance Requirements while in a shutdown condition. However, the appropriate plant conditions for performance of the Surveillance will continue to be controlled in plant procedures. The control method has been previously determined to be acceptable as indicated in NRC Generic Letter No. 91-04.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
GENERIC CHANGES

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGES – CATEGORY 9
DELETION OF REPORTING REQUIREMENTS

The Florida Power & Light Company (FPL) is converting St. Lucie Plant to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5.0, "Standard Technical Specifications, Combustion Engineering Plants." Some of the proposed changes involve the deletion of requirements in the Current Technical Specifications (CTS) to send reports to the NRC.

The CTS includes requirements to submit reports to the NRC under certain circumstances. However, the ITS eliminates these requirements for many such reports and, in many cases, relies on the reporting requirements of 10 CFR 50.73 or other regulatory requirements. The ITS changes to reporting requirements are acceptable because the regulations provide adequate reporting requirements, or the reports do not affect continued plant operation. Therefore, this change has no effect on the safe operation of the plant. These changes are generally made to conform with NUREG-1432 and have been evaluated to not be detrimental to plant safety.

FPL has evaluated whether or not a significant hazards consideration is involved with these proposed Technical Specification changes by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. **Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?**

   Response: No.

   The proposed change deletes reporting requirements. Sending reports to the NRC is not an initiator of any accident previously evaluated. Consequently, the probability of any accident previously evaluated is not significantly increased. Sending reports to the NRC has no effect on the ability of equipment to mitigate an accident previously evaluated. As a result, the consequences of any accident previously evaluated is not significantly affected. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. **Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?**

   Response: No.

   The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or changes in methods governing normal plant operation. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

Response: No.

The deletion of reporting requirements does not result in a significant reduction in the margin of safety. The ITS eliminates the requirements for many such reports and, in many cases, relies on the reporting requirements of 10 CFR 50.73 or other regulatory requirements. The change to reporting requirements does not affect the margin of safety because the regulations provide adequate reporting requirements, or the reports do not affect continued plant operation. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

ENVIRONMENTAL ASSESSMENT

The Florida Power & Light Company (FPL) has evaluated this license amendment against the criteria for identification of licensing and regulatory actions requiring environmental assessment in accordance with 10 CFR 51.21. FPL has determined that this license amendment meets the criteria for a categorical exclusion set forth in 10 CFR 51.22(c)(9). This determination is based on the fact that this change is being proposed as an amendment to a license issued pursuant to 10 CFR 50, that changes a requirement with respect to installation or use of a facility component located within the restricted area, as defined in 10 CFR 20, or that changes an inspection or a surveillance requirement, and the amendment meets the following specific criteria.

(i) The amendment involves no significant hazards consideration.

As demonstrated in the generic and specific Determination of No Significant Hazards Considerations, this proposed amendment does not involve a significant hazards consideration.

(ii) There is no significant change in the types or significant increase in the amounts of any effluents that may be released offsite.

The proposed amendment does not affect the generation of any radioactive effluents, and does not affect any of the permitted effluent release paths.

(iii) There is no significant increase in individual or cumulative occupational radiation exposure.

The proposed changes will not cause radiological exposure in excess of the dose criteria for restricted and unrestricted access specified in 10 CFR 20. Individual worker exposures will be maintained within acceptable limits by the St. Lucie Plant Radiation Protection Program.

Therefore, pursuant to 10 CFR 51.22 (b), no environmental impact statement or environmental assessment need be prepared in connection with the proposed amendment.

ATTACHMENT 1

ITS Chapter 1.0, Definitions

Current Technical Specifications (CTS) Markup and Discussion of Changes (DOCs)

1.0 DEFINITIONS

NOTE The defined terms of this section appear in capitalized type and are applicable throughout these Technical Specifications and Bases.

A12

ACTIONS

ACTION

1.1 ACTION shall be that part of a specification which prescribes Required Actions to be taken that are remedial measures required under designated conditions within specified Completion Times.

A01

AXIAL SHAPE INDEX (ASI)

AXIAL SHAPE INDEX (ASI)

1.2 The AXIAL SHAPE INDEX (Y_E) is the power level detected by the lower excore nuclear instrument detectors (L) less the power level detected by the upper excore nuclear instrument detectors (U) divided by the sum of these power levels. The AXIAL SHAPE INDEX (Y_I) used for the trip and pretrip signals in the reactor protection system is the above value (Y_E) modified by an appropriate multiplier (A) and a constant (B) to determine the true core axial power distribution for that channel.

LA01

$$Y_E = \frac{L - U}{L + U} \qquad Y_I = AY_E + B$$

AZIMUTHAL POWER TILT – T_q

AZIMUTHAL POWER TILT – T_q

1.3 AZIMUTHAL POWER TILT shall be the maximum difference between the power generated in any core quadrant (upper or lower) and the average power of all quadrants in that half (upper or lower) of the core divided by the average power of all quadrants in that half (upper or lower) of the core.

$$\text{AZIMUTHAL POWER TILT} = \max\left[\frac{\text{Power in any core quadrant (upper or lower)}}{\text{Average power of all quadrants (upper or lower)}}\right] - 1$$

A01

CHANNEL CALIBRATION

CHANNEL CALIBRATION

1.4 A CHANNEL CALIBRATION shall be the adjustment, as necessary, of the channel output such that it responds with the necessary range and accuracy to known values of the parameter which the channel monitors. The CHANNEL CALIBRATION shall encompass the entire channel including the sensor and alarm and/or trip functions, and shall include the CHANNEL FUNCTIONAL TEST. The CHANNEL CALIBRATION may be performed by any series of sequential, overlapping or total channel steps such that the entire channel is calibrated.

A02

CHANNEL CHECK

CHANNEL CHECK

1.5 A CHANNEL CHECK shall be the qualitative assessment of channel behavior during operation by observation. This determination shall include, where possible, comparison of the channel indication and/or status with other indications and/or status derived from independent instrument channels measuring the same parameter.

A02

A02 **INSERT 1**

Calibration of instrument channels with resistance temperature detector (RTD) or thermocouple sensors may consist of an inplace qualitative assessment of sensor behavior and normal calibration of the remaining adjustable devices in the channel.

A02 **INSERT 2**

, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step.

1.1 → **DEFINITIONS**

CHANNEL FUNCTIONAL TEST

CHANNEL FUNCTIONAL TEST

L01

or actual

~~1.6~~ A CHANNEL FUNCTIONAL TEST shall be the injection of a simulated signal into the channel as close to the ~~primary~~ sensor as practicable to verify OPERABILITY ~~including alarm and/or trip functions.~~

A01

Insert 3

A03

CONTAINMENT VESSEL INTEGRITY

A04

1.7 CONTAINMENT VESSEL INTEGRITY shall exist when:

See ITS 3.6.1

a. All containment vessel penetrations required to be closed during accident conditions are either:

1. Capable of being closed by an OPERABLE containment automatic isolation valve system, or

2. Closed by manual valves, blind flanges, or deactivated automatic valves secured in their closed position except for valves that are open on an intermittent basis under administrative control.

See ITS 3.6.3

b. All containment vessel equipment hatches are closed and sealed,

c. Each containment vessel air lock is in compliance with the requirements of Specification 3.6.1.3,

See ITS 3.6.2

d. The containment leakage rates are within the limits of Specification 3.6.1.2, and

e. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.

~~CONTROLLED LEAKAGE~~

~~1.8 CONTROLLED LEAKAGE shall be the seal water flow supplied from the reactor coolant pump seals.~~

~~CORE ALTERATION~~

~~1.9 CORE ALTERATION shall be the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity within the reactor vessel with the vessel head removed and fuel in the vessel. Exceptions to the above include shared (4 fingered) control element assemblies (CEAs) withdrawn into the upper guide structure (UGS) or evolutions performed with the UGS in place such as CEA latching/unlatching or verification of latching/unlatching which do not constitute a CORE ALTERATION. Suspension of CORE ALTERATIONS shall not preclude completion of movement of a component to a safe position.~~

A04

CORE OPERATING LIMITS REPORT (COLR)

CORE OPERATING LIMITS REPORT (COLR)

~~1.9a~~ THE COLR is the unit-specific document that provides cycle specific parameter limits for the current ~~operating~~ reload cycle. These cycle-specific parameter limits shall be determined for each reload cycle in accordance with Specification 5.6.3 → ~~6.9.1.11~~. Plant operation within these limits is addressed in individual Specifications.

A01

A03

INSERT 3

of all devices in the channel required for channel OPERABILITY. The CHANNEL FUNCTIONAL TEST may be performed by means of any series of sequential, overlapping, or total channel steps, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step.

1.1 DEFINITIONS

DOSE EQUIVALENT I-131

DOSE EQUIVALENT I-131

when inhaled as the combined activities of iodine isotopes

microcuries per gram

that

1.10 DOSE EQUIVALENT I-131 shall be that concentration of I-131 (~~μCi/gram~~) ~~which~~ alone would produce the same ~~thyroid~~ dose ~~as the quantity and isotopic mixture of~~ I-131, I-132, I-133, I-134 and I-135 actually present. The ~~thyroid dose conversion factors used for this calculation shall be those listed in Federal Guidance Report 11, "Limiting Values of Radionuclide Intake and Air Concentration and Dose Conversion Factors for Inhalation, Submersion, and Ingestion."~~

A01

determination of DOSE EQUIVALENT I-131 shall be performed using Committed Dose Equivalent (CDE) or Committed Effective Dose Equivalent (CEDE) dose conversion factors from Table 2.1 of EPA Federal Guidance Report No. 11.

DOSE EQUIVALENT XE-133

DOSE EQUIVALENT XE-133

microcuries per gram

1.11 DOSE EQUIVALENT XE-133 shall be that concentration of Xe-133 (~~μCi/gram~~) that alone would produce the same acute dose to the whole body as the combined activities of noble gas nuclides Kr-85m, Kr-85, Kr-87, Kr-88, Xe-131m, Xe-133m, Xe-133, Xe-135m, Xe-135, and Xe-138 actually present. If a specific noble gas nuclide is not detected, it should be assumed to be present at the minimum detectable activity. The determination of DOSE EQUIVALENT XE-133 shall be performed using effective dose conversion factors for air submersion listed in Table III.1 of EPA Federal Guidance Report No. 12, 1993, “External Exposure to Radionuclides in Air, Water, and Soil.”

ENGINEERED SAFETY FEATURES (ESF) RESPONSE TIME

(ESF)

ENGINEERED SAFETY FEATURES RESPONSE TIME

A01

ESF

S

1.12 The ~~ENGINEERED SAFETY FEATURES~~ REPONSE TIME shall be that time interval from when the monitored parameter exceeds its ESF actuation setpoint at the channel sensor until the ESF equipment is capable of performing its safety function (i.e., the valves travel to their required positions, pump discharge pressures reach their required values, etc.). Times shall include diesel generator starting and sequence loading delays where applicable. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC~~.~~

,

, or the components have been evaluated in accordance with an NRC approved methodology.

L02

~~FREQUENCY NOTATION~~

LA02

~~1.13 The FREQUENCY NOTATION specified for the performance of Surveillance Requirements shall correspond to the intervals defined in Table 1.1.~~

~~GASEOUS RADWASTE TREATMENT SYSTEM~~

~~1.14 A GASEOUS RADWASTE TREATMENT SYSTEM is any system designed and installed to reduce radioactive gaseous effluents by collecting primary coolant system offgases from the primary system and providing for delay or holdup for the purpose of reducing the total radioactivity prior to release to the environment.~~

A04

1.1 **DEFINITIONS**

LEAKAGE

~~IDENTIFED~~ LEAKAGE

~~1.15~~ ~~IDENTIFIED~~ LEAKAGE shall be:

a. Identified LEAKAGE — is

1. ~~a.~~ ~~Leakage (except CONTROLLED~~ LEAKAGE~~) into closed systems~~, such as pump seal or valve packing ~~leaks~~ that ~~are~~ captured~~,~~ and conducted to a sump or collecting tank~~,~~ ~~or~~

(except reactor coolant pump (RCP) seal water injection or leakoff),

that from — s

collection systems or

;

A01

2. ~~b.~~ Leakage into the containment atmosphere from sources that are both specifically located and known ~~either not~~ to interfere with the operation of leakage detection systems ~~or not to be PRESSURE BOUNDARY LEAKAGE,~~ or

A05

(RCS) — not

;

3. ~~c.~~ Reactor Coolant System leakage through a steam generator to the secondary system (Primary~~-~~to~~-~~secondary leakage)~~.~~

;

b. Unidentified LEAKAGE — see CTS 1.34 Markup

c. Pressure Boundary LEAKAGE — see CTS 1.22 Markup

INSERVICE TESTING PROGRAM

INSERVICE TESTING PROGRAM

~~1.16~~ The INSERVICE TESTING PROGRAM is the licensee program that fulfills the requirements of 10 CFR 50.55a(f).

A01

~~MEMBER(S) OF THE PUBLIC~~

~~1.17~~ ~~MEMBER OF THE PUBLIC means an individual in a controlled or unrestricted area. However, an individual is not a member of the public during any period in which the individual receives an occupational dose~~.

A04

OFFSITE DOSE CALCULATION MANUAL (ODCM)

1.18 THE OFFSITE DOSE CALCULATION MANUAL (ODCM) shall contain the methodology and parameters used in the calculation of offsite doses resulting from radioactive gaseous and liquid effluents, in the calculation of gaseous and liquid effluent monitoring Alarm/Trip Setpoints, and in the conduct of the Environmental Radiological Monitoring Program. The ODCM shall also contain (1) the Radioactive Effluent Controls and Radiological Environmental Monitoring Programs required by Section 6.8.4 and (2) descriptions of the information that should be included in the Annual Radiological Environmental Operating and Annual Radioactive Effluent Release Reports required by Specifications 6.9.1.7 and 6.9.1.8.

A04

See ITS 5.5.1

1.1 DEFINITIONS

OPERABLE – OPERABILITY

~~1.19~~ A system, subsystem, train, component or device shall be OPERABLE or have OPERABILITY when it is capable of performing its specified function(s)~~,~~ and when all necessary attendant instrumentation, controls, electrical power, cooling ~~or~~ seal water, lubrication ~~or~~ other auxiliary equipment that are required for the system, subsystem, train, component or device to perform its function(s) are also capable of performing their related support function(s).

~~OPERATIONAL~~ MODE

~~1.20~~ A~~n OPERATIONAL~~ MODE ~~(i.e., MODE)~~ shall correspond to any one inclusive combination of core reactivity condition, power level~~, and~~ average reactor coolant temperature specified in Table ~~1.2~~.

PHYSICS TESTS

~~1.21~~ PHYSICS TESTS shall be those tests performed to measure the fundamental nuclear characteristics of the reactor core and related instrumentation ~~and~~ ~~(1)~~ described in Chapter 14.0 of the FSAR, ~~(2)~~ authorized under the provisions of 10 CFR 50.59, or ~~(3)~~ otherwise approved by the Commission.

~~PRESSURE BOUNDARY~~ LEAKAGE

~~1.22~~ PRESSURE BOUNDARY LEAKAGE ~~shall be leakage~~ (except primary~~-~~to~~-~~secondary leakage) through a ~~non-isolable~~ fault in ~~a Reactor Coolant System~~ component body, pipe wall or vessel wall.

~~PROCESS CONTROL PROGRAM (PCP)~~

~~1.23 The PROCESS CONTROL PROGRAM (PCP) shall contain the current formulas, sampling, analyses, test, and determinations to be made to ensure that processing and packing of solid radioactive wastes based on demonstrated processing of actual or simulated wet solid wastes will be accomplished in such a way as to assure compliance with 10 CFR Parts 20, 61, and 71, State regulations, burial ground requirements, and other requirements governing the disposal of solid radioactive waste.~~

~~PURGE – PURGING~~

~~1.24 PURGE or PURGING is the controlled process of discharging air or gas from a confinement to maintain temperature, pressure, humidity, concentration or other operating condition, in such a manner that replacement air or gas is required to purify the confinement~~.

1.1 **DEFINITIONS**

RATED THERMAL POWER

RATED THERMAL POWER (RTP)

RTP

~~1.25 RATED THERMAL POWER~~ shall be a total reactor core heat transfer rate to the reactor coolant of 3020 MWt.

REACTOR PROTECTION SYSTEM (RPS) RESPONSE TIME

PROTECTION (RPS)

REACTOR ~~TRIP~~ SYSTEM RESPONSE TIME

RPS s RPS that

~~1.26~~ The ~~REACTOR TRIP SYSTEM~~ RESPONSE TIME shall be ~~the~~ time interval from when the monitored parameter exceeds its trip setpoint at the channel sensor until electrical power to the CEA drive mechanism is interrupted. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC.

A01

, or the components have been evaluated in accordance with an NRC approved methodology.

L02

~~REPORTABLE EVENT~~

~~1.27 A REPORTABLE EVENT shall be any of those conditions specified in Section 50.73 to 10 CFR Part 50.~~

A04

SHIELD BUILDING INTEGRITY

A04

1.28 SHIELD BUILDING INTEGRITY shall exist when:

See ITS 3.6.7

a. Each door is closed except when the access opening is being used for normal transit entry and exit;

b. The shield building ventilation system is in compliance with Specification 3.6.6.1, and

See ITS 3.6.9

c. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.

SHUTDOWN MARGIN

SHUTDOWN MARGIN SDM

SDM

~~1.29 SHUTDOWN MARGIN~~ shall be the instantaneous amount of reactivity by which the reactor is subcritical or would be subcritical from its present condition assuming all ~~full-length control element assemblies~~ (shutdown and regulating) are fully inserted except for the single ~~assembly~~ of highest reactivity worth which is assumed to be fully withdrawn.

A01

ITS

3/4.1 REACTIVITY CONTROL SYSTEMS

3/4.1.1 BORATION CONTROL

See ITS 3.1.1

SHUTDOWN MARGIN - T_{avg} > 200 °F

LIMITING CONDITION FOR OPERATION

3.1.1.1 The SHUTDOWN MARGIN shall be within the limits specified in the COLR.

APPLICABILITY: MODES 1, 2*, 3 and 4.

ACTION:

With the SHUTDOWN MARGIN not within limits immediately initiate and continue boration at ≥ 40 gpm of greater than or equal to 1900 ppm boron or equivalent until the required SHUTDOWN MARGIN is restored.

SURVEILLANCE REQUIREMENTS

4.1.1.1.1 The SHUTDOWN MARGIN shall be determined to be within the COLR limits:

a. Within one hour after detection of an inoperable CEA(s) and at least once per 12 hours thereafter while the CEA(s) is inoperable. ~~If the inoperable~~ CEA ~~is~~ not fully inserted, ~~and is immovable as a result of excessive friction or mechanical interference or is known to be untrippable,~~ the ~~above required SHUTDOWN MARGIN shall be increased by an amount at least equal to the withdrawn~~ worth of ~~the immovable or untrippable~~ CEA~~(s)~~.

With any | s | capable of being | SHUTDOWN MARGIN | A01 | these | must be accounted for in the determination of SDM | reactivity

b. When in MODES 1 or 2#, in accordance with the Surveillance Frequency Control Program by verifying that CEA group withdrawal is within the Power Dependent Insertion Limits of Specification 3.1.3.6.

c. When in MODE 2## at least once during CEA withdrawal and in accordance with the Surveillance Frequency Control Program until the reactor is critical.

d. Prior to initial operation above 5% RATED THERMAL POWER after each fuel loading, by consideration of the factors of e below, with the CEA groups at the Power Dependent Insertion Limits of Specification 3.1.3.6.

---

* See Special Test Exception 3.10.1.

\# With K_{eff} ≥ 1.0.

\## With K_{eff} < 1.0.

ITS

REACTIVITY CONTROL SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

e. When in MODES 3 or 4, in accordance with the Surveillance Frequency Control Program by consideration of the following factors:

1. Reactor coolant system boron concentration,
2. CEA position,*
3. Reactor coolant system average temperature,
4. Fuel burnup based on gross thermal energy generation,
5. Xenon concentration, and
6. Samarium concentration.

See ITS 3.1.1

4.1.1.1.2 The overall core reactivity balance shall be compared to predicted values to demonstrate agreement within ± 1000 pcm in accordance with the Surveillance Frequency Control Program. This comparison shall consider at least those factors stated in Specification 4.1.1.1.1.e, above. The predicted reactivity values shall be adjusted (normalized) to correspond to the actual core conditions prior to exceeding a fuel burnup of 60 Effective Full Power Days after each fuel loading.

See ITS 3.1.2

SHUTDOWN MARGIN

* ~~For Modes 3 and 4, during calculation of shutdown margin~~ with all CEA~~'~~s verified fully inserted~~, the single CEA with the highest reactivity worth need not be assumed to be stuck in the fully withdrawn position~~.

L03

A13

by two independent means, it is not necessary to account for a stuck CEA in the SDM calculation

However,

ITS

REACTIVITY CONTROL SYSTEMS

SHUTDOWN MARGIN - T_{avg} ≤ 200 °F

See ITS 3.1.1

LIMITING CONDITION FOR OPERATION

3.1.1.2 The SHUTDOWN MARGIN shall be:

Within the limits specified in the COLR, and in addition with the Reactor Coolant System drained below the hot leg centerline, one charging pump shall be rendered inoperable.*

APPLICABILITY: MODE 5.

ACTION:

If the SHUTDOWN MARGIN requirements cannot be met, immediately initiate and continue boration at ≥ 40 gpm of greater than or equal to 1900 ppm boron or equivalent until the required SHUTDOWN MARGIN is restored.

SURVEILLANCE REQUIREMENTS

4.1.1.2 The SHUTDOWN MARGIN requirements of Specification 3.1.1.2 shall be determined:

SHUTDOWN MARGIN

With any | s not capable of being fully inserted

a. Within one hour after detection of an inoperable CEA(s) and at least once per 12 hours thereafter while the CEA(s) is inoperable. ~~If the inoperable~~ CEA ~~is immovable or untrippable~~, the ~~above required SHUTDOWN MARGIN shall be increased by an amount at least equal to the withdrawn~~ worth of ~~the immovable or untrippable~~ CEA~~(s)~~. (A01)

reactivity

these | must be accounted for in the determination of SDM

b. In accordance with the Surveillance Frequency Control Program by consideration of the following factors:

1. Reactor coolant system boron concentration,
2. CEA position,
3. Reactor coolant system average temperature,
4. Fuel burnup based on gross thermal energy generation,
5. Xenon concentration, and
6. Samarium concentration.

c. At least once per 24 hours, when the Reactor Coolant System is drained below the hot leg centerline, by consideration of the factors in 4.1.1.2.b and by verifying at least one charging pump is rendered inoperable.*

* Breaker racked-out.

A12

ACTIONS

ACTION

S

1.1 ACTION shall be that part of a specification which prescribes remedial measures required under designated conditions.

that | Required Actions to be taken | within specified Completion Times

A01

AXIAL SHAPE INDEX (ASI)

AXIAL SHAPE INDEX (ASI)

(ASI)

1.2 The AXIAL SHAPE INDEX (Y_E) is the power level detected by the lower excore nuclear instrument detectors (L) less the power level detected by the upper excore nuclear instrument detectors (U) divided by the sum of these power levels. The AXIAL SHAPE INDEX (Y_I) used for the trip and pretrip signals in the reactor protection system is the above value (Y_E) modified by an appropriate multiplier (A) and a constant (B) to determine the true core axial power distribution for that channel.

ASI shall be | generated in | generated in | half of the core | half of the core, | generated in the lower and upper halves of the core.

LA01

$$Y_E = \frac{L - U}{L + U} \qquad Y_I = AY_E + B$$

ASI = (LOWER – UPPER) / LOWER + UPPER)

AZIMUTHAL POWER TILT (T_q)

AZIMUTHAL POWER TILT – T_q

1.3 AZIMUTHAL POWER TILT shall be the maximum difference between the power generated in any core quadrant (upper or lower) and the average power of all quadrants in that half (upper or lower) of the core divided by the average power of all quadrants in that half (upper or lower) of the core.

(P_{quad}) | of the | (P_{avg}) | ,

$$\text{AZIMUTHAL POWER TILT} = \text{MAX}\left[\frac{\text{Power in any core quadrant (upper or lower)}}{\text{Average power of all quadrants (upper or lower)}} - 1\right]$$

$T_q = \text{MAX} \mid (P_{quad} - P_{avg}) / P_{avg} \mid$

A01

CHANNEL CALIBRATION

CHANNEL CALIBRATION

that

1.4 A CHANNEL CALIBRATION shall be the adjustment, as necessary, of the channel output such that it responds with the necessary range and accuracy to known values of the parameter which the channel monitors. The CHANNEL CALIBRATION shall encompass the entire channel including the sensor and alarm and/or trip functions, and shall include the CHANNEL FUNCTIONAL TEST. The CHANNEL CALIBRATION may be performed by any series of sequential, overlapping or total channel steps such that the entire channel is calibrated.

INSERT 1

A02

all devices in | means of | required for channel OPERABILITY

CHANNEL CHECK

CHANNEL CHECK

INSERT 2

A02

1.5 A CHANNEL CHECK shall be the qualitative assessment of channel behavior during operation by observation. This determination shall include, where possible, comparison of the channel indication and/or status with other indications and/or status derived from independent instrument channels measuring the same parameter.

, by observation,

to

A02 **INSERT 1**

Calibration of instrument channels with resistance temperature detector (RTD) or thermocouple sensors may consist of an inplace qualitative assessment of sensor behavior and normal calibration of the remaining adjustable devices in the channel.

A02 **INSERT 2**

, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step.

1.1 DEFINITIONS

CHANNEL FUNCTIONAL TEST

CHANNEL FUNCTIONAL TEST

~~1.6~~ A CHANNEL FUNCTIONAL TEST shall be the injection of a simulated or actual signal into the channel as close to the ~~primary~~ sensor as practicable to verify OPERABILITY ~~including alarm and/or trip functions.~~

Insert 3

L01 A01 A03

CONTAINMENT VESSEL INTEGRITY

A04

1.7 CONTAINMENT VESSEL INTEGRITY shall exist when:

See ITS 3.6.1

a. All containment vessel penetrations required to be closed during accident conditions are either:

   1. Capable of being closed by an OPERABLE containment automatic isolation valve system, or

   2. Closed by manual valves, blind flanges, or deactivated automatic valves secured in their closed positions, except for valves that are open on an intermittent basis under administrative control.

See ITS 3.6.3

b. All containment vessel equipment hatches are closed and sealed,

c. Each containment vessel air lock is in compliance with the requirements of Specification 3.6.1.3,

See ITS 3.6.2

d. The containment leakage rates are within the limits of Specification 3.6.1.2, and

e. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.

~~CONTROLLED LEAKAGE~~

~~1.8 CONTROLLED LEAKAGE shall be the seal water flow supplied from the reactor coolant pump seals.~~

~~CORE ALTERATION~~

~~1.9 CORE ALTERATION shall be the movement or manipulation of any fuel, sources, reactivity control components, or other components affecting reactivity within the reactor vessel with the vessel head removed and fuel in the vessel. Exceptions to the above include evolutions performed with the upper guide structure (UGS) in place such as control element assembly (CEA) latching/unlatching or verification of latching/unlatching which do not constitute a CORE ALTERATION. Suspension of CORE ALTERATIONS shall not preclude completion of movement of a component to a safe position.~~

A04

CORE OPERATING LIMITS REPORT (COLR)

CORE OPERATING LIMITS REPORT (COLR)

~~1.9a~~ THE COLR is the unit-specific document that provides cycle specific parameter limits for the current ~~operating~~ reload cycle. These cycle-specific parameter limits shall be determined for each reload cycle in accordance with Specification ~~6.9.1.11~~. Plant operation within these limits is addressed in individual Specifications.

5.6.3

A01

A03

INSERT 3

of all devices in the channel required for channel OPERABILITY. The CHANNEL FUNCTIONAL TEST may be performed by means of any series of sequential, overlapping, or total channel steps, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step.

1.1 **DEFINITIONS**

DOSE EQUIVALENT I-131

DOSE EQUIVALENT I-131

~~1.10~~ DOSE EQUIVALENT I-131 shall be that concentration of I-131 (microcuries/gram) ~~which~~ alone would produce the same ~~thyroid~~ dose ~~as the quantity and isotopic mixture of~~ I-131, I-132, I-133, I-134 and I-135 actually present. The ~~thyroid dose conversion factors used for this calculation shall be those listed in Federal Guidance Report 11, "Limiting Values of Radionuclide Intake and Air Concentration and Dose Conversion Factors for Inhalation, Submersion, and Ingestion."~~

when inhaled as the combined activities of iodine isotopes

that

determination of DOSE EQUIVALENT I-131 shall be performed using Committed Dose Equivalent (CDE) or Committed Effective Dose Equivalent (CEDE) dose conversion factors from Table 2.1 of EPA Federal Guidance Report No. 11.

A01

DOSE EQUIVALENT XE-133

DOSE EQUIVALENT XE-133

~~1.11~~ DOSE EQUIVALENT XE-133 shall be that concentration of Xe-133 (~~µ~~Ci/gram) that alone would produce the same acute dose to the whole body as the combined activities of noble gas nuclides Kr-85m, Kr-85, Kr-87, Kr-88, Xe-131m, Xe-133m, Xe-133, Xe-135m, Xe-135, and Xe-138 actually present. If a specific noble gas nuclide is not detected, it should be assumed to be present at the minimum detectable activity. The determination of DOSE EQUIVALENT XE-133 shall be performed using effective dose conversion factors for air submersion listed in Table III.1 of EPA Federal Guidance Report No. 12, 1993, "External Exposure to Radionuclides in Air, Water, and Soil."

microcuries per gram

ENGINEERED SAFETY FEATURES (ESF) RESPONSE TIME

ENGINEERED SAFETY FEATURE~~S~~ RESPONSE TIME

(ESF)

ESF

~~1.12~~ The ~~ENGINEERED SAFETY FEATURES~~ RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its ESF actuation setpoint at the channel sensor until the ESF equipment is capable of performing its safety function (i.e., the valves travel to their required positions, pump discharge pressures reach their required values, etc.). Times shall include diesel generator starting and sequence loading delays where applicable. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC~~.~~

,

, or the components have been evaluated in accordance with an NRC approved methodology.

A01

L02

~~**FREQUENCY NOTATION**~~

~~1.13 The FREQUENCY NOTATION specified for the performance of Surveillance Requirements shall correspond to the intervals defined in Table 1.1.~~

LA02

~~**GASEOUS RADWASTE TREATMENT SYSTEM**~~

~~1.14 A GASEOUS RADWASTE TREATMENT SYSTEM is any system designed and installed to reduce radioactive gaseous effluents by collecting primary coolant system offgases from the primary system and providing for delay or holdup for the purpose of reducing the total radioactivity prior to release to the environment.~~

A04

LEAKAGE

~~**IDENTIFIED** **LEAKAGE**~~

a. Identified LEAKAGE

~~1.15 IDENTIFIED~~ LEAKAGE shall be:

1. ~~a.~~ ~~Leakage (except CONTROLLED~~ LEAKAGE~~) into closed systems~~, such as pump seal or valve packing ~~leaks~~ that ~~are~~ captured~~,~~ and conducted to a sump or collecting tank~~, or~~

s

is

that from

(except reactor coolant pump (RCP) seal water injection or leakoff),

;

collection systems or

2. ~~b.~~ Leakage into the containment atmosphere from sources that are both specifically located and known ~~either not~~ to interfere with the operation of leakage detection systems ~~or not to be PRESSURE BOUNDARY LEAKAGE,~~ or

;

3. ~~c.~~ Reactor Coolant System (RCS) leakage through a steam generator to the secondary system (primary~~-~~to~~-~~secondary leakage)~~.~~

not

;

b. Unidentified LEAKAGE see CTS 1.34 Markup

c. Pressure Boundary LEAKAGE see CTS 1.22 Markup

A01

A08

MODE

~~OPERATIONAL MODE –~~ MODE

~~1.20~~ A~~n OPERATIONAL~~ MODE ~~(i.e., MODE)~~ shall correspond to any one inclusive combination of core reactivity condition, power level ~~and~~ average reactor coolant temperature specified in Table ~~1.2~~.

,

,

and reactor vessel head closure bolt tensioning

1.1-1 with fuel in the reactor vessel

A01

PHYSICS TESTS

PHYSICS TESTS

~~1.21~~ PHYSICS TESTS shall be those tests performed to measure the fundamental nuclear characteristics of the reactor core and related instrumentation ~~and (1)~~ described in Chapter 14.0 of the FSAR, ~~(2)~~ authorized under the provisions of 10 CFR 50.59, or ~~(3)~~ otherwise approved by the Commission.

. These tests are:

a.

, Initial Test Program

b.

c.

Nuclear Regulatory

A06

A01

1.1 **DEFINITIONS**

LEAKAGE

~~PRESSURE BOUNDARY~~ LEAKAGE

c.

an RCS

LEAKAGE

~~1.22~~ PRESSURE BOUNDARY LEAKAGE ~~shall be leakage~~ (except primary-to-secondary leakage) through a ~~non-isolable~~ fault in ~~a Reactor Coolant System~~ component body, pipe wall, or vessel wall.

,

LEAKAGE past seals, packing, and gaskets is not pressure boundary LEAKAGE.

A14

A01

A05

~~PROCESS CONTROL PROGRAM (PCP)~~

~~1.23 The PROCESS CONTROL PROGRAM (PCP) shall contain the current formulas, sampling, analyses, test, and determinations to be made to ensure that processing and packaging of solid radioactive wastes based on demonstrated processing of actual or simulated wet solid wastes will be accomplished in such a way as to assure compliance with 10 CFR Parts 20, 61, and 71, State regulations, burial ground requirements, and other requirements governing the disposal of solid radioactive waste.~~

A04

~~PURGE – PURGING~~

~~1.24 PURGE or PURGING is the controlled process of discharging air or gas from a confinement to maintain temperature, pressure, humidity, concentration or other operating condition, in such a manner that replacement air or gas is required to purify the confinement.~~

RATED THERMAL POWER

RATED THERMAL POWER

(RTP)

RTP

~~1.25 RATED THERMAL POWER~~ shall be a total reactor core heat transfer rate to the reactor coolant of 3020 MWt.

REACTOR PROTECTION SYSTEM (RPS) RESPONSE TIME

PROTECTION

(RPS)

REACTOR ~~TRIP~~ SYSTEM RESPONSE TIME

RPS

s

RPS

that

~~1.26~~ The ~~REACTOR TRIP SYSTEM~~ RESPONSE TIME shall be ~~the~~ time interval from when the monitored parameter exceeds its trip setpoint at the channel sensor until electrical power to the CEA drive mechanism is interrupted. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC~~.~~

, or the components have been evaluated in accordance with an NRC approved methodology.

L02

A01

~~REPORTABLE EVENT~~

~~1.27 A REPORTABLE EVENT shall be any of those conditions specified in Section 50.73 to 10 CFR Part 50.~~

A04

SHIELD BUILDING INTEGRITY

A04

1.28 SHIELD BUILDING INTEGRITY shall exist when:

See ITS 3.6.7

a. Each door is closed except when the access opening is being used for normal transit entry and exit;

b. The shield building ventilation system is in compliance with Specification 3.6.6.1, and

See ITS 3.6.9

c. The sealing mechanism associated with each penetration (e.g., welds, bellows or O-rings) is OPERABLE.

1.1 DEFINITIONS

SHUTDOWN MARGIN

SHUTDOWN MARGIN

SDM

SDM

~~1.29~~ ~~SHUTDOWN MARGIN~~ shall be the instantaneous amount of reactivity by which the reactor is subcritical or would be subcritical from its present condition assuming all ~~full-length~~ ~~control element assemblies~~ (shutdown and regulating) are fully inserted except for the single ~~assembly~~ of highest reactivity worth which is assumed to be fully withdrawn.

See ITS 3.1.1

SHUTDOWN MARGIN - T_{avg} GREATER THAN 200°F

LIMITING CONDITION FOR OPERATION

3.1.1.1 The SHUTDOWN MARGIN shall be within the limits specified in the COLR.

APPLICABILITY: MODES 1, 2*, 3 and 4.

ACTION:

With the SHUTDOWN MARGIN outside the COLR limits, immediately initiate and continue boration at greater than or equal to 40 gpm of a solution containing greater than or equal to 1900 ppm boron or equivalent until the required SHUTDOWN MARGIN is restored.

SURVEILLANCE REQUIREMENTS

4.1.1.1.1 The SHUTDOWN MARGIN shall be determined to be within the COLR limits:

SHUTDOWN MARGIN

capable of being

With any

s

a. Within one hour after detection of an inoperable CEA(s) and at least once per 12 hours thereafter while the CEA(s) is inoperable. ~~If the inoperable~~ CEA~~is~~ not fully inserted, ~~and is immovable as a result of excessive friction or mechanical interference or is known to be untrippable,~~ the ~~above required SHUTDOWN MARGIN shall be verified acceptable with an increased allowance for the withdrawn~~ worth of ~~the immovable or untrippable~~ CEA~~s~~.

A01

reactivity

these

must be accounted for in the determination of SDM

b. When in MODE 1 or MODE 2 with Keff greater than or equal to 1.0, in accordance with the Surveillance Frequency Control Program by verifying that CEA group withdrawal is within the Power Dependent Insertion Limits of Specification 3.1.3.6.

c. When in MODE 2 with Keff less than 1.0, within 4 hours prior to achieving reactor criticality by verifying that the predicted critical CEA position is within the limits of Specification 3.1.3.6.

---

* See Special Test Exception 3.10.1.

ITS

REACTIVITY CONTROL SYSTEMS

SHUTDOWN MARGIN - T_{avg} LESS THAN OR EQUAL TO 200°F

See ITS 3.1.1

LIMITING CONDITION FOR OPERATION

3.1.1.2 The SHUTDOWN MARGIN shall be within the limits specified in the COLR.

APPLICABILITY: MODE 5.

ACTION:

With the SHUTDOWN MARGIN outside the COLR limits, immediately initiate and continue boration at greater than or equal to 40 gpm of a solution containing greater than or equal to 1900 ppm boron or equivalent until the required SHUTDOWN MARGIN is restored.

SURVEILLANCE REQUIREMENTS

4.1.1.2 The SHUTDOWN MARGIN shall be determined to be within the COLR limits:

not capable of being fully inserted

With any

s

a. Within 1 hour after detection of an inoperable CEA(s) and at least once per 12 hours thereafter while the CEA(s) is inoperable. ~~If the inoperable~~ CEA ~~is immovable or untrippable~~, the ~~above required SHUTDOWN MARGIN shall be increased by an amount at least equal to the withdrawn~~ worth of ~~the immovable or untrippable~~ CEA~~(s)~~.

A01

SHUTDOWN MARGIN

these

must be accounted for in the determination of SDM

reactivity

b. In accordance with the Surveillance Frequency Control Program by consideration of the following factors:

1. Reactor coolant system boron concentration,
2. CEA position,
3. Reactor coolant system average temperature,
4. Fuel burnup based on gross thermal energy generation,
5. Xenon concentration, and
6. Samarium concentration.

c. At least once per 24 hours, when the Reactor Coolant System is drained below the hot leg centerline, by consideration of the factors in 4.1.1.2b and by verifying at least two charging pumps are rendered inoperable by racking out their motor circuit breakers.

DISCUSSION OF CHANGES
ITS 1.0, USE AND APPLICATIONS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 1.4 defines a CHANNEL CALIBRATION as "the adjustment, as necessary, of the channel output such that it responds with the necessary range and accuracy to known values of the parameter which the channel monitors. The CHANNEL CALIBRATION shall encompass the entire channel including the sensor and alarm and/or trip functions, and shall include the CHANNEL FUNCTIONAL TEST. The CHANNEL CALIBRATION may be performed by any series of sequential, overlapping or total channel steps such that the entire channel is calibrated." ITS defines a CHANNEL CALIBRATION as "the adjustment, as necessary, of the channel output such that it responds within the necessary range and accuracy to known values of the parameter that the channel monitors. The CHANNEL CALIBRATION shall encompass all devices in the channel required for channel OPERABILITY and the CHANNEL FUNCTIONAL TEST. Calibration of instrument channels with resistance temperature detector (RTD) or thermocouple sensors may consist of an in place qualitative assessment of sensor behavior and normal calibration of the remaining adjustable devices in the channel. The CHANNEL CALIBRATION may be performed by means of any series of sequential, overlapping, or total channel steps and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step." This results in a number of changes to the CTS.

- The CTS definition states, "The CHANNEL CALIBRATION shall encompass the entire channel including the sensor and alarm and/or trip functions and shall include the CHANNEL FUNCTIONAL TEST." The ITS states, "The CHANNEL CALIBRATION shall encompass all devices in the channel required for channel OPERABILITY and the CHANNEL FUNCTIONAL TEST."

  This change is acceptable because the statements are equivalent in that both require that all needed portions of the channel be tested. The ITS definition reflects the CTS understanding that the CHANNEL CALIBRATION includes only those portions of the channel needed to perform the safety function including the required devices associated with the CHANNEL FUNCTIONAL TEST.

- The ITS adds the statement, "Calibration of instrument channels with resistance temperature detector (RTD) or thermocouple sensors may consist of an in place qualitative assessment of sensor behavior and normal

calibration of the remaining adjustable devices in the channel." The purpose of a CHANNEL CALIBRATION is to adjust the channel output so that the channel responds within the necessary range and accuracy to known values of the parameters that the channel monitors.

This change is acceptable because resistance temperature detectors and thermocouples are designed such that they have a fixed input/output response, which cannot be adjusted or changed once installed. Calibration of a channel containing an RTD or thermocouple is performed by applying the RTD or thermocouple fixed input/output relationship to the remainder of the channel, and making the necessary adjustments to the adjustable devices in the remainder of the channel to obtain the necessary output range and accuracy. Therefore, unlike other sensors, an RTD or thermocouple is not actually calibrated. The ITS CHANNEL CALIBRATION allowance for channels containing RTDs and thermocouples is consistent with the CTS calibration practices of these channels. This information is included in the ITS to avoid confusion but does not change the current CHANNEL CALIBRATION practices for these types of channels.

- The ITS adds the statement, "and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step."

  This change is acceptable because it results in no technical changes to the Technical Specifications. The CTS have implemented the Surveillance Frequency Control Program.

These changes are designated as administrative because they do not result in a technical change to the Technical Specifications.

A03 CTS Section 1.0 defines CHANNEL FUNCTIONAL TEST as "the injection of a simulated signal into the channel as close to the primary sensor as practicable to verify OPERABILITY including alarm and/or trip functions." ITS Section 1.1 defines it as "the injection of a simulated or actual signal into the channel as close to the sensor as practicable to verify OPERABILITY of all devices in the channel required for channel OPERABILITY. The CHANNEL FUNCTIONAL TEST may be performed by means of any series of sequential, overlapping, or total channel steps, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step." This changes the CHANNEL FUNCTIONAL TEST by stating that the CHANNEL FUNCTIONAL TEST may include “the injection of a simulated or actual signal”, applies to “all devices in the channel required for OPERABILITY”, may “be performed by means of any series of sequential, overlapping, or total channel steps”, and “each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step.” The addition of use of an actual signal is discussed in DOC L01.

- The CTS definition states that the CHANNEL FUNCTIONAL TEST shall verify that the channel is OPERABLE "including alarm and/or trip functions." Similarly, the ITS requirement states that the CHANNEL FUNCTIONAL TEST

shall verify OPERABILITY of "all devices in the channel required for channel OPERABILITY."

This change is acceptable because the statements are equivalent in that both require verification of channel OPERABILITY. The CTS and the ITS use different examples of what is included in a channel, but this does not change the intent of the requirement. The ITS use of the phrase "all devices in the channel required for channel OPERABILITY" reflects the CTS understanding that the test includes only those portions of the channel needed to perform the specified safety function(s).

- The ITS states "The CHANNEL FUNCTIONAL TEST may be performed by means of any series of sequential, overlapping, or total channel steps."

  This change is acceptable because it states current Industry practice and is consistent with the current implementation of the CHANNEL FUNCTIONAL TEST. Therefore, this change does not result in a technical change to the Technical Specifications.

- The ITS adds the statement, "and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step."

  This change is acceptable because it results in no technical changes to the Technical Specifications. The CTS have implemented the Surveillance Frequency Control Program.

These changes are designated as administrative because they do not result in a technical change to the Technical Specifications.

A04 CTS Section 1.0 includes the following definitions:

- CONTAINMENT VESSEL INTEGRITY
- CONTROLLED LEAKAGE
- CORE ALTERATION
- FREQUENCY NOTATION
- GASEOUS RADWASTE TREATMENT SYSTEM
- MEMBER(S) OF THE PUBLIC
- OFFSITE DOSE CALCULATION MANUAL (ODCM)
- PROCESS CONTROL PROGRAM (PCP)
- PURGE – PURGING
- REPORTABLE EVENT
- SHIELD BULIDING INTEGRITY
- SITE BOUNDARY
- SOURCE CHECK
- STAGGERED TEST BASIS
- UNRESTRICTED AREA
- UNRODDED INTEGRATED RADIAL PEAKING FACTOR - F_r
- VENTILATION EXHAUST TREATMENT SYSTEM (PSL Unit 2 Only)

The ITS does not use this terminology and ITS Section 1.1 does not contain these definitions. The FREQUENCY NOTATION definition deletion is discussed in DOC LA02. The VENTILATION EXHAUST TREATMENT SYSTEM definition deletion is only applicable to PSL Unit 2 because this definition is not contained in the PSL Unit 1 TS.

These changes are acceptable because the terms are not used as defined terms in the ITS. Discussions of any technical changes related to the deletion of these terms are included in the DOCs for the CTS sections in which the terms are used. These changes are designated as administrative because they eliminate defined terms that are no longer used.

A05 CTS Section 1.0 provides definitions for IDENTIFIED LEAKAGE, PRESSURE BOUNDARY LEAKAGE, and UNIDENTIFIED LEAKAGE. ITS Section 1.1 includes these requirements in one definition called LEAKAGE (which includes three categories: identified LEAKAGE, unidentified LEAKAGE, and pressure boundary LEAKAGE). This changes the CTS by incorporating the definitions into the ITS LEAKAGE definition with no technical changes.

This change is acceptable because it results in no technical changes to the Technical Specifications. This change is designated an administrative change in that it rearranges existing definitions, with no change in intent.

A06 CTS Section 1.20 and Table 1.2, OPERATIONAL MODES" provide a description of the MODES. CTS Table 1.2 contains Note ** that states, "Fuel in the reactor vessel with the vessel head closure bolts less than fully tensioned or with the head removed." ITS Section 1.1 and Table 1.1-1, "MODES," changes the CTS MODE definitions in the following ways:

- The CTS Table 1.2 Note ** condition "fuel in the vessel" is moved to the ITS MODE definition.

  This change is acceptable because it moves information within the Technical Specifications with no change in intent. Each MODE in the Table includes fuel in the vessel.

- CTS Table 1.1, Note ** in part states, "…with the vessel head closure bolts less than fully tensioned or with the head removed." ITS splits this portion of the Note into two Notes, Notes (b), and (c). ITS Note (b) states, "All reactor vessel head closure bolts fully tensioned," while Note (c) states, "One or more reactor vessel head closure bolts less than fully tensioned." This change simplifies what CTS is stating by clearly defining when the reactor is in a refueling condition instead of a shutdown condition.

  This change is acceptable because the revised phrase is consistent with the current interpretation and usage. MODE 6 is currently declared when the first vessel head closure bolt is detensioned. This change also eliminates a redundant phrase. The reactor vessel head cannot be removed unless the reactor vessel head closure bolts are unbolted and they cannot be unbolted

unless they are detensioned. Since “vessel head closure bolts less then fully tensioned” is already specified in the CTS Note, including “or with the reactor head removed” is unnecessary.

- ITS Table 1.1-1 contains a new Note b, which applies to MODES 4 and 5. Note b states "All reactor vessel head closure bolts fully tensioned." This Note is the opposite of CTS Note ** and ITS Table 1.1-1 Note (c).

  This change is acceptable because it avoids a conflict between the definition of MODE 6 and the other MODES should RCS temperature increase above the CTS MODE 6 temperature limit while a reactor vessel head closure bolt is less than fully tensioned. This ITS Note is included only for clarity. It is consistent with the current use of MODES 4 and 5 and does not result in any technical change to the application of the MODES.

- For consistency with the Notes in ITS Table 1.1-1, the ITS definition of MODE adds, "reactor vessel head closure bolt tensioning" to the list of characteristics that define a MODE. Currently, the CTS definition does not include this clarification.

  This change is acceptable because the definition of MODE should be consistent with the MODE table in order to avoid confusion. This change is made only for consistency and results in no technical changes to the Technical Specifications.

These changes are designated as administrative because they clarify the application of the MODES and no technical changes to the MODE definitions are made. The clarifications are consistent with the current use and application of the MODES.

A07 The CTS Section 1.0 definition of OPERABLE - OPERABILITY requires that “all necessary attendant instrumentation, controls, electrical power, cooling or seal water, lubrication or other auxiliary equipment that are required for the system, subsystem, train, component or device to perform its function(s) are also capable of performing their related support function(s).” The ITS Section 1.1 definition of OPERABLE - OPERABILITY will replace the phrase “electrical power" with "normal or emergency electrical power." This changes the CTS definition of OPERABLE - OPERABILITY by allowing a device to be considered OPERABLE with either normal or emergency power available.

The OPERABILITY requirements for normal and emergency power sources are addressed in CTS Section 3/4.8. These requirements allow only the normal or the emergency electrical power source to be OPERABLE, provided its redundant system(s), subsystem(s), train(s), component(s), and device(s) (redundant to the systems, subsystems, trains, components, and devices with an inoperable power source) are OPERABLE. Therefore, the ITS definition uses the words "normal or emergency" consistent with CTS Section 3/4.8. This change is designated administrative since the ITS definition is effectively the same as the CTS definition.

A08 The CTS Section 1.0 definition of OPERABLE - OPERABILITY requires that “A system, subsystem, train, component, or device shall be OPERABLE or have OPERABILITY when it is capable of performing its specified function(s) and when all necessary attendant instrumentation, controls, electrical power, cooling or seal water, lubrication or other auxiliary equipment that are required for the system, subsystem, train, component or device to perform its function(s) are also capable of performing their related support function(s).” The ITS Section 1.1 definition of OPERABLE - OPERABILITY will replace the phrase “specified function(s)” with "specified safety functions" and will replace the phrase “function(s)” with "specified safety functions."

The CTS Section 1.0 definition of OPERABLE - OPERABILITY requires a system, subsystem, train, component, or device to be capable of performing its "specified function(s)" and all necessary support systems to also be capable of performing their "function(s)." The ITS Section 1.1 definition of OPERABLE - OPERABILITY requires the system, subsystem, train, component, or device to be capable of performing the "specified safety function(s)," and requires all necessary support systems that are required for the system, subsystem, train, component, or device to perform its "specified safety function(s)" to also be capable of performing their related support functions. This changes the CTS by altering the requirement to be able to perform "functions" to a requirement to be able to perform "safety functions."

The purpose of the CTS and ITS definitions of OPERABLE - OPERABILITY are to ensure that the safety analysis assumptions regarding equipment and variables are valid. This change is acceptable because the intent of both the CTS and ITS definitions is to address the safety function(s) assumed in the accident analysis and not encompass other non-safety functions a system may also perform. These non-safety functions are not assumed in the safety analysis and are not needed in order to protect the public health and safety. This change is consistent with the current interpretation and use of the terms OPERABLE and OPERABILITY. This change is designated as administrative as it does not change the current use and application of the Technical Specifications.

A09 CTS Section 1.0 provides a definition of SHUTDOWN MARGIN (SDM). The ITS Section 1.1 definition of SDM contains the following difference from the CTS definition.

- The CTS definition of SDM does not include a statement requiring an increased allowance for the withdrawn worth of an immovable or untrippable CEA(s). This requirement is contained in CTS 4.1.1.1.1.a and CTS 4.1.1.2.a. The ITS definition of SDM includes this increased allowance by stating, “ With any CEAs not capable of being fully inserted, the reactivity worth of these CEAs must be accounted for in the determination of SDM.” This changes the CTS definition of SDM to include the requirement in CTS 4.1.1.1.1.a and CTS 4.1.1.2.a for an increased allowance for the withdrawn worth of the immovable or untrippable CEA(s).

This change is acceptable because it is consistent with the existing SDM requirements associated with a CEA not capable of being fully inserted as specified in CTS 3.1.1.1 and 3.1.1.2.

This change is designated as administrative because it does not represent a technical change to the Technical Specifications

A10 ITS Sections 1.2, 1.3, and 1.4 contain information that is not in the CTS. This change to the CTS adds explanatory information on ITS usage that is not applicable to the CTS. The added sections are:

- Section 1.2 - Logical Connectors

  Section 1.2 provides specific examples of the logical connectors "AND" and "OR" and the numbering sequence associated with their use.

- Section 1.3 - Completion Times

  Section 1.3 provides guidance on the proper use and interpretation of Completion Times. The section also provides specific examples that aid in the use and understanding of Completion Times

- Section 1.4 – Frequency

  Section 1.4 provides guidance on the proper use and interpretation of Surveillance Frequencies. The section also provides specific examples that aid in the use and understanding of Surveillance Frequency.

This change is acceptable because it aids in the understanding and use of the format and presentation style of the ITS. The addition of these sections does not add or delete technical requirements, and will be discussed specifically in those Technical Specifications where application of the added sections results in a change. This change is designated as administrative because it does not result in a technical change to the Technical Specifications.

A11 CTS Table 1.2, OPERATIONAL MODES, is revised. The corresponding table in ITS Section 1.1 is Table 1.1-1, MODES. The changes to the CTS are:

- CTS Table 1.2 minimum average reactor coolant temperature for MODES 1 and 2 is changed from ≥ 325°F to "NA" (not applicable) in ITS Table 1.1-1.

  This change is acceptable because ITS LCO 3.4.2, RCS Minimum Temperature for Criticality, provides the minimum reactor coolant temperature limits for MODES 1 and 2. Therefore, the 325°F minimum temperature does not provide any useful information in ITS Table 1.1-1, and is deleted from the CTS.

- CTS Table 1.2 MODE 6 upper limit on average reactor coolant temperature (< 140°F) is removed. In ITS Table 1.1-1, the MODE 6 average reactor coolant temperature limit is specified as "NA" (not applicable).

This change is acceptable because it eliminates a conflict in the CTS MODE Table. If the average coolant temperature exceeds the upper limit with the reactor vessel head closure bolts less than fully tensioned, the CTS Table could be misinterpreted as no MODE being applicable. This is not the intent of the CTS or ITS MODE 6 definitions. By removing the temperature reference, this ambiguity is eliminated.

- CTS Table 1.2 % RATED THERMAL POWER limit of 0% for MODES 3, 4, 5, and 6 is changed in ITS Table 1.1-1 to "NA" (not applicable).

  This change is acceptable because the reactivity and plant equipment limitations in MODES 3, 4, 5, and 6 do not allow power operation. Therefore, it is not necessary to have these restrictions in the MODE Table.

- CTS Table 1.2 contains the unit designators of percent (%) and degrees Fahrenheit (°F) next to the values. This is changed in ITS Table 1.1-1 by removing the designator from the individual value(s).

  This change is acceptable because the designators are contained in the labels associated with the columns. Therefore, it is not necessary to have these designators in the MODE Table.

These changes are designated as administrative because they result in no technical changes to the Technical Specifications.

A12 CTS 1.0 states, "The defined terms of this section appear in capitalized type and are applicable throughout these Technical Specifications." The Note for ITS Section 1.1 states, "The defined terms of this section appear in capitalized type and are applicable throughout these Technical Specifications and Bases." The ITS Note adds a clarification phrase that the defined terms also apply to the Bases.

The ITS Section 1.0 Note serves the same purpose as the CTS 1.0 statement. ITS Section 1.1 Note clarifies that the defined terms also apply to the Bases. This change is consistent with formatting requirements in the ISTS and is consistent with the current use. This change is designated as administrative because it does not represent a technical change to the Technical Specifications.

A13 **Unit 1 only:** CTS Section 1.0 provides a definition of SHUTDOWN MARGIN (SDM). An *note to Unit 1 CTS 4.1.1.1.1.e.2 modifies the CTS definition by stating that for Modes 3 and 4, during calculation of shutdown margin with all CEA's verified fully inserted, the single CEA with the highest reactivity worth need not be assumed to be stuck in the fully withdrawn position. The definition of SDM in ITS Section 1.1 incorporates the aspect of the CTS *note by clarifying, “However, with all CEAs verified fully inserted by two independent means, it is not necessary to account for a stuck CEA in the SDM calculation.”

This changes the CTS by embedding the *note in Unit 1 CTS 4.1.1.1.1.e.2 into the SDM definition. Although not explicitly stated, the intent of the Unit 1 CTS

*note is based on the CEA position indicating system design for plants with a Combustion Engineering nuclear steam supply system, which includes independent and diverse methods of verifying CEA position. Therefore, the ITS definition of SDM clarifies this intent of verifying the CEAs are fully inserted by two independent means.

This change is designated as administrative because it does not represent a technical change to the method of calculating SDM when the CEAs are verified fully inserted by two independent means.

Unit 2 CTS related to SDM does not contain a clarifying note like the *note in Unit 1 CTS 4.1.1.1.1.e.2 and the *note in the Unit 1 CTS is limited to Modes 3 and 4. The equivalent change to the Unit 2 SDM definition and the expanded allowance for Unit 1 SDM definition to include all modes with CEAs inserted are discussed in DOC L03.

A14 CTS 1.22, PRESSURE BOUNDARY LEAKAGE, states that PRESSURE BOUNDARY LEAKAGE shall be leakage (except primary-to-secondary LEAKAGE) through a non-isolable fault in a Reactor Coolant System component body, pipe wall or vessel wall." The ITS definition states that "Pressure Boundary LEAKAGE is LEAKAGE (except primary to secondary LEAKAGE) through a fault in an RCS component body, pipe wall, or vessel wall. LEAKAGE past seals, packing, and gaskets is not pressure boundary LEAKAGE." This changes the CTS by revising the pressure boundary LEAKAGE definition to delete the word "non-isolable and adding the sentence "LEAKAGE past seals, packing, and gaskets is not pressure boundary LEAKAGE." These changes are consistent with Technical Specification Task Force (TSTF) traveler TSTF-554-A, Revision 1, "Revise Reactor Coolant Leakage Requirements." As stated in the NRC Safety Evaluation (SE) accompanying TSTF-554-A, deletion of the word "nonisolable" does not alter the fundamental meaning that pressure boundary leakage represents degradation that could ultimately result in a loss of structural integrity. The NRC concluded that deleting the word "nonisolable" provides a clearer definition of pressure boundary leakage and does not conflict with the reactor coolant pressure boundary definition in 10 CFR 50.2. Additionally, the sentence "LEAKAGE past seals, packing, and gaskets is not pressure boundary LEAKAGE," is consistent with the discussion in NRC Regulatory Guide 1.45 that pressure boundary leakage is not leakage from seals, gaskets, or packing. That considered, the changes to the definition of pressure boundary leakage are acceptable.

TSTF traveler TSTF-554-A incorporated changes to the Standard Technical Specifications (STSs) under the consolidated line item improvement process (CLIIP). TSTF-554-A was approved for use by the NRC as documented in the accompanying SE dated December 18, 2020 (ADAMS Accession No. ML20322A361, ML20322A024). PSL has reviewed the NRC SE and concluded that the justification presented in TSTF-554-A and the SE prepared by the NRC staff are applicable to PSL and justify this change. TSTF-554-A revised the technical specifications related to the LEAKAGE definition. Related changes are made to ITS 3.4.13, RCS Operational LEAKAGE, as discussed in ITS 3.4.13 DOC L01.

This change is designated as administrative because it provides clarification and does not represent a technical change to the Technical Specifications.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* The ITS definition for AXIAL SHAPE INDEX moves the discussion and equation regarding modification of the trip signals in the reactor protection system to determine the core axial power distribution for a given channel to the COLR. The AXIAL SHAPE INDEX curves are provided in the COLR.

CTS 2.2.1 requires reactor protective instrumentation setpoints be set consistent with the Trip Setpoint values shown in Table 2.2-1, Reactor Protective Instrumentation Trip Setpoint Limits. The Applicability is for each channel in Table 3.3-1, Reactor Protective Instrumentation. CTS 3.2.1 Action references COLR Figure 3.2-2, “AXIAL SHAPE INDEX vs. Maximum Allowable Power Level” and CTS LCO 3.2.5.d references COLR Figure 3.2-4 “AXIAL SHAPE INDEX Operating Limits vs. THERMAL POWER.”

ITS LCO 3.2.1 requires that the LHR shall not exceed the limits specified in the COLR, and ITS LCO 3.2.5 requires that the ASI shall not exceed the limits specified in the COLR.

The removal of these details for performing actions from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains AXIAL SHAPE INDEX regarding modification of the trip signals in the reactor protection system to determine the core axial power distribution for a given channel. Also, this change is acceptable because these types of procedural details will be adequately controlled in the COLR. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA02 *(Type 4 – Removal of LCO, SR, or other TS requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program, or Surveillance Frequency Control Program).* CTS 1.13 and CTS Table 1.1 state FREQUENCY NOTATION for the performance of Surveillance Requirements in the CTS. The ITS state periodic Frequency as "In accordance with the Surveillance Frequency Control Program." The CTS have implemented the Surveillance Frequency Control Program. This changes the CTS by deleting the FREQUENCY NOTATION definition and moving the FREQUENCY NOTATION Table to the Surveillance Frequency Control Program.

The removal of FREQUENCY NOTATION for the performance of Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement by stating "In accordance with the Surveillance Frequency Control Program". This change is acceptable because these types of procedural details will be adequately controlled in the Surveillance Frequency Control Program. This change is designated as a less restrictive removal of detail change because the FREQUENCY NOTATION for the performance of Surveillance Frequencies is being removed from the Technical Specifications and placed in a license control document.

LA03 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS Table 1.2, OPERATIONAL MODES, states that MODE 6 is restricted to reactivity conditions with $k_{eff} \leq 0.95$. ITS Table 1.1-1, MODES, does not contain this restriction.

This change is acceptable because the core reactivity requirements for MODE 6 are covered in ITS 3.9.1, "Boron Concentration," by requiring the boron concentration in the Reactor Coolant System to be maintained within the limits specified in the COLR. The ITS LCO section of the 3.9.1 Bases states "The boron concentration limit specified in the COLR ensures that a core k_{eff} of ≤ 0.95 is maintained during fuel handling operations." Moving this detail from the MODE Table to the LCO 3.9.1 Bases eliminates the potential to misinterpret the MODE table and not apply the MODE 6 requirements if the reactor vessel head closure bolts are less than fully tensioned, fuel is in the reactor vessel, and core reactivity exceeds a keff of 0.95. ITS LCO 3.9.1 will ensure that the appropriate reactivity conditions are maintained in MODE 6, so it is not necessary to have this restriction in the MODE Table in order to provide adequate protection of the public health and safety. Once moved to the Bases, any changes to the core reactivity requirement will be controlled by the Technical Specifications Bases Control Program described in Chapter 5 of the ITS. This change is designated a less restrictive removal of detail because it moves information from the Technical Specifications to the Bases.

LESS RESTRICTIVE CHANGES

L01 CTS Section 1.0 definition of CHANNEL FUNCTIONAL TEST requires the use of a simulated signal when performing the test. ITS Section 1.1 allows the use of a

simulated or actual signal when performing the test. This changes the CTS by allowing the use of unplanned actuations to perform the Surveillance based on the collection of sufficient information to satisfy the surveillance test requirements.

This change is acceptable because the channel itself cannot discriminate between an "actual" or "simulated" signal. Therefore, the results of the testing are unaffected by the type of signal used to initiate the test. This change is designated as less restrictive because it allows an actual signal to be credited for Surveillance where only a simulated signal was previously allowed.

L02 CTS Section 1.0 definition of Engineered Safety Feature (ESF) Response Time and Reactor Protection System (RPS) response time require that in lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC. ITS Section 1.1 allows components to be evaluated in accordance with an NRC approved methodology.

The change revises the CTS definition for ESF Response Time and RPS response time that are referenced in Surveillance Requirements (SRs), hereafter referred to as response time testing (RTT). The definitions are revised to add the statement “or the components have been evaluated in accordance with an NRC approved methodology” at the end of the last sentence in the definitions. The changes are based on Technical Specifications Task Force (TSTF) traveler TSTF-569, Revision 2, “Revise Response Time Testing Definition,” dated June 25, 2019 (ADAMS Accession No. ML19176A034). The NRC issued a final safety evaluation (SE) approving TSTF-569, Revision 2, on August 14, 2019 (ADAMS Accession No. ML19176A191). | R1

This change is acceptable because the changes are based on TSTF-569, Revision 2 and there are no proposed variations from the TS changes described in TSTF-569, Revision 2. This change is designated as less restrictive because it allows use of additional NRC approved methodology for evaluation of RTT.

L03 **Unit 2 only:** CTS Section 1.0 definition of SHUTDOWN MARGIN (SDM) requires that the calculation assume that all CEAs (shutdown and regulating) are fully inserted except for the single CEA of highest reactivity worth which is assumed to be fully withdrawn. The ITS definition allows that with all CEAs verified fully inserted by two independent means, it is not necessary to account for a stuck CEA in the SDM calculation.

This change revises the Technical Specifications to include the allowance that with all CEAs verified inserted by two independent means, it is not necessary to account for a stuck CEA in determination of SDM. Consistent with the Combustion Engineering nuclear steam supply system design, the PSL Unit 1 and Unit 2 design include two independent and diverse CEA position indicating systems. The independent systems are the pulse counting CEA position indication system and the reed switch CEA position indication system.

This change is acceptable because the CTS definition was developed considering a worst case condition to assure sufficient SDM is available. However, if all rods can be verified to be fully inserted, the worst case condition is not applicable and the requirement to assume a rod is stuck in the fully withdrawn position is overly conservative and unnecessary to assure safe plant operation. The provision of the ITS exception that requires the rod positions to be verified by two independent means provides adequate assurance that all rods are fully inserted and that SDM may be calculated without the conservative assumption of a fully withdrawn rod. PSL Unit 1 and Unit 2 design provide two independent systems to verify all CEAs are fully inserted. This change is designated as less restrictive because it allows for an exception to the CTS requirements.

Improved Standard Technical Specifications (ISTS) Markup and Justification for Deviations (JFDs)

1.0 USE AND APPLICATION

1.1 Definitions

----------NOTE----------
The defined terms of this section appear in capitalized type and are applicable throughout these Technical Specifications and Bases.

	Term	Definition
1.1	ACTIONS	ACTIONS shall be that part of a Specification that prescribes Required Actions to be taken under designated Conditions within specified Completion Times.
1.2	AXIAL SHAPE INDEX (ASI)	ASI shall be the power generated in the lower half of the core less the power generated in the upper half of the core, divided by the sum of the power generated in the lower and upper halves of the core. ASI = (LOWER - UPPER) / (LOWER + UPPER)
	~~AZIMUTHAL POWER TILT (T_q) - Digital~~	~~AZIMUTHAL POWER TILT shall be the power asymmetry between azimuthally symmetric fuel assemblies.~~
1.3	AZIMUTHAL POWER TILT (T_q) ~~- Analog~~	AZIMUTHAL POWER TILT shall be the maximum of the difference between the power generated in any core quadrant (upper or lower) (P_{quad}) and the average power of all quadrants (P_{avg}) in that half (upper or lower) of the core, divided by the average power of all quadrants in that half (upper or lower) of the core. T_q = Max $\lvert (P_{quad} - P_{avg}) / P_{avg} \rvert$
1.4	CHANNEL CALIBRATION	A CHANNEL CALIBRATION shall be the adjustment, as necessary, of the channel output such that it responds within the necessary range and accuracy to known values of the parameter that the channel monitors. The CHANNEL CALIBRATION shall encompass all devices in the channel required for channel OPERABILITY and the CHANNEL FUNCTIONAL TEST. Calibration of instrument channels with resistance temperature detector (RTD) or thermocouple sensors may consist of an inplace qualitative assessment of sensor behavior and normal calibration of the remaining adjustable devices in the channel. The CHANNEL CALIBRATION may be performed by means of any series of sequential, overlapping, or total channel steps~~[~~, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step~~]~~.

1.1 Definitions

1.5	CHANNEL CHECK	A CHANNEL CHECK shall be the qualitative assessment, by observation, of channel behavior during operation. This determination shall include, where possible, comparison of the channel indication and status to other indications or status derived from independent instrument channels measuring the same parameter.
1.6	CHANNEL FUNCTIONAL TEST	A CHANNEL FUNCTIONAL TEST shall be~~:~~ ~~a. Analog and bistable channels –~~ the injection of a simulated or actual signal into the channel as close to the sensor as practicable to verify OPERABILITY of all devices in the channel required for channel OPERABILITY~~, and~~ ~~b. Digital computer channels - the use of diagnostic programs to test digital computer hardware and the injection of simulated process data into the channel to verify OPERABILITY of all devices in the channel required for channel OPERABILITY.~~ The CHANNEL FUNCTIONAL TEST may be performed by means of any series of sequential, overlapping, or total channel steps~~[~~, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step~~]~~.
1.9a	CORE OPERATING LIMITS REPORT (COLR)	The COLR is the unit specific document that provides cycle specific parameter limits for the current reload cycle. These cycle specific parameter limits shall be determined for each reload cycle in accordance with Specification 5.6.3. Plant operation within these limits is addressed in individual Specifications.
1.10	DOSE EQUIVALENT I-131	DOSE EQUIVALENT I-131 shall be that concentration of I-131 (microcuries per gram) that alone would produce the same dose when inhaled as the combined activities of iodine isotopes I-131, I-132, I-133, I-134, and I-135 actually present. The determination of DOSE EQUIVALENT I-131 shall be performed using ~~---------- Reviewer's Note ----------~~ ~~The first set of thyroid dose conversion factors shall be used for plants licensed to 10 CFR 100.11. The following Committed Dose Equivalent (CDE) or Committed Effective Dose Equivalent (CEDE) conversion factors shall be used for plants licensed to 10 CFR 50.67.~~ ~~----------~~

1.1 Definitions

1.10 DOSE EQUIVALENT I-131 (continued)

~~[thyroid dose conversion factors from:~~

~~a. Table III of TID-14844, AEC, 1962, "Calculation of Distance Factors for Power and Test Reactor Sites," or~~

~~b. Table E-7 of Regulatory Guide 1.109, Rev. 1, NRC, 1977, or~~ 3

~~c. ICRP-30, 1979, Supplement to Part 1, page 192-212, Table titled, "Committed Dose Equivalent in Target Organs or Tissues per Intake of Unit Activity," or~~

~~d. Table 2.1 of EPA Federal Guidance Report No. 11, 1988, "Limiting Values of Radionuclide Intake and Air Concentration and Dose Conversion Factors for Inhalation, Submersion, and Ingestion."~~

~~OR~~

Committed Dose Equivalent (CDE) or Committed Effective Dose Equivalent (CEDE) dose conversion factors from Table 2.1 of EPA Federal Guidance Report No. 11.~~]~~ 3

1.11 DOSE EQUIVALENT XE-133

DOSE EQUIVALENT XE-133 shall be that concentration of Xe-133 (microcuries per gram) that alone would produce the same acute dose to the whole body as the combined activities of noble gas nuclides ~~[~~Kr-85m, Kr-85, Kr-87, Kr-88, Xe-131m, Xe-133m, Xe-133, Xe-135m, Xe-135, and Xe-138~~]~~ actually present. If a specific noble gas nuclide is not detected, it should be assumed to be present at the minimum detectable activity. The determination of DOSE EQUIVALENT XE-133 shall be performed using ~~[~~effective dose conversion factors for air submersion listed in Table III.1 of EPA Federal Guidance Report No. 12, 1993, "External Exposure to Radionuclides in Air, Water, and Soil" ~~or the average gamma disintegration energies as provided in ICRP Publication 38, "Radionuclide Transformations" or similar source]~~. 2 4

1.12 ENGINEERED SAFETY FEATURE (ESF) RESPONSE TIME

The ESF RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its ESF actuation setpoint at the channel sensor until the ESF equipment is capable of performing its safety function (i.e., the valves travel to their required positions, pump discharge pressures reach their required values, etc.). Times shall include diesel generator starting and sequence loading delays, where

1.1 Definitions

1.12 ENGINEERED SAFETY FEATURE (ESF) RESPONSE TIME (continued)

applicable. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC, or the components have been evaluated in accordance with an NRC approved methodology.

1.16 INSERVICE TESTING PROGRAM

The INSERVICE TESTING PROGRAM is the licensee program that fulfills the requirements of 10 CFR 50.55a(f).

1.15 LEAKAGE

LEAKAGE shall be:

a. Identified LEAKAGE

1. LEAKAGE, such as that from pump seals or valve packing (except reactor coolant pump (RCP) seal water injection or leakoff), that is captured and conducted to collection systems or a sump or collecting tank;

2. LEAKAGE into the containment atmosphere from sources that are both specifically located and known to not interfere with the operation of leakage detection systems; or

3. Reactor Coolant System (RCS) LEAKAGE through a steam generator to the Secondary System (primary to secondary LEAKAGE);

1.34

b. Unidentified LEAKAGE

All LEAKAGE (except RCP seal water injection or leakoff) that is not identified LEAKAGE; and

c. Pressure Boundary LEAKAGE

1.22

LEAKAGE (except primary to secondary LEAKAGE) through a fault in an RCS component body, pipe wall, or vessel wall. LEAKAGE past seals, packing, and gaskets is not pressure boundary LEAKAGE.

1.1 Definitions

1.20	MODE	A MODE shall correspond to any one inclusive combination of core reactivity condition, power level, average reactor coolant temperature, and reactor vessel head closure bolt tensioning specified in Table 1.1-1 with fuel in the reactor vessel.
1.19	OPERABLE – OPERABILITY	A system, subsystem, train, component, or device shall be OPERABLE or have OPERABILITY when it is capable of performing its specified safety function(s) and when all necessary attendant instrumentation, controls, normal or emergency electrical power, cooling and seal water, lubrication, and other auxiliary equipment that are required for the system, subsystem, train, component, or device to perform its specified safety function(s) are also capable of performing their related support function(s).
1.21	PHYSICS TESTS	PHYSICS TESTS shall be those tests performed to measure the fundamental nuclear characteristics of the reactor core and related instrumentation. These tests are: a. Described in Chapter [14, Initial Test Program] of the FSAR, (2) b. Authorized under the provisions of 10 CFR 50.59, or c. Otherwise approved by the Nuclear Regulatory Commission.
	~~PRESSURE AND TEMPERATURE LIMITS REPORT (PTLR)~~	~~The PTLR is the unit specific document that provides the reactor vessel pressure and temperature limits, including heatup and cooldown rates, for the current reactor vessel fluence period. These pressure and temperature limits shall be determined for each fluence period in accordance with Specification 5.6.4.~~ (5)
1.25	RATED THERMAL POWER (RTP)	RTP shall be a total reactor core heat transfer rate to the reactor coolant of ~~[3410]~~ 3020 MWt. (2)

1.1 Definitions

1.26	REACTOR PROTECTION SYSTEM (RPS) RESPONSE TIME	The RPS RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its RPS trip setpoint at the channel sensor until electrical power to the CEAs drive mechanism is interrupted. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC, or the components have been evaluated in accordance with an NRC approved methodology.
1.29	SHUTDOWN MARGIN (SDM)	SDM shall be the instantaneous amount of reactivity by which the reactor is subcritical or would be subcritical from its present condition assuming~~:~~ ~~a.~~ All ~~full length~~ CEAs (shutdown and regulating) are fully inserted except for the single CEA of highest reactivity worth, which is assumed to be fully withdrawn. However, with all CEAs verified fully inserted by two independent means, it is not necessary to account for a stuck CEA in the SDM calculation. With any CEAs not capable of being fully inserted, the reactivity worth of these CEAs must be accounted for in the determination of SDM~~, and~~ ~~[b. There is no change in part length CEA position.]~~
	~~[STAGGERED TEST BASIS~~	~~A STAGGERED TEST BASIS shall consist of the testing of one of the systems, subsystems, channels, or other designated components during the interval specified by the Surveillance Frequency, so that all systems, subsystems, channels, or other designated components are tested during *n* Surveillance Frequency intervals, where *n* is the total number of systems, subsystems, channels, or other designated components in the associated function.]~~
1.33	THERMAL POWER	THERMAL POWER shall be the total reactor core heat transfer rate to the reactor coolant.

Table 1.1-1 (page 1 of 1)
MODES

MODE	TITLE	REACTIVITY CONDITION (k_{eff})	% RATED THERMAL POWER[(a)]	AVERAGE REACTOR COOLANT TEMPERATURE (°F)
1	Power Operation	≥ 0.99	> 5	NA
2	Startup	≥ 0.99	≤ 5	NA
3	Hot Standby	< 0.99	NA	325 ≥ ~~[350]~~ (2)
4	Hot Shutdown[(b)]	< 0.99	NA	~~[350]~~ > T_{avg} > ~~[~~200~~]~~ (2)
5	Cold Shutdown[(b)]	< 0.99	NA	≤ ~~[~~200~~]~~ (2)
6	Refueling[(c)]	NA	NA	NA

(a) Excluding decay heat.

(b) All reactor vessel head closure bolts fully tensioned.

(c) One or more reactor vessel head closure bolts less than fully tensioned.

1.0 USE AND APPLICATION

1.2 Logical Connectors

PURPOSE	The purpose of this section is to explain the meaning of logical connectors. Logical connectors are used in Technical Specifications (TS) to discriminate between, and yet connect, discrete Conditions, Required Actions, Completion Times, Surveillances, and Frequencies. The only logical connectors that appear in TS are AND and OR. The physical arrangement of these connectors constitutes logical conventions with specific meanings.
BACKGROUND	Several levels of logic may be used to state Required Actions. These levels are identified by the placement (or nesting) of the logical connectors and by the number assigned to each Required Action. The first level of logic is identified by the first digit of the number assigned to a Required Action and the placement of the logical connector in the first level of nesting (i.e., left justified with the number of the Required Action). The successive levels of logic are identified by additional digits of the Required Action number and by successive indentions of the logical connectors. When logical connectors are used to state a Condition, Completion Time, Surveillance, or Frequency, only the first level of logic is used, and the logical connector is left justified with the statement of the Condition, Completion Time, Surveillance, or Frequency.
EXAMPLES	The following examples illustrate the use of logical connectors.

1.2 Logical Connectors

EXAMPLES (continued)

EXAMPLE 1.2-1

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. LCO not met.	A.1 Verify . . . AND A.2 Restore . . .	

In this example the logical connector AND is used to indicate that when in Condition A, both Required Actions A.1 and A.2 must be completed.

1.2 Logical Connectors

EXAMPLES (continued)

EXAMPLE 1.2-2

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. LCO not met.	A.1 Trip . . . OR A.2.1 Verify . . . AND A.2.2.1 Reduce . . . OR A.2.2.2 Perform . . . OR A.3 Align . . .	

This example represents a more complicated use of logical connectors. Required Actions A.1, A.2, and A.3 are alternative choices, only one of which must be performed as indicated by the use of the logical connector OR and the left justified placement. Any one of these three Actions may be chosen. If A.2 is chosen, then both A.2.1 and A.2.2 must be performed as indicated by the logical connector AND. Required Action A.2.2 is met by performing A.2.2.1 or A.2.2.2. The indented position of the logical connector OR indicates that A.2.2.1 and A.2.2.2 are alternative choices, only one of which must be performed.

1.0 USE AND APPLICATION

1.3 Completion Times

PURPOSE	The purpose of this section is to establish the Completion Time convention and to provide guidance for its use.
BACKGROUND	Limiting Conditions for Operation (LCOs) specify minimum requirements for ensuring safe operation of the unit. The ACTIONS associated with an LCO state Conditions that typically describe the ways in which the requirements of the LCO can fail to be met. Specified with each stated Condition are Required Action(s) and Completion Time(s).
DESCRIPTION	The Completion Time is the amount of time allowed for completing a Required Action. It is referenced to the discovery of a situation (e.g., inoperable equipment or variable not within limits) that requires entering an ACTIONS Condition unless otherwise specified, providing the unit is in a MODE or specified condition stated in the Applicability of the LCO. Unless otherwise specified, the Completion Time begins when a senior licensed operator on the operating shift crew with responsibility for plant operations makes the determination that an LCO is not met and an ACTIONS Condition is entered. The "otherwise specified" exceptions are varied, such as a Required Action Note or Surveillance Requirement Note that provides an alternative time to perform specific tasks, such as testing, without starting the Completion Time. While utilizing the Note, should a Condition be applicable for any reason not addressed by the Note, the Completion Time begins. Should the time allowance in the Note be exceeded, the Completion Time begins at that point. The exceptions may also be incorporated into the Completion Time. For example, LCO 3.8.1, "AC Sources - Operating," Required Action B.2, requires declaring required feature(s) supported by an inoperable diesel generator, inoperable when the redundant required feature(s) are inoperable. The Completion Time states, "4 hours from discovery of Condition B concurrent with inoperability of redundant required feature(s)." In this case the Completion Time does not begin until the conditions in the Completion Time are satisfied. Required Actions must be completed prior to the expiration of the specified Completion Time. An ACTIONS Condition remains in effect and the Required Actions apply until the Condition no longer exists or the unit is not within the LCO Applicability. If situations are discovered that require entry into more than one Condition at a time within a single LCO (multiple Conditions), the Required Actions for each Condition must be performed within the associated Completion Time. When in multiple Conditions, separate

1.3 Completion Times

DESCRIPTION (continued)

Completion Times are tracked for each Condition starting from the discovery of the situation that required entry into the Condition, unless otherwise specified.

Once a Condition has been entered, subsequent trains, subsystems, components, or variables expressed in the Condition, discovered to be inoperable or not within limits, will not result in separate entry into the Condition, unless specifically stated. The Required Actions of the Condition continue to apply to each additional failure, with Completion Times based on initial entry into the Condition, unless otherwise specified.

However, when a subsequent train, subsystem, component, or variable expressed in the Condition is discovered to be inoperable or not within limits, the Completion Time(s) may be extended. To apply this Completion Time extension, two criteria must first be met. The subsequent inoperability:

a. Must exist concurrent with the first inoperability and

b. Must remain inoperable or not within limits after the first inoperability is resolved.

The total Completion Time allowed for completing a Required Action to address the subsequent inoperability shall be limited to the more restrictive of either:

a. The stated Completion Time, as measured from the initial entry into the Condition, plus an additional 24 hours or

b. The stated Completion Time as measured from discovery of the subsequent inoperability.

The above Completion Time extensions do not apply to those Specifications that have exceptions that allow completely separate re-entry into the Condition (for each train, subsystem, component, or variable expressed in the Condition) and separate tracking of Completion Times based on this re-entry. These exceptions are stated in individual Specifications.

The above Completion Time extension does not apply to a Completion Time with a modified "time zero." This modified "time zero" may be expressed as a repetitive time (i.e., "once per 8 hours," where the Completion Time is referenced from a previous completion of the Required Action versus the time of Condition entry) or as a time modified by the phrase "from discovery . . ."

1.3 Completion Times

EXAMPLES

The following examples illustrate the use of Completion Times with different types of Conditions and changing Conditions.

EXAMPLE 1.3-1

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

Condition B has two Required Actions. Each Required Action has its own separate Completion Time. Each Completion Time is referenced to the time that Condition B is entered.

The Required Actions of Condition B are to be in MODE 3 within 6 hours AND in MODE 5 within 36 hours. A total of 6 hours is allowed for reaching MODE 3 and a total of 36 hours (not 42 hours) is allowed for reaching MODE 5 from the time that Condition B was entered. If MODE 3 is reached within 3 hours, the time allowed for reaching MODE 5 is the next 33 hours because the total time allowed for reaching MODE 5 is 36 hours.

If Condition B is entered while in MODE 3, the time allowed for reaching MODE 5 is the next 36 hours.

1.3 Completion Times

EXAMPLES (continued)

EXAMPLE 1.3-2

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One pump inoperable.	A.1 Restore pump to OPERABLE status.	7 days
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

When a pump is declared inoperable, Condition A is entered. If the pump is not restored to OPERABLE status within 7 days, Condition B is also entered and the Completion Time clocks for Required Actions B.1 and B.2 start. If the inoperable pump is restored to OPERABLE status after Condition B is entered, Conditions A and B are exited, and therefore, the Required Actions of Condition B may be terminated.

When a second pump is declared inoperable while the first pump is still inoperable, Condition A is not re-entered for the second pump. LCO 3.0.3 is entered, since the ACTIONS do not include a Condition for more than one inoperable pump. The Completion Time clock for Condition A does not stop after LCO 3.0.3 is entered, but continues to be tracked from the time Condition A was initially entered.

While in LCO 3.0.3, if one of the inoperable pumps is restored to OPERABLE status and the Completion Time for Condition A has not expired, LCO 3.0.3 may be exited and operation continued in accordance with Condition A.

While in LCO 3.0.3, if one of the inoperable pumps is restored to OPERABLE status and the Completion Time for Condition A has expired, LCO 3.0.3 may be exited and operation continued in accordance with Condition B. The Completion Time for Condition B is tracked from the time the Condition A Completion Time expired.

1.3 Completion Times

EXAMPLES (continued)

On restoring one of the pumps to OPERABLE status, the Condition A Completion Time is not reset, but continues from the time the first pump was declared inoperable. This Completion Time may be extended if the pump restored to OPERABLE status was the first inoperable pump. A 24 hour extension to the stated 7 days is allowed, provided this does not result in the second pump being inoperable for > 7 days.

EXAMPLE 1.3-3

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One Function X train inoperable.	A.1 Restore Function X train to OPERABLE status.	7 days
B. One Function Y train inoperable.	B.1 Restore Function Y train to OPERABLE status.	72 hours
C. One Function X train inoperable. AND One Function Y train inoperable.	C.1 Restore Function X train to OPERABLE status. OR C.2 Restore Function Y train to OPERABLE status.	72 hours 72 hours

When one Function X train and one Function Y train are inoperable, Condition A and Condition B are concurrently applicable. The Completion Times for Condition A and Condition B are tracked separately for each train starting from the time each train was declared inoperable and the Condition was entered. A separate Completion Time is established for Condition C and tracked from the time the second train was declared inoperable (i.e., the time the situation described in Condition C was discovered).

1.3 Completion Times

EXAMPLES (continued)

If Required Action C.2 is completed within the specified Completion Time, Conditions B and C are exited. If the Completion Time for Required Action A.1 has not expired, operation may continue in accordance with Condition A. The remaining Completion Time in Condition A is measured from the time the affected train was declared inoperable (i.e., initial entry into Condition A).

It is possible to alternate between Conditions A, B, and C in such a manner that operation could continue indefinitely without ever restoring systems to meet the LCO. However, doing so would be inconsistent with the basis of the Completion Times. Therefore, there shall be administrative controls to limit the maximum time allowed for any combination of Conditions that result in a single contiguous occurrence of failing to meet the LCO. These administrative controls shall ensure that the Completion Times for those Conditions are not inappropriately extended.

EXAMPLE 1.3-4

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more valves inoperable.	A.1 Restore valve(s) to OPERABLE status.	4 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 4.	6 hours 12 hours

A single Completion Time is used for any number of valves inoperable at the same time. The Completion Time associated with Condition A is based on the initial entry into Condition A and is not tracked on a per valve basis. Declaring subsequent valves inoperable, while Condition A is still in effect, does not trigger the tracking of separate Completion Times.

1.3 Completion Times

EXAMPLES (continued)

Once one of the valves has been restored to OPERABLE status, the Condition A Completion Time is not reset, but continues from the time the first valve was declared inoperable. The Completion Time may be extended if the valve restored to OPERABLE status was the first inoperable valve. The Condition A Completion Time may be extended for up to 4 hours provided this does not result in any subsequent valve being inoperable for > 4 hours.

If the Completion Time of 4 hours (including the extension) expires while one or more valves are still inoperable, Condition B is entered.

EXAMPLE 1.3-5

ACTIONS

----------NOTE----------
Separate Condition entry is allowed for each inoperable valve.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more valves inoperable.	A.1 Restore valve to OPERABLE status.	4 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 4.	6 hours 12 hours

The Note above the ACTIONS Table is a method of modifying how the Completion Time is tracked. If this method of modifying how the Completion Time is tracked was applicable only to a specific Condition, the Note would appear in that Condition rather than at the top of the ACTIONS Table.

1.3 Completion Times

EXAMPLES (continued)

The Note allows Condition A to be entered separately for each inoperable valve, and Completion Times tracked on a per valve basis. When a valve is declared inoperable, Condition A is entered and its Completion Time starts. If subsequent valves are declared inoperable, Condition A is entered for each valve and separate Completion Times start and are tracked for each valve.

If the Completion Time associated with a valve in Condition A expires, Condition B is entered for that valve. If the Completion Times associated with subsequent valves in Condition A expire, Condition B is entered separately for each valve and separate Completion Times start and are tracked for each valve. If a valve that caused entry into Condition B is restored to OPERABLE status, Condition B is exited for that valve.

Since the Note in this example allows multiple Condition entry and tracking of separate Completion Times, Completion Time extensions do not apply.

EXAMPLE 1.3-6

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One channel inoperable.	A.1 Perform SR 3.x.x.x. OR A.2 Reduce THERMAL POWER to ≤ 50% RTP.	Once per 8 hours 8 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours

1.3 Completion Times

EXAMPLES (continued)

Entry into Condition A offers a choice between Required Action A.1 or A.2. Required Action A.1 has a "once per" Completion Time, which qualifies for the 25% extension, per SR 3.0.2, to each performance after the initial performance. The initial 8 hour interval of Required Action A.1 begins when Condition A is entered and the initial performance of Required Action A.1 must be complete within the first 8 hour interval. If Required Action A.1 is followed and the Required Action is not met within the Completion Time (plus the extension allowed by SR 3.0.2), Condition B is entered. If Required Action A.2 is followed and the Completion Time of 8 hours is not met, Condition B is entered.

If after entry into Condition B, Required Action A.1 or A.2 is met, Condition B is exited and operation may then continue in Condition A.

EXAMPLE 1.3-7

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One subsystem inoperable.	A.1 Verify affected subsystem isolated. AND A.2 Restore subsystem to OPERABLE status.	1 hour AND Once per 8 hours thereafter 72 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

1.3 Completion Times

EXAMPLES (continued)

Required Action A.1 has two Completion Times. The 1 hour Completion Time begins at the time the Condition is entered and each "Once per 8 hours thereafter" interval begins upon performance of Required Action A.1.

If after Condition A is entered, Required Action A.1 is not met within either the initial 1 hour or any subsequent 8 hour interval from the previous performance (plus the extension allowed by SR 3.0.2), Condition B is entered. The Completion Time clock for Condition A does not stop after Condition B is entered, but continues from the time Condition A was initially entered. If Required Action A.1 is met after Condition B is entered, Condition B is exited and operation may continue in accordance with Condition A, provided the Completion Time for Required Action A.2 has not expired.

---------- Reviewer's Note ----------
Example 1.3-8 is only applicable to plants that have adopted the Risk Informed Completion Time Program.
---------- 6

[EXAMPLE 1.3-8

2

ACTIONS

6

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One subsystem inoperable.	A.1 Restore subsystem to OPERABLE status.	7 days OR In accordance with the Risk Informed Completion Time Program
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

1.3 Completion Times

EXAMPLES (continued)

When a subsystem is declared inoperable, Condition A is entered. The 7 day Completion Time may be applied as discussed in Example 1.3-2. However, the licensee may elect to apply the Risk Informed Completion Time Program which permits calculation of a Risk Informed Completion Time (RICT) that may be used to complete the Required Action beyond the 7 day Completion Time. The RICT cannot exceed 30 days. After the 7 day Completion Time has expired, the subsystem must be restored to OPERABLE status within the RICT or Condition B must also be entered.

The Risk Informed Completion Time Program requires recalculation of the RICT to reflect changing plant conditions. For planned changes, the revised RICT must be determined prior to implementation of the change in configuration. For emergent conditions, the revised RICT must be determined within the time limits of the Required Action Completion Time (i.e., not the RICT) or 12 hours after the plant configuration change, whichever is less.

If the 7 day Completion Time clock of Condition A has expired and subsequent changes in plant condition result in exiting the applicability of the Risk Informed Completion Time Program without restoring the inoperable subsystem to OPERABLE status, Condition B is also entered and the Completion Time clocks for Required Actions B.1 and B.2 start.

If the RICT expires or is recalculated to be less than the elapsed time since the Condition was entered and the inoperable subsystem has not been restored to OPERABLE status, Condition B is also entered and the Completion Time clocks for Required Actions B.1 and B.2 start. If the inoperable subsystems are restored to OPERABLE status after Condition B is entered, Condition A is exited, and therefore, the Required Actions of Condition B may be terminated. ~~]~~ 1

IMMEDIATE COMPLETION TIME

When "Immediately" is used as a Completion Time, the Required Action should be pursued without delay and in a controlled manner.

1.0 USE AND APPLICATION

1.4 Frequency

PURPOSE	The purpose of this section is to define the proper use and application of Frequency requirements.
DESCRIPTION	Each Surveillance Requirement (SR) has a specified Frequency in which the Surveillance must be met in order to meet the associated LCO. An understanding of the correct application of the specified Frequency is necessary for compliance with the SR. The "specified Frequency" is referred to throughout this section and each of the Specifications of Section 3.0~~.2~~, Surveillance Requirement (SR) Applicability. The "specified Frequency" consists of the requirements of the Frequency column of each SR, as well as certain Notes in the Surveillance column that modify performance requirements. (7) Sometimes special situations dictate when the requirements of a Surveillance are to be met. They are "otherwise stated" conditions allowed by SR 3.0.1. They may be stated as clarifying Notes in the Surveillance, as part of the Surveillances, or both. Situations where a Surveillance could be required (i.e., its Frequency could expire), but where it is not possible or not desired that it be performed until sometime after the associated LCO is within its Applicability, represent potential SR 3.0.4 conflicts. To avoid these conflicts, the SR (i.e., the Surveillance or the Frequency) is stated such that it is only "required" when it can be and should be performed. With an SR satisfied, SR 3.0.4 imposes no restriction. The use of "met" or "performed" in these instances conveys specific meanings. A Surveillance is "met" only when the acceptance criteria are satisfied. Known failure of the requirements of a Surveillance, even without a Surveillance specifically being "performed," constitutes a Surveillance not "met." "Performance" refers only to the requirement to specifically determine the ability to meet the acceptance criteria. Some Surveillances contain Notes that modify the Frequency of performance or the conditions during which the acceptance criteria must be satisfied. For these Surveillances, the MODE-entry restrictions of SR 3.0.4 may not apply. Such a Surveillance is not required to be performed prior to entering a MODE or other specified condition in the Applicability of the associated LCO if any of the following three conditions are satisfied:

1.4 Frequency

DESCRIPTION (continued)

a. The Surveillance is not required to be met in the MODE or other specified condition to be entered; or

b. The Surveillance is required to be met in the MODE or other specified condition to be entered, but has been performed within the specified Frequency (i.e., it is current) and is known not to be failed; or

c. The Surveillance is required to be met, but not performed, in the MODE or other specified condition to be entered, and is known not to be failed.

Examples 1.4-3, 1.4-4, 1.4-5, and 1.4-6 discuss these special situations.

EXAMPLES The following examples illustrate the various ways that Frequencies are specified. In these examples, the Applicability of the LCO (LCO not shown) is MODES 1, 2, and 3.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-1

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
Perform CHANNEL CHECK.	12 hours

Example 1.4-1 contains the type of SR most often encountered in the Technical Specifications (TS). The Frequency specifies an interval (12 hours) during which the associated Surveillance must be performed at least one time. Performance of the Surveillance initiates the subsequent interval. Although the Frequency is stated as 12 hours, an extension of the time interval to 1.25 times the stated Frequency is allowed by SR 3.0.2 for operational flexibility. The measurement of this interval continues at all times, even when the SR is not required to be met per SR 3.0.1 (such as when the equipment is inoperable, a variable is outside specified limits, or the unit is outside the Applicability of the LCO). If the interval specified by SR 3.0.2 is exceeded while the unit is in a MODE or other specified condition in the Applicability of the LCO, and the performance of the Surveillance is not otherwise modified (refer to Example 1.4-3), then SR 3.0.3 becomes applicable.

If the interval as specified by SR 3.0.2 is exceeded while the unit is not in a MODE or other specified condition in the Applicability of the LCO for which performance of the SR is required, then SR 3.0.4 becomes applicable. The Surveillance must be performed within the Frequency requirements of SR 3.0.2, as modified by SR 3.0.3, prior to entry into the MODE or other specified condition or the LCO is considered not met (in accordance with SR 3.0.1) and LCO 3.0.4 becomes applicable.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-2

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
Verify flow is within limits.	Once within 12 hours after ≥ 25% RTP AND 24 hours thereafter

Example 1.4-2 has two Frequencies. The first is a one time performance Frequency, and the second is of the type shown in Example 1.4-1. The logical connector "AND" indicates that both Frequency requirements must be met. Each time reactor power is increased from a power level < 25% RTP to ≥ 25% RTP, the Surveillance must be performed within 12 hours.

The use of "once" indicates a single performance will satisfy the specified Frequency (assuming no other Frequencies are connected by "AND"). This type of Frequency does not qualify for the extension allowed by SR 3.0.2. "Thereafter" indicates future performances must be established per SR 3.0.2, but only after a specified condition is first met (i.e., the "once" performance in this example). If reactor power decreases to < 25% RTP, the measurement of both intervals stops. New intervals start upon reactor power reaching 25% RTP.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-3

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
----------NOTE---------- Not required to be performed until 12 hours after ≥ 25% RTP. ----------	
Perform channel adjustment.	7 days

The interval continues, whether or not the unit operation is < 25% RTP between performances.

As the Note modifies the required performance of the Surveillance, it is construed to be part of the "specified Frequency." Should the 7 day interval be exceeded while operation is < 25% RTP, this Note allows 12 hours after power reaches ≥ 25% RTP to perform the Surveillance. The Surveillance is still considered to be performed within the "specified Frequency." Therefore, if the Surveillance were not performed within the 7 day (plus the extension allowed by SR 3.0.2) interval, but operation was < 25% RTP, it would not constitute a failure of the SR or failure to meet the LCO. Also, no violation of SR 3.0.4 occurs when changing MODES, even with the 7 day Frequency not met, provided operation does not exceed 12 hours (plus the extension allowed by SR 3.0.2) with power ≥ 25% RTP.

Once the unit reaches 25% RTP, 12 hours would be allowed for completing the Surveillance. If the Surveillance were not performed within this 12 hour interval (plus the extension allowed by SR 3.0.2), there would then be a failure to perform a Surveillance within the specified Frequency, and the provisions of SR 3.0.3 would apply.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-4

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
----------NOTE---------- Only required to be met in MODE 1. ----------	
Verify leakage rates are within limits.	24 hours

Example 1.4-4 specifies that the requirements of this Surveillance do not have to be met until the unit is in MODE 1. The interval measurement for the Frequency of this Surveillance continues at all times, as described in Example 1.4-1. However, the Note constitutes an "otherwise stated" exception to the Applicability of this Surveillance. Therefore, if the Surveillance were not performed within the 24 hour interval (plus the extension allowed by SR 3.0.2), but the unit was not in MODE 1, there would be no failure of the SR nor failure to meet the LCO. Therefore, no violation of SR 3.0.4 occurs when changing MODES, even with the 24 hour Frequency exceeded, provided the MODE change was not made into MODE 1. Prior to entering MODE 1 (assuming again that the 24 hour Frequency were not met), SR 3.0.4 would require satisfying the SR.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-5

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
----------NOTE---------- Only required to be performed in MODE 1. ----------	
Perform complete cycle of the valve.	7 days

The interval continues, whether or not the unit operation is in MODE 1, 2, or 3 (the assumed Applicability of the associated LCO) between performances.

As the Note modifies the required performance of the Surveillance, the Note is construed to be part of the "specified Frequency." Should the 7 day interval be exceeded while operation is not in MODE 1, this Note allows entry into and operation in MODES 2 and 3 to perform the Surveillance. The Surveillance is still considered to be performed within the "specified Frequency" if completed prior to entering MODE 1. Therefore, if the Surveillance were not performed within the 7 day (plus the extension allowed by SR 3.0.2) interval, but operation was not in MODE 1, it would not constitute a failure of the SR or failure to meet the LCO. Also, no violation of SR 3.0.4 occurs when changing MODES, even with the 7 day Frequency not met, provided operation does not result in entry into MODE 1.

Once the unit reaches MODE 1, the requirement for the Surveillance to be performed within its specified Frequency applies and would require that the Surveillance had been performed. If the Surveillance were not performed prior to entering MODE 1, there would then be a failure to perform a Surveillance within the specified Frequency, and the provisions of SR 3.0.3 would apply.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-6

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
----------NOTE---------- Not required to be met in MODE 3. ----------	
Verify parameter is within limits.	24 hours

Example 1.4-~~[~~6~~]~~ specifies that the requirements of this Surveillance do not have to be met while the unit is in MODE 3 (the assumed Applicability of the associated LCO is MODES 1, 2, and 3). The interval measurement for the Frequency of this Surveillance continues at all times, as described in Example 1.4-1. However, the Note constitutes an "otherwise stated" exception to the Applicability of this Surveillance. Therefore, if the Surveillance were not performed within the 24 hour interval (plus the extension allowed by SR 3.0.2), and the unit was in MODE 3, there would be no failure of the SR nor failure to meet the LCO. Therefore, no violation of SR 3.0.4 occurs when changing MODES to enter MODE 3, even with the 24 hour Frequency exceeded, provided the MODE change does not result in entry into MODE 2. Prior to entering MODE 2 (assuming again that the 24 hour Frequency were not met), SR 3.0.4 would require satisfying the SR.

1

1.0 USE AND APPLICATION

1.1 Definitions

----------NOTE----------
The defined terms of this section appear in capitalized type and are applicable throughout these Technical Specifications and Bases.

	Term	Definition
1.1	ACTIONS	ACTIONS shall be that part of a Specification that prescribes Required Actions to be taken under designated Conditions within specified Completion Times.
1.2	AXIAL SHAPE INDEX (ASI)	ASI shall be the power generated in the lower half of the core less the power generated in the upper half of the core, divided by the sum of the power generated in the lower and upper halves of the core. ASI = (LOWER - UPPER) / (LOWER + UPPER)
	~~AZIMUTHAL POWER TILT (T_q) - Digital~~	~~AZIMUTHAL POWER TILT shall be the power asymmetry between azimuthally symmetric fuel assemblies.~~
1.3	AZIMUTHAL POWER TILT (T_q) ~~- Analog~~	AZIMUTHAL POWER TILT shall be the maximum of the difference between the power generated in any core quadrant (upper or lower) (P_{quad}) and the average power of all quadrants (P_{avg}) in that half (upper or lower) of the core, divided by the average power of all quadrants in that half (upper or lower) of the core. T_q = Max $\lvert (P_{quad} - P_{avg}) / P_{avg} \rvert$
1.4	CHANNEL CALIBRATION	A CHANNEL CALIBRATION shall be the adjustment, as necessary, of the channel output such that it responds within the necessary range and accuracy to known values of the parameter that the channel monitors. The CHANNEL CALIBRATION shall encompass all devices in the channel required for channel OPERABILITY and the CHANNEL FUNCTIONAL TEST. Calibration of instrument channels with resistance temperature detector (RTD) or thermocouple sensors may consist of an inplace qualitative assessment of sensor behavior and normal calibration of the remaining adjustable devices in the channel. The CHANNEL CALIBRATION may be performed by means of any series of sequential, overlapping, or total channel steps~~[~~, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step~~]~~.

1.1 Definitions

1.5 **CHANNEL CHECK**

A CHANNEL CHECK shall be the qualitative assessment, by observation, of channel behavior during operation. This determination shall include, where possible, comparison of the channel indication and status to other indications or status derived from independent instrument channels measuring the same parameter.

1.6 **CHANNEL FUNCTIONAL TEST**

A CHANNEL FUNCTIONAL TEST shall be~~:~~

~~a. Analog and bistable channels – the injection of a simulated or actual signal into the channel as close to the sensor as practicable to verify OPERABILITY of all devices in the channel required for channel OPERABILITY; and~~

~~b. Digital computer channels - the use of diagnostic programs to test digital computer hardware and the injection of simulated process data into the channel to verify OPERABILITY of all devices in the channel required for channel OPERABILITY.~~

The CHANNEL FUNCTIONAL TEST may be performed by means of any series of sequential, overlapping, or total channel steps~~[~~, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step~~]~~.

1.9a **CORE OPERATING LIMITS REPORT (COLR)**

The COLR is the unit specific document that provides cycle specific parameter limits for the current reload cycle. These cycle specific parameter limits shall be determined for each reload cycle in accordance with Specification 5.6.3. Plant operation within these limits is addressed in individual Specifications.

1.10 **DOSE EQUIVALENT I-131**

DOSE EQUIVALENT I-131 shall be that concentration of I-131 (microcuries per gram) that alone would produce the same dose when inhaled as the combined activities of iodine isotopes I-131, I-132, I-133, I-134, and I-135 actually present. The determination of DOSE EQUIVALENT I-131 shall be performed using

~~---------- Reviewer's Note ----------~~
~~The first set of thyroid dose conversion factors shall be used for plants licensed to 10 CFR 100.11. The following Committed Dose Equivalent (CDE) or Committed Effective Dose Equivalent (CEDE) conversion factors shall be used for plants licensed to 10 CFR 50.67.~~
~~----------~~

1.1 Definitions

1.10 DOSE EQUIVALENT I-131 (continued)

~~[thyroid dose conversion factors from:~~

~~a. Table III of TID-14844, AEC, 1962, "Calculation of Distance Factors for Power and Test Reactor Sites," or~~

~~b. Table E-7 of Regulatory Guide 1.109, Rev. 1, NRC, 1977, or~~ 3

~~c. ICRP-30, 1979, Supplement to Part 1, page 192-212, Table titled, "Committed Dose Equivalent in Target Organs or Tissues per Intake of Unit Activity," or~~

~~d. Table 2.1 of EPA Federal Guidance Report No. 11, 1988, "Limiting Values of Radionuclide Intake and Air Concentration and Dose Conversion Factors for Inhalation, Submersion, and Ingestion."~~

~~OR~~

Committed Dose Equivalent (CDE) or Committed Effective Dose Equivalent (CEDE) dose conversion factors from Table 2.1 of EPA Federal Guidance Report No. 11.~~]~~ 3

1.11 DOSE EQUIVALENT XE-133

DOSE EQUIVALENT XE-133 shall be that concentration of Xe-133 (microcuries per gram) that alone would produce the same acute dose to the whole body as the combined activities of noble gas nuclides ~~[~~Kr-85m, Kr-85, Kr-87, Kr-88, Xe-131m, Xe-133m, Xe-133, Xe-135m, Xe-135, and Xe-138~~]~~ actually present. If a specific noble gas nuclide is not detected, it should be assumed to be present at the minimum detectable activity. The determination of DOSE EQUIVALENT XE-133 shall be performed using ~~[~~effective dose conversion factors for air submersion listed in Table III.1 of EPA Federal Guidance Report No. 12, 1993, "External Exposure to Radionuclides in Air, Water, and Soil" ~~or the average gamma disintegration energies as provided in ICRP Publication 38, "Radionuclide Transformations" or similar source]~~. 2 4

1.12 ENGINEERED SAFETY FEATURE (ESF) RESPONSE TIME

The ESF RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its ESF actuation setpoint at the channel sensor until the ESF equipment is capable of performing its safety function (i.e., the valves travel to their required positions, pump discharge pressures reach their required values, etc.). Times shall include diesel generator starting and sequence loading delays, where

1.1 Definitions

1.12 ENGINEERED SAFETY FEATURE (ESF) RESPONSE TIME (continued)

applicable. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC, or the components have been evaluated in accordance with an NRC approved methodology.

1.16 INSERVICE TESTING PROGRAM

The INSERVICE TESTING PROGRAM is the licensee program that fulfills the requirements of 10 CFR 50.55a(f).

1.15 LEAKAGE

LEAKAGE shall be:

a. Identified LEAKAGE

1. LEAKAGE, such as that from pump seals or valve packing (except reactor coolant pump (RCP) seal water injection or leakoff), that is captured and conducted to collection systems or a sump or collecting tank;

2. LEAKAGE into the containment atmosphere from sources that are both specifically located and known to not interfere with the operation of leakage detection systems; or

3. Reactor Coolant System (RCS) LEAKAGE through a steam generator to the Secondary System (primary to secondary LEAKAGE);

1.34 b. Unidentified LEAKAGE

All LEAKAGE (except RCP seal water injection or leakoff) that is not identified LEAKAGE; and

1.22 c. Pressure Boundary LEAKAGE

LEAKAGE (except primary to secondary LEAKAGE) through a fault in an RCS component body, pipe wall, or vessel wall. LEAKAGE past seals, packing, and gaskets is not pressure boundary LEAKAGE.

1.1 Definitions

1.20	MODE	A MODE shall correspond to any one inclusive combination of core reactivity condition, power level, average reactor coolant temperature, and reactor vessel head closure bolt tensioning specified in Table 1.1-1 with fuel in the reactor vessel.
1.19	OPERABLE – OPERABILITY	A system, subsystem, train, component, or device shall be OPERABLE or have OPERABILITY when it is capable of performing its specified safety function(s) and when all necessary attendant instrumentation, controls, normal or emergency electrical power, cooling and seal water, lubrication, and other auxiliary equipment that are required for the system, subsystem, train, component, or device to perform its specified safety function(s) are also capable of performing their related support function(s).
1.21	PHYSICS TESTS	PHYSICS TESTS shall be those tests performed to measure the fundamental nuclear characteristics of the reactor core and related instrumentation. These tests are: a. Described in Chapter ~~[~~14, Initial Test Program~~]~~ of the FSAR, (2) b. Authorized under the provisions of 10 CFR 50.59, or c. Otherwise approved by the Nuclear Regulatory Commission.
	~~PRESSURE AND TEMPERATURE LIMITS REPORT (PTLR)~~	~~The PTLR is the unit specific document that provides the reactor vessel pressure and temperature limits, including heatup and cooldown rates, for the current reactor vessel fluence period. These pressure and temperature limits shall be determined for each fluence period in accordance with Specification 5.6.4.~~ (5)
1.25	RATED THERMAL POWER (RTP)	RTP shall be a total reactor core heat transfer rate to the reactor coolant of ~~[3410]~~ 3020 MWt. (2)

1.1 Definitions

1.26	REACTOR PROTECTION SYSTEM (RPS) RESPONSE TIME	The RPS RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its RPS trip setpoint at the channel sensor until electrical power to the CEAs drive mechanism is interrupted. The response time may be measured by means of any series of sequential, overlapping, or total steps so that the entire response time is measured. In lieu of measurement, response time may be verified for selected components provided that the components and methodology for verification have been previously reviewed and approved by the NRC, or the components have been evaluated in accordance with an NRC approved methodology.
1.29	SHUTDOWN MARGIN (SDM)	SDM shall be the instantaneous amount of reactivity by which the reactor is subcritical or would be subcritical from its present condition assuming~~:~~ ~~a.~~ All ~~full length~~ CEAs (shutdown and regulating) are fully inserted except for the single CEA of highest reactivity worth, which is assumed to be fully withdrawn. However, with all CEAs verified fully inserted by two independent means, it is not necessary to account for a stuck CEA in the SDM calculation. With any CEAs not capable of being fully inserted, the reactivity worth of these CEAs must be accounted for in the determination of SDM~~, and~~ ~~[b. There is no change in part length CEA position.]~~
	~~[STAGGERED TEST BASIS~~	~~A STAGGERED TEST BASIS shall consist of the testing of one of the systems, subsystems, channels, or other designated components during the interval specified by the Surveillance Frequency, so that all systems, subsystems, channels, or other designated components are tested during *n* Surveillance Frequency intervals, where *n* is the total number of systems, subsystems, channels, or other designated components in the associated function.]~~
1.33	THERMAL POWER	THERMAL POWER shall be the total reactor core heat transfer rate to the reactor coolant.

Table 1.1-1 (page 1 of 1)
MODES

MODE	TITLE	REACTIVITY CONDITION (k_{eff})	% RATED THERMAL POWER[(a)]	AVERAGE REACTOR COOLANT TEMPERATURE (°F)
1	Power Operation	≥ 0.99	> 5	NA
2	Startup	≥ 0.99	≤ 5	NA
3	Hot Standby	< 0.99	NA	325 ≥ ~~[350]~~ (2)
4	Hot Shutdown[(b)]	< 0.99	NA	~~[350]~~ > T_{avg} > ~~[~~200~~]~~ (2)
5	Cold Shutdown[(b)]	< 0.99	NA	≤ ~~[~~200~~]~~ (2)
6	Refueling[(c)]	NA	NA	NA

(a) Excluding decay heat.

(b) All reactor vessel head closure bolts fully tensioned.

(c) One or more reactor vessel head closure bolts less than fully tensioned.

1.0 USE AND APPLICATION

1.2 Logical Connectors

PURPOSE	The purpose of this section is to explain the meaning of logical connectors. Logical connectors are used in Technical Specifications (TS) to discriminate between, and yet connect, discrete Conditions, Required Actions, Completion Times, Surveillances, and Frequencies. The only logical connectors that appear in TS are AND and OR. The physical arrangement of these connectors constitutes logical conventions with specific meanings.
BACKGROUND	Several levels of logic may be used to state Required Actions. These levels are identified by the placement (or nesting) of the logical connectors and by the number assigned to each Required Action. The first level of logic is identified by the first digit of the number assigned to a Required Action and the placement of the logical connector in the first level of nesting (i.e., left justified with the number of the Required Action). The successive levels of logic are identified by additional digits of the Required Action number and by successive indentions of the logical connectors. When logical connectors are used to state a Condition, Completion Time, Surveillance, or Frequency, only the first level of logic is used, and the logical connector is left justified with the statement of the Condition, Completion Time, Surveillance, or Frequency.
EXAMPLES	The following examples illustrate the use of logical connectors.

1.2 Logical Connectors

EXAMPLES (continued)

EXAMPLE 1.2-1

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. LCO not met.	A.1 Verify . . . AND A.2 Restore . . .	

In this example the logical connector AND is used to indicate that when in Condition A, both Required Actions A.1 and A.2 must be completed.

1.2 Logical Connectors

EXAMPLES (continued)

EXAMPLE 1.2-2

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. LCO not met.	A.1 Trip . . . OR A.2.1 Verify . . . AND A.2.2.1 Reduce . . . OR A.2.2.2 Perform . . . OR A.3 Align . . .	

This example represents a more complicated use of logical connectors. Required Actions A.1, A.2, and A.3 are alternative choices, only one of which must be performed as indicated by the use of the logical connector OR and the left justified placement. Any one of these three Actions may be chosen. If A.2 is chosen, then both A.2.1 and A.2.2 must be performed as indicated by the logical connector AND. Required Action A.2.2 is met by performing A.2.2.1 or A.2.2.2. The indented position of the logical connector OR indicates that A.2.2.1 and A.2.2.2 are alternative choices, only one of which must be performed.

1.0 USE AND APPLICATION

1.3 Completion Times

PURPOSE	The purpose of this section is to establish the Completion Time convention and to provide guidance for its use.
BACKGROUND	Limiting Conditions for Operation (LCOs) specify minimum requirements for ensuring safe operation of the unit. The ACTIONS associated with an LCO state Conditions that typically describe the ways in which the requirements of the LCO can fail to be met. Specified with each stated Condition are Required Action(s) and Completion Time(s).
DESCRIPTION	The Completion Time is the amount of time allowed for completing a Required Action. It is referenced to the discovery of a situation (e.g., inoperable equipment or variable not within limits) that requires entering an ACTIONS Condition unless otherwise specified, providing the unit is in a MODE or specified condition stated in the Applicability of the LCO. Unless otherwise specified, the Completion Time begins when a senior licensed operator on the operating shift crew with responsibility for plant operations makes the determination that an LCO is not met and an ACTIONS Condition is entered. The "otherwise specified" exceptions are varied, such as a Required Action Note or Surveillance Requirement Note that provides an alternative time to perform specific tasks, such as testing, without starting the Completion Time. While utilizing the Note, should a Condition be applicable for any reason not addressed by the Note, the Completion Time begins. Should the time allowance in the Note be exceeded, the Completion Time begins at that point. The exceptions may also be incorporated into the Completion Time. For example, LCO 3.8.1, "AC Sources - Operating," Required Action B.2, requires declaring required feature(s) supported by an inoperable diesel generator, inoperable when the redundant required feature(s) are inoperable. The Completion Time states, "4 hours from discovery of Condition B concurrent with inoperability of redundant required feature(s)." In this case the Completion Time does not begin until the conditions in the Completion Time are satisfied. Required Actions must be completed prior to the expiration of the specified Completion Time. An ACTIONS Condition remains in effect and the Required Actions apply until the Condition no longer exists or the unit is not within the LCO Applicability. If situations are discovered that require entry into more than one Condition at a time within a single LCO (multiple Conditions), the Required Actions for each Condition must be performed within the associated Completion Time. When in multiple Conditions, separate

1.3 Completion Times

DESCRIPTION (continued)

Completion Times are tracked for each Condition starting from the discovery of the situation that required entry into the Condition, unless otherwise specified.

Once a Condition has been entered, subsequent trains, subsystems, components, or variables expressed in the Condition, discovered to be inoperable or not within limits, will not result in separate entry into the Condition, unless specifically stated. The Required Actions of the Condition continue to apply to each additional failure, with Completion Times based on initial entry into the Condition, unless otherwise specified.

However, when a subsequent train, subsystem, component, or variable expressed in the Condition is discovered to be inoperable or not within limits, the Completion Time(s) may be extended. To apply this Completion Time extension, two criteria must first be met. The subsequent inoperability:

a. Must exist concurrent with the first inoperability and

b. Must remain inoperable or not within limits after the first inoperability is resolved.

The total Completion Time allowed for completing a Required Action to address the subsequent inoperability shall be limited to the more restrictive of either:

a. The stated Completion Time, as measured from the initial entry into the Condition, plus an additional 24 hours or

b. The stated Completion Time as measured from discovery of the subsequent inoperability.

The above Completion Time extensions do not apply to those Specifications that have exceptions that allow completely separate re-entry into the Condition (for each train, subsystem, component, or variable expressed in the Condition) and separate tracking of Completion Times based on this re-entry. These exceptions are stated in individual Specifications.

The above Completion Time extension does not apply to a Completion Time with a modified "time zero." This modified "time zero" may be expressed as a repetitive time (i.e., "once per 8 hours," where the Completion Time is referenced from a previous completion of the Required Action versus the time of Condition entry) or as a time modified by the phrase "from discovery . . ."

1.3 Completion Times

EXAMPLES

The following examples illustrate the use of Completion Times with different types of Conditions and changing Conditions.

EXAMPLE 1.3-1

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

Condition B has two Required Actions. Each Required Action has its own separate Completion Time. Each Completion Time is referenced to the time that Condition B is entered.

The Required Actions of Condition B are to be in MODE 3 within 6 hours AND in MODE 5 within 36 hours. A total of 6 hours is allowed for reaching MODE 3 and a total of 36 hours (not 42 hours) is allowed for reaching MODE 5 from the time that Condition B was entered. If MODE 3 is reached within 3 hours, the time allowed for reaching MODE 5 is the next 33 hours because the total time allowed for reaching MODE 5 is 36 hours.

If Condition B is entered while in MODE 3, the time allowed for reaching MODE 5 is the next 36 hours.

1.3 Completion Times

EXAMPLES (continued)

EXAMPLE 1.3-2

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One pump inoperable.	A.1 Restore pump to OPERABLE status.	7 days
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

When a pump is declared inoperable, Condition A is entered. If the pump is not restored to OPERABLE status within 7 days, Condition B is also entered and the Completion Time clocks for Required Actions B.1 and B.2 start. If the inoperable pump is restored to OPERABLE status after Condition B is entered, Conditions A and B are exited, and therefore, the Required Actions of Condition B may be terminated.

When a second pump is declared inoperable while the first pump is still inoperable, Condition A is not re-entered for the second pump. LCO 3.0.3 is entered, since the ACTIONS do not include a Condition for more than one inoperable pump. The Completion Time clock for Condition A does not stop after LCO 3.0.3 is entered, but continues to be tracked from the time Condition A was initially entered.

While in LCO 3.0.3, if one of the inoperable pumps is restored to OPERABLE status and the Completion Time for Condition A has not expired, LCO 3.0.3 may be exited and operation continued in accordance with Condition A.

While in LCO 3.0.3, if one of the inoperable pumps is restored to OPERABLE status and the Completion Time for Condition A has expired, LCO 3.0.3 may be exited and operation continued in accordance with Condition B. The Completion Time for Condition B is tracked from the time the Condition A Completion Time expired.

1.3 Completion Times

EXAMPLES (continued)

On restoring one of the pumps to OPERABLE status, the Condition A Completion Time is not reset, but continues from the time the first pump was declared inoperable. This Completion Time may be extended if the pump restored to OPERABLE status was the first inoperable pump. A 24 hour extension to the stated 7 days is allowed, provided this does not result in the second pump being inoperable for > 7 days.

EXAMPLE 1.3-3

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One Function X train inoperable.	A.1 Restore Function X train to OPERABLE status.	7 days
B. One Function Y train inoperable.	B.1 Restore Function Y train to OPERABLE status.	72 hours
C. One Function X train inoperable. AND One Function Y train inoperable.	C.1 Restore Function X train to OPERABLE status. OR C.2 Restore Function Y train to OPERABLE status.	72 hours 72 hours

When one Function X train and one Function Y train are inoperable, Condition A and Condition B are concurrently applicable. The Completion Times for Condition A and Condition B are tracked separately for each train starting from the time each train was declared inoperable and the Condition was entered. A separate Completion Time is established for Condition C and tracked from the time the second train was declared inoperable (i.e., the time the situation described in Condition C was discovered).

1.3 Completion Times

EXAMPLES (continued)

If Required Action C.2 is completed within the specified Completion Time, Conditions B and C are exited. If the Completion Time for Required Action A.1 has not expired, operation may continue in accordance with Condition A. The remaining Completion Time in Condition A is measured from the time the affected train was declared inoperable (i.e., initial entry into Condition A).

It is possible to alternate between Conditions A, B, and C in such a manner that operation could continue indefinitely without ever restoring systems to meet the LCO. However, doing so would be inconsistent with the basis of the Completion Times. Therefore, there shall be administrative controls to limit the maximum time allowed for any combination of Conditions that result in a single contiguous occurrence of failing to meet the LCO. These administrative controls shall ensure that the Completion Times for those Conditions are not inappropriately extended.

EXAMPLE 1.3-4

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more valves inoperable.	A.1 Restore valve(s) to OPERABLE status.	4 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 4.	6 hours 12 hours

A single Completion Time is used for any number of valves inoperable at the same time. The Completion Time associated with Condition A is based on the initial entry into Condition A and is not tracked on a per valve basis. Declaring subsequent valves inoperable, while Condition A is still in effect, does not trigger the tracking of separate Completion Times.

1.3 Completion Times

EXAMPLES (continued)

Once one of the valves has been restored to OPERABLE status, the Condition A Completion Time is not reset, but continues from the time the first valve was declared inoperable. The Completion Time may be extended if the valve restored to OPERABLE status was the first inoperable valve. The Condition A Completion Time may be extended for up to 4 hours provided this does not result in any subsequent valve being inoperable for > 4 hours.

If the Completion Time of 4 hours (including the extension) expires while one or more valves are still inoperable, Condition B is entered.

EXAMPLE 1.3-5

ACTIONS

----------NOTE----------
Separate Condition entry is allowed for each inoperable valve.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more valves inoperable.	A.1 Restore valve to OPERABLE status.	4 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 4.	6 hours 12 hours

The Note above the ACTIONS Table is a method of modifying how the Completion Time is tracked. If this method of modifying how the Completion Time is tracked was applicable only to a specific Condition, the Note would appear in that Condition rather than at the top of the ACTIONS Table.

1.3 Completion Times

EXAMPLES (continued)

The Note allows Condition A to be entered separately for each inoperable valve, and Completion Times tracked on a per valve basis. When a valve is declared inoperable, Condition A is entered and its Completion Time starts. If subsequent valves are declared inoperable, Condition A is entered for each valve and separate Completion Times start and are tracked for each valve.

If the Completion Time associated with a valve in Condition A expires, Condition B is entered for that valve. If the Completion Times associated with subsequent valves in Condition A expire, Condition B is entered separately for each valve and separate Completion Times start and are tracked for each valve. If a valve that caused entry into Condition B is restored to OPERABLE status, Condition B is exited for that valve.

Since the Note in this example allows multiple Condition entry and tracking of separate Completion Times, Completion Time extensions do not apply.

EXAMPLE 1.3-6

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One channel inoperable.	A.1 Perform SR 3.x.x.x. OR A.2 Reduce THERMAL POWER to ≤ 50% RTP.	Once per 8 hours 8 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours

1.3 Completion Times

EXAMPLES (continued)

Entry into Condition A offers a choice between Required Action A.1 or A.2. Required Action A.1 has a "once per" Completion Time, which qualifies for the 25% extension, per SR 3.0.2, to each performance after the initial performance. The initial 8 hour interval of Required Action A.1 begins when Condition A is entered and the initial performance of Required Action A.1 must be complete within the first 8 hour interval. If Required Action A.1 is followed and the Required Action is not met within the Completion Time (plus the extension allowed by SR 3.0.2), Condition B is entered. If Required Action A.2 is followed and the Completion Time of 8 hours is not met, Condition B is entered.

If after entry into Condition B, Required Action A.1 or A.2 is met, Condition B is exited and operation may then continue in Condition A.

EXAMPLE 1.3-7

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One subsystem inoperable.	A.1 Verify affected subsystem isolated. AND A.2 Restore subsystem to OPERABLE status.	1 hour AND Once per 8 hours thereafter 72 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

1.3 Completion Times

EXAMPLES (continued)

Required Action A.1 has two Completion Times. The 1 hour Completion Time begins at the time the Condition is entered and each "Once per 8 hours thereafter" interval begins upon performance of Required Action A.1.

If after Condition A is entered, Required Action A.1 is not met within either the initial 1 hour or any subsequent 8 hour interval from the previous performance (plus the extension allowed by SR 3.0.2), Condition B is entered. The Completion Time clock for Condition A does not stop after Condition B is entered, but continues from the time Condition A was initially entered. If Required Action A.1 is met after Condition B is entered, Condition B is exited and operation may continue in accordance with Condition A, provided the Completion Time for Required Action A.2 has not expired.

---------- Reviewer's Note ----------
Example 1.3-8 is only applicable to plants that have adopted the Risk Informed Completion Time Program.
---------- 6

[EXAMPLE 1.3-8

2

ACTIONS

6

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One subsystem inoperable.	A.1 Restore subsystem to OPERABLE status.	7 days OR In accordance with the Risk Informed Completion Time Program
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours

1.3 Completion Times

EXAMPLES (continued)

When a subsystem is declared inoperable, Condition A is entered. The 7 day Completion Time may be applied as discussed in Example 1.3-2. However, the licensee may elect to apply the Risk Informed Completion Time Program which permits calculation of a Risk Informed Completion Time (RICT) that may be used to complete the Required Action beyond the 7 day Completion Time. The RICT cannot exceed 30 days. After the 7 day Completion Time has expired, the subsystem must be restored to OPERABLE status within the RICT or Condition B must also be entered.

The Risk Informed Completion Time Program requires recalculation of the RICT to reflect changing plant conditions. For planned changes, the revised RICT must be determined prior to implementation of the change in configuration. For emergent conditions, the revised RICT must be determined within the time limits of the Required Action Completion Time (i.e., not the RICT) or 12 hours after the plant configuration change, whichever is less.

If the 7 day Completion Time clock of Condition A has expired and subsequent changes in plant condition result in exiting the applicability of the Risk Informed Completion Time Program without restoring the inoperable subsystem to OPERABLE status, Condition B is also entered and the Completion Time clocks for Required Actions B.1 and B.2 start.

If the RICT expires or is recalculated to be less than the elapsed time since the Condition was entered and the inoperable subsystem has not been restored to OPERABLE status, Condition B is also entered and the Completion Time clocks for Required Actions B.1 and B.2 start. If the inoperable subsystems are restored to OPERABLE status after Condition B is entered, Condition A is exited, and therefore, the Required Actions of Condition B may be terminated. ~~]~~

IMMEDIATE COMPLETION TIME

When "Immediately" is used as a Completion Time, the Required Action should be pursued without delay and in a controlled manner.

1.0 USE AND APPLICATION

1.4 Frequency

PURPOSE	The purpose of this section is to define the proper use and application of Frequency requirements.
DESCRIPTION	Each Surveillance Requirement (SR) has a specified Frequency in which the Surveillance must be met in order to meet the associated LCO. An understanding of the correct application of the specified Frequency is necessary for compliance with the SR. The "specified Frequency" is referred to throughout this section and each of the Specifications of Section 3.0~~.2~~, Surveillance Requirement (SR) Applicability. The "specified Frequency" consists of the requirements of the Frequency column of each SR, as well as certain Notes in the Surveillance column that modify performance requirements. (7) Sometimes special situations dictate when the requirements of a Surveillance are to be met. They are "otherwise stated" conditions allowed by SR 3.0.1. They may be stated as clarifying Notes in the Surveillance, as part of the Surveillances, or both. Situations where a Surveillance could be required (i.e., its Frequency could expire), but where it is not possible or not desired that it be performed until sometime after the associated LCO is within its Applicability, represent potential SR 3.0.4 conflicts. To avoid these conflicts, the SR (i.e., the Surveillance or the Frequency) is stated such that it is only "required" when it can be and should be performed. With an SR satisfied, SR 3.0.4 imposes no restriction. The use of "met" or "performed" in these instances conveys specific meanings. A Surveillance is "met" only when the acceptance criteria are satisfied. Known failure of the requirements of a Surveillance, even without a Surveillance specifically being "performed," constitutes a Surveillance not "met." "Performance" refers only to the requirement to specifically determine the ability to meet the acceptance criteria. Some Surveillances contain Notes that modify the Frequency of performance or the conditions during which the acceptance criteria must be satisfied. For these Surveillances, the MODE-entry restrictions of SR 3.0.4 may not apply. Such a Surveillance is not required to be performed prior to entering a MODE or other specified condition in the Applicability of the associated LCO if any of the following three conditions are satisfied:

1.4 Frequency

DESCRIPTION (continued)

a. The Surveillance is not required to be met in the MODE or other specified condition to be entered; or

b. The Surveillance is required to be met in the MODE or other specified condition to be entered, but has been performed within the specified Frequency (i.e., it is current) and is known not to be failed; or

c. The Surveillance is required to be met, but not performed, in the MODE or other specified condition to be entered, and is known not to be failed.

Examples 1.4-3, 1.4-4, 1.4-5, and 1.4-6 discuss these special situations.

EXAMPLES The following examples illustrate the various ways that Frequencies are specified. In these examples, the Applicability of the LCO (LCO not shown) is MODES 1, 2, and 3.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-1

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
Perform CHANNEL CHECK.	12 hours

Example 1.4-1 contains the type of SR most often encountered in the Technical Specifications (TS). The Frequency specifies an interval (12 hours) during which the associated Surveillance must be performed at least one time. Performance of the Surveillance initiates the subsequent interval. Although the Frequency is stated as 12 hours, an extension of the time interval to 1.25 times the stated Frequency is allowed by SR 3.0.2 for operational flexibility. The measurement of this interval continues at all times, even when the SR is not required to be met per SR 3.0.1 (such as when the equipment is inoperable, a variable is outside specified limits, or the unit is outside the Applicability of the LCO). If the interval specified by SR 3.0.2 is exceeded while the unit is in a MODE or other specified condition in the Applicability of the LCO, and the performance of the Surveillance is not otherwise modified (refer to Example 1.4-3), then SR 3.0.3 becomes applicable.

If the interval as specified by SR 3.0.2 is exceeded while the unit is not in a MODE or other specified condition in the Applicability of the LCO for which performance of the SR is required, then SR 3.0.4 becomes applicable. The Surveillance must be performed within the Frequency requirements of SR 3.0.2, as modified by SR 3.0.3, prior to entry into the MODE or other specified condition or the LCO is considered not met (in accordance with SR 3.0.1) and LCO 3.0.4 becomes applicable.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-2

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
Verify flow is within limits.	Once within 12 hours after ≥ 25% RTP AND 24 hours thereafter

Example 1.4-2 has two Frequencies. The first is a one time performance Frequency, and the second is of the type shown in Example 1.4-1. The logical connector "AND" indicates that both Frequency requirements must be met. Each time reactor power is increased from a power level < 25% RTP to ≥ 25% RTP, the Surveillance must be performed within 12 hours.

The use of "once" indicates a single performance will satisfy the specified Frequency (assuming no other Frequencies are connected by "AND"). This type of Frequency does not qualify for the extension allowed by SR 3.0.2. "Thereafter" indicates future performances must be established per SR 3.0.2, but only after a specified condition is first met (i.e., the "once" performance in this example). If reactor power decreases to < 25% RTP, the measurement of both intervals stops. New intervals start upon reactor power reaching 25% RTP.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-3

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
----------NOTE---------- Not required to be performed until 12 hours after ≥ 25% RTP. ----------	
Perform channel adjustment.	7 days

The interval continues, whether or not the unit operation is < 25% RTP between performances.

As the Note modifies the required performance of the Surveillance, it is construed to be part of the "specified Frequency." Should the 7 day interval be exceeded while operation is < 25% RTP, this Note allows 12 hours after power reaches ≥ 25% RTP to perform the Surveillance. The Surveillance is still considered to be performed within the "specified Frequency." Therefore, if the Surveillance were not performed within the 7 day (plus the extension allowed by SR 3.0.2) interval, but operation was < 25% RTP, it would not constitute a failure of the SR or failure to meet the LCO. Also, no violation of SR 3.0.4 occurs when changing MODES, even with the 7 day Frequency not met, provided operation does not exceed 12 hours (plus the extension allowed by SR 3.0.2) with power ≥ 25% RTP.

Once the unit reaches 25% RTP, 12 hours would be allowed for completing the Surveillance. If the Surveillance were not performed within this 12 hour interval (plus the extension allowed by SR 3.0.2), there would then be a failure to perform a Surveillance within the specified Frequency, and the provisions of SR 3.0.3 would apply.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-4

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
----------NOTE---------- Only required to be met in MODE 1. ----------	
Verify leakage rates are within limits.	24 hours

Example 1.4-4 specifies that the requirements of this Surveillance do not have to be met until the unit is in MODE 1. The interval measurement for the Frequency of this Surveillance continues at all times, as described in Example 1.4-1. However, the Note constitutes an "otherwise stated" exception to the Applicability of this Surveillance. Therefore, if the Surveillance were not performed within the 24 hour interval (plus the extension allowed by SR 3.0.2), but the unit was not in MODE 1, there would be no failure of the SR nor failure to meet the LCO. Therefore, no violation of SR 3.0.4 occurs when changing MODES, even with the 24 hour Frequency exceeded, provided the MODE change was not made into MODE 1. Prior to entering MODE 1 (assuming again that the 24 hour Frequency were not met), SR 3.0.4 would require satisfying the SR.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-5

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
----------NOTE---------- Only required to be performed in MODE 1. ----------	
Perform complete cycle of the valve.	7 days

The interval continues, whether or not the unit operation is in MODE 1, 2, or 3 (the assumed Applicability of the associated LCO) between performances.

As the Note modifies the required performance of the Surveillance, the Note is construed to be part of the "specified Frequency." Should the 7 day interval be exceeded while operation is not in MODE 1, this Note allows entry into and operation in MODES 2 and 3 to perform the Surveillance. The Surveillance is still considered to be performed within the "specified Frequency" if completed prior to entering MODE 1. Therefore, if the Surveillance were not performed within the 7 day (plus the extension allowed by SR 3.0.2) interval, but operation was not in MODE 1, it would not constitute a failure of the SR or failure to meet the LCO. Also, no violation of SR 3.0.4 occurs when changing MODES, even with the 7 day Frequency not met, provided operation does not result in entry into MODE 1.

Once the unit reaches MODE 1, the requirement for the Surveillance to be performed within its specified Frequency applies and would require that the Surveillance had been performed. If the Surveillance were not performed prior to entering MODE 1, there would then be a failure to perform a Surveillance within the specified Frequency, and the provisions of SR 3.0.3 would apply.

1.4 Frequency

EXAMPLES (continued)

EXAMPLE 1.4-6

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
----------NOTE---------- Not required to be met in MODE 3. ----------	
Verify parameter is within limits.	24 hours

Example 1.4-~~[~~6~~]~~ specifies that the requirements of this Surveillance do not have to be met while the unit is in MODE 3 (the assumed Applicability of the associated LCO is MODES 1, 2, and 3). The interval measurement for the Frequency of this Surveillance continues at all times, as described in Example 1.4-1. However, the Note constitutes an "otherwise stated" exception to the Applicability of this Surveillance. Therefore, if the Surveillance were not performed within the 24 hour interval (plus the extension allowed by SR 3.0.2), and the unit was in MODE 3, there would be no failure of the SR nor failure to meet the LCO. Therefore, no violation of SR 3.0.4 occurs when changing MODES to enter MODE 3, even with the 24 hour Frequency exceeded, provided the MODE change does not result in entry into MODE 2. Prior to entering MODE 2 (assuming again that the 24 hour Frequency were not met), SR 3.0.4 would require satisfying the SR.

1

JUSTIFICATION FOR DEVIATIONS
ITS 1.0, USE AND APPLICATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The ISTS definition for DOSE EQUIVALENT I-131 includes a Reviewer's Note. The Reviewer's Note has been deleted. The Note informs the NRC Reviewer what is needed to meet this requirement. The Reviewer's Note is not meant to be retained in the final version of the ITS. St. Lucie Plant (PSL) Unit 1 and Unit 2 are licensed to 10 CFR 50.67.

4. The ISTS definition for DOSE EQUIVALENT XE-133 contains bracketed information with two options for “effective dose conversion factors for air submission.” PSL Unit 1 and Unit 2 are licensed to the effective dose conversion factors for air submersion listed in Table III.1 of EPA Federal Guidance Report No. 12, 1993, "External Exposure to Radionuclides in Air, Water, and Soil" Therefore, this option will be maintained.

5. PSL does not propose to use a PRESSURE AND TEMPERATURE LIMITS REPORT (PTLR) and will not relocate the Pressure and Temperature limits from the Technical Specifications. The current limits will be retained in the ITS. Therefore, the definition of PTLR has not been incorporated into the ITS.

6. PSL ITS 1.3, Example 1.3-8 Reviewer’s Note states “Example 1.3-8 is only applicable to plants that have adopted the Risk Informed Completion Time Program.” PSL Unit 1 has implemented the Risk Informed Completion Time Program as approved in License Amendment No. 247 (ADAMS Accession No. ML19113A099). PSL Unit 2 has implemented the Risk Informed Completion Time Program as approved in License Amendment No. 199 (ADAMS Accession No. ML19113A099). Therefore, the Reviewer’s Note is deleted, and the Example 1.3-8 brackets are deleted.

7. Typographical error is corrected. The proper section for Surveillance Requirement (SR) Applicability is Section 3.0.

8. The ISTS definition of SHUTDOWN MARGIN deletes “full length” as related to control element assemblies (CEAs). Part length CEAs are not used at PSL Unit 1 and PSL Unit 2.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 1.0, USE AND APPLICATION

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGE L01

Florida Power & Light Company (FPL) is converting St. Lucie Plant Unit 1 and Unit 2 to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5, "Standard Technical Specifications, Combustion Engineering Plants." The proposed change involves making the Current Technical Specifications (CTS) less restrictive. Below is the description of this less restrictive change and the determination of no significant hazards considerations for conversion to NUREG-1432.

The CTS Section 1.0 definition of CHANNEL FUNCTIONAL TEST requires the use of a simulated signal when performing the test. ITS Section 1.1 allows the use of a simulated or actual signal when performing the test. This changes the CTS by allowing the use of unplanned actuations to perform the Surveillance based on the collection of sufficient information to satisfy the surveillance test requirements.

FPL has evaluated whether or not a significant hazards consideration is involved with the proposed generic change by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of Amendment," as discussed below:

1. Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?

   Response: No.

   The proposed change adds an allowance that an actual as well as a simulated signal can be credited during the CHANNEL FUNCTIONAL TEST. This change allows taking credit for unplanned actuations if sufficient information is collected to satisfy the surveillance test requirements. This change is acceptable because the channel itself cannot discriminate between an "actual" or "simulated" signal, and the proposed requirement does not change the technical content or validity of the test. This change will not affect the probability of an accident. The source of the signal sent to components during a Surveillance is not assumed to be an initiator of any analyzed event. The consequence of an accident is not affected by this change. The results of the testing, and, therefore, the likelihood of discovering an inoperable component, are unaffected. As a result, the assurance that equipment will be available to mitigate the consequences of an accident is unaffected.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

   Response: No.

   The proposed change adds an allowance that an actual as well as a simulated signal can be credited during the CHANNEL FUNCTIONAL TEST. This change will not

physically alter the plant (no new or different type of equipment will be installed). The change does not require any new or revised operator actions.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

   Response: No.

   The proposed change adds an allowance that an actual as well as a simulated signal can be credited during the CHANNEL FUNCTIONAL TEST. The margin of safety is not affected by this change. This change allows taking credit for unplanned actuations if sufficient information is collected to satisfy the surveillance test requirements. This change is acceptable because the channel itself cannot discriminate between an "actual" or "simulated" signal. As a result, the proposed requirement does not change the technical content or validity of the test.

   Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 1.0, USE AND APPLICATION

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGE L02

Florida Power & Light Company (FPL) is converting St. Lucie Plant Unit 1 and Unit 2 to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5, "Standard Technical Specifications, Combustion Engineering Plants." The proposed change involves making the Current Technical Specifications (CTS) less restrictive. Below is the description of this less restrictive change and the determination of no significant hazards considerations for conversion to NUREG-1432.

The change revises the CTS definitions for Engineered Safety Feature (ESF) Response Time and Reactor Protection System (RPS) response time that are referenced in Surveillance Requirements (SRs), hereafter referred to as response time testing (RTT). The definitions are revised to add the statement “or the components have been evaluated in accordance with an NRC approved methodology” at the end of the last sentence in the definitions. The changes are based on Technical Specifications Task Force (TSTF) traveler TSTF-569, Revision 2, “Revise Response Time Testing Definition,” dated June 25, 2019 (ADAMS Accession No. ML19176A034). The NRC issued a final safety evaluation (SE) approving TSTF-569, Revision 2, on August 14, 2019 (ADAMS Accession No. ML19176A191). FPL is not proposing any variations from the TS changes described in TSTF-569, Revision 2, or the applicable parts of the NRC SE of TSTF-569, Revision 2.

FPL has evaluated whether or not a significant hazards consideration is involved with the proposed generic change by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of Amendment," as discussed below:

1. Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?

   Response: No.

   The proposed change revises the CTS Definition of RPS and ESF instrumentation response time to permit FPL to evaluate using an NRC-approved methodology and apply a bounding response time for some components in lieu of measurement. The requirement for the instrumentation to actuate within the response time assumed in the accident analysis is unaffected.

   The response time associated with the RPS and ESF instrumentation is not an initiator of any accident. Therefore, the proposed change has no significant effect on the probability of any accident previously evaluated.

   The affected RPS and ESF instrumentation are assumed to actuate their respective components within the required response time to mitigate accidents previously evaluated. Revising the TS definition for RPS and ESF instrumentation response times to allow an NRC-approved methodology for verifying response time for some components does not alter the surveillance requirements that verify the RPS and ESF instrumentation response times are within the required limits. As such, the TS will continue to assure that the RPS and ESF instrumentation actuate their

associated components within the specified response time to accomplish the required safety functions assumed in the accident analyses.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

   Response: No.

   The proposed change revises the CTS Definition of RPS and ESF instrumentation response time to permit FPL to evaluate using an NRC-approved methodology and apply a bounding response time for some components in lieu of measurement. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change does not alter any assumptions made in the safety analyses. The proposed change does not alter the limiting conditions for operation for the RPS or ESF instrumentation, nor does it change the Surveillance Requirement to verify the RPS and ESF instrumentation response times are within the required limits. As such, the proposed change does not alter the operability requirements for the RPS and ESF instrumentation, and therefore, does not introduce any new failure modes.

   Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

   Response: No.

   The proposed change revises the CTS Definition of RPS and ESF instrumentation response time to permit the licensee to evaluate using an NRC-approved methodology and apply a bounding response time for some components in lieu of measurement. The proposed change has no effect on the required RPS and ESF instrumentation response times or setpoints assumed in the safety analyses and the TS requirements to verify those response times and setpoints. The proposed change does not alter any Safety Limits or analytical limits in the safety analysis. The proposed change does not alter the TS operability requirements for the RP] and ESF instrumentation. The RPS and ESF instrumentation actuation of the required systems and components at the required setpoints and within the specified response times will continue to accomplish the design basis safety functions of the associated systems and components in the same manner as before. As such, the RPS and ESF instrumentation will continue to perform the required safety functions as assumed in the safety analyses for all previously evaluated accidents.

   Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 1.0, USE AND APPLICATION

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGE L03

Florida Power & Light Company (FPL) is converting St. Lucie Plant Unit 1 and Unit 2 to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5, "Standard Technical Specifications, Combustion Engineering Plants." The proposed change involves making the Current Technical Specifications (CTS) less restrictive. Below is the description of this less restrictive change and the determination of no significant hazards considerations for conversion to NUREG-1432.

CTS Section 1.0 definition of SHUTDOWN MARGIN (SDM) requires that the calculation assume that all CEAs (shutdown and regulating) are fully inserted except for the single rod assembly of highest reactivity worth which is assumed to be fully withdrawn. The ITS definition allows that with all CEAs verified fully inserted by two independent means, it is not necessary to account for a stuck CEA in the SDM calculation. This change revises the Technical Specifications to include the allowance that with all CEAs verified inserted by two independent means, it is not necessary to account for a stuck CEA in determination of SDM. PSL Unit 1 and Unit 2 design include two independent CEA position indicating systems. The independent systems are the pulse counting CEA position indication system and the reed switch CEA position indication system.

This change is acceptable because the CTS definition was developed considering a worst case condition to assure sufficient SDM is available. However, if all rods can be verified to be fully inserted, the worst case condition is not applicable and the requirement to assume a rod is stuck in the fully withdrawn position is overly conservative and unnecessary to assure safe plant operation. The provision of the ITS exception that requires the rod positions to be verified by two independent means provides adequate assurance that all rods are fully inserted and that SDM may be calculated without the conservative assumption of a fully withdrawn rod. PSL Unit 1 and Unit 2 design provide two independent systems to verify all CEAs are fully inserted. This change is designated as less restrictive because it allows for an exception to the CTS requirements.

FPL has evaluated whether or not a significant hazards consideration is involved with the proposed change by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of Amendment," as discussed below:

1. Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?

   Response: No.

   This change revises the Technical Specifications to include the allowance that with all CEAs verified inserted by two independent means, it is not necessary to account for a stuck CEA in the SDM calculation. The proposed change adds an exception to the SDM definition. This change allows the SDM to be determined without assuming a rod is fully withdrawn when all CEAs are verified by two independent means to be fully inserted. The proposed change continues to assure adequate SDM is maintained consistent with the actual plant conditions. PSL Unit 1 and Unit 2 design

provide two independent systems to verify all CEAs inserted by two independent means. The proposed change will not affect the probability of an accident. The proposed change does not affect any accident initiators. The consequence of an accident is not affected by the proposed change because adequate SDM is maintained. The assumptions of accidents previously evaluated remain unaffected. Therefore, this change will not involve a significant increase in the probability or consequence of an accident previously evaluated.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

   Response: No.

   The proposed change provides an exception to the SDM definition requirement to assume one CEA fully withdrawn. This change will not physically alter the plant (no new or different type of equipment will be installed). PSL Unit 1 and Unit 2 design provide two independent systems to verify all CEAs inserted by two independent means.

   Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

   Response: No.

   The proposed change provides an exception to the SDM definition requirement to assume one rod fully withdrawn when all rods are adequately verified to be fully inserted. PSL Unit 1 and Unit 2 design provide two independent systems to verify all CEAs inserted by two independent means. The proposed change continues to assure sufficient SDM is maintained consistent with the assumptions of the accident analyses. The proposed change does not affect the assumptions of any accident analysis and does not adversely affect the safe operation of the plant. As such, the margin of safety is not affected by this change.

   Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

REACTOR TRIP SETPOINTS

2.2.1 The reactor protective instrumentation setpoints shall be set consistent with the Trip Setpoint values shown in Table 2.2-1.

APPLICABILITY: AS SHOWN FOR EACH CHANNEL IN TABLE 3.3-1.

ACTION:

With a reactor protective instrumentation setpoint less conservative than the value shown in the Allowable Values column of Table 2.2-1, declare the channel inoperable and apply the applicable ACTION statement requirement of Specification 3.3.1.1 until the channel is restored to OPERABLE status with its trip setpoint adjusted consistent with the Trip Setpoint value.

TABLE 2.2-1

DISCUSSION OF CHANGES
ITS CHAPTER 2.0, SAFETY LIMITS (SLs)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 1 only:** CTS Figure 2.1-1 states “Reactor Coolant System total flow rate – specified in LCO 3.2.5.” ITS Figure 2.1.1-1 does not contain the statement. This changes the CTS by not including a cross reference to the equivalent reference ITS 3.4.1, "RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits," which contains the Reactor Coolant System total flowrate. This change is acceptable because the CTS Figure 2.1-1 detail used to alert the user that the Reactor Coolant System total flowrate is covered under a separate LCO requirement is an unnecessary presentation preference. ITS does not include information only type of cross references to other Specifications. ITS Figure 2.1.1-1, Reactor Core Thermal Margin Safety Limit, is retained without the cross reference detail.

This change is designated as administrative as it incorporates an ITS convention with no technical change.

A03 PSL Unit 1 CTS Figure 2.1-1, Reactor Core Thermal Margin Safety Limit – Four Reactor Coolant Pumps Operating contains an operational limit line showing thermal power limited to a maximum of 112% of RATED THERMAL POWER by the High Power Trip. PSL Unit 2 CTS Figure 2.1-1, Reactor Core Thermal Margin Safety Limit – Four Reactor Coolant Pumps Operating contains an operational limit line showing thermal power limited to a maximum of 107% of RATED THERMAL POWER by the High Power Level Trip, and contains an operational limit line showing limits on maximum cold leg temperature due to secondary safety valve actuation. Additionally, the Unit 1 and Unit 2 figure titles include the statement “Four Reactor Coolant Pumps Operating.”

The RPS operational limit line is removed from the Unit 1 and Unit 2 figures. This operational limit could be violated during a transient; however, it does not necessarily mean the reactor core SL was violated. Removing the operational limit line shifts the unacceptable area to the actual SL limits based on RCS pressure lines. The RPS operational limit is provided in the ITS Bases. The figure title text “Four Reactor Coolant Pumps Operating” is deleted from the Unit 1 and Unit 2 figures. Unit 1 and Unit 2 only operate with four reactor coolant pumps. Therefore, this text is deleted for consistency with ISTS Figure 2.1.1-1 title. The operational limit line showing limits on maximum cold leg temperature due to secondary safety valve actuation is removed from the Unit 2 figure. This operational limit could be violated during a transient; however, it does not necessarily mean the reactor core SL was violated. Removing this operational

limit line shifts the unacceptable area to the actual SL limits based on RCS pressure lines.

This change is designated as administrative as it incorporates an ITS convention to remove superfluous lines not directly related to violation of the safety limit with no technical change.

MORE RESTRICTIVE CHANGES

M01 CTS 2.1.1 does not contain a Safety Limit to ensure fuel centerline temperature remains below the fuel melt temperature during normal operating conditions or design anticipated operational occurrences with adjustments for burnup and burnable poison. ITS requires Reactor Core Safety Limit 2.1.1.2, to ensure fuel centerline temperature remains below the fuel melt temperature during normal operating conditions or design anticipated operational occurrences with adjustments for burnup and burnable poison.

The purpose of ITS 2.1.1.2 is to provide a Safety Limit to ensure fuel centerline temperature remains below the fuel melt temperature during normal operating conditions or design anticipated operational occurrences with adjustments for burnup and burnable poison. This change is acceptable because it adds a Reactor Core Safety Limit that is not in the CTS.

This change is designated as more restrictive because it adds a Reactor Core Safety Limit to the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 2.1.1 states “The combination of THERMAL POWER, pressurizer pressure, and maximum cold leg coolant temperature shall not exceed the limits shown on Figure 2.1-1.” ITS states “The combination of THERMAL POWER, pressurizer pressure, and the highest operating loop cold leg coolant temperature shall not exceed the limits shown in Figure 2.1.1-1.” This changes the CTS by moving details shown on the CTS Figure 2.1-1 to the ITS Bases.

PSL Unit 1 CTS Figure 2.1-1 statements “Reactor operation limited to less than 580°F by actuation of Main Steam Safety Valves”, “Limits contain no allowance for instruments error or fluctuations”, “Based on the Axial Shape Index on Figure B 2.1-1,” and “THERMAL POWER limited to a maximum of 112% of RATED THERMAL POWER by the high power trip level” are moved from the Technical Specifications to the ITS Bases. The line showing THERMAL POWER at 112%

is deleted. The Reactor Core Safety Limits are retained in Technical Specification Chapter 2.0.

PSL Unit 2 CTS Figure 2.1-1 statements “Reactor Conditions limited to less than the temperatures defined by the actuation of the secondary safety valves”, “Limits contain no allowance for instruments error or fluctuations”, “Valid for Total Integrated Radial Peaking Factors less than specified in Tech Spec 3.2.3” and “THERMAL POWER limited to a maximum of 107% of RATED THERMAL POWER by the high power level trip” are moved from the Technical Specifications to the ITS Bases. The Reactor Core Safety Limits are retained in Technical Specification Chapter 2.0.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 2.1.1.1 retains the Reactor Core Safety Limit and Figure 2.1.1-1, Reactor Core Thermal Margin Safety Limit. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

JUSTIFICATION FOR DEVIATIONS
ISTS CHAPTER 2.0, SAFETY LIMITS (SLs)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis. PSL does not currently require an SL regarding peak fuel centerline temperature. However, peak fuel centerline temperature is maintained below the fuel melt temperature specified in the COLR. The fuel melt temperature is determined using the NRC approved methodology in Siemens Topical Report XN-NF-79-56(P)(A) Revision 1 and Supplement 1, “Gadolinia Fuel Properties for LWR Fuel Safety Evaluation,” dated October 1981.

3. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 2.0 SAFETY LIMITS (SLs) ~~(Analog)~~

B 2.1.1 Reactor Core SLs ~~(Analog)~~ 5

BASES

BACKGROUND

GDC 10 (Ref. 1) requires and SLs ensure that specified acceptable fuel design limits are not exceeded during steady state operation, normal operation transients, and anticipated operational occurrences (AOOs). This is accomplished by having a departure from nucleate boiling (DNB) design basis, which corresponds to a 95% probability at a 95% confidence level (95/95 DNB criterion) that DNB will not occur and by requiring that fuel centerline temperature stays below the melting temperature.

The restrictions of this SL prevent overheating of the fuel and cladding and possible cladding perforation that would result in the release of fission products to the reactor coolant. Overheating of the fuel is prevented by maintaining the steady state peak linear heat rate (LHR) below the level at which fuel centerline melting occurs. Overheating of the fuel cladding is prevented by restricting fuel operation to within the nucleate boiling regime, where the heat transfer coefficient is large and the cladding surface temperature is slightly above the coolant saturation temperature.

Fuel centerline melting occurs when the local LHR, or power peaking, in a region of the fuel is high enough to cause the fuel centerline temperature to reach the melting point of the fuel. Expansion of the pellet upon centerline melting may cause the pellet to stress the cladding to the point of failure, allowing an uncontrolled release of activity to the reactor coolant.

Operation above the boundary of the nucleate boiling regime could result in excessive cladding temperature because of the onset of DNB and the resultant sharp reduction in heat transfer coefficient. Inside the steam film, high cladding temperatures are reached, and a cladding water (zirconium water) reaction may take place. This chemical reaction results in oxidation of the fuel cladding to a structurally weaker form. This weaker form may lose its integrity, resulting in an uncontrolled release of activity to the reactor coolant.

The Reactor Protective System (RPS), in combination with the LCOs, is designed to prevent any anticipated combination of transient conditions for Reactor Coolant System (RCS) temperature, pressure, and THERMAL POWER level that would result in a violation of the reactor core SLs.

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation and AOOs. The reactor core SLs are established to preclude violation of the following fuel design criteria:

a. There must be at least 95% probability at a 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB and

b. The hot fuel pellet in the core must not experience fuel centerline melting.

The RPS setpoints, LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation," in combination with all the LCOs, are designed to prevent any anticipated combination of transient conditions for RCS temperature, pressure, and THERMAL POWER level that would result in a departure from nucleate boiling ratio (DNBR) of less than the DNBR limit and preclude the existence of flow instabilities.

Automatic enforcement of these reactor core SLs is provided by the following functions:

a. Pressurizer Pressure High trip,

b. Variable ~~High Power~~ trip, (1) R1
Power Level - High

c. Power Rate of Change - High trip,

d. Reactor Coolant Flow - Low trip,

e. Steam Generator Pressure - Low trip,

f. Steam Generator Level - Low trip,

g. ~~Axial Power Distribution~~ - High trip, (1)
Local Power Density

h. Thermal Margin/Low Pressure trip,

i. Steam Generator Pressure Difference trip, and

j. Steam Generator Safety Valves.

The SL represents a design requirement for establishing the RPS trip setpoints identified previously. LCO 3.2.1, "Linear Heat Rate (LHR)," and LCO 3.2.~~5~~, "AXIAL SHAPE INDEX (ASI)," or the assumed initial conditions of the safety analyses (as indicated in the FSAR, Ref. 2) provide more restrictive limits to ensure that the SLs are not exceeded. (1)
4 U

5

BASES

The SL contains no allowance for instrument error. Actuation of the main steam safety valves limits reactor coolant temperature.

4

SAFETY LIMITS

The curves provided in Figure ~~B~~ 2.1.1-1 show the loci of points of THERMAL POWER, pressurizer pressure, and highest operating loop cold leg temperature, for which the minimum ~~-~~DNBR is not less than the safety analysis limit. SL 2.1.1.2 ensures that fuel centerline temperature remains below melting.

3

SL 2.1.1.2 ensures that fuel centerline temperature remains below the fuel melt temperature ~~of [5080]°F~~ during normal operating conditions or design AOOs with adjustments for burnup and burnable poison. ~~An adjustment of [58°F per 10,000 MWD/MTU] has been established in [Topical Report CEN-386-P-A] (Ref. 3) and adjustments for burnable poisons are established based on [Topical Reports CENPD-275-P] (Ref. 4) and [CENPD-382-P-A] (Ref.5).~~

limits specified in the COLR

2

2

APPLICABILITY

SL 2.1.1 only applies in MODES 1 and 2 because these are the only MODES in which the reactor is critical. Automatic protection functions are required to be OPERABLE during MODES 1 and 2 to ensure operation within the reactor core SLs. The steam generator safety valves or automatic protection actions serve to prevent RCS heatup to the reactor core SL conditions or to initiate a reactor trip ~~-~~function, which forces the unit into MODE 3. Setpoints for the reactor trip functions are specified in LCO 3.3.1.

3

In MODES 3, 4, 5, and 6, Applicability is not required, since the reactor is not generating significant THERMAL POWER.

SAFETY LIMIT VIOLATIONS

The following SL violation responses are applicable to the reactor core SLs.

2.2.1

If SL 2.1.1 is violated, the requirement to go to MODE 3 places the unit in a MODE in which this SL is not applicable.

The allowed Completion Time of 1 hour recognizes the importance of bringing the unit to a MODE of operation where this SL is not applicable and reduces the probability of fuel damage.

Fuel melt temperature is determined using the NRC approved methodology in Reference 3. The fuel melt temperature limit is defined as [(2790 - 17.9 x P - 3.2 x B) x 1.8 + 32] °F, where P is the maximum weight percent of Gadolinia (%) and B is the maximum pin burnup (GWD/MTU).

B 2.0 SAFETY LIMITS (SLs) ~~(Analog)~~

5

B 2.1.2 Reactor Coolant System (RCS) Pressure SL ~~(Analog)~~

BASES

BACKGROUND

The SL on RCS pressure protects the integrity of the RCS against overpressurization. In the event of fuel cladding failure, fission products are released into the reactor coolant. The RCS then serves as the primary barrier in preventing the release of fission products into the atmosphere. By establishing an upper limit on RCS pressure, continued RCS integrity is ensured. According to 10 CFR 50, Appendix A, GDC 14, "Reactor Coolant Pressure Boundary," and GDC 15, "Reactor Coolant System Design" (Ref. 1), the reactor coolant pressure boundary (RCPB) design conditions are not to be exceeded during normal operation and anticipated operational occurrences (AOOs). Also, according to GDC 28 (Ref. 1), "Reactivity Limits," reactivity accidents, including rod ejection, do not result in damage to the RCPB greater than limited local yielding.

The design pressure of the RCS is 2500 psia. During normal operation and AOOs, the RCS pressure is kept from exceeding the design pressure by more than 10%, in accordance with Section III of the ASME Code (Ref. 2). To ensure system integrity, all RCS components are hydrostatically tested at 125% of design pressure, according to the ASME Code requirements prior to initial operation, when there is no fuel in the core. Following inception of unit operation, RCS components shall be pressure tested, in accordance with the requirements of ASME Code, Section XI (Ref. 3).

Overpressurization of the RCS could result in a breach of the RCPB. If this occurs in conjunction with a fuel cladding failure, fission products could enter the containment atmosphere, raising concerns relative to limits on radioactive releases specified in 10 CFR 100, "Reactor Site Criteria" (Ref. 4).

APPLICABLE SAFETY ANALYSES

The RCS pressurizer safety valves, the main steam safety valves (MSSVs), and the Reactor Pressure - High trip have settings established to ensure that the RCS pressure SL will not be exceeded.

The RCS pressurizer safety valves are sized to prevent system pressure from exceeding the design pressure by more than 10%, in accordance with Section III of the ASME Code for Nuclear Power Plant Components (Ref. 2). The transient that establishes the required relief capacity, and

BASES

APPLICABLE SAFETY ANALYSES (continued)

turbine-generator

hence the valve size requirements and lift settings, is a ~~[~~complete loss of ~~external~~ load without a direct reactor trip~~]~~. During the transient, no control actions are assumed except that the safety valves on the secondary plant are assumed to open when the steam pressure reaches the secondary plant safety valve settings, and nominal feedwater supply is maintained. 2

The Reactor Protective System (RPS) trip setpoints (LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation"), together with the settings of the MSSVs (LCO 3.7.1, "Main Steam Safety Valves (MSSVs)") and the pressurizer safety valves, provide pressure protection for normal operation and AOOs. In particular, the Pressurizer Pressure - High trip setpoint is specifically set to provide protection against overpressurization (Ref. 5). Safety analyses for both the Pressure - High trip and the RCS pressurizer safety valves are performed, using conservative assumptions relative to pressure control devices.

More specifically, no credit is taken for operation of any of the following:

a. Pressurizer power operated relief valves (PORVs),

b. Steam Bypass Control System,

c. Pressurizer Level Control System, or

d. Pressurizer Pressure Control System.

SAFETY LIMITS

The maximum transient pressure allowable in the RCS pressure vessel under the ASME Code, Section III, is 110% of design pressure. The maximum transient pressure allowable in the RCS piping, valves, and fittings under ~~[~~USAS, Section B31.1 (Ref. 6)~~]~~, is 120% of design pressure. The most limiting of these two allowances is the 110% of design pressure; therefore, the SL on maximum allowable RCS pressure is established at 2750 psia. 2

APPLICABILITY

SL 2.1.2 applies in MODES 1, 2, 3, 4, and 5 because this SL could be approached or exceeded in these MODES due to overpressurization events. The SL is not applicable in MODE 6 because the reactor vessel head closure bolts are not fully tightened, making it unlikely that the RCS can be pressurized.

5

BASES

SAFETY LIMIT VIOLATIONS

The following SL violation responses are applicable to the RCS pressure SL.

2.2.2.1

If the RCS pressure SL is violated when the reactor is in MODE 1 or 2, the requirement is to restore compliance and be in MODE 3 within 1 hour.

With RCS pressure greater than the value specified in SL 2.1.2 in MODE 1 or 2, the pressure must be reduced to below this value. A pressure greater than the value specified in SL 2.1.2 exceeds 110% of the RCS design pressure and may challenge system integrity.

The allowed Completion Time of 1 hour provides the operator time to complete the necessary actions to reduce RCS pressure by terminating the cause of the pressure increase, removing mass or energy from the RCS, or a combination of these actions, and to establish MODE 3 conditions.

2.2.2.2

If the RCS pressure SL is exceeded in MODE 3, 4, or 5, RCS pressure must be restored to within the SL value within 5 minutes.

Exceeding the RCS pressure SL in MODE 3, 4, or 5 is potentially more severe than exceeding this SL in MODE 1 or 2, since the reactor vessel temperature may be lower and the vessel material, consequently, less ductile. As such, pressure must be reduced to less than the SL within 5 minutes. This action does not require reducing MODES, since this would require reducing temperature, which would compound the problem by adding thermal gradient stresses to the existing pressure stress.

B 2.0 SAFETY LIMITS (SLs) ~~(Analog)~~ 5

B 2.1.1 Reactor Core SLs ~~(Analog)~~

BASES

BACKGROUND

GDC 10 (Ref. 1) requires and SLs ensure that specified acceptable fuel design limits are not exceeded during steady state operation, normal operation transients, and anticipated operational occurrences (AOOs). This is accomplished by having a departure from nucleate boiling (DNB) design basis, which corresponds to a 95% probability at a 95% confidence level (95/95 DNB criterion) that DNB will not occur and by requiring that fuel centerline temperature stays below the melting temperature.

The restrictions of this SL prevent overheating of the fuel and cladding and possible cladding perforation that would result in the release of fission products to the reactor coolant. Overheating of the fuel is prevented by maintaining the steady state peak linear heat rate (LHR) below the level at which fuel centerline melting occurs. Overheating of the fuel cladding is prevented by restricting fuel operation to within the nucleate boiling regime, where the heat transfer coefficient is large and the cladding surface temperature is slightly above the coolant saturation temperature.

Fuel centerline melting occurs when the local LHR, or power peaking, in a region of the fuel is high enough to cause the fuel centerline temperature to reach the melting point of the fuel. Expansion of the pellet upon centerline melting may cause the pellet to stress the cladding to the point of failure, allowing an uncontrolled release of activity to the reactor coolant.

Operation above the boundary of the nucleate boiling regime could result in excessive cladding temperature because of the onset of DNB and the resultant sharp reduction in heat transfer coefficient. Inside the steam film, high cladding temperatures are reached, and a cladding water (zirconium water) reaction may take place. This chemical reaction results in oxidation of the fuel cladding to a structurally weaker form. This weaker form may lose its integrity, resulting in an uncontrolled release of activity to the reactor coolant.

The Reactor Protective System (RPS), in combination with the LCOs, is designed to prevent any anticipated combination of transient conditions for Reactor Coolant System (RCS) temperature, pressure, and THERMAL POWER level that would result in a violation of the reactor core SLs.

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation and AOOs. The reactor core SLs are established to preclude violation of the following fuel design criteria:

a. There must be at least 95% probability at a 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB and

b. The hot fuel pellet in the core must not experience fuel centerline melting.

The RPS setpoints, LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation," in combination with all the LCOs, are designed to prevent any anticipated combination of transient conditions for RCS temperature, pressure, and THERMAL POWER level that would result in a departure from nucleate boiling ratio (DNBR) of less than the DNBR limit and preclude the existence of flow instabilities.

Automatic enforcement of these reactor core SLs is provided by the following functions:

a. Pressurizer Pressure High trip,

b. Variable ~~High Power~~ trip, (1) R1
Power Level - High

c. Power Rate of Change - High trip,

d. Reactor Coolant Flow - Low trip,

e. Steam Generator Pressure - Low trip,

f. Steam Generator Level - Low trip,

g. ~~Axial Power Distribution~~ - High trip, (1)
Local Power Density

h. Thermal Margin/Low Pressure trip,

i. Steam Generator Pressure Difference trip, and

j. Steam Generator Safety Valves.

The SL represents a design requirement for establishing the RPS trip setpoints identified previously. LCO 3.2.1, "Linear Heat Rate (LHR) ," and LCO 3.2.~~5~~, "AXIAL SHAPE INDEX (ASI)," or the assumed initial conditions of the safety analyses (as indicated in the FSAR, Ref. 2) provide more restrictive limits to ensure that the SLs are not exceeded. (1)
4 U

5

BASES

The SL contains no allowance for instrument error. Actuation of the main steam safety valves limits reactor coolant temperature.

4

SAFETY LIMITS

The curves provided in Figure ~~B~~ 2.1.1-1 show the loci of points of THERMAL POWER, pressurizer pressure, and highest operating loop cold leg temperature, for which the minimum ~~-~~DNBR is not less than the safety analysis limit. SL 2.1.1.2 ensures that fuel centerline temperature remains below melting.

3

SL 2.1.1.2 ensures that fuel centerline temperature remains below the fuel melt temperature ~~of [5080]°F~~ during normal operating conditions or design AOOs with adjustments for burnup and burnable poison. ~~An adjustment of [58°F per 10,000 MWD/MTU] has been established in [Topical Report CEN-386-P-A] (Ref. 3) and adjustments for burnable poisons are established based on [Topical Reports CENPD-275-P] (Ref. 4) and [CENPD-382-P-A] (Ref.5)~~.

limits specified in the COLR

2

2

APPLICABILITY

SL 2.1.1 only applies in MODES 1 and 2 because these are the only MODES in which the reactor is critical. Automatic protection functions are required to be OPERABLE during MODES 1 and 2 to ensure operation within the reactor core SLs. The steam generator safety valves or automatic protection actions serve to prevent RCS heatup to the reactor core SL conditions or to initiate a reactor trip ~~-~~function, which forces the unit into MODE 3. Setpoints for the reactor trip functions are specified in LCO 3.3.1.

3

In MODES 3, 4, 5, and 6, Applicability is not required, since the reactor is not generating significant THERMAL POWER.

SAFETY LIMIT VIOLATIONS

The following SL violation responses are applicable to the reactor core SLs.

2.2.1

If SL 2.1.1 is violated, the requirement to go to MODE 3 places the unit in a MODE in which this SL is not applicable.

The allowed Completion Time of 1 hour recognizes the importance of bringing the unit to a MODE of operation where this SL is not applicable and reduces the probability of fuel damage.

Fuel melt temperature is determined using the NRC approved methodology in Reference 3. The fuel melt temperature limit is defined as [(2790 - 17.9 x P - 3.2 x B) x 1.8 + 32] °F, where P is the maximum weight percent of Gadolinia (%) and B is the maximum pin burnup (GWD/MTU).

Reactor Core Thermal Margin Safety Limit

B 2.0 SAFETY LIMITS (SLs) ~~(Analog)~~ 5

B 2.1.2 Reactor Coolant System (RCS) Pressure SL ~~(Analog)~~

BASES

BACKGROUND

The SL on RCS pressure protects the integrity of the RCS against overpressurization. In the event of fuel cladding failure, fission products are released into the reactor coolant. The RCS then serves as the primary barrier in preventing the release of fission products into the atmosphere. By establishing an upper limit on RCS pressure, continued RCS integrity is ensured. According to 10 CFR 50, Appendix A, GDC 14, "Reactor Coolant Pressure Boundary," and GDC 15, "Reactor Coolant System Design" (Ref. 1), the reactor coolant pressure boundary (RCPB) design conditions are not to be exceeded during normal operation and anticipated operational occurrences (AOOs). Also, according to GDC 28 (Ref. 1), "Reactivity Limits," reactivity accidents, including rod ejection, do not result in damage to the RCPB greater than limited local yielding.

The design pressure of the RCS is 2500 psia. During normal operation and AOOs, the RCS pressure is kept from exceeding the design pressure by more than 10%, in accordance with Section III of the ASME Code (Ref. 2). To ensure system integrity, all RCS components are hydrostatically tested at 125% of design pressure, according to the ASME Code requirements prior to initial operation, when there is no fuel in the core. Following inception of unit operation, RCS components shall be pressure tested, in accordance with the requirements of ASME Code, Section XI (Ref. 3).

Overpressurization of the RCS could result in a breach of the RCPB. If this occurs in conjunction with a fuel cladding failure, fission products could enter the containment atmosphere, raising concerns relative to limits on radioactive releases specified in 10 CFR 100, "Reactor Site Criteria" (Ref. 4).

APPLICABLE SAFETY ANALYSES

The RCS pressurizer safety valves, the main steam safety valves (MSSVs), and the Reactor Pressure - High trip have settings established to ensure that the RCS pressure SL will not be exceeded.

The RCS pressurizer safety valves are sized to prevent system pressure from exceeding the design pressure by more than 10%, in accordance with Section III of the ASME Code for Nuclear Power Plant Components (Ref. 2). The transient that establishes the required relief capacity, and

BASES

APPLICABLE SAFETY ANALYSES (continued)

turbine-generator

hence the valve size requirements and lift settings, is a ~~[~~complete loss of ~~external~~ load without a direct reactor trip~~]~~. During the transient, no control actions are assumed except that the safety valves on the secondary plant are assumed to open when the steam pressure reaches the secondary plant safety valve settings, and nominal feedwater supply is maintained. 2

The Reactor Protective System (RPS) trip setpoints (LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation"), together with the settings of the MSSVs (LCO 3.7.1, "Main Steam Safety Valves (MSSVs)") and the pressurizer safety valves, provide pressure protection for normal operation and AOOs. In particular, the Pressurizer Pressure - High trip setpoint is specifically set to provide protection against overpressurization (Ref. 5). Safety analyses for both the Pressure - High trip and the RCS pressurizer safety valves are performed, using conservative assumptions relative to pressure control devices.

More specifically, no credit is taken for operation of any of the following:

a. Pressurizer power operated relief valves (PORVs),

b. Steam Bypass Control System,

c. Pressurizer Level Control System, or

d. Pressurizer Pressure Control System.

SAFETY LIMITS

The maximum transient pressure allowable in the RCS pressure vessel under the ASME Code, Section III, is 110% of design pressure. The maximum transient pressure allowable in the RCS piping, valves, and fittings under ~~[~~USAS, Section B31.1 (Ref. 6)~~]~~, is 120% of design pressure. The most limiting of these two allowances is the 110% of design pressure; therefore, the SL on maximum allowable RCS pressure is established at 2750 psia. 2

APPLICABILITY

SL 2.1.2 applies in MODES 1, 2, 3, 4, and 5 because this SL could be approached or exceeded in these MODES due to overpressurization events. The SL is not applicable in MODE 6 because the reactor vessel head closure bolts are not fully tightened, making it unlikely that the RCS can be pressurized.

5

BASES

SAFETY LIMIT VIOLATIONS

The following SL violation responses are applicable to the RCS pressure SL.

2.2.2.1

If the RCS pressure SL is violated when the reactor is in MODE 1 or 2, the requirement is to restore compliance and be in MODE 3 within 1 hour.

With RCS pressure greater than the value specified in SL 2.1.2 in MODE 1 or 2, the pressure must be reduced to below this value. A pressure greater than the value specified in SL 2.1.2 exceeds 110% of the RCS design pressure and may challenge system integrity.

The allowed Completion Time of 1 hour provides the operator time to complete the necessary actions to reduce RCS pressure by terminating the cause of the pressure increase, removing mass or energy from the RCS, or a combination of these actions, and to establish MODE 3 conditions.

2.2.2.2

If the RCS pressure SL is exceeded in MODE 3, 4, or 5, RCS pressure must be restored to within the SL value within 5 minutes.

Exceeding the RCS pressure SL in MODE 3, 4, or 5 is potentially more severe than exceeding this SL in MODE 1 or 2, since the reactor vessel temperature may be lower and the vessel material, consequently, less ductile. As such, pressure must be reduced to less than the SL within 5 minutes. This action does not require reducing MODES, since this would require reducing temperature, which would compound the problem by adding thermal gradient stresses to the existing pressure stress.

JUSTIFICATION FOR DEVIATIONS
ISTS CHAPTER 2.0, BASES, SAFETY LIMITS (SLs)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. Grammatical error is corrected. Double spacing between sentences and single spacing between words. Single spacing is corrected.

4. CTS Figure 2.1-1 contained details that are moved to the Bases. The details are added to the ITS Figure 2.1.1-1 Bases. See DOC LA01.

5. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

3/4 LIMITING CONDITIONS FOR OPERATION AND SURVEILLANCE REQUIREMENTS

3/4.0 APPLICABILITY

LIMITING CONDITION FOR OPERATION

LCO 3.0.1 3.0.1 Limiting Conditions for Operation (LCOs) shall be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2.

LCO 3.0.2 3.0.2 Upon discovery of a failure to meet an LCO, the ACTIONS shall be met, except as provided in LCO 3.0.5 and LCO 3.0.6. If the LCO is met or is no longer applicable prior to expiration of the specified time interval(s), completion of the Required ACTIONS is not required, unless otherwise stated.

LCO 3.0.3 3.0.3 When a Limiting Condition for Operation (LCO) is not met, except as provided in the associated ACTION requirements, within 1 hour action shall be initiated to place the unit in a MODE in which specification does not apply by placing it, as applicable in:

1. At least HOT STANDBY within the next 6 hours,
2. At least HOT SHUTDOWN within the following 6 hours, and
3. At least COLD SHUTDOWN within the subsequent 24 hours.

Where corrective measures are completed that permit operation under the ACTION requirements, the ACTION may be taken in accordance with the specified time limits as measured from the time of failure to meet the LCO. Exceptions to these requirements are stated in the individual specifications.

This specification is not applicable in MODES 5 or 6.

LCO 3.0.4 3.0.4 When an LCO is not met, entry into a MODE or other specified condition in the Applicability shall only be made:

a. When the associated ACTIONS to be entered permit continued operation in the MODE or other specified condition in the Applicability for an unlimited period of time;

b. After performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering the MODE or other specified condition in the Applicability, and establishment of risk management actions, if appropriate (exceptions to this Specification are stated in the individual Specifications); or

c. When an allowance is stated in the individual value, parameter, or other Specification.

This Specification shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

LCO 3.0.5 3.0.5 Equipment removed from service or declared inoperable to comply with ACTION(s) may be returned to service under administrative control solely to perform testing required to demonstrate its OPERABILITY or the OPERABILITY of other equipment. This is an exception to LCO 3.0.2 for the system returned to service under administrative control to perform the testing required to demonstrate OPERABILITY.

INSERT 1

are not met, an associated ACTION is not provided, or if directed by the associated ACTIONS, the unit shall be placed in a MODE or other specified condition in which the LCO is not applicable. Action shall be initiated within 1 hour to place the unit, as applicable, in A03 A01

INSERT 2 A05

in accordance with the LCO or ACTIONS, completion of the actions required by LCO 3.0.3 is not required

LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4.

INSERT 3 A06

LCO 3.0.7 Special test exception (STE) LCO 3.1.8, "Special Test Exceptions (STE) – MODES 1 and 2" allows specified Technical Specifications (TS) requirements to be changed to permit performance of special tests and operations. Unless otherwise specified, all other TS requirements remain unchanged. Compliance with STE LCOs is optional. When an STE LCO is desired to be met but is not met, the ACTIONS of the STE LCO shall be met. When an STE LCO is not desired to be met, entry into a MODE or other specified condition in the Applicability shall only be made in accordance with the other applicable Specifications.

INSERT 4 A07

LCO 3.0.8 When one or more required snubbers are unable to perform their associated support function(s), any affected supported LCO(s) are not required to be declared not met solely for this reason if risk is assessed and managed, and:

a. the snubbers not able to perform their associated support function(s) are associated with only one train or subsystem of a multiple train or subsystem supported system or are associated with a single train or subsystem supported system and are able to perform their associated support function within 72 hours; or

b. the snubbers not able to perform their associated support function(s) are associated with more than one train or subsystem of a multiple train or subsystem supported system and are able to perform their associated support function within 12 hours. M01

At the end of the specified period the required snubbers must be able to perform their associated support function(s), or the affected supported system LCO(s) shall be declared not met.

INSERT 5

L01

LCO 3.0.9 When one or more required barriers are unable to perform their related support function(s), any supported system LCO(s) are not required to be declared not met solely for this reason for up to 30 days provided that at least one train or subsystem of the supported system is OPERABLE and supported by barriers capable of providing their related support function(s), and risk is assessed and managed. This specification may be concurrently applied to more than one train or subsystem of a multiple train or subsystem supported system provided at least one train or subsystem of the supported system is OPERABLE and the barriers supporting each of these trains or subsystems provide their related support function(s) for different categories of initiating events.

If the required OPERABLE train or subsystem becomes inoperable while this specification is in use, it must be restored to OPERABLE status within 24 hours or the provisions of this specification cannot be applied to the trains or subsystems supported by the barriers that cannot perform their related support function(s).

At the end of the specified period, the required barriers must be able to perform their related support function(s) or the supported system LCO(s) shall be declared not met.

3/4 LIMITING CONDITIONS FOR OPERATION AND SURVEILLANCE REQUIREMENTS

3/4.0 APPLICABILITY

LIMITING CONDITION FOR OPERATION

LCO 3.0.1 3.0.1 Limiting Conditions for Operation (LCOs) shall be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2.

LCO 3.0.2 3.0.2 Upon discovery of a failure to meet an LCO, the ACTIONS shall be met, except as provided in LCO 3.0.5 and LCO 3.0.6. If the LCO is met or is no longer applicable prior to expiration of the specified time interval(s), completion of the ACTIONS is not required, unless otherwise stated.

LCO 3.0.3 3.0.3 When a Limiting Condition for Operation is not met, except as provided in the associated ACTION requirements, within 1 hour, action shall be initiated to place the unit in a MODE in which specification does not apply by placing it, as applicable, in:

1. At least HOT STANDBY within the next 6 hours,
2. At least HOT SHUTDOWN within the following 6 hours, and
3. At least COLD SHUTDOWN within the subsequent 24 hours.

Where corrective measures are completed that permit operation under the ACTION requirements, the ACTION may be taken in accordance with the specified time limits as measured from the time of failure to meet the Limiting Condition for Operation.

Exceptions to these requirements are stated in the individual specifications.

This specification is not applicable in MODE 5 or 6.

LCO 3.0.4 3.0.4 When an LCO is not met, entry into a MODE or other specified condition in the Applicability shall only be made:

a. When the associated ACTIONS to be entered permit continued operation in the MODE or other specified condition in the Applicability for an unlimited period of time;

b. After performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering the MODE or other specified condition in the Applicability, and establishment of risk management actions, if appropriate (exceptions to this Specification are stated in the individual Specifications); or

c. When an allowance is stated in the individual value, parameter, or other Specification.

This Specification shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

LCO 3.0.5 3.0.5 Equipment removed from service or declared inoperable to comply with ACTION(s) may be returned to service under administrative control solely to perform testing required to demonstrate its OPERABILITY or the OPERABILITY of other equipment. This is an exception to LCO 3.0.2 for the system returned to service under administrative control to perform the testing required to demonstrate OPERABILITY.

INSERT 1

are not met, an associated ACTION is not provided, or if directed by the associated ACTIONS, the unit shall be placed in a MODE or other specified condition in which the LCO is not applicable. Action shall be initiated within 1 hour to place the unit, as applicable, in A03 A01

INSERT 2 A05

in accordance with the LCO or ACTIONS, completion of the actions required by LCO 3.0.3 is not required

LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4.

~~APPLICABILITY~~

LCO Applicability

~~LIMITING CONDITION FOR OPERATION~~ (continued)

A01

LCO 3.0.6

3.0.6 When a supported system LCO is not met solely due to a support system LCO not being met, the ~~ACTIONS~~ associated with this supported system are not required to be entered. Only the support system LCO ACTIONS are required to be entered. This is an exception to LCO 3.0.2 for the supported system. In this event, an evaluation shall be performed in accordance with Specification ~~6.8.4.t~~ 5.5.12 "Safety Function Determination Program (SFDP)." If a loss of safety function is determined to exist by this program, the appropriate ~~ACTIONS~~ of the LCO in which the loss of safety function exists are required to be entered.

A01

When a support system's ~~ACTION~~ Required Action directs a supported system to be declared inoperable or directs entry into ~~ACTIONS~~ Conditions and Required Actions for a supported system, the applicable ~~ACTIONS~~ shall be entered in accordance with LCO 3.0.2.

INSERT 3

A06

LCO 3.0.7 Special test exception (STE) LCO 3.1.8, “Special Test Exceptions (STE) – MODES 1 and 2” allows specified Technical Specifications (TS) requirements to be changed to permit performance of special tests and operations. Unless otherwise specified, all other TS requirements remain unchanged. Compliance with STE LCOs is optional. When an STE LCO is desired to be met but is not met, the ACTIONS of the STE LCO shall be met. When an STE LCO is not desired to be met, entry into a MODE or other specified condition in the Applicability shall only be made in accordance with the other applicable Specifications.

INSERT 4

A07

LCO 3.0.8 When one or more required snubbers are unable to perform their associated support function(s), any affected supported LCO(s) are not required to be declared not met solely for this reason if risk is assessed and managed, and:

a. the snubbers not able to perform their associated support function(s) are associated with only one train or subsystem of a multiple train or subsystem supported system or are associated with a single train or subsystem supported system and are able to perform their associated support function within 72 hours; or

b. the snubbers not able to perform their associated support function(s) are associated with more than one train or subsystem of a multiple train or subsystem supported system and are able to perform their associated support function within 12 hours.

M01

At the end of the specified period the required snubbers must be able to perform their associated support function(s), or the affected supported system LCO(s) shall be declared not met.

INSERT 5

L01

LCO 3.0.9 When one or more required barriers are unable to perform their related support function(s), any supported system LCO(s) are not required to be declared not met solely for this reason for up to 30 days provided that at least one train or subsystem of the supported system is OPERABLE and supported by barriers capable of providing their related support function(s), and risk is assessed and managed. This specification may be concurrently applied to more than one train or subsystem of a multiple train or subsystem supported system provided at least one train or subsystem of the supported system is OPERABLE and the barriers supporting each of these trains or subsystems provide their related support function(s) for different categories of initiating events.

If the required OPERABLE train or subsystem becomes inoperable while this specification is in use, it must be restored to OPERABLE status within 24 hours or the provisions of this specification cannot be applied to the trains or subsystems supported by the barriers that cannot perform their related support function(s).

At the end of the specified period, the required barriers must be able to perform their related support function(s) or the supported system LCO(s) shall be declared not met.

Page removed from submittal

DISCUSSION OF CHANGES
ITS 3.0, LCO AND SR APPLICABILITY

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS) and additional Technical Specification Task Force (TSTF) travelers included in this submittal.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.0.1 states “Limiting Conditions for Operation (LCO) shall be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2." ITS LCO 3.0.1 states, "LCOs shall be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2, LCO 3.0.7, LCO 3.0.8, and LCO 3.0.9." This results in changes to the CTS.

- ITS LCO 3.0.7, LCO 3.0.8, and LCO 3.0.9 are added exceptions in ITS LCO 3.0.1. ITS LCO 3.0.7 describes Test Exceptions LCOs, which are exceptions to other LCOs. ITS LCO 3.0.8 addresses snubber inoperabilities, which is also an exception to other LCOs. ITS LCO 3.0.9 addresses barrier inoperabilities which is also an exception to other LCOs. Changes resulting from the incorporation of ITS LCO 3.0.8 are discussed in DOCs A07 and M01. Changes resulting from the incorporation of ITS LCO 3.0.9 are discussed in DOC L01.

  This change is acceptable because adding the exceptions for LCO 3.0.7, LCO 3.0.8, and LCO 3.0.9 prevent a conflict within the Applicability section. This addition is needed for consistency in the ITS requirements and does not change the intent or application of the Technical Specifications.

- Certain phrases are revised to be consistent with the equivalent phrase used in the ITS. Specifically, "OPERATIONAL MODES or other conditions specified therein" is changed to "MODES or other specified conditions in the Applicability" to be consistent with the ITS definition of MODE and the terminology used in the ITS.

  This change is acceptable because it results in no change in the intent or application of the Technical Specifications, but merely reflect editorial preferences used in the ITS.

A03 CTS 3.0.3, in part, is applicable "When a Limiting Condition for Operation (LCO) is not met, except as provided in the associated ACTION requirements." ITS LCO 3.0.3 expands those applicability requirements so that the requirement is applicable "When an LCO is not met and the associated ACTIONS are not met, an associated ACTION is not provided, or if directed by the associated ACTIONS." This changes the CTS to add two new applicability conditions.

- ITS LCO 3.0.3 is applicable when the LCO is not met and there is no applicable ACTION to be taken.

  This change is acceptable because it is consistent with the current understanding and application of CTS 3.0.3.

- ITS LCO 3.0.3 is applicable when directed by the associated ACTIONS. The CTS and the ITS contain such requirements. Any technical changes related to directing LCO 3.0.3 entry in an ACTION will be discussed in the affected Technical Specifications.

  This change is acceptable because it is consistent with the current understanding and application of CTS 3.0.3.

These changes are designated as administrative because they do not result in any technical changes to the Technical Specifications.

A04 CTS 3.0.3, in part, states that within one hour action shall be initiated to place the unit in a MODE in which the Specification does not apply by placing it, as applicable, in: Hot Standby within the next 6 hours, Hot Shutdown within the following 6 hours, and at least Cold Shutdown within the subsequent 24 hours. ITS LCO 3.0.3 states that action shall be initiated within 1 hour to place the unit, as applicable, in MODE 3 within 7 hours, MODE 4 within 13 hours, and MODE 5 within 37 hours. This changes the CTS by using the sum of the times (i.e., the ITS Completion Time of 37 hours to enter MODE 5 is the same as the sum of the CTS allowance of 1 hour, 6 hours, 6 hours, and 24 hours) instead of sequential times (i.e., each time is measured from the completion of the previous step). The stated times in CTS 3.0.3 and ITS 3.0.3 are listed below:

Mode	Title	CTS Time to Enter Mode	ITS Time to Enter Mode
--	(Current Mode)	1 hour to begin action	1 hour to begin action
3	Hot Standby	within the next 6 hours	7 hours
4	Hot Shutdown	within the following 6 hours	13 hours
5	Cold Shutdown	within the subsequent 24 hours	37 hours

The purpose of CTS 3.0.3 is to establish the shutdown requirements that must be implemented when an LCO is not met and the condition is not specifically addressed in the associated ACTION requirements. The delineated time limit allows the unit to be placed in a safe shutdown MODE when the plant cannot be maintained within the limits for safe operation. The time limit, specified in CTS 3.0.3 to reach the lower MODES of operation, permits the shutdown to proceed in a controlled manner that is well within the specified maximum cooldown rate. Furthermore, the time limit is within the cooldown capabilities of the plant

assuming only the minimum required equipment is OPERABLE. This reduces thermal stresses on components of the primary coolant system and the potential for a plant upset that could challenge safety systems under conditions for which this specification applies. In the CTS, this is accomplished by allowing a total of 37 hours for the plant to be in Cold Shutdown when a shutdown is required during the MODE of Operation. In the absence of specific guidance within the CTS, current PSL practice if the unit is in a lower MODE of Operation and a CTS 3.0.3 shutdown is required, is to apply the time limit for reaching the lower MODE of operation (i.e., each time limit is measured from the time the previous MODE is reached). In the ITS, the time limits for ITS LCO 3.0.3 allow 37 hours for the unit to be in MODE 5 when a shutdown is required during MODE 1 operation. If the unit is in a lower mode of operation when an ITS LCO 3.0.3 shutdown is required, the time limit for reaching the next lower MODE applies (i.e., if the plant is in MODE 3, 13 hours is allowed to reach MODE 4). ITS 3.0 Bases gives a detailed discussion on the use of applying the allowed outage times when the unit is in a lower MODE when ITS LCO 3.0.3 is entered. This is further explained, with examples, in the discussion of Section 1.3, "Completion Times." This change is acceptable because ITS and CTS both allow 37 hours to reach MODE 5 from power operation. In addition, the CTS 3.0.3 statement " within one hour action shall be initiated to place the unit in a MODE in which the Specification does not apply" has been editorially reworded in ITS LCO 3.0.3 to "the unit shall be placed in a MODE or other specified condition in which the LCO is not applicable. ACTION shall be initiated within 1 hour to place the unit..." These changes are considered changes to the CTS presentation. These changes are designated as administrative as they apply rules of usage established by ITS without resulting in technical changes to the Technical Specifications.

A05 CTS 3.0.3 states "Where corrective measures are completed that permit operation under the ACTION requirements, the ACTION may be taken in accordance with the specified time limits as measured from the time of failure to meet the LCO." ITS LCO 3.0.3 states "Where corrective measures are completed that permit operation in accordance with the LCO or ACTIONS, completion of the actions required by LCO 3.0.3 is not required. LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4."

This change is acceptable because the changes to CTS 3.0.3 are editorial. Both the CTS and ITS state that LCO 3.0.3 can be exited if the LCO which led to the entry into LCO 3.0.3 is met, or if one of the ACTIONS of that LCO is applicable. The CTS requirement also specifies that the time to complete the ACTIONS in the LCO is based on the initial failure to meet the LCO. Reentering the LCO after exiting LCO 3.0.3 does not reset the ACTION statement time requirements. This information is not explicitly stated in ITS LCO 3.0.3 but is true under the multiple condition entry concept of the ITS.

In addition, CTS 3.0.3 states “This specification is not applicable in MODES 5 or 6.” ITS LCO 3.0.3 states “LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4.” CTS 3.0.3 and ITS LCO 3.0.3 require the unit to be placed only as low as COLD SHUTDOWN (MODE 5). Once the unit is in MODE 5, there are no further requirements. Thus, CTS 3.0.3 and ITS LCO 3.0.3 are effectively only applicable

in MODES 1, 2, 3, and 4, and the addition of the sentence merely reflects editorial preferences used in the ITS.

These changes are designated as administrative because there is no change in the intent or application of the CTS 3.0.3 requirements.

A06 ITS LCO 3.0.7 is added to the CTS. ITS LCO 3.0.7 states "Special Test Exception (STE) LCO 3.1.8 allows specified Technical Specification (TS) requirements to be changed to permit performance of special tests and operations. Unless otherwise specified, all other TS requirements remain unchanged. Compliance with Test Exception LCOs is optional. When an STE LCO is desired to be met but is not met, the ACTIONS of the STE LCO shall be met. When an STE LCO is not desired to be met, entry into a MODE or other specified condition in the Applicability shall only be made in accordance with the other applicable Specifications."

This change is acceptable because the CTS contain test exception specifications that allow certain LCOs to not be met for the purpose of special tests and operations. However, the CTS does not contain the equivalent of ITS LCO 3.0.7. As a result, there could be confusion regarding which LCOs are applicable during special tests. LCO 3.0.7 was crafted to avoid that possible confusion. LCO 3.0.7 is consistent with the use and application of CTS test exception Specifications and does not provide any new restriction or allowance. This change is designated as administrative because it does not technically change the Technical Specifications.

A07 CTS Section 3.0 does not contain an allowance when snubbers are unable to perform their associated support function. Unit 1 CTS 3.7.10 and Unit 2 CTS 3.7.9 provide the action for inoperable safety related snubbers and requires replacement or restoration of the inoperable snubber(s) within 72 hours or declare the supported system inoperable. Unit 1 CTS 3.7.10 and Unit 2 CTS 3.7.9 are relocated to the Technical Requirements Manual as part of the ITS conversion. Consistent with Technical Specifications Task Force (TSTF) traveler TSTF- 372, Revision 4, “Addition of LCO 3.0.8, Inoperability of Snubbers,“ dated April 23, 2004 (ADAMS Accession No. ML041200567) allowances, the proposed change to CTS 3.0, "LCO Applicability" adds a new LCO 3.0.8 with actions for inoperable required snubbers incorporated. When one or more required snubbers are unable to perform their associated support function(s), any affected supported LCO(s) are not required to be declared not met solely for this reason if risk is assessed and managed, and either: a) the snubbers not able to perform their associated support function(s) are associated with only one train or subsystem of a multiple train or subsystem supported system and are able to perform their associated function within 72 hours; or b) the snubbers not able to perform their associated support function(s) are associated with more than one train or subsystem of a multiple train or subsystem supported system and are able to perform their associated support function within 12 hours. At the end of the specified period (i.e., 12 hours or 72 hours) snubbers must be able to perform their associated function(s), or the affected support system LCO(s) shall be declared not met and the associated ACTIONS taken.

ITS LCO 3.0.8.a allows 72 hours to restore the snubber(s) before declaring the supported system inoperable, provided only a single subsystem is affected. This 72 hour time is consistent with the CTS. The impact and technical analysis of this change is discussed in detail in TSTF-372, Revision 4.

The change, except as discussed in DOC M01 is designated as administrative because there is no change in the intent or application of the Unit 1 CTS 3.7.10 and Unit 2 CTS 3.7.9 requirements as justified in TSTF-372, Revision 4.

A08 CTS 4.0.2 states, "Each Surveillance Requirement shall be performed within the specified surveillance interval with a maximum allowable extension not to exceed 25% of the specified surveillance interval." ITS SR 3.0.2 states, "The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met. For Frequencies specified as "once," the above interval extension does not apply. If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance. Exceptions to this Specification are stated in the individual Specifications." This results in several changes to the CTS.

- ITS SR 3.0.2 adds to the CTS "For Frequencies specified as "once," the above interval extension does not apply." This is described in DOC M02.

- ITS SR 3.0.2 adds to the CTS "If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance." This is covered by DOC L02.

- CTS 4.0.2 states, "Each Surveillance Requirement shall be performed within the specified surveillance interval with a maximum allowable extension not to exceed 25% of the specified surveillance interval." ITS SR 3.0.2 states, in part, "The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency." This change is being made to be consistent with the ITS terminology and to clarify the concept of the specified SR Frequency being met.

  This change is acceptable since it does not change the intent of the requirements.

- ITS SR 3.0.2 is more specific regarding the state of the Frequency by stating, "as measured from the previous performance or as measured from the time a specified condition of the Frequency is met." This direction is consistent with the current use and application of the Technical Specifications.

  This change is acceptable because the ITS intent is the same as the CTS requirement.

- ITS SR 3.0.2 adds to the CTS "Exceptions to this Specification are stated in the individual Specifications."

  This change is acceptable because it reflects practices used in the ITS that are not used in the CTS. Any changes to a Technical Specification, by inclusion of such an exception, will be addressed in the affected Technical Specification.

The changes, except as discussed in DOC M02 and DOC L02, are designated as administrative because they reflect presentation and usage rules of the ITS without making technical changes to the Technical Specifications.

MORE RESTRICTIVE CHANGES

M01 CTS Section 3.0 does not contain an allowance when snubbers are unable to perform their associated support function. Unit 1 CTS 3.7.10 and Unit 2 CTS 3.7.9 provide the action for inoperable safety related snubbers and requires replacement or restoration of the inoperable snubber(s) within 72 hours or declare the supported system inoperable. Unit 1 CTS 3.7.10 and Unit 2 CTS 3.7.9 are relocated to the Technical Requirements Manual as part of the ITS conversion. Consistent with TSTF-372, Revision 4 allowances, the proposed change to CTS 3.0, "LCO Applicability" adds a new LCO 3.0.8 with actions for inoperable required snubbers incorporated. When one or more required snubbers are unable to perform their associated support function(s), any affected supported LCO(s) are not required to be declared not met solely for this reason if risk is assessed and managed, and either: a) the snubbers not able to perform their associated support function(s) are associated with only one train or subsystem of a multiple train or subsystem supported system and are able to perform their associated function within 72 hours; or b) the snubbers not able to perform their associated support function(s) are associated with more than one train or subsystem of a multiple train or subsystem supported system and are able to perform their associated support function within 12 hours. At the end of the specified period (i.e., 12 hours or 72 hours) snubbers must be able to perform their associated function(s), or the affected support system LCO(s) shall be declared not met and the associated ACTIONS taken.

ITS LCO 3.0.8.b allows 12 hours to restore the snubber(s) before declaring the supported system inoperable when the snubbers are associated with more than one train or subsystem of a multiple train or subsystem supported system. The 12 hour time is appropriate based on the relative risk considered with respect to other plant maintenance activities and integration of the of the risk assessment and management aspect of the LCO into the plant’s existing 10 CFR 50.65(a)(4) process as provided in the technical analysis of this change in TSTF-372, Revision 4.

The proposed change, except as discussed in DOC A07, is designated as more restrictive because it imposes a new shorter specified period for restoration of snubbers that are associated with more than one train or subsystem than allowed in Unit 1 CTS 3.7.10 and Unit 2 CTS 3.7.9.

M02 CTS 4.0.2 states, "Each Surveillance Requirement shall be performed within the specified surveillance interval with a maximum allowable extension not to exceed 25% of the specified surveillance interval." ITS SR 3.0.2 states, "The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met. For Frequencies specified as "once," the above interval extension does not apply. If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance. Exceptions to this Specification are stated in the individual Specifications." This changes the CTS by adding "For Frequencies specified as "once," the above interval extension does not apply." The remaining changes to CTS 4.0.2 are discussed in DOCs A08 and L02.

The purpose of the 1.25 extension allowance to Surveillance Frequencies is to allow for flexibility in scheduling tests. This change is acceptable because Frequencies specified as "once" are typically condition-based Surveillances in which the first performance demonstrates the acceptability of the current condition. Such demonstrations should be accomplished within the specified Frequency without extension in order to avoid operation in unacceptable conditions. This change is designated as more restrictive because an allowance to extend Frequencies by 25% is eliminated for some Surveillances.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program)* CTS 4.0.5 provides requirements for the inservice inspection of ASME Code Class 1, 2 and 3 components. The ITS does not include Inservice Inspection Program requirements. This changes the CTS by moving these Surveillance Requirements from the Technical Specifications to the Inservice Inspection (ISI) Program.

The removal of these requirements is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The Technical Specifications still retain requirements for the affected components to be OPERABLE. Also, this change is acceptable because these requirements will be adequately controlled by the ISI Program, which is required by 10 CFR 50.55a. Compliance with 10 CFR 50.55a is required by the operating licenses of Units 1 and 2. This change is designated as a less restrictive removal of requirement change because requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 1 – Relaxation of LCO Requirements)* CTS Section 3.0 does not contain an allowance when barriers cannot support their support function. The proposed change to CTS 3.0, "LCO Applicability" adds a new LCO 3.0.9. The addition of LCO 3.0.9 to the CTS is to address barriers which cannot perform their related support function for Technical Specification systems. ITS LCO 3.0.9 allows barriers to be able to not perform their safety function for up to 30 days before declaring the supported system inoperable. Furthermore, due to this addition, an allowance is also needed in LCO 3.0.1. This allowance has been added. | R1

Barriers are defined as doors, walls, floor plugs, curbs, hatches, installed structures or components, or other devices, not explicitly described in Technical Specifications, which are designed to provide for the performance of the safety function for the Technical Specification system after the occurrence of one or more initiating events.

The barrier which cannot perform its related support function will be evaluated and managed under the Maintenance Rule plant configuration control requirement, 10 CFR 50.65(a)(4), and the associated industry guidance (NUMARC 93-01, Revision 4A). This provision is applicable whether the barrier is affected due to planned maintenance or due to a discovered condition. Should the risk assessment and risk management actions for a specific plant configuration or emergent condition not support the 30 day allowed time, the Maintenance Rule risk management determined allowed time and actions must be implemented or the supported system’s LCO be considered not met.

Application of LCO 3.0.9 is dependent on the OPERABILITY of at least one train or subsystem of the supported Technical Specification system and the system's ability to mitigate the consequences of the specified initiating events. However, during the 30 day period allowed by LCO 3.0.9, there exists the possibility that the train or subsystem required to be OPERABLE will unexpectedly become inoperable. Absent any further consideration, this would likely result in both trains of a Technical Specification required system being declared inoperable (i.e., the train supported by the barriers to which LCO 3.0.9 was being applied and the emergent condition of the inoperable train). This would likely result in entering LCO 3.0.3 and a rapid plant shutdown. While this scenario is of low likelihood, it is of very high consequence to PSL and, therefore, should be avoided unless necessary to avoid an actual plant risk. As a result, LCO 3.0.9 contains a provision which addresses the emergent condition of the required OPERABLE train or subsystem becoming inoperable while LCO 3.0.9 is being used. LCO 3.0.9 provides 24 hours to either restore the inoperable train or subsystem or to cease relying on the provisions of LCO 3.0.9 to consider the train or subsystem supported by the affected barrier(s) OPERABLE. This 24 hour period is not based on a generic risk evaluation, as it would be difficult to perform such an analysis in a generic fashion. Rather, plant risk during this 24 hour allowance is managed using the contemporaneous risk assessment and management required by 10 CFR 50.65(a)(4) and recognizes the unquantified advantage to plant safety of avoiding a plant shutdown with the associated transition risk.

A risk impact of the 30 day allowance for barriers was performed. All PSL initiating events are located on the table depicted in Technical Specifications Task Force (TSTF) traveler TSTF-427, Revision 2, “Allowance for Non Technical Specification Barrier Degradation on Supported System OPERABILITY,“ dated May 3, 2006 (ADAMS Accession No. ML061240055) or St. Lucie has evaluated the use of LCO 3.0.9 for a barrier protecting against an initiating event not on the table located in TSTF-427, Revision 2 and calculated the frequency ranges within the ranges in the table so the above analysis is applicable for those initiators. Therefore, LCO 3.0.9 can be utilized when inoperable barriers affect Systems, Structures, or Components.

L02 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.0.2 states, "Each Surveillance Requirement shall be performed within the specified surveillance interval with a maximum allowable extension not to exceed 25% of the specified surveillance interval." ITS SR 3.0.2 states, " The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met. For Frequencies specified as "once," the above interval extension does not apply. If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance. Exceptions to this Specification are stated in the individual Specifications." This changes the CTS by adding, " If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance." The remaining changes to CTS 4.0.2 are discussed in DOCs A08 and M02. | R1

This change is acceptable because the 25% Frequency extension given to provide scheduling flexibility for Surveillances is equally applicable to Required Actions that must be performed periodically. The initial performance is excluded because the first performance demonstrates the acceptability of the current condition. Such demonstrations should be accomplished within the specified Completion Time with extension in order to avoid operation in unacceptable conditions. This change is designated as less restrictive because addition time is provided to perform some periodic Required Actions.

L03 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.0.3 states, in part, "If it is discovered that a Surveillance was not performed within its specified frequency, then compliance with the requirement to declare the Limiting Condition of Operation not met may be delayed, from the time of discovery, up to 24 hours or up to the limit of the specified frequency, whichever is greater. This delay period is permitted to allow performance of the Surveillance." ITS SR 3.0.3 states, in part, "If it is discovered that a Surveillance was not performed within its specified frequency, then compliance with the requirement to declare the Limiting Condition of Operation not met may be delayed, from the time of discovery, up to 24 hours or up to the limit of the specified frequency, whichever is greater. This delay period is permitted to allow performance of the Surveillance. The delay period is only applicable when there is a reasonable expectation the surveillance will be met when performed." This changes the CTS by adding, "The delay | R1

period is only applicable when there is a reasonable expectation the surveillance will be met when performed."

The purpose of CTS 4.0.3 is to establish flexibility to defer declaring affected equipment inoperable or an affected variable outside the specified limits when a Surveillance has not been performed within the specified Frequency. One premise for this flexibility is that the SR was satisfactorily met in the past and the most probable result of performing the SR is the verification of conformance with the requirements. Therefore, there is a reasonable expectation the SR will be met when performed. However, there are instances in which an SR may not have been performed in the past, but there is still a reasonable expectation the SR will be met when performed. This change is acceptable because it supports the premise that there is a reasonable expectation that the SR will be met when performed. This change has been approved by the NRC in Technical Specifications Task Force (TSTF) traveler TSTF-529, Revision 4, “Clarify Use and Application Rules,“ dated April 21, 2016 (ADAMS Accession No. ML16060A455). The NRC staff determined the application of the delay period provided by ISTS SR 3.0.3 acceptable for use on SRs that have never been performed as long as licensees can provide an adequate determination of reasonable expectation the SR will be met when performed. This change is designated as less restrictive because an allowance to defer declaring affected equipment inoperable is extended to SRs that have not been performed if a reasonable expectation the surveillance will be met when performed can be shown.

Improved Standard Technical Specifications (ISTS) Markup and Justification for Deviations (JFDs)

3.0 LIMITING CONDITION FOR OPERATION (LCO) APPLICABILITY

3.0.1 LCO 3.0.1 LCOs shall be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2, LCO 3.0.7, LCO 3.0.8, and LCO 3.0.9.

3.0.2 LCO 3.0.2 Upon discovery of a failure to meet an LCO, the Required Actions of the associated Conditions shall be met, except as provided in LCO 3.0.5 and LCO 3.0.6.

If the LCO is met or is no longer applicable prior to expiration of the specified Completion Time(s), completion of the Required Action(s) is not required, unless otherwise stated.

3.0.3 LCO 3.0.3 When an LCO is not met and the associated ACTIONS are not met, an associated ACTION is not provided, or if directed by the associated ACTIONS, the unit shall be placed in a MODE or other specified condition in which the LCO is not applicable. Action shall be initiated within 1 hour to place the unit, as applicable, in:

a. MODE 3 within 7 hours,

b. ~~[~~MODE 4 within 13~~]~~ hours, and

c. MODE 5 within 37 hours.

2

Exceptions to this Specification are stated in the individual Specifications.

Where corrective measures are completed that permit operation in accordance with the LCO or ACTIONS, completion of the actions required by LCO 3.0.3 is not required.

LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4.

3.0.4 LCO 3.0.4 When an LCO is not met, entry into a MODE or other specified condition in the Applicability shall only be made:

a. When the associated ACTIONS to be entered permit continued operation in the MODE or other specified condition in the Applicability for an unlimited period of time;

b. After performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering the MODE or other specified condition in the Applicability, and establishment of risk management actions, if appropriate (exceptions to this Specification are stated in the individual Specifications); or

c. When an allowance is stated in the individual value, parameter, or other Specification.

3.0 LCO Applicability

3.0.4 LCO 3.0.4 (continued)

This Specification shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

3.0.5 LCO 3.0.5

Equipment removed from service or declared inoperable to comply with ACTIONS may be returned to service under administrative control solely to perform testing required to demonstrate its OPERABILITY or the OPERABILITY of other equipment. This is an exception to LCO 3.0.2 for the system returned to service under administrative control to perform the testing required to demonstrate OPERABILITY.

3.0.6 LCO 3.0.6

When a supported system LCO is not met solely due to a support system LCO not being met, the Conditions and Required Actions associated with this supported system are not required to be entered. Only the support system LCO ACTIONS are required to be entered. This is an exception to LCO 3.0.2 for the supported system. In this event, an evaluation shall be performed in accordance with Specification 5.5.14, "Safety Function Determination Program (SFDP)." If a loss of safety function is determined to exist by this program, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.

When a support system's Required Action directs a supported system to be declared inoperable or directs entry into Conditions and Required Actions for a supported system, the applicable Conditions and Required Actions shall be entered in accordance with LCO 3.0.2.

DOC A06 LCO 3.0.7

Special test exception (STE) LCOs ~~[in each applicable LCO section]~~ allow specified Technical Specifications (TS) requirements to be changed to permit performance of special tests and operations. Unless otherwise specified, all other TS requirements remain unchanged. Compliance with STE LCOs is optional. When an STE LCO is desired to be met but is not met, the ACTIONS of the STE LCO shall be met. When an STE LCO is not desired to be met, entry into a MODE or other specified condition in the Applicability shall only be made in accordance with the other applicable Specifications.

DOC A07 LCO 3.0.8

When one or more required snubbers are unable to perform their associated support function(s), any affected supported LCO(s) are not required to be declared not met solely for this reason if risk is assessed and managed, and:

2

3

s

1

2

3.1.8; “Special Test Exceptions (STE) – MODES 1 and 2,”

3.0 LCO Applicability

DOC A07

LCO 3.0.8 (continued)

a. the snubbers not able to perform their associated support function(s) are associated with only one train or subsystem of a multiple train or subsystem supported system or are associated with a single train or subsystem supported system and are able to perform their associated support function within 72 hours; or

b. the snubbers not able to perform their associated support function(s) are associated with more than one train or subsystem of a multiple train or subsystem supported system and are able to perform their associated support function within 12 hours.

At the end of the specified period the required snubbers must be able to perform their associated support function(s), or the affected supported system LCO(s) shall be declared not met.

DOC L01

LCO 3.0.9

When one or more required barriers are unable to perform their related support function(s), any supported system LCO(s) are not required to be declared not met solely for this reason for up to 30 days provided that at least one train or subsystem of the supported system is OPERABLE and supported by barriers capable of providing their related support function(s), and risk is assessed and managed. This specification may be concurrently applied to more than one train or subsystem of a multiple train or subsystem supported system provided at least one train or subsystem of the supported system is OPERABLE and the barriers supporting each of these trains or subsystems provide their related support function(s) for different categories of initiating events.

If the required OPERABLE train or subsystem becomes inoperable while this specification is in use, it must be restored to OPERABLE status within 24 hours or the provisions of this specification cannot be applied to the trains or subsystems supported by the barriers that cannot perform their related support function(s).

At the end of the specified period, the required barriers must be able to perform their related support function(s) or the supported system LCO(s) shall be declared not met.

3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY

4.0.1	SR 3.0.1	SRs shall be met during the MODES or other specified conditions in the Applicability for individual LCOs, unless otherwise stated in the SR. Failure to meet a Surveillance, whether such failure is experienced during the performance of the Surveillance or between performances of the Surveillance, shall be failure to meet the LCO. Failure to perform a Surveillance within the specified Frequency shall be failure to meet the LCO except as provided in SR 3.0.3. Surveillances do not have to be performed on inoperable equipment or variables outside specified limits.
4.0.2	SR 3.0.2	The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met. For Frequencies specified as "once," the above interval extension does not apply. If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance. Exceptions to this Specification are stated in the individual Specifications.
4.0.3	SR 3.0.3	If it is discovered that a Surveillance was not performed within its specified Frequency, then compliance with the requirement to declare the LCO not met may be delayed, from the time of discovery, up to 24 hours or up to the limit of the specified Frequency, whichever is greater. This delay period is permitted to allow performance of the Surveillance. The delay period is only applicable when there is a reasonable expectation the Surveillance will be met when performed. A risk evaluation shall be performed for any Surveillance delayed greater than 24 hours and the risk impact shall be managed. If the Surveillance is not performed within the delay period, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered. When the Surveillance is performed within the delay period and the Surveillance is not met, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered.

3.0 SR Applicability

4.0.4

SR 3.0.4	Entry into a MODE or other specified condition in the Applicability of an LCO shall only be made when the LCO's Surveillances have been met within their specified Frequency, except as provided by SR 3.0.3. When an LCO is not met due to Surveillances not having been met, entry into a MODE or other specified condition in the Applicability shall only be made in accordance with LCO 3.0.4. This provision shall not prevent entry into MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

3.0 LIMITING CONDITION FOR OPERATION (LCO) APPLICABILITY

3.0.1 LCO 3.0.1 LCOs shall be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2, LCO 3.0.7, LCO 3.0.8, and LCO 3.0.9.

3.0.2 LCO 3.0.2 Upon discovery of a failure to meet an LCO, the Required Actions of the associated Conditions shall be met, except as provided in LCO 3.0.5 and LCO 3.0.6.

If the LCO is met or is no longer applicable prior to expiration of the specified Completion Time(s), completion of the Required Action(s) is not required, unless otherwise stated.

3.0.3 LCO 3.0.3 When an LCO is not met and the associated ACTIONS are not met, an associated ACTION is not provided, or if directed by the associated ACTIONS, the unit shall be placed in a MODE or other specified condition in which the LCO is not applicable. Action shall be initiated within 1 hour to place the unit, as applicable, in:

a. MODE 3 within 7 hours,

b. ~~[~~MODE 4 within 13~~]~~ hours, and

c. MODE 5 within 37 hours.

2

Exceptions to this Specification are stated in the individual Specifications.

Where corrective measures are completed that permit operation in accordance with the LCO or ACTIONS, completion of the actions required by LCO 3.0.3 is not required.

LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4.

3.0.4 LCO 3.0.4 When an LCO is not met, entry into a MODE or other specified condition in the Applicability shall only be made:

a. When the associated ACTIONS to be entered permit continued operation in the MODE or other specified condition in the Applicability for an unlimited period of time;

b. After performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering the MODE or other specified condition in the Applicability, and establishment of risk management actions, if appropriate (exceptions to this Specification are stated in the individual Specifications); or

c. When an allowance is stated in the individual value, parameter, or other Specification.

3.0 LCO Applicability

3.0.4 LCO 3.0.4 (continued)

This Specification shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

3.0.5 LCO 3.0.5

Equipment removed from service or declared inoperable to comply with ACTIONS may be returned to service under administrative control solely to perform testing required to demonstrate its OPERABILITY or the OPERABILITY of other equipment. This is an exception to LCO 3.0.2 for the system returned to service under administrative control to perform the testing required to demonstrate OPERABILITY.

3.0.6 LCO 3.0.6

When a supported system LCO is not met solely due to a support system LCO not being met, the Conditions and Required Actions associated with this supported system are not required to be entered. Only the support system LCO ACTIONS are required to be entered. This is an exception to LCO 3.0.2 for the supported system. In this event, an evaluation shall be performed in accordance with Specification 5.5.14, "Safety Function Determination Program (SFDP)." If a loss of safety function is determined to exist by this program, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.

When a support system's Required Action directs a supported system to be declared inoperable or directs entry into Conditions and Required Actions for a supported system, the applicable Conditions and Required Actions shall be entered in accordance with LCO 3.0.2.

DOC A06 LCO 3.0.7

Special test exception (STE) LCOs ~~[in each applicable LCO section]~~ allow specified Technical Specifications (TS) requirements to be changed to permit performance of special tests and operations. Unless otherwise specified, all other TS requirements remain unchanged. Compliance with STE LCOs is optional. When an STE LCO is desired to be met but is not met, the ACTIONS of the STE LCO shall be met. When an STE LCO is not desired to be met, entry into a MODE or other specified condition in the Applicability shall only be made in accordance with the other applicable Specifications.

DOC A07 LCO 3.0.8

When one or more required snubbers are unable to perform their associated support function(s), any affected supported LCO(s) are not required to be declared not met solely for this reason if risk is assessed and managed, and:

3.1.8; "Special Test Exceptions (STE) – MODES 1 and 2,"

3.0 LCO Applicability

DOC A07 LCO 3.0.8 (continued)

a. the snubbers not able to perform their associated support function(s) are associated with only one train or subsystem of a multiple train or subsystem supported system or are associated with a single train or subsystem supported system and are able to perform their associated support function within 72 hours; or

b. the snubbers not able to perform their associated support function(s) are associated with more than one train or subsystem of a multiple train or subsystem supported system and are able to perform their associated support function within 12 hours.

At the end of the specified period the required snubbers must be able to perform their associated support function(s), or the affected supported system LCO(s) shall be declared not met.

DOC L01 LCO 3.0.9

When one or more required barriers are unable to perform their related support function(s), any supported system LCO(s) are not required to be declared not met solely for this reason for up to 30 days provided that at least one train or subsystem of the supported system is OPERABLE and supported by barriers capable of providing their related support function(s), and risk is assessed and managed. This specification may be concurrently applied to more than one train or subsystem of a multiple train or subsystem supported system provided at least one train or subsystem of the supported system is OPERABLE and the barriers supporting each of these trains or subsystems provide their related support function(s) for different categories of initiating events.

If the required OPERABLE train or subsystem becomes inoperable while this specification is in use, it must be restored to OPERABLE status within 24 hours or the provisions of this specification cannot be applied to the trains or subsystems supported by the barriers that cannot perform their related support function(s).

At the end of the specified period, the required barriers must be able to perform their related support function(s) or the supported system LCO(s) shall be declared not met.

3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY

4.0.1 **SR 3.0.1**

SRs shall be met during the MODES or other specified conditions in the Applicability for individual LCOs, unless otherwise stated in the SR. Failure to meet a Surveillance, whether such failure is experienced during the performance of the Surveillance or between performances of the Surveillance, shall be failure to meet the LCO. Failure to perform a Surveillance within the specified Frequency shall be failure to meet the LCO except as provided in SR 3.0.3. Surveillances do not have to be performed on inoperable equipment or variables outside specified limits.

4.0.2 **SR 3.0.2**

The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met.

For Frequencies specified as "once," the above interval extension does not apply.

If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance.

Exceptions to this Specification are stated in the individual Specifications.

4.0.3 **SR 3.0.3**

If it is discovered that a Surveillance was not performed within its specified Frequency, then compliance with the requirement to declare the LCO not met may be delayed, from the time of discovery, up to 24 hours or up to the limit of the specified Frequency, whichever is greater. This delay period is permitted to allow performance of the Surveillance. The delay period is only applicable when there is a reasonable expectation the Surveillance will be met when performed. A risk evaluation shall be performed for any Surveillance delayed greater than 24 hours and the risk impact shall be managed.

If the Surveillance is not performed within the delay period, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered.

When the Surveillance is performed within the delay period and the Surveillance is not met, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered.

3.0 SR Applicability

4.0.4

SR 3.0.4	Entry into a MODE or other specified condition in the Applicability of an LCO shall only be made when the LCO's Surveillances have been met within their specified Frequency, except as provided by SR 3.0.3. When an LCO is not met due to Surveillances not having been met, entry into a MODE or other specified condition in the Applicability shall only be made in accordance with LCO 3.0.4. This provision shall not prevent entry into MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

JUSTIFICATION FOR DEVIATIONS
ITS 3.0, LCO AND SR APPLICABILITY

1. Changes are made (additions, deletions, and/or changes) to the ISTS which reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is changed to reflect the current licensing basis.

3. Changes are made to be consistent with changes made to the referenced ISTS Specification.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.0 LIMITING CONDITION FOR OPERATION (LCO) APPLICABILITY

BASES

LCOs	LCO 3.0.1 through LCO 3.0.9 establish the general requirements applicable to all Specifications and apply at all times unless otherwise stated.
LCO 3.0.1	LCO 3.0.1 establishes the Applicability statement within each individual Specification as the requirement for when the LCO is required to be met (i.e., when the unit is in the MODES or other specified conditions of the Applicability statement of each Specification).
LCO 3.0.2	LCO 3.0.2 establishes that upon discovery of a failure to meet an LCO, the associated ACTIONS shall be met. The Completion Time of each Required Action for an ACTIONS Condition is applicable from the point in time that an ACTIONS Condition is entered, unless otherwise specified. The Required Actions establish those remedial measures that must be taken within specified Completion Times when the requirements of an LCO are not met. This Specification establishes that: a. Completion of the Required Actions within the specified Completion Times constitutes compliance with a Specification and b. Completion of the Required Actions is not required when an LCO is met within the specified Completion Time, unless otherwise specified. There are two basic types of Required Actions. The first type of Required Action specifies a time limit in which the LCO must be met. This time limit is the Completion Time to restore an inoperable system or component to OPERABLE status or to restore variables to within specified limits. If this type of Required Action is not completed within the specified Completion Time, a shutdown may be required to place the unit in a MODE or condition in which the Specification is not applicable. (Whether stated as a Required Action or not, correction of the entered Condition is an action that may always be considered upon entering ACTIONS.) The second type of Required Action specifies the remedial measures that permit continued operation of the unit that is not further restricted by the Completion Time. In this case, compliance with the Required Actions provides an acceptable level of safety for continued operation. Completing the Required Actions is not required when an LCO is met or is no longer applicable, unless otherwise stated in the individual Specifications.

BASES

LCO 3.0.2 (continued)

The nature of some Required Actions of some Conditions necessitates that, once the Condition is entered, the Required Actions must be completed even though the associated Conditions no longer exist. The individual LCO's ACTIONS specify the Required Actions where this is the case. An example of this is in LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits."

The Completion Times of the Required Actions are also applicable when a system or component is removed from service intentionally. The ACTIONS for not meeting a single LCO adequately manage any increase in plant risk, provided any unusual external conditions (e.g., severe weather, offsite power instability) are considered. In addition, the increased risk associated with simultaneous removal of multiple structures, systems, trains or components from service is assessed and managed in accordance with 10 CFR 50.65(a)(4). Individual Specifications may specify a time limit for performing an SR when equipment is removed from service or bypassed for testing. In this case, the Completion Times of the Required Actions are applicable when this time limit expires, if the equipment remains removed from service or bypassed.

When a change in MODE or other specified condition is required to comply with Required Actions, the unit may enter a MODE or other specified condition in which another Specification becomes applicable. In this case, the Completion Times of the associated Required Actions would apply from the point in time that the new Specification becomes applicable and the ACTIONS Condition(s) are entered.

LCO 3.0.3

LCO 3.0.3 establishes the actions that must be implemented when an LCO is not met and either:

a. An associated Required Action and Completion Time is not met and no other Condition applies or

b. The condition of the unit is not specifically addressed by the associated ACTIONS. This means that no combination of Conditions stated in the ACTIONS can be made that exactly corresponds to the actual condition of the unit. Sometimes, possible combinations of Conditions are such that entering LCO 3.0.3 is warranted; in such cases, the ACTIONS specifically state a Condition corresponding to such combinations and also that LCO 3.0.3 be entered immediately.

BASES

LCO 3.0.3 (continued)

This Specification delineates the time limits for placing the unit in a safe MODE or other specified condition when operation cannot be maintained within the limits for safe operation as defined by the LCO and its ACTIONS. Planned entry into LCO 3.0.3 should be avoided. If it is not practicable to avoid planned entry into LCO 3.0.3, plant risk should be assessed and managed in accordance with 10 CFR 50.65(a)(4), and the planned entry into LCO 3.0.3 should have less effect on plant safety than other practicable alternatives.

Upon entering LCO 3.0.3, 1 hour is allowed to prepare for an orderly shutdown before initiating a change in unit operation. This includes time to permit the operator to coordinate the reduction in electrical generation with the load dispatcher to ensure the stability and availability of the electrical grid. The time limits specified to enter lower MODES of operation permit the shutdown to proceed in a controlled and orderly manner that is well within the specified maximum cooldown rate and within the capabilities of the unit, assuming that only the minimum required equipment is OPERABLE. This reduces thermal stresses on components of the Reactor Coolant System and the potential for a plant upset that could challenge safety systems under conditions to which this Specification applies. The use and interpretation of specified times to complete the actions of LCO 3.0.3 are consistent with the discussion of Section 1.3, Completion Times.

A unit shutdown required in accordance with LCO 3.0.3 may be terminated and LCO 3.0.3 exited if any of the following occurs:

a. The LCO is now met,

b. The LCO is no longer applicable,

c. A Condition exists for which the Required Actions have now been performed, or

d. ACTIONS exist that do not have expired Completion Times. These Completion Times are applicable from the point in time that the Condition is initially entered and not from the time LCO 3.0.3 is exited.

The time limits of LCO 3.0.3 allow 37 hours for the unit to be in MODE 5 when a shutdown is required during MODE 1 operation. If the unit is in a lower MODE of operation when a shutdown is required, the time limit for entering the next lower MODE applies. If a lower MODE is entered in less time than allowed, however, the total allowable time to enter

BASES

LCO 3.0.3 (continued)

MODE 5, or other applicable MODE, is not reduced. For example, if MODE 3 is entered in 2 hours, then the time allowed for entering MODE 4 is the next 11 hours, because the total time for entering MODE 4 is not reduced from the allowable limit of 13 hours. Therefore, if remedial measures are completed that would permit a return to MODE 1, a penalty is not incurred by having to enter a lower MODE of operation in less than the total time allowed.

In MODES 1, 2, 3, and 4, LCO 3.0.3 provides actions for Conditions not covered in other Specifications. The requirements of LCO 3.0.3 do not apply in MODES 5 and 6 because the unit is already in the most restrictive Condition required by LCO 3.0.3. The requirements of LCO 3.0.3 do not apply in other specified conditions of the Applicability (unless in MODE 1, 2, 3, or 4) because the ACTIONS of individual Specifications sufficiently define the remedial measures to be taken.

Exceptions to LCO 3.0.3 are provided in instances where requiring a unit shutdown, in accordance with LCO 3.0.3, would not provide appropriate remedial measures for the associated condition of the unit. An example of this is in LCO 3.7.16, "Fuel Storage Pool Water Level." LCO 3.7.16 has an Applicability of "During movement of irradiated fuel assemblies in the fuel storage pool." Therefore, this LCO can be applicable in any or all MODES. If the LCO and the Required Actions of LCO 3.7.16 are not met while in MODE 1, 2, or 3, there is no safety benefit to be gained by placing the unit in a shutdown condition. The Required Action of LCO 3.7.16 of "Suspend movement of irradiated fuel assemblies in fuel storage pool" is the appropriate Required Action to complete in lieu of the actions of LCO 3.0.3. These exceptions are addressed in the individual Specifications.

Spent
3
spent
3
3
spent
1

[The requirement to be in MODE 4 in 13 hours is plant specific and depends on the ability to cool the pressurizer and degas.]

2

LCO 3.0.4

LCO 3.0.4 establishes limitations on changes in MODES or other specified conditions in the Applicability when an LCO is not met. It allows placing the unit in a MODE or other specified condition stated in that Applicability (e.g., the Applicability desired to be entered) when unit conditions are such that the requirements of the LCO would not be met, in accordance with either LCO 3.0.4.a, LCO 3.0.4.b, or LCO 3.0.4.c.

BASES

LCO 3.0.4 (continued)

LCO 3.0.4.a allows entry into a MODE or other specified condition in the Applicability with the LCO not met when the associated ACTIONS to be entered following entry into the MODE or other specified condition in the Applicability will permit continued operation within the MODE or other specified condition for an unlimited period of time. Compliance with ACTIONS that permit continued operation of the unit for an unlimited period of time in a MODE or other specified condition provides an acceptable level of safety for continued operation. This is without regard to the status of the unit before or after the MODE change. Therefore, in such cases, entry into a MODE or other specified condition in the Applicability may be made and the Required Actions followed after entry into the Applicability.

For example, LCO 3.0.4.a may be used when the Required Action to be entered states that an inoperable instrument channel must be placed in the trip condition within the Completion Time. Transition into a MODE or other specified in condition in the Applicability may be made in accordance with LCO 3.0.4 and the channel is subsequently placed in the tripped condition within the Completion Time, which begins when the Applicability is entered. If the instrument channel cannot be placed in the tripped condition and the subsequent default ACTION ("Required Action and associated Completion Time not met") allows the OPERABLE train to be placed in operation, use of LCO 3.0.4.a is acceptable because the subsequent ACTIONS to be entered following entry into the MODE include ACTIONS (place the OPERABLE train in operation) that permit safe plant operation for an unlimited period of time in the MODE or other specified condition to be entered.

LCO 3.0.4.b allows entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering the MODE or other specified condition in the Applicability, and establishment of risk management actions, if appropriate.

The risk assessment may use quantitative, qualitative, or blended approaches, and the risk assessment will be conducted using the plant program, procedures, and criteria in place to implement 10 CFR 50.65(a)(4), which requires that risk impacts of maintenance activities to be assessed and managed. The risk assessment, for the purposes of LCO 3.0.4.b, must take into account all inoperable Technical Specification equipment regardless of whether the equipment is included in the normal 10 CFR 50.65(a)(4) risk assessment scope. The risk

BASES

LCO 3.0.4 (continued)

assessments will be conducted using the procedures and guidance endorsed by Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants." Regulatory Guide 1.160 endorses the guidance in Section 11 of NUMARC 93-01, “Industry Guideline for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants.” These documents address general guidance for conduct of the risk assessment, quantitative and qualitative guidelines for establishing risk management actions, and example risk management actions. These include actions to plan and conduct other activities in a manner that controls overall risk, increased risk awareness by shift and management personnel, actions to reduce the duration of the condition, actions to minimize the magnitude of risk increases (establishment of backup success paths or compensatory measures), and determination that the proposed MODE change is acceptable. Consideration should also be given to the probability of completing restoration such that the requirements of the LCO would be met prior to the expiration of ACTIONS Completion Times that would require exiting the Applicability.

LCO 3.0.4.b may be used with single, or multiple systems and components unavailable. NUMARC 93-01 provides guidance relative to consideration of simultaneous unavailability of multiple systems and components.

The results of the risk assessment shall be considered in determining the acceptability of entering the MODE or other specified condition in the Applicability, and any corresponding risk management actions. The LCO 3.0.4.b risk assessments do not have to be documented.

The Technical Specifications allow continued operation with equipment unavailable in MODE 1 for the duration of the Completion Time. Since this is allowable, and since in general the risk impact in that particular MODE bounds the risk of transitioning into and through the applicable MODES or other specified conditions in the Applicability of the LCO, the use of the LCO 3.0.4.b allowance should be generally acceptable, as long as the risk is assessed and managed as stated above. However, there is a small subset of systems and components that have been determined to be more important to risk and use of the LCO 3.0.4.b allowance is prohibited. The LCOs governing these systems and components contain Notes prohibiting the use of LCO 3.0.4.b by stating that LCO 3.0.4.b is not applicable.

BASES

LCO 3.0.4 (continued)

LCO 3.0.4.c allows entry into a MODE or other specified condition in the Applicability with the LCO not met based on a Note in the Specification which states LCO 3.0.4.c is applicable. These specific allowances permit entry into MODES or other specified conditions in the Applicability when the associated ACTIONS to be entered do not provide for continued operation for an unlimited period of time and a risk assessment has not been performed. This allowance may apply to all the ACTIONS or to a specific Required Action of a Specification. The risk assessments performed to justify the use of LCO 3.0.4.b usually only consider systems and components. For this reason, LCO 3.0.4.c is typically applied to Specifications which describe values and parameters (e.g., RCS Specific Activity), and may be applied to other Specifications based on NRC plant specific approval.

The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or components to OPERABLE status before entering an associated MODE or other specified condition in the Applicability.

The provisions of LCO 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of LCO 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that result from any unit shutdown. In this context, a unit shutdown is defined as a change in MODE or other specified condition in the Applicability associated with transitioning from MODE 1 to MODE 2, MODE 2 to MODE 3, MODE 3 to MODE 4, and MODE 4 to MODE 5.

Upon entry into a MODE or other specified condition in the Applicability with the LCO not met, LCO 3.0.1 and LCO 3.0.2 require entry into the applicable Conditions and Required Actions until the Condition is resolved, until the LCO is met, or until the unit is not within the Applicability of the Technical Specification.

Surveillances do not have to be performed on the associated inoperable equipment (or on variables outside the specified limits), as permitted by SR 3.0.1. Therefore, utilizing LCO 3.0.4 is not a violation of SR 3.0.1 or SR 3.0.4 for any Surveillances that have not been performed on inoperable equipment. However, SRs must be met to ensure OPERABILITY prior to declaring the associated equipment OPERABLE (or variable within limits) and restoring compliance with the affected LCO.

BASES

LCO 3.0.5

LCO 3.0.5 establishes the allowance for restoring equipment to service under administrative controls when it has been removed from service or declared inoperable to comply with ACTIONS. The sole purpose of this Specification is to provide an exception to LCO 3.0.2 (e.g., to not comply with the applicable Required Action(s)) to allow the performance of required testing to demonstrate either:

a. The OPERABILITY of the equipment being returned to service or

b. The OPERABILITY of other equipment.

The administrative controls ensure the time the equipment is returned to service in conflict with the requirements of the ACTIONS is limited to the time absolutely necessary to perform the required testing to demonstrate OPERABILITY. This Specification does not provide time to perform any other preventive or corrective maintenance. LCO 3.0.5 should not be used in lieu of other practicable alternatives that comply with Required Actions and that do not require changing the MODE or other specified conditions in the Applicability in order to demonstrate equipment is OPERABLE. LCO 3.0.5 is not intended to be used repeatedly.

An example of demonstrating equipment is OPERABLE with the Required Actions not met is opening a manual valve that was closed to comply with Required Actions to isolate a flowpath with excessive Reactor Coolant System (RCS) Pressure Isolation Valve (PIV) leakage in order to perform testing to demonstrate that RCS PIV leakage is now within limit.

Examples of demonstrating equipment OPERABILITY include instances in which it is necessary to take an inoperable channel or trip system out of a tripped condition that was directed by a Required Action, if there is no Required Action Note for this purpose. An example of verifying OPERABILITY of equipment removed from service is taking a tripped channel out of the tripped condition to permit the logic to function and indicate the appropriate response during performance of required testing on the inoperable channel. Examples of demonstrating the OPERABILITY of other equipment are taking an inoperable channel or trip system out of the tripped condition 1) to prevent the trip function from occurring during the performance of required testing on another channel in the other trip system, or 2) to permit the logic to function and indicate the appropriate response during the performance of required testing on another channel in the same trip system.

BASES

LCO 3.0.5 (continued)

The administrative controls in LCO 3.0.5 apply in all cases to systems or components in Chapter 3 of the Technical Specifications, as long as the testing could not be conducted while complying with the Required Actions. This includes the realignment or repositioning of redundant or alternate equipment or trains previously manipulated to comply with ACTIONS, as well as equipment removed from service or declared inoperable to comply with ACTIONS.

LCO 3.0.6

LCO 3.0.6 establishes an exception to LCO 3.0.2 for supported systems that have a support system LCO specified in the Technical Specifications (TS). This exception is provided because LCO 3.0.2 would require that the Conditions and Required Actions of the associated inoperable supported system LCO be entered solely due to the inoperability of the support system. This exception is justified because the actions that are required to ensure the unit is maintained in a safe condition are specified in the support system LCO's Required Actions. These Required Actions may include entering the supported system's Conditions and Required Actions or may specify other Required Actions.

When a support system is inoperable and there is an LCO specified for it in the TS, the supported system(s) are required to be declared inoperable if determined to be inoperable as a result of the support system inoperability. However, it is not necessary to enter into the supported systems' Conditions and Required Actions unless directed to do so by the support system's Required Actions. The potential confusion and inconsistency of requirements related to the entry into multiple support and supported systems' LCOs' Conditions and Required Actions are eliminated by providing all the actions that are necessary to ensure the unit is maintained in a safe condition in the support system's Required Actions.

However, there are instances where a support system's Required Action may either direct a supported system to be declared inoperable or direct entry into Conditions and Required Actions for the supported system. This may occur immediately or after some specified delay to perform some other Required Action. Regardless of whether it is immediate or after some delay, when a support system's Required Action directs a supported system to be declared inoperable or directs entry into Conditions and Required Actions for a supported system, the applicable Conditions and Required Actions shall be entered in accordance with LCO 3.0.2.

BASES

LCO 3.0.6 (continued)

Specification 5.5.14, "Safety Function Determination Program (SFDP)," ensures loss of safety function is detected and appropriate actions are taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other limitations, remedial actions, or compensatory actions may be identified as a result of the support system inoperability and corresponding exception to entering supported system Conditions and Required Actions. The SFDP implements the requirements of LCO 3.0.6.

The following examples use Figure B 3.0-1 to illustrate loss of safety function conditions that may result when a TS support system is inoperable. In this figure, the fifteen systems that comprise Train A are independent and redundant to the fifteen systems that comprise Train B. To correctly use the figure to illustrate the SFDP provisions for a cross train check, the figure establishes a relationship between support and supported systems as follows: the figure shows System 1 as a support system for System 2 and System 3; System 2 as a support system for System 4 and System 5; and System 4 as a support system for System 8 and System 9. Specifically, a loss of safety function may exist when a support system is inoperable and:

a. A system redundant to system(s) supported by the inoperable support system is also inoperable (EXAMPLE B 3.0.6-1),

b. A system redundant to system(s) in turn supported by the inoperable supported system is also inoperable (EXAMPLE B 3.0.6-2), or

c. A system redundant to support system(s) for the supported systems (a) and (b) above is also inoperable (EXAMPLE B 3.0.6-3).

For the following examples, refer to Figure B 3.0-1.

EXAMPLE B 3.0.6-1

If System 2 of Train A is inoperable and System 5 of Train B is inoperable, a loss of safety function exists in Systems 5, 10, and 11.

EXAMPLE B 3.0.6-2

If System 2 of Train A is inoperable, and System 11 of Train B is inoperable, a loss of safety function exists in System 11.

BASES

LCO 3.0.6 (continued)

EXAMPLE B 3.0.6-3

If System 2 of Train A is inoperable, and System 1 of Train B is inoperable, a loss of safety function exists in Systems 2, 4, 5, 8, 9, 10 and 11.

If an evaluation determines that a loss of safety function exists, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.

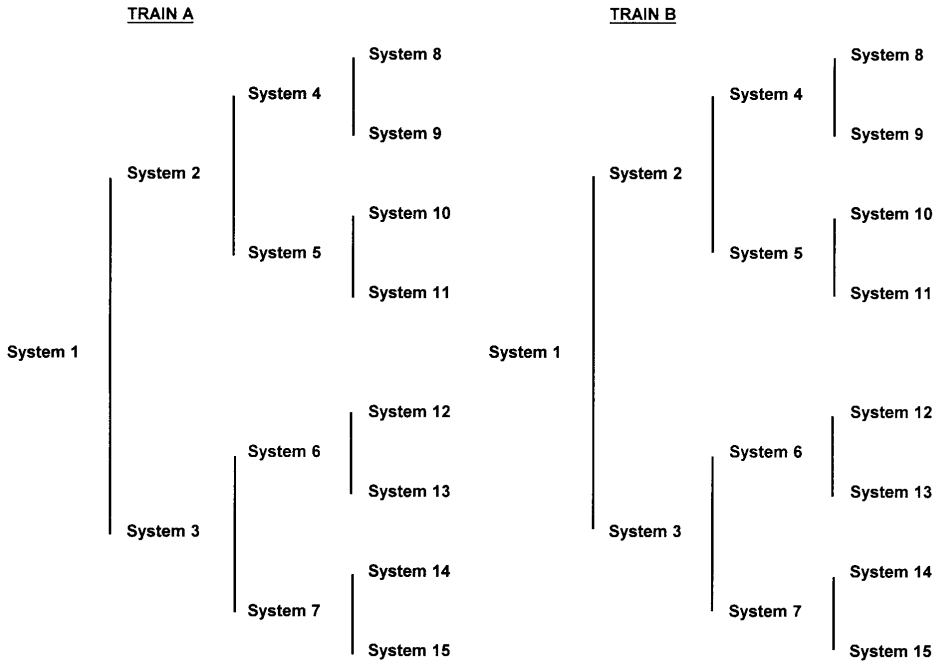

Figure B 3.0-1
Configuration of Trains and Systems

This loss of safety function does not require the assumption of additional single failures or loss of offsite power. Since operations are being restricted in accordance with the ACTIONS of the support system, any resulting temporary loss of redundancy or single failure protection is taken into account. Similarly, the ACTIONS for inoperable offsite circuit(s) and inoperable diesel generator(s) provide the necessary restriction for cross train inoperabilities. This explicit cross train verification for inoperable AC

BASES

LCO 3.0.6 (continued)

electrical power sources also acknowledges that supported system(s) are not declared inoperable solely as a result of inoperability of a normal or emergency electrical power source (refer to the definition of OPERABILITY).

When loss of safety function is determined to exist, and the SFDP requires entry into the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists, consideration must be given to the specific type of function affected. Where a loss of function is solely due to a single Technical Specification support system (e.g., loss of automatic start due to inoperable instrumentation, or loss of pump suction source due to low tank level) the appropriate LCO is the LCO for the support system. The ACTIONS for a support system LCO adequately address the inoperabilities of that system without reliance on entering its supported system LCO. When the loss of function is the result of multiple support systems, the appropriate LCO is the LCO for the supported system.

LCO 3.0.7

Special tests and operations are required at various times over the unit's life to demonstrate performance characteristics, to perform maintenance activities, and to perform special evaluations. Because TS normally preclude these tests and operations, special test exceptions (STEs) allow specified requirements to be changed or suspended under controlled conditions. STEs are included in applicable sections of the Specifications. Unless otherwise specified, all other TS requirements remain unchanged and in effect as applicable. This will ensure that all appropriate requirements of the MODE or other specified condition not directly associated with or required to be changed or suspended to perform the special test or operation will remain in effect.

The Applicability of an STE LCO represents a condition not necessarily in compliance with the normal requirements of the TS. Compliance with STE LCOs is optional.

A special test may be performed under either the provisions of the appropriate STE LCO or the other applicable TS requirements. If it is desired to perform the special test under the provisions of the STE LCO, the requirements of the STE LCO shall be followed. This includes the SRs specified in the STE LCO.

Some of the STE LCOs require that one or more of the LCOs for normal operation be met (i.e., meeting the STE LCO requires meeting the specified normal LCOs). The Applicability, ACTIONS, and SRs of the specified normal LCOs, however, are not required to be met in order to meet the STE LCO when it is in effect. This means that, upon failure to meet a specified normal LCO, the associated ACTIONS of the STE LCO

BASES

LCO 3.0.7 (continued)

apply, in lieu of the ACTIONS of the normal LCO. Exceptions to the above do exist. There are instances when the Applicability of the specified normal LCO must be met, where its ACTIONS must be taken, where certain of its Surveillances must be performed, or where all of these requirements must be met concurrently with the requirements of the STE LCO.

Unless the SRs of the specified normal LCOs are suspended or changed by the special test, those SRs that are necessary to meet the specified normal LCOs must be met prior to performing the special test. During the conduct of the special test, those Surveillances need not be performed unless specified by the ACTIONS or SRs of the STE LCO.

ACTIONS for STE LCOs provide appropriate remedial measures upon failure to meet the STE LCO. Upon failure to meet these ACTIONS, suspend the performance of the special test and enter the ACTIONS for all LCOs that are then not met. Entry into LCO 3.0.3 may possibly be required, but this determination should not be made by considering only the failure to meet the ACTIONS of the STE LCO.

LCO 3.0.8

LCO 3.0.8 establishes conditions under which systems are considered to remain capable of performing their intended safety function when associated snubbers are not capable of providing their associated support function(s). This LCO states that the supported system is not considered to be inoperable solely due to one or more snubbers not capable of performing their associated support function(s). This is appropriate because a limited length of time is allowed for maintenance, testing, or repair of one or more snubbers not capable of performing their associated support function(s) and appropriate compensatory measures are specified in the snubber requirements, which are located outside of the Technical Specifications (TS) under licensee control. The snubber requirements do not meet the criteria in 10 CFR 50.36(c)(2)(ii), and, as such, are appropriate for control by the licensee.

If the allowed time expires and the snubber(s) are unable to perform their associated support function(s), the affected supported system's LCO(s) must be declared not met and the Conditions and Required Actions entered in accordance with LCO 3.0.2.

LCO 3.0.8.a applies when one or more snubbers are not capable of providing their associated support function(s) to a single train or subsystem of a multiple train or subsystem supported system or to a single train or subsystem supported system. LCO 3.0.8.a allows 72 hours to restore the snubber(s) before declaring the supported system

BASES

LCO 3.0.8 (continued)

inoperable. The 72 hour Completion Time is reasonable based on the low probability of a seismic event concurrent with an event that would require operation of the supported system occurring while the snubber(s) are not capable of performing their associated support function and due to the availability of the redundant train of the supported system.

LCO 3.0.8.b applies when one or more snubbers are not capable of providing their associated support function(s) to more than one train or subsystem of a multiple train or subsystem supported system. LCO 3.0.8.b allows 12 hours to restore the snubber(s) before declaring the supported system inoperable. The 12 hour Completion Time is reasonable based on the low probability of a seismic event concurrent with an event that would require operation of the supported system occurring while the snubber(s) are not capable of performing their associated support function.

LCO 3.0.8 requires that risk be assessed and managed. Industry and NRC guidance on the implementation of 10 CFR 50.65(a)(4) (the Maintenance Rule) does not address seismic risk. However, use of LCO 3.0.8 should be considered with respect to other plant maintenance activities, and integrated into the existing Maintenance Rule process to the extent possible so that maintenance on any unaffected train or subsystem is properly controlled, and emergent issues are properly addressed. The risk assessment need not be quantified, but may be a qualitative awareness of the vulnerability of systems and components when one or more snubbers are not able to perform their associated support function.

LCO 3.0.9

~~REVIEWER'S NOTE~~

~~Adoption of LCO 3.0.9 requires the licensee to make the following commitments:~~

~~1. [LICENSEE] commits to the guidance of NUMARC 93-01, Revision [4F], Section 11, which provides guidance and details on the assessment and management of risk during maintenance.~~

~~2. [LICENSEE] commits to the guidance of NEI 04-08, "Allowance for Non Technical Specification Barrier Degradation on Supported System OPERABILITY (TSTF-427) Industry Implementation Guidance," March 2006.~~

LCO 3.0.9 establishes conditions under which systems described in the Technical Specifications are considered to remain OPERABLE when required barriers are not capable of providing their related support function(s).

BASES

LCO 3.0.9 (continued)

Barriers are doors, walls, floor plugs, curbs, hatches, installed structures or components, or other devices, not explicitly described in Technical Specifications, that support the performance of the safety function of systems described in the Technical Specifications. This LCO states that the supported system is not considered to be inoperable solely due to required barriers not capable of performing their related support function(s) under the described conditions. LCO 3.0.9 allows 30 days before declaring the supported system(s) inoperable and the LCO(s) associated with the supported system(s) not met. A maximum time is placed on each use of this allowance to ensure that as required barriers are found or are otherwise made unavailable, they are restored. However, the allowable duration may be less than the specified maximum time based on the risk assessment.

If the allowed time expires and the barriers are unable to perform their related support function(s), the supported system's LCO(s) must be declared not met and the Conditions and Required Actions entered in accordance with LCO 3.0.2.

This provision does not apply to barriers which support ventilation systems or to fire barriers. The Technical Specifications for ventilation systems provide specific Conditions for inoperable barriers. Fire barriers are addressed by other regulatory requirements and associated plant programs. This provision does not apply to barriers which are not required to support system OPERABILITY (see NRC Regulatory Issue Summary 2001-09, "Control of Hazard Barriers," dated April 2, 2001).

The provisions of LCO 3.0.9 are justified because of the low risk associated with required barriers not being capable of performing their related support function. This provision is based on consideration of the following initiating event categories:

~~REVIEWER'S NOTE~~

~~LCO 3.0.9 may be expanded to other initiating event categories provided plant-specific analysis demonstrates that the frequency of the additional initiating events is bounded by the generic analysis or if plant-specific approval is obtained from the NRC.~~

3

- Loss of coolant accidents;
- High energy line breaks;
- Feedwater line breaks;
- Internal flooding;
- External flooding;
- Turbine missile ejection; and
- Tornado or high wind.

BASES

LCO 3.0.9 (continued)

The risk impact of the barriers which cannot perform their related support function(s) must be addressed pursuant to the risk assessment and management provision of the Maintenance Rule, 10 CFR 50.65 (a)(4), and the associated implementation guidance, Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants." Regulatory Guide 1.160 endorses the guidance in Section 11 of NUMARC 93-01, "Industry Guideline for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants." This guidance provides for the consideration of dynamic plant configuration issues, emergent conditions, and other aspects pertinent to plant operation with the barriers unable to perform their related support function(s). These considerations may result in risk management and other compensatory actions being required during the period that barriers are unable to perform their related support function(s).

LCO 3.0.9 may be applied to one or more trains or subsystems of a system supported by barriers that cannot provide their related support function(s), provided that risk is assessed and managed (including consideration of the effects on Large Early Release and from external events). If applied concurrently to more than one train or subsystem of a multiple train or subsystem supported system, the barriers supporting each of these trains or subsystems must provide their related support function(s) for different categories of initiating events. For example, LCO 3.0.9 may be applied for up to 30 days for more than one train of a multiple train supported system if the affected barrier for one train protects against internal flooding and the affected barrier for the other train protects against tornado missiles. In this example, the affected barrier may be the same physical barrier but serve different protection functions for each train.

If during the time that LCO 3.0.9 is being used, the required OPERABLE train or subsystem becomes inoperable, it must be restored to OPERABLE status within 24 hours. Otherwise, the train(s) or subsystem(s) supported by barriers that cannot perform their related support function(s) must be declared inoperable and the associated LCOs declared not met. This 24 hour period provides time to respond to emergent conditions that would otherwise likely lead to entry into LCO 3.0.3 and a rapid plant shutdown, which is not justified given the low probability of an initiating event which would require the barrier(s) not capable of performing their related support function(s). During this 24 hour period, the plant risk associated with the existing conditions is assessed and managed in accordance with 10 CFR 50.65(a)(4).

B 3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY

BASES

SRs	SR 3.0.1 through SR 3.0.4 establish the general requirements applicable to all Specifications and apply at all times, unless otherwise stated. SR 3.0.2 and SR 3.0.3 apply in Chapter 5 only when invoked by a Chapter 5 Specification.
SR 3.0.1	SR 3.0.1 establishes the requirement that SRs must be met during the MODES or other specified conditions in the Applicability for which the requirements of the LCO apply, unless otherwise specified in the individual SRs. This Specification is to ensure that Surveillances are performed to verify the OPERABILITY of systems and components, and that variables are within specified limits. Failure to meet a Surveillance within the specified Frequency, in accordance with SR 3.0.2, constitutes a failure to meet an LCO. Surveillances may be performed by means of any series of sequential, overlapping, or total steps provided the entire Surveillance is performed within the specified Frequency. Additionally, the definitions related to instrument testing (e.g., CHANNEL CALIBRATION) specify that these tests are performed by means of any series of sequential, overlapping, or total steps. Systems and components are assumed to be OPERABLE when the associated SRs have been met. Nothing in this Specification, however, is to be construed as implying that systems or components are OPERABLE when either: a. The systems or components are known to be inoperable, although still meeting the SRs or b. The requirements of the Surveillance(s) are known to be not met between required Surveillance performances. Surveillances do not have to be performed when the unit is in a MODE or other specified condition for which the requirements of the associated LCO are not applicable, unless otherwise specified. The SRs associated with a special test exception (STE) are only applicable when the STE is used as an allowable exception to the requirements of a Specification. Unplanned events may satisfy the requirements (including applicable acceptance criteria) for a given SR. In this case, the unplanned event may be credited as fulfilling the performance of the SR. This allowance includes those SRs whose performance is normally precluded in a given MODE or other specified condition.

BASES

SR 3.0.1 (continued)

Surveillances, including Surveillances invoked by Required Actions, do not have to be performed on inoperable equipment because the ACTIONS define the remedial measures that apply. Surveillances have to be met and performed in accordance with SR 3.0.2, prior to returning equipment to OPERABLE status.

Upon completion of maintenance, appropriate post maintenance testing is required to declare equipment OPERABLE. This includes ensuring applicable Surveillances are not failed and their most recent performance is in accordance with SR 3.0.2. Post maintenance testing may not be possible in the current MODE or other specified conditions in the Applicability due to the necessary unit parameters not having been established. In these situations, the equipment may be considered OPERABLE provided testing has been satisfactorily completed to the extent possible and the equipment is not otherwise believed to be incapable of performing its function. This will allow operation to proceed to a MODE or other specified condition where other necessary post maintenance tests can be completed.

Some examples of this process are:

a. Auxiliary feedwater (AFW) pump turbine maintenance during refueling that requires testing at steam pressures > 800 psi. However, if other appropriate testing is satisfactorily completed, the AFW System can be considered OPERABLE. This allows startup and other necessary testing to proceed until the plant reaches the steam pressure required to perform the testing.

b. High pressure safety injection (HPSI) maintenance during shutdown that requires system functional tests at a specified pressure. Provided other appropriate testing is satisfactorily completed, startup can proceed with HPSI considered OPERABLE. This allows operation to reach the specified pressure to complete the necessary post maintenance testing.

SR 3.0.2

SR 3.0.2 establishes the requirements for meeting the specified Frequency for Surveillances and any Required Action with a Completion Time that requires the periodic performance of the Required Action on a "once per..." interval.

SR 3.0.2 permits a 25% extension of the interval specified in the Frequency. This extension facilitates Surveillance scheduling and considers plant operating conditions that may not be suitable for conducting the Surveillance (e.g., transient conditions or other ongoing Surveillance or maintenance activities).

BASES

SR 3.0.2 (continued)

When a Section 5.5, "Programs and Manuals," specification states that the provisions of SR 3.0.2 are applicable, a 25% extension of the testing interval, whether stated in the specification or incorporated by reference, is permitted.

The 25% extension does not significantly degrade the reliability that results from performing the Surveillance at its specified Frequency. This is based on the recognition that the most probable result of any particular Surveillance being performed is the verification of conformance with the SRs.

The exceptions to SR 3.0.2 are those Surveillances for which the 25% extension of the interval specified in the Frequency does not apply. These exceptions are stated in the individual Specifications. The requirements of regulations take precedence over the TS. Examples of where SR 3.0.2 does not apply are the Containment Leakage Rate Testing Program required by 10 CFR 50, Appendix J, and the inservice testing of pumps and valves in accordance with applicable American Society of Mechanical Engineers Operation and Maintenance Code, as required by 10 CFR 50.55a. These programs establish testing requirements and Frequencies in accordance with the requirements of regulations. The TS cannot in and of themselves extend a test interval specified in the regulations directly or by reference.

As stated in SR 3.0.2, the 25% extension also does not apply to the initial portion of a periodic Completion Time that requires performance on a "once per ..." basis. The 25% extension applies to each performance after the initial performance. The initial performance of the Required Action, whether it is a particular Surveillance or some other remedial action, is considered a single action with a single Completion Time. One reason for not allowing the 25% extension to this Completion Time is that such an action usually verifies that no loss of function has occurred by checking the status of redundant or diverse components or accomplishes the function of the inoperable equipment in an alternative manner.

The provisions of SR 3.0.2 are not intended to be used repeatedly to extend Surveillance intervals (other than those consistent with refueling intervals) or periodic Completion Time intervals beyond those specified.

SR 3.0.3

SR 3.0.3 establishes the flexibility to defer declaring affected equipment inoperable or an affected variable outside the specified limits when a Surveillance has not been performed within the specified Frequency. A delay period of up to 24 hours or up to the limit of the specified

BASES

SR 3.0.3 (continued)

Frequency, whichever is greater, applies from the point in time that it is discovered that the Surveillance has not been performed in accordance with SR 3.0.2, and not at the time that the specified Frequency was not met.

When a Section 5.5, "Programs and Manuals," specification states that the provisions of SR 3.0.3 are applicable, it permits the flexibility to defer declaring the testing requirement not met in accordance with SR 3.0.3 when the testing has not been completed within the testing interval (including the allowance of SR 3.0.2 if invoked by the Section 5.5 specification).

This delay period provides adequate time to perform Surveillances that have been missed. This delay period permits the performance of a Surveillance before complying with Required Actions or other remedial measures that might preclude performance of the Surveillance.

The basis for this delay period includes consideration of unit conditions, adequate planning, availability of personnel, the time required to perform the Surveillance, the safety significance of the delay in completing the required Surveillance, and the recognition that the most probable result of any particular Surveillance being performed is the verification of conformance with the requirements.

When a Surveillance with a Frequency based not on time intervals, but upon specified unit conditions, operating situations, or requirements of regulations (e.g., prior to entering MODE 1 after each fuel loading, or in accordance with 10 CFR 50, Appendix J, as modified by approved exemptions, etc.) is discovered to not have been performed when specified, SR 3.0.3 allows for the full delay period of up to the specified Frequency to perform the Surveillance. However, since there is not a time interval specified, the missed Surveillance should be performed at the first reasonable opportunity.

SR 3.0.3 provides a time limit for, and allowances for the performance of, Surveillances that become applicable as a consequence of MODE changes imposed by Required Actions.

SR 3.0.3 is only applicable if there is a reasonable expectation the associated equipment is OPERABLE or that variables are within limits, and it is expected that the Surveillance will be met when performed. Many factors should be considered, such as the period of time since the Surveillance was last performed, or whether the Surveillance, or a portion thereof, has ever been performed, and any other indications, tests, or

BASES

SR 3.0.3 (continued)

activities that might support the expectation that the Surveillance will be met when performed. An example of the use of SR 3.0.3 would be a relay contact that was not tested as required in accordance with a particular SR, but previous successful performances of the SR included the relay contact; the adjacent, physically connected relay contacts were tested during the SR performance; the subject relay contact has been tested by another SR; or historical operation of the subject relay contact has been successful. It is not sufficient to infer the behavior of the associated equipment from the performance of similar equipment. The rigor of determining whether there is a reasonable expectation a Surveillance will be met when performed should increase based on the length of time since the last performance of the Surveillance. If the Surveillance has been performed recently, a review of the Surveillance history and equipment performance may be sufficient to support a reasonable expectation that the Surveillance will be met when performed. For Surveillances that have not been performed for a long period or that have never been performed, a rigorous evaluation based on objective evidence should provide a high degree of confidence that the equipment is OPERABLE. The evaluation should be documented in sufficient detail to allow a knowledgeable individual to understand the basis for the determination.

Failure to comply with specified Frequencies for SRs is expected to be an infrequent occurrence. Use of the delay period established by SR 3.0.3 is a flexibility which is not intended to be used repeatedly to extend Surveillance intervals. While up to 24 hours or the limit of the specified Frequency is provided to perform the missed Surveillance, it is expected that the missed Surveillance will be performed at the first reasonable opportunity. The determination of the first reasonable opportunity should include consideration of the impact on plant risk (from delaying the Surveillance as well as any plant configuration changes required or shutting the plant down to perform the Surveillance) and impact on any analysis assumptions, in addition to unit conditions, planning, availability of personnel, and the time required to perform the Surveillance. This risk impact should be managed through the program in place to implement 10 CFR 50.65(a)(4) and its implementation guidance, NRC Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants." This Regulatory Guide addresses consideration of temporary and aggregate risk impacts, determination of risk management action thresholds, and risk management action up to and including plant shutdown. The missed Surveillance should be treated as an emergent condition as discussed in the Regulatory Guide. The risk evaluation may use quantitative, qualitative, or blended methods. The degree of depth and rigor of the evaluation should be commensurate with the importance of the component. Missed Surveillances for important

BASES

SR 3.0.3 (continued)

components should be analyzed quantitatively. If the results of the risk evaluation determine the risk increase is significant, this evaluation should be used to determine the safest course of action. All missed Surveillances will be placed in the licensee's Corrective Action Program.

If a Surveillance is not completed within the allowed delay period, then the equipment is considered inoperable or the variable is considered outside the specified limits and the Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon expiration of the delay period. If a Surveillance is failed within the delay period, then the equipment is inoperable, or the variable is outside the specified limits and the Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon the failure of the Surveillance.

Completion of the Surveillance within the delay period allowed by this Specification, or within the Completion Time of the ACTIONS, restores compliance with SR 3.0.1.

SR 3.0.4

SR 3.0.4 establishes the requirement that all applicable SRs must be met before entry into a MODE or other specified condition in the Applicability.

This Specification ensures that system and component OPERABILITY requirements and variable limits are met before entry into MODES or other specified conditions in the Applicability for which these systems and components ensure safe operation of the unit. The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or components to OPERABLE status before entering an associated MODE or other specified condition in the Applicability.

A provision is included to allow entry into a MODE or other specified condition in the Applicability when an LCO is not met due to a Surveillance not being met in accordance with LCO 3.0.4.

However, in certain circumstances, failing to meet an SR will not result in SR 3.0.4 restricting a MODE change or other specified condition change. When a system, subsystem, division, component, device, or variable is inoperable or outside its specified limits, the associated SR(s) are not required to be performed, per SR 3.0.1, which states that surveillances do not have to be performed on inoperable equipment. When equipment is inoperable, SR 3.0.4 does not apply to the associated SR(s) since the requirement for the SR(s) to be performed is removed. Therefore, failing

BASES

SR 3.0.4 (continued)

to perform the Surveillance(s) within the specified Frequency does not result in an SR 3.0.4 restriction to changing MODES or other specified conditions of the Applicability. However, since the LCO is not met in this instance, LCO 3.0.4 will govern any restrictions that may (or may not) apply to MODE or other specified condition changes. SR 3.0.4 does not restrict changing MODES or other specified conditions of the Applicability when a Surveillance has not been performed within the specified Frequency, provided the requirement to declare the LCO not met has been delayed in accordance with SR 3.0.3.

The provisions of SR 3.0.4 shall not prevent entry into MODES or other specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of SR 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that result from any unit shutdown. In this context, a unit shutdown is defined as a change in MODE or other specified condition in the Applicability associated with transitioning from MODE 1 to MODE 2, MODE 2 to MODE 3, MODE 3 to MODE 4, and MODE 4 to MODE 5.

The precise requirements for performance of SRs are specified such that exceptions to SR 3.0.4 are not necessary. The specific time frames and conditions necessary for meeting the SRs are specified in the Frequency, in the Surveillance, or both. This allows performance of Surveillances when the prerequisite condition(s) specified in a Surveillance procedure require entry into the MODE or other specified condition in the Applicability of the associated LCO prior to the performance or completion of a Surveillance. A Surveillance that could not be performed until after entering the LCO's Applicability, would have its Frequency specified such that it is not "due" until the specific conditions needed are met. Alternately, the Surveillance may be stated in the form of a Note, as not required (to be met or performed) until a particular event, condition, or time has been reached. Further discussion of the specific formats of SRs' annotation is found in Section 1.4, Frequency.

B 3.0 LIMITING CONDITION FOR OPERATION (LCO) APPLICABILITY

BASES

LCOs	LCO 3.0.1 through LCO 3.0.9 establish the general requirements applicable to all Specifications and apply at all times unless otherwise stated.
LCO 3.0.1	LCO 3.0.1 establishes the Applicability statement within each individual Specification as the requirement for when the LCO is required to be met (i.e., when the unit is in the MODES or other specified conditions of the Applicability statement of each Specification).
LCO 3.0.2	LCO 3.0.2 establishes that upon discovery of a failure to meet an LCO, the associated ACTIONS shall be met. The Completion Time of each Required Action for an ACTIONS Condition is applicable from the point in time that an ACTIONS Condition is entered, unless otherwise specified. The Required Actions establish those remedial measures that must be taken within specified Completion Times when the requirements of an LCO are not met. This Specification establishes that: a. Completion of the Required Actions within the specified Completion Times constitutes compliance with a Specification and b. Completion of the Required Actions is not required when an LCO is met within the specified Completion Time, unless otherwise specified. There are two basic types of Required Actions. The first type of Required Action specifies a time limit in which the LCO must be met. This time limit is the Completion Time to restore an inoperable system or component to OPERABLE status or to restore variables to within specified limits. If this type of Required Action is not completed within the specified Completion Time, a shutdown may be required to place the unit in a MODE or condition in which the Specification is not applicable. (Whether stated as a Required Action or not, correction of the entered Condition is an action that may always be considered upon entering ACTIONS.) The second type of Required Action specifies the remedial measures that permit continued operation of the unit that is not further restricted by the Completion Time. In this case, compliance with the Required Actions provides an acceptable level of safety for continued operation. Completing the Required Actions is not required when an LCO is met or is no longer applicable, unless otherwise stated in the individual Specifications.

BASES

LCO 3.0.2 (continued)

The nature of some Required Actions of some Conditions necessitates that, once the Condition is entered, the Required Actions must be completed even though the associated Conditions no longer exist. The individual LCO's ACTIONS specify the Required Actions where this is the case. An example of this is in LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits."

The Completion Times of the Required Actions are also applicable when a system or component is removed from service intentionally. The ACTIONS for not meeting a single LCO adequately manage any increase in plant risk, provided any unusual external conditions (e.g., severe weather, offsite power instability) are considered. In addition, the increased risk associated with simultaneous removal of multiple structures, systems, trains or components from service is assessed and managed in accordance with 10 CFR 50.65(a)(4). Individual Specifications may specify a time limit for performing an SR when equipment is removed from service or bypassed for testing. In this case, the Completion Times of the Required Actions are applicable when this time limit expires, if the equipment remains removed from service or bypassed.

When a change in MODE or other specified condition is required to comply with Required Actions, the unit may enter a MODE or other specified condition in which another Specification becomes applicable. In this case, the Completion Times of the associated Required Actions would apply from the point in time that the new Specification becomes applicable and the ACTIONS Condition(s) are entered.

LCO 3.0.3

LCO 3.0.3 establishes the actions that must be implemented when an LCO is not met and either:

a. An associated Required Action and Completion Time is not met and no other Condition applies or

b. The condition of the unit is not specifically addressed by the associated ACTIONS. This means that no combination of Conditions stated in the ACTIONS can be made that exactly corresponds to the actual condition of the unit. Sometimes, possible combinations of Conditions are such that entering LCO 3.0.3 is warranted; in such cases, the ACTIONS specifically state a Condition corresponding to such combinations and also that LCO 3.0.3 be entered immediately.

BASES

LCO 3.0.3 (continued)

This Specification delineates the time limits for placing the unit in a safe MODE or other specified condition when operation cannot be maintained within the limits for safe operation as defined by the LCO and its ACTIONS. Planned entry into LCO 3.0.3 should be avoided. If it is not practicable to avoid planned entry into LCO 3.0.3, plant risk should be assessed and managed in accordance with 10 CFR 50.65(a)(4), and the planned entry into LCO 3.0.3 should have less effect on plant safety than other practicable alternatives.

Upon entering LCO 3.0.3, 1 hour is allowed to prepare for an orderly shutdown before initiating a change in unit operation. This includes time to permit the operator to coordinate the reduction in electrical generation with the load dispatcher to ensure the stability and availability of the electrical grid. The time limits specified to enter lower MODES of operation permit the shutdown to proceed in a controlled and orderly manner that is well within the specified maximum cooldown rate and within the capabilities of the unit, assuming that only the minimum required equipment is OPERABLE. This reduces thermal stresses on components of the Reactor Coolant System and the potential for a plant upset that could challenge safety systems under conditions to which this Specification applies. The use and interpretation of specified times to complete the actions of LCO 3.0.3 are consistent with the discussion of Section 1.3, Completion Times.

A unit shutdown required in accordance with LCO 3.0.3 may be terminated and LCO 3.0.3 exited if any of the following occurs:

a. The LCO is now met,

b. The LCO is no longer applicable,

c. A Condition exists for which the Required Actions have now been performed, or

d. ACTIONS exist that do not have expired Completion Times. These Completion Times are applicable from the point in time that the Condition is initially entered and not from the time LCO 3.0.3 is exited.

The time limits of LCO 3.0.3 allow 37 hours for the unit to be in MODE 5 when a shutdown is required during MODE 1 operation. If the unit is in a lower MODE of operation when a shutdown is required, the time limit for entering the next lower MODE applies. If a lower MODE is entered in less time than allowed, however, the total allowable time to enter

BASES

LCO 3.0.3 (continued)

MODE 5, or other applicable MODE, is not reduced. For example, if MODE 3 is entered in 2 hours, then the time allowed for entering MODE 4 is the next 11 hours, because the total time for entering MODE 4 is not reduced from the allowable limit of 13 hours. Therefore, if remedial measures are completed that would permit a return to MODE 1, a penalty is not incurred by having to enter a lower MODE of operation in less than the total time allowed.

In MODES 1, 2, 3, and 4, LCO 3.0.3 provides actions for Conditions not covered in other Specifications. The requirements of LCO 3.0.3 do not apply in MODES 5 and 6 because the unit is already in the most restrictive Condition required by LCO 3.0.3. The requirements of LCO 3.0.3 do not apply in other specified conditions of the Applicability (unless in MODE 1, 2, 3, or 4) because the ACTIONS of individual Specifications sufficiently define the remedial measures to be taken.

Exceptions to LCO 3.0.3 are provided in instances where requiring a unit shutdown, in accordance with LCO 3.0.3, would not provide appropriate remedial measures for the associated condition of the unit. An example of this is in LCO 3.7.16, "Fuel Storage Pool Water Level." LCO 3.7.16 has an Applicability of "During movement of irradiated fuel assemblies in the fuel storage pool." Therefore, this LCO can be applicable in any or all MODES. If the LCO and the Required Actions of LCO 3.7.16 are not met while in MODE 1, 2, or 3, there is no safety benefit to be gained by placing the unit in a shutdown condition. The Required Action of LCO 3.7.16 of "Suspend movement of irradiated fuel assemblies in fuel storage pool" is the appropriate Required Action to complete in lieu of the actions of LCO 3.0.3. These exceptions are addressed in the individual Specifications.

Spent
3
spent
3
3
spent
1

~~[The requirement to be in MODE 4 in 13 hours is plant specific and depends on the ability to cool the pressurizer and degas.]~~ 2

LCO 3.0.4 LCO 3.0.4 establishes limitations on changes in MODES or other specified conditions in the Applicability when an LCO is not met. It allows placing the unit in a MODE or other specified condition stated in that Applicability (e.g., the Applicability desired to be entered) when unit conditions are such that the requirements of the LCO would not be met, in accordance with either LCO 3.0.4.a, LCO 3.0.4.b, or LCO 3.0.4.c.

BASES

LCO 3.0.4 (continued)

LCO 3.0.4.a allows entry into a MODE or other specified condition in the Applicability with the LCO not met when the associated ACTIONS to be entered following entry into the MODE or other specified condition in the Applicability will permit continued operation within the MODE or other specified condition for an unlimited period of time. Compliance with ACTIONS that permit continued operation of the unit for an unlimited period of time in a MODE or other specified condition provides an acceptable level of safety for continued operation. This is without regard to the status of the unit before or after the MODE change. Therefore, in such cases, entry into a MODE or other specified condition in the Applicability may be made and the Required Actions followed after entry into the Applicability.

For example, LCO 3.0.4.a may be used when the Required Action to be entered states that an inoperable instrument channel must be placed in the trip condition within the Completion Time. Transition into a MODE or other specified in condition in the Applicability may be made in accordance with LCO 3.0.4 and the channel is subsequently placed in the tripped condition within the Completion Time, which begins when the Applicability is entered. If the instrument channel cannot be placed in the tripped condition and the subsequent default ACTION ("Required Action and associated Completion Time not met") allows the OPERABLE train to be placed in operation, use of LCO 3.0.4.a is acceptable because the subsequent ACTIONS to be entered following entry into the MODE include ACTIONS (place the OPERABLE train in operation) that permit safe plant operation for an unlimited period of time in the MODE or other specified condition to be entered.

LCO 3.0.4.b allows entry into a MODE or other specified condition in the Applicability with the LCO not met after performance of a risk assessment addressing inoperable systems and components, consideration of the results, determination of the acceptability of entering the MODE or other specified condition in the Applicability, and establishment of risk management actions, if appropriate.

The risk assessment may use quantitative, qualitative, or blended approaches, and the risk assessment will be conducted using the plant program, procedures, and criteria in place to implement 10 CFR 50.65(a)(4), which requires that risk impacts of maintenance activities to be assessed and managed. The risk assessment, for the purposes of LCO 3.0.4.b, must take into account all inoperable Technical Specification equipment regardless of whether the equipment is included in the normal 10 CFR 50.65(a)(4) risk assessment scope. The risk

BASES

LCO 3.0.4 (continued)

assessments will be conducted using the procedures and guidance endorsed by Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants." Regulatory Guide 1.160 endorses the guidance in Section 11 of NUMARC 93-01, “Industry Guideline for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants.” These documents address general guidance for conduct of the risk assessment, quantitative and qualitative guidelines for establishing risk management actions, and example risk management actions. These include actions to plan and conduct other activities in a manner that controls overall risk, increased risk awareness by shift and management personnel, actions to reduce the duration of the condition, actions to minimize the magnitude of risk increases (establishment of backup success paths or compensatory measures), and determination that the proposed MODE change is acceptable. Consideration should also be given to the probability of completing restoration such that the requirements of the LCO would be met prior to the expiration of ACTIONS Completion Times that would require exiting the Applicability.

LCO 3.0.4.b may be used with single, or multiple systems and components unavailable. NUMARC 93-01 provides guidance relative to consideration of simultaneous unavailability of multiple systems and components.

The results of the risk assessment shall be considered in determining the acceptability of entering the MODE or other specified condition in the Applicability, and any corresponding risk management actions. The LCO 3.0.4.b risk assessments do not have to be documented.

The Technical Specifications allow continued operation with equipment unavailable in MODE 1 for the duration of the Completion Time. Since this is allowable, and since in general the risk impact in that particular MODE bounds the risk of transitioning into and through the applicable MODES or other specified conditions in the Applicability of the LCO, the use of the LCO 3.0.4.b allowance should be generally acceptable, as long as the risk is assessed and managed as stated above. However, there is a small subset of systems and components that have been determined to be more important to risk and use of the LCO 3.0.4.b allowance is prohibited. The LCOs governing these systems and components contain Notes prohibiting the use of LCO 3.0.4.b by stating that LCO 3.0.4.b is not applicable.

BASES

LCO 3.0.4 (continued)

LCO 3.0.4.c allows entry into a MODE or other specified condition in the Applicability with the LCO not met based on a Note in the Specification which states LCO 3.0.4.c is applicable. These specific allowances permit entry into MODES or other specified conditions in the Applicability when the associated ACTIONS to be entered do not provide for continued operation for an unlimited period of time and a risk assessment has not been performed. This allowance may apply to all the ACTIONS or to a specific Required Action of a Specification. The risk assessments performed to justify the use of LCO 3.0.4.b usually only consider systems and components. For this reason, LCO 3.0.4.c is typically applied to Specifications which describe values and parameters (e.g., RCS Specific Activity), and may be applied to other Specifications based on NRC plant specific approval.

The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or components to OPERABLE status before entering an associated MODE or other specified condition in the Applicability.

The provisions of LCO 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of LCO 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that result from any unit shutdown. In this context, a unit shutdown is defined as a change in MODE or other specified condition in the Applicability associated with transitioning from MODE 1 to MODE 2, MODE 2 to MODE 3, MODE 3 to MODE 4, and MODE 4 to MODE 5.

Upon entry into a MODE or other specified condition in the Applicability with the LCO not met, LCO 3.0.1 and LCO 3.0.2 require entry into the applicable Conditions and Required Actions until the Condition is resolved, until the LCO is met, or until the unit is not within the Applicability of the Technical Specification.

Surveillances do not have to be performed on the associated inoperable equipment (or on variables outside the specified limits), as permitted by SR 3.0.1. Therefore, utilizing LCO 3.0.4 is not a violation of SR 3.0.1 or SR 3.0.4 for any Surveillances that have not been performed on inoperable equipment. However, SRs must be met to ensure OPERABILITY prior to declaring the associated equipment OPERABLE (or variable within limits) and restoring compliance with the affected LCO.

BASES

LCO 3.0.5

LCO 3.0.5 establishes the allowance for restoring equipment to service under administrative controls when it has been removed from service or declared inoperable to comply with ACTIONS. The sole purpose of this Specification is to provide an exception to LCO 3.0.2 (e.g., to not comply with the applicable Required Action(s)) to allow the performance of required testing to demonstrate either:

a. The OPERABILITY of the equipment being returned to service or

b. The OPERABILITY of other equipment.

The administrative controls ensure the time the equipment is returned to service in conflict with the requirements of the ACTIONS is limited to the time absolutely necessary to perform the required testing to demonstrate OPERABILITY. This Specification does not provide time to perform any other preventive or corrective maintenance. LCO 3.0.5 should not be used in lieu of other practicable alternatives that comply with Required Actions and that do not require changing the MODE or other specified conditions in the Applicability in order to demonstrate equipment is OPERABLE. LCO 3.0.5 is not intended to be used repeatedly.

An example of demonstrating equipment is OPERABLE with the Required Actions not met is opening a manual valve that was closed to comply with Required Actions to isolate a flowpath with excessive Reactor Coolant System (RCS) Pressure Isolation Valve (PIV) leakage in order to perform testing to demonstrate that RCS PIV leakage is now within limit.

Examples of demonstrating equipment OPERABILITY include instances in which it is necessary to take an inoperable channel or trip system out of a tripped condition that was directed by a Required Action, if there is no Required Action Note for this purpose. An example of verifying OPERABILITY of equipment removed from service is taking a tripped channel out of the tripped condition to permit the logic to function and indicate the appropriate response during performance of required testing on the inoperable channel. Examples of demonstrating the OPERABILITY of other equipment are taking an inoperable channel or trip system out of the tripped condition 1) to prevent the trip function from occurring during the performance of required testing on another channel in the other trip system, or 2) to permit the logic to function and indicate the appropriate response during the performance of required testing on another channel in the same trip system.

BASES

LCO 3.0.5 (continued)

The administrative controls in LCO 3.0.5 apply in all cases to systems or components in Chapter 3 of the Technical Specifications, as long as the testing could not be conducted while complying with the Required Actions. This includes the realignment or repositioning of redundant or alternate equipment or trains previously manipulated to comply with ACTIONS, as well as equipment removed from service or declared inoperable to comply with ACTIONS.

LCO 3.0.6

LCO 3.0.6 establishes an exception to LCO 3.0.2 for supported systems that have a support system LCO specified in the Technical Specifications (TS). This exception is provided because LCO 3.0.2 would require that the Conditions and Required Actions of the associated inoperable supported system LCO be entered solely due to the inoperability of the support system. This exception is justified because the actions that are required to ensure the unit is maintained in a safe condition are specified in the support system LCO's Required Actions. These Required Actions may include entering the supported system's Conditions and Required Actions or may specify other Required Actions.

When a support system is inoperable and there is an LCO specified for it in the TS, the supported system(s) are required to be declared inoperable if determined to be inoperable as a result of the support system inoperability. However, it is not necessary to enter into the supported systems' Conditions and Required Actions unless directed to do so by the support system's Required Actions. The potential confusion and inconsistency of requirements related to the entry into multiple support and supported systems' LCOs' Conditions and Required Actions are eliminated by providing all the actions that are necessary to ensure the unit is maintained in a safe condition in the support system's Required Actions.

However, there are instances where a support system's Required Action may either direct a supported system to be declared inoperable or direct entry into Conditions and Required Actions for the supported system. This may occur immediately or after some specified delay to perform some other Required Action. Regardless of whether it is immediate or after some delay, when a support system's Required Action directs a supported system to be declared inoperable or directs entry into Conditions and Required Actions for a supported system, the applicable Conditions and Required Actions shall be entered in accordance with LCO 3.0.2.

BASES

LCO 3.0.6 (continued)

Specification 5.5.14, "Safety Function Determination Program (SFDP)," ensures loss of safety function is detected and appropriate actions are taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other limitations, remedial actions, or compensatory actions may be identified as a result of the support system inoperability and corresponding exception to entering supported system Conditions and Required Actions. The SFDP implements the requirements of LCO 3.0.6.

The following examples use Figure B 3.0-1 to illustrate loss of safety function conditions that may result when a TS support system is inoperable. In this figure, the fifteen systems that comprise Train A are independent and redundant to the fifteen systems that comprise Train B. To correctly use the figure to illustrate the SFDP provisions for a cross train check, the figure establishes a relationship between support and supported systems as follows: the figure shows System 1 as a support system for System 2 and System 3; System 2 as a support system for System 4 and System 5; and System 4 as a support system for System 8 and System 9. Specifically, a loss of safety function may exist when a support system is inoperable and:

a. A system redundant to system(s) supported by the inoperable support system is also inoperable (EXAMPLE B 3.0.6-1),

b. A system redundant to system(s) in turn supported by the inoperable supported system is also inoperable (EXAMPLE B 3.0.6-2), or

c. A system redundant to support system(s) for the supported systems (a) and (b) above is also inoperable (EXAMPLE B 3.0.6-3).

For the following examples, refer to Figure B 3.0-1.

EXAMPLE B 3.0.6-1

If System 2 of Train A is inoperable and System 5 of Train B is inoperable, a loss of safety function exists in Systems 5, 10, and 11.

EXAMPLE B 3.0.6-2

If System 2 of Train A is inoperable, and System 11 of Train B is inoperable, a loss of safety function exists in System 11.

BASES

LCO 3.0.6 (continued)

EXAMPLE B 3.0.6-3

If System 2 of Train A is inoperable, and System 1 of Train B is inoperable, a loss of safety function exists in Systems 2, 4, 5, 8, 9, 10 and 11.

If an evaluation determines that a loss of safety function exists, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.

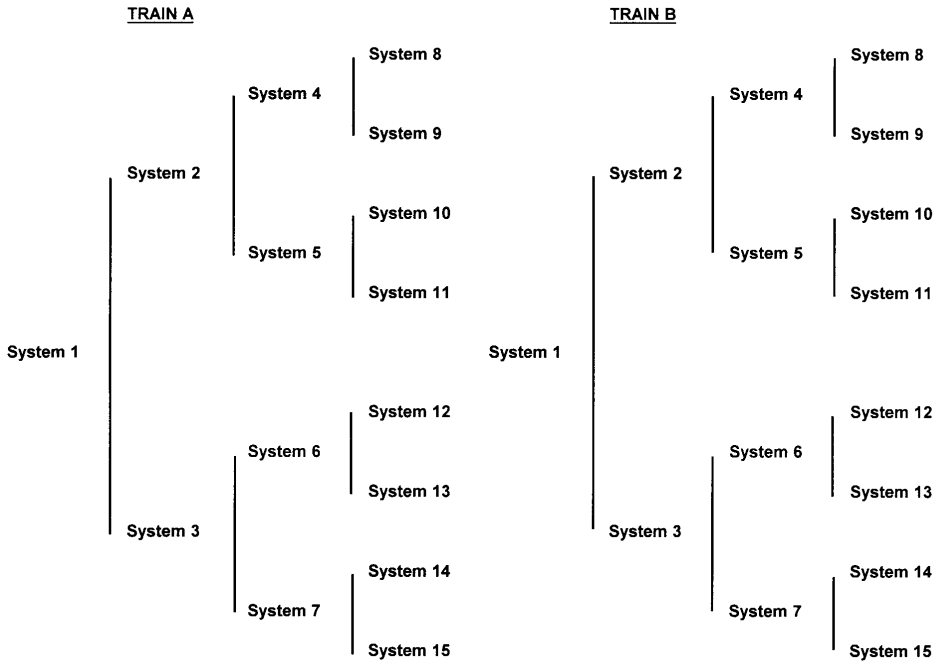

Figure B 3.0-1
Configuration of Trains and Systems

This loss of safety function does not require the assumption of additional single failures or loss of offsite power. Since operations are being restricted in accordance with the ACTIONS of the support system, any resulting temporary loss of redundancy or single failure protection is taken into account. Similarly, the ACTIONS for inoperable offsite circuit(s) and inoperable diesel generator(s) provide the necessary restriction for cross train inoperabilities. This explicit cross train verification for inoperable AC

BASES

LCO 3.0.6 (continued)

electrical power sources also acknowledges that supported system(s) are not declared inoperable solely as a result of inoperability of a normal or emergency electrical power source (refer to the definition of OPERABILITY).

When loss of safety function is determined to exist, and the SFDP requires entry into the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists, consideration must be given to the specific type of function affected. Where a loss of function is solely due to a single Technical Specification support system (e.g., loss of automatic start due to inoperable instrumentation, or loss of pump suction source due to low tank level) the appropriate LCO is the LCO for the support system. The ACTIONS for a support system LCO adequately address the inoperabilities of that system without reliance on entering its supported system LCO. When the loss of function is the result of multiple support systems, the appropriate LCO is the LCO for the supported system.

LCO 3.0.7

Special tests and operations are required at various times over the unit's life to demonstrate performance characteristics, to perform maintenance activities, and to perform special evaluations. Because TS normally preclude these tests and operations, special test exceptions (STEs) allow specified requirements to be changed or suspended under controlled conditions. STEs are included in applicable sections of the Specifications. Unless otherwise specified, all other TS requirements remain unchanged and in effect as applicable. This will ensure that all appropriate requirements of the MODE or other specified condition not directly associated with or required to be changed or suspended to perform the special test or operation will remain in effect.

The Applicability of an STE LCO represents a condition not necessarily in compliance with the normal requirements of the TS. Compliance with STE LCOs is optional.

A special test may be performed under either the provisions of the appropriate STE LCO or the other applicable TS requirements. If it is desired to perform the special test under the provisions of the STE LCO, the requirements of the STE LCO shall be followed. This includes the SRs specified in the STE LCO.

Some of the STE LCOs require that one or more of the LCOs for normal operation be met (i.e., meeting the STE LCO requires meeting the specified normal LCOs). The Applicability, ACTIONS, and SRs of the specified normal LCOs, however, are not required to be met in order to meet the STE LCO when it is in effect. This means that, upon failure to meet a specified normal LCO, the associated ACTIONS of the STE LCO

BASES

LCO 3.0.7 (continued)

apply, in lieu of the ACTIONS of the normal LCO. Exceptions to the above do exist. There are instances when the Applicability of the specified normal LCO must be met, where its ACTIONS must be taken, where certain of its Surveillances must be performed, or where all of these requirements must be met concurrently with the requirements of the STE LCO.

Unless the SRs of the specified normal LCOs are suspended or changed by the special test, those SRs that are necessary to meet the specified normal LCOs must be met prior to performing the special test. During the conduct of the special test, those Surveillances need not be performed unless specified by the ACTIONS or SRs of the STE LCO.

ACTIONS for STE LCOs provide appropriate remedial measures upon failure to meet the STE LCO. Upon failure to meet these ACTIONS, suspend the performance of the special test and enter the ACTIONS for all LCOs that are then not met. Entry into LCO 3.0.3 may possibly be required, but this determination should not be made by considering only the failure to meet the ACTIONS of the STE LCO.

LCO 3.0.8

LCO 3.0.8 establishes conditions under which systems are considered to remain capable of performing their intended safety function when associated snubbers are not capable of providing their associated support function(s). This LCO states that the supported system is not considered to be inoperable solely due to one or more snubbers not capable of performing their associated support function(s). This is appropriate because a limited length of time is allowed for maintenance, testing, or repair of one or more snubbers not capable of performing their associated support function(s) and appropriate compensatory measures are specified in the snubber requirements, which are located outside of the Technical Specifications (TS) under licensee control. The snubber requirements do not meet the criteria in 10 CFR 50.36(c)(2)(ii), and, as such, are appropriate for control by the licensee.

If the allowed time expires and the snubber(s) are unable to perform their associated support function(s), the affected supported system's LCO(s) must be declared not met and the Conditions and Required Actions entered in accordance with LCO 3.0.2.

LCO 3.0.8.a applies when one or more snubbers are not capable of providing their associated support function(s) to a single train or subsystem of a multiple train or subsystem supported system or to a single train or subsystem supported system. LCO 3.0.8.a allows 72 hours to restore the snubber(s) before declaring the supported system

BASES

LCO 3.0.8 (continued)

inoperable. The 72 hour Completion Time is reasonable based on the low probability of a seismic event concurrent with an event that would require operation of the supported system occurring while the snubber(s) are not capable of performing their associated support function and due to the availability of the redundant train of the supported system.

LCO 3.0.8.b applies when one or more snubbers are not capable of providing their associated support function(s) to more than one train or subsystem of a multiple train or subsystem supported system. LCO 3.0.8.b allows 12 hours to restore the snubber(s) before declaring the supported system inoperable. The 12 hour Completion Time is reasonable based on the low probability of a seismic event concurrent with an event that would require operation of the supported system occurring while the snubber(s) are not capable of performing their associated support function.

LCO 3.0.8 requires that risk be assessed and managed. Industry and NRC guidance on the implementation of 10 CFR 50.65(a)(4) (the Maintenance Rule) does not address seismic risk. However, use of LCO 3.0.8 should be considered with respect to other plant maintenance activities, and integrated into the existing Maintenance Rule process to the extent possible so that maintenance on any unaffected train or subsystem is properly controlled, and emergent issues are properly addressed. The risk assessment need not be quantified, but may be a qualitative awareness of the vulnerability of systems and components when one or more snubbers are not able to perform their associated support function.

LCO 3.0.9

~~REVIEWER'S NOTE~~

~~Adoption of LCO 3.0.9 requires the licensee to make the following commitments:~~

~~1. [LICENSEE] commits to the guidance of NUMARC 93-01, Revision [4F], Section 11, which provides guidance and details on the assessment and management of risk during maintenance.~~

~~2. [LICENSEE] commits to the guidance of NEI 04-08, "Allowance for Non Technical Specification Barrier Degradation on Supported System OPERABILITY (TSTF-427) Industry Implementation Guidance," March 2006.~~

LCO 3.0.9 establishes conditions under which systems described in the Technical Specifications are considered to remain OPERABLE when required barriers are not capable of providing their related support function(s).

BASES

LCO 3.0.9 (continued)

Barriers are doors, walls, floor plugs, curbs, hatches, installed structures or components, or other devices, not explicitly described in Technical Specifications, that support the performance of the safety function of systems described in the Technical Specifications. This LCO states that the supported system is not considered to be inoperable solely due to required barriers not capable of performing their related support function(s) under the described conditions. LCO 3.0.9 allows 30 days before declaring the supported system(s) inoperable and the LCO(s) associated with the supported system(s) not met. A maximum time is placed on each use of this allowance to ensure that as required barriers are found or are otherwise made unavailable, they are restored. However, the allowable duration may be less than the specified maximum time based on the risk assessment.

If the allowed time expires and the barriers are unable to perform their related support function(s), the supported system's LCO(s) must be declared not met and the Conditions and Required Actions entered in accordance with LCO 3.0.2.

This provision does not apply to barriers which support ventilation systems or to fire barriers. The Technical Specifications for ventilation systems provide specific Conditions for inoperable barriers. Fire barriers are addressed by other regulatory requirements and associated plant programs. This provision does not apply to barriers which are not required to support system OPERABILITY (see NRC Regulatory Issue Summary 2001-09, "Control of Hazard Barriers," dated April 2, 2001).

The provisions of LCO 3.0.9 are justified because of the low risk associated with required barriers not being capable of performing their related support function. This provision is based on consideration of the following initiating event categories:

~~REVIEWER'S NOTE~~

~~LCO 3.0.9 may be expanded to other initiating event categories provided plant-specific analysis demonstrates that the frequency of the additional initiating events is bounded by the generic analysis or if plant-specific approval is obtained from the NRC.~~

3

- Loss of coolant accidents;
- High energy line breaks;
- Feedwater line breaks;
- Internal flooding;
- External flooding;
- Turbine missile ejection; and
- Tornado or high wind.

BASES

LCO 3.0.9 (continued)

The risk impact of the barriers which cannot perform their related support function(s) must be addressed pursuant to the risk assessment and management provision of the Maintenance Rule, 10 CFR 50.65 (a)(4), and the associated implementation guidance, Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants." Regulatory Guide 1.160 endorses the guidance in Section 11 of NUMARC 93-01, "Industry Guideline for Monitoring the Effectiveness of Maintenance at Nuclear Power Plants." This guidance provides for the consideration of dynamic plant configuration issues, emergent conditions, and other aspects pertinent to plant operation with the barriers unable to perform their related support function(s). These considerations may result in risk management and other compensatory actions being required during the period that barriers are unable to perform their related support function(s).

LCO 3.0.9 may be applied to one or more trains or subsystems of a system supported by barriers that cannot provide their related support function(s), provided that risk is assessed and managed (including consideration of the effects on Large Early Release and from external events). If applied concurrently to more than one train or subsystem of a multiple train or subsystem supported system, the barriers supporting each of these trains or subsystems must provide their related support function(s) for different categories of initiating events. For example, LCO 3.0.9 may be applied for up to 30 days for more than one train of a multiple train supported system if the affected barrier for one train protects against internal flooding and the affected barrier for the other train protects against tornado missiles. In this example, the affected barrier may be the same physical barrier but serve different protection functions for each train.

If during the time that LCO 3.0.9 is being used, the required OPERABLE train or subsystem becomes inoperable, it must be restored to OPERABLE status within 24 hours. Otherwise, the train(s) or subsystem(s) supported by barriers that cannot perform their related support function(s) must be declared inoperable and the associated LCOs declared not met. This 24 hour period provides time to respond to emergent conditions that would otherwise likely lead to entry into LCO 3.0.3 and a rapid plant shutdown, which is not justified given the low probability of an initiating event which would require the barrier(s) not capable of performing their related support function(s). During this 24 hour period, the plant risk associated with the existing conditions is assessed and managed in accordance with 10 CFR 50.65(a)(4).

B 3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY

BASES

SRs

SR 3.0.1 through SR 3.0.4 establish the general requirements applicable to all Specifications and apply at all times, unless otherwise stated. SR 3.0.2 and SR 3.0.3 apply in Chapter 5 only when invoked by a Chapter 5 Specification.

SR 3.0.1

SR 3.0.1 establishes the requirement that SRs must be met during the MODES or other specified conditions in the Applicability for which the requirements of the LCO apply, unless otherwise specified in the individual SRs. This Specification is to ensure that Surveillances are performed to verify the OPERABILITY of systems and components, and that variables are within specified limits. Failure to meet a Surveillance within the specified Frequency, in accordance with SR 3.0.2, constitutes a failure to meet an LCO. Surveillances may be performed by means of any series of sequential, overlapping, or total steps provided the entire Surveillance is performed within the specified Frequency. Additionally, the definitions related to instrument testing (e.g., CHANNEL CALIBRATION) specify that these tests are performed by means of any series of sequential, overlapping, or total steps.

Systems and components are assumed to be OPERABLE when the associated SRs have been met. Nothing in this Specification, however, is to be construed as implying that systems or components are OPERABLE when either:

a. The systems or components are known to be inoperable, although still meeting the SRs or

b. The requirements of the Surveillance(s) are known to be not met between required Surveillance performances.

Surveillances do not have to be performed when the unit is in a MODE or other specified condition for which the requirements of the associated LCO are not applicable, unless otherwise specified. The SRs associated with a special test exception (STE) are only applicable when the STE is used as an allowable exception to the requirements of a Specification.

Unplanned events may satisfy the requirements (including applicable acceptance criteria) for a given SR. In this case, the unplanned event may be credited as fulfilling the performance of the SR. This allowance includes those SRs whose performance is normally precluded in a given MODE or other specified condition.

BASES

SR 3.0.1 (continued)

Surveillances, including Surveillances invoked by Required Actions, do not have to be performed on inoperable equipment because the ACTIONS define the remedial measures that apply. Surveillances have to be met and performed in accordance with SR 3.0.2, prior to returning equipment to OPERABLE status.

Upon completion of maintenance, appropriate post maintenance testing is required to declare equipment OPERABLE. This includes ensuring applicable Surveillances are not failed and their most recent performance is in accordance with SR 3.0.2. Post maintenance testing may not be possible in the current MODE or other specified conditions in the Applicability due to the necessary unit parameters not having been established. In these situations, the equipment may be considered OPERABLE provided testing has been satisfactorily completed to the extent possible and the equipment is not otherwise believed to be incapable of performing its function. This will allow operation to proceed to a MODE or other specified condition where other necessary post maintenance tests can be completed.

Some examples of this process are:

a. Auxiliary feedwater (AFW) pump turbine maintenance during refueling that requires testing at steam pressures > 800 psi. However, if other appropriate testing is satisfactorily completed, the AFW System can be considered OPERABLE. This allows startup and other necessary testing to proceed until the plant reaches the steam pressure required to perform the testing.

b. High pressure safety injection (HPSI) maintenance during shutdown that requires system functional tests at a specified pressure. Provided other appropriate testing is satisfactorily completed, startup can proceed with HPSI considered OPERABLE. This allows operation to reach the specified pressure to complete the necessary post maintenance testing.

SR 3.0.2

SR 3.0.2 establishes the requirements for meeting the specified Frequency for Surveillances and any Required Action with a Completion Time that requires the periodic performance of the Required Action on a "once per..." interval.

SR 3.0.2 permits a 25% extension of the interval specified in the Frequency. This extension facilitates Surveillance scheduling and considers plant operating conditions that may not be suitable for conducting the Surveillance (e.g., transient conditions or other ongoing Surveillance or maintenance activities).

BASES

SR 3.0.2 (continued)

When a Section 5.5, "Programs and Manuals," specification states that the provisions of SR 3.0.2 are applicable, a 25% extension of the testing interval, whether stated in the specification or incorporated by reference, is permitted.

The 25% extension does not significantly degrade the reliability that results from performing the Surveillance at its specified Frequency. This is based on the recognition that the most probable result of any particular Surveillance being performed is the verification of conformance with the SRs.

The exceptions to SR 3.0.2 are those Surveillances for which the 25% extension of the interval specified in the Frequency does not apply. These exceptions are stated in the individual Specifications. The requirements of regulations take precedence over the TS. Examples of where SR 3.0.2 does not apply are the Containment Leakage Rate Testing Program required by 10 CFR 50, Appendix J, and the inservice testing of pumps and valves in accordance with applicable American Society of Mechanical Engineers Operation and Maintenance Code, as required by 10 CFR 50.55a. These programs establish testing requirements and Frequencies in accordance with the requirements of regulations. The TS cannot in and of themselves extend a test interval specified in the regulations directly or by reference.

As stated in SR 3.0.2, the 25% extension also does not apply to the initial portion of a periodic Completion Time that requires performance on a "once per ..." basis. The 25% extension applies to each performance after the initial performance. The initial performance of the Required Action, whether it is a particular Surveillance or some other remedial action, is considered a single action with a single Completion Time. One reason for not allowing the 25% extension to this Completion Time is that such an action usually verifies that no loss of function has occurred by checking the status of redundant or diverse components or accomplishes the function of the inoperable equipment in an alternative manner.

The provisions of SR 3.0.2 are not intended to be used repeatedly to extend Surveillance intervals (other than those consistent with refueling intervals) or periodic Completion Time intervals beyond those specified.

SR 3.0.3

SR 3.0.3 establishes the flexibility to defer declaring affected equipment inoperable or an affected variable outside the specified limits when a Surveillance has not been performed within the specified Frequency. A delay period of up to 24 hours or up to the limit of the specified

BASES

SR 3.0.3 (continued)

Frequency, whichever is greater, applies from the point in time that it is discovered that the Surveillance has not been performed in accordance with SR 3.0.2, and not at the time that the specified Frequency was not met.

When a Section 5.5, "Programs and Manuals," specification states that the provisions of SR 3.0.3 are applicable, it permits the flexibility to defer declaring the testing requirement not met in accordance with SR 3.0.3 when the testing has not been completed within the testing interval (including the allowance of SR 3.0.2 if invoked by the Section 5.5 specification).

This delay period provides adequate time to perform Surveillances that have been missed. This delay period permits the performance of a Surveillance before complying with Required Actions or other remedial measures that might preclude performance of the Surveillance.

The basis for this delay period includes consideration of unit conditions, adequate planning, availability of personnel, the time required to perform the Surveillance, the safety significance of the delay in completing the required Surveillance, and the recognition that the most probable result of any particular Surveillance being performed is the verification of conformance with the requirements.

When a Surveillance with a Frequency based not on time intervals, but upon specified unit conditions, operating situations, or requirements of regulations (e.g., prior to entering MODE 1 after each fuel loading, or in accordance with 10 CFR 50, Appendix J, as modified by approved exemptions, etc.) is discovered to not have been performed when specified, SR 3.0.3 allows for the full delay period of up to the specified Frequency to perform the Surveillance. However, since there is not a time interval specified, the missed Surveillance should be performed at the first reasonable opportunity.

SR 3.0.3 provides a time limit for, and allowances for the performance of, Surveillances that become applicable as a consequence of MODE changes imposed by Required Actions.

SR 3.0.3 is only applicable if there is a reasonable expectation the associated equipment is OPERABLE or that variables are within limits, and it is expected that the Surveillance will be met when performed. Many factors should be considered, such as the period of time since the Surveillance was last performed, or whether the Surveillance, or a portion thereof, has ever been performed, and any other indications, tests, or

BASES

SR 3.0.3 (continued)

activities that might support the expectation that the Surveillance will be met when performed. An example of the use of SR 3.0.3 would be a relay contact that was not tested as required in accordance with a particular SR, but previous successful performances of the SR included the relay contact; the adjacent, physically connected relay contacts were tested during the SR performance; the subject relay contact has been tested by another SR; or historical operation of the subject relay contact has been successful. It is not sufficient to infer the behavior of the associated equipment from the performance of similar equipment. The rigor of determining whether there is a reasonable expectation a Surveillance will be met when performed should increase based on the length of time since the last performance of the Surveillance. If the Surveillance has been performed recently, a review of the Surveillance history and equipment performance may be sufficient to support a reasonable expectation that the Surveillance will be met when performed. For Surveillances that have not been performed for a long period or that have never been performed, a rigorous evaluation based on objective evidence should provide a high degree of confidence that the equipment is OPERABLE. The evaluation should be documented in sufficient detail to allow a knowledgeable individual to understand the basis for the determination.

Failure to comply with specified Frequencies for SRs is expected to be an infrequent occurrence. Use of the delay period established by SR 3.0.3 is a flexibility which is not intended to be used repeatedly to extend Surveillance intervals. While up to 24 hours or the limit of the specified Frequency is provided to perform the missed Surveillance, it is expected that the missed Surveillance will be performed at the first reasonable opportunity. The determination of the first reasonable opportunity should include consideration of the impact on plant risk (from delaying the Surveillance as well as any plant configuration changes required or shutting the plant down to perform the Surveillance) and impact on any analysis assumptions, in addition to unit conditions, planning, availability of personnel, and the time required to perform the Surveillance. This risk impact should be managed through the program in place to implement 10 CFR 50.65(a)(4) and its implementation guidance, NRC Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants." This Regulatory Guide addresses consideration of temporary and aggregate risk impacts, determination of risk management action thresholds, and risk management action up to and including plant shutdown. The missed Surveillance should be treated as an emergent condition as discussed in the Regulatory Guide. The risk evaluation may use quantitative, qualitative, or blended methods. The degree of depth and rigor of the evaluation should be commensurate with the importance of the component. Missed Surveillances for important

BASES

SR 3.0.3 (continued)

components should be analyzed quantitatively. If the results of the risk evaluation determine the risk increase is significant, this evaluation should be used to determine the safest course of action. All missed Surveillances will be placed in the licensee's Corrective Action Program.

If a Surveillance is not completed within the allowed delay period, then the equipment is considered inoperable or the variable is considered outside the specified limits and the Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon expiration of the delay period. If a Surveillance is failed within the delay period, then the equipment is inoperable, or the variable is outside the specified limits and the Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon the failure of the Surveillance.

Completion of the Surveillance within the delay period allowed by this Specification, or within the Completion Time of the ACTIONS, restores compliance with SR 3.0.1.

SR 3.0.4

SR 3.0.4 establishes the requirement that all applicable SRs must be met before entry into a MODE or other specified condition in the Applicability.

This Specification ensures that system and component OPERABILITY requirements and variable limits are met before entry into MODES or other specified conditions in the Applicability for which these systems and components ensure safe operation of the unit. The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or components to OPERABLE status before entering an associated MODE or other specified condition in the Applicability.

A provision is included to allow entry into a MODE or other specified condition in the Applicability when an LCO is not met due to a Surveillance not being met in accordance with LCO 3.0.4.

However, in certain circumstances, failing to meet an SR will not result in SR 3.0.4 restricting a MODE change or other specified condition change. When a system, subsystem, division, component, device, or variable is inoperable or outside its specified limits, the associated SR(s) are not required to be performed, per SR 3.0.1, which states that surveillances do not have to be performed on inoperable equipment. When equipment is inoperable, SR 3.0.4 does not apply to the associated SR(s) since the requirement for the SR(s) to be performed is removed. Therefore, failing

BASES

SR 3.0.4 (continued)

to perform the Surveillance(s) within the specified Frequency does not result in an SR 3.0.4 restriction to changing MODES or other specified conditions of the Applicability. However, since the LCO is not met in this instance, LCO 3.0.4 will govern any restrictions that may (or may not) apply to MODE or other specified condition changes. SR 3.0.4 does not restrict changing MODES or other specified conditions of the Applicability when a Surveillance has not been performed within the specified Frequency, provided the requirement to declare the LCO not met has been delayed in accordance with SR 3.0.3.

The provisions of SR 3.0.4 shall not prevent entry into MODES or other specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of SR 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that result from any unit shutdown. In this context, a unit shutdown is defined as a change in MODE or other specified condition in the Applicability associated with transitioning from MODE 1 to MODE 2, MODE 2 to MODE 3, MODE 3 to MODE 4, and MODE 4 to MODE 5.

The precise requirements for performance of SRs are specified such that exceptions to SR 3.0.4 are not necessary. The specific time frames and conditions necessary for meeting the SRs are specified in the Frequency, in the Surveillance, or both. This allows performance of Surveillances when the prerequisite condition(s) specified in a Surveillance procedure require entry into the MODE or other specified condition in the Applicability of the associated LCO prior to the performance or completion of a Surveillance. A Surveillance that could not be performed until after entering the LCO's Applicability, would have its Frequency specified such that it is not "due" until the specific conditions needed are met. Alternately, the Surveillance may be stated in the form of a Note, as not required (to be met or performed) until a particular event, condition, or time has been reached. Further discussion of the specific formats of SRs' annotation is found in Section 1.4, Frequency.

JUSTIFICATION FOR DEVIATIONS
ITS 3.0, LCO AND SR APPLICABILITY BASES

1. Changes are made (additions, deletions, and/or changes) to the ISTS Bases which reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is changed to reflect the current licensing basis.

3. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.0, LCO AND SR APPLICABILITY

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGE L01

Florida Power & Light Company (FPL) is converting St. Lucie Plant (PSL) Unit 1 and Unit 2 to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5, "Standard Technical Specifications, Combustion Engineering Plants." The proposed change involves making the Current Technical Specifications (CTS) Less Restrictive. Below is the description of this less restrictive change and the determination of No Significant Hazards Considerations for conversion to NUREG-1432.

CTS Section 3.0 does not contain an allowance when barriers cannot support their support function. The proposed change to CTS 3.0, "LCO Applicability" adds a new LCO 3.0.9. The addition of LCO 3.0.9 to the CTS is to address barriers which cannot perform their related support function for Technical Specification systems. ITS LCO 3.0.9 allows barriers to be able to not perform their safety function for up to 30 days before declaring the supported system inoperable. Furthermore, due to this addition, an allowance is also needed in LCO 3.0.1. This allowance has been added.

Barriers are defined as doors, walls, floor plugs, curbs, hatches, installed structures or components, or other devices, not explicitly described in Technical Specifications, which are designed to provide for the performance of the safety function for the Technical Specification system after the occurrence of one or more initiating events.

The barrier which cannot perform its related support function will be evaluated and managed under the Maintenance Rule plant configuration control requirement, 10 CFR 50.65(a)(4), and the associated industry guidance (NUMARC 93-01, Revision 4A). This provision is applicable whether the barrier is affected due to planned maintenance or due to a discovered condition. Should the risk assessment and risk management actions for a specific plant configuration or emergent condition not support the 30 day allowed time, the Maintenance Rule risk management determined allowed time and actions must be implemented or the supported system’s LCO be considered not met.

Application of LCO 3.0.9 is dependent on the OPERABILITY of at least one train or subsystem of the supported Technical Specification system and the system's ability to mitigate the consequences of the specified initiating events. However, during the 30 day period allowed by LCO 3.0.9, there exists the possibility that the train or subsystem required to be OPERABLE will unexpectedly become inoperable. Absent any further consideration, this would likely result in both trains of a Technical Specification required system being declared inoperable (i.e., the train supported by the barriers to which LCO 3.0.9 was being applied and the emergent condition of the inoperable train). This would likely result in entering LCO 3.0.3 and a plant shutdown. While this scenario is of low likelihood, it is of very high consequence to the licensee and, therefore, should be avoided unless necessary to avoid an actual plant risk. As a result, LCO 3.0.9 contains a provision which addresses the emergent condition of the required OPERABLE train or subsystem becoming inoperable while LCO 3.0.9 is being used. LCO 3.0.9 provides 24 hours to either restore the inoperable train or subsystem or to cease relying on the provisions of LCO 3.0.9 to consider the train or subsystem supported by the affected barrier(s) OPERABLE. This 24 hour period is not based on a generic risk evaluation, as it would be difficult to perform such an analysis in a generic fashion. Rather, plant risk

during this 24 hour allowance is managed using the contemporaneous risk assessment and management required by 10 CFR 50.65(a)(4) and recognizes the unquantified advantage to plant safety of avoiding a plant shutdown with the associated transition risk.

A risk impact of the 30 day allowance for barriers was performed. PSL initiating events are located on the table depicted in Technical Specifications Task Force (TSTF) traveler TSTF-427, Revision 2, “Allowance for Non Technical Specification Barrier Degradation on Supported System OPERABILITY,“ dated May 3, 2006 (ADAMS Accession No. ML061240055) or PSL has evaluated the use of LCO 3.0.9 for a barrier protecting against an initiating event not on the table located in TSTF-427 and calculated the frequency ranges within the ranges in the table so the above analysis is applicable for those initiators. Therefore, LCO 3.0.9 can be utilized when inoperable barriers affect Systems, Structures, or Components (SSCs).

FPL has evaluated whether a significant hazards consideration is involved with the proposed generic change by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of Amendment," as discussed below:

1. Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?

   Response: No.

   Barriers are not an initiator to any accident previously evaluated. The probability of an accident previously evaluated is not significantly increased. Barriers support the operation of equipment assumed to mitigate the effects of accidents previously evaluated. The proposed relaxation may only be applied to a single train or subsystem of a multiple train or subsystem Technical Specification system at a given time for a given category of initiating event, or to multiple trains or subsystems of a multiple train or subsystem Technical Specification system provided the affected barriers protect against different categories of initiating events. Therefore, for any given category of initiating event, the ability to perform the assumed safety function is preserved. The consequences of an accident occurring during the time allowed when barriers are not capable of performing their related support function are no different from the consequences of the same accident while relying on the Actions of the supported Technical Specification systems.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

   Response: No.

   No new or different accidents result from using the proposed change. The changes do not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed) or a change in the methods governing normal plant operation. In addition, the changes do not impose any new or different requirements or eliminate any existing requirements. The changes do not alter assumptions made

in the safety analysis. The proposed changes are consistent with the safety analysis assumptions and current plant operating practice.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

   Response: No.

   The proposed change allows for a limited period of time in which barriers may be unable to perform their related support function without declaring the supported systems inoperable. A risk analysis has shown that this provision will not have a significant effect on plant risk. In addition, regulatory requirements in 10 CFR 50.65(a)(4) require risk assessment and risk management, which will ensure that plant risk is not significantly increased.

   Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.0, LCO AND SR APPLICABILITY

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGE L02

Florida Power & Light Company (FPL) is converting St. Lucie Plant (PSL) Unit 1 and Unit 2 to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5, "Standard Technical Specifications, Combustion Engineering Plants." The proposed change involves making the Current Technical Specifications (CTS) Less Restrictive. Below is the description of this less restrictive change and the determination of No Significant Hazards Considerations for conversion to NUREG-1432.

CTS 4.0.2 states, "Each Surveillance Requirement shall be performed within the specified surveillance interval with a maximum allowable extension not to exceed 25% of the specified surveillance interval." ITS SR 3.0.2 states, " The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met. For Frequencies specified as "once," the above interval extension does not apply. If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance. Exceptions to this Specification are stated in the individual Specifications." This changes the CTS by adding, " If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance."

This change is acceptable because the 25% Frequency extension given to provide scheduling flexibility for Surveillances is equally applicable to Required Actions that must be performed periodically. The initial performance is excluded because the first performance demonstrates the acceptability of the current condition. Such demonstrations should be accomplished within the specified Completion Time with extension in order to avoid operation in unacceptable conditions. This change is designated as less restrictive because addition time is provided to perform some periodic Required Actions.

FPL has evaluated whether a significant hazards consideration is involved with the proposed generic change by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of Amendment," as discussed below:

1. Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?

   Response: No.

   The proposed change allows the Completion Time for periodic actions to be extended by 25%. This change does not significantly affect the probability of an accident. The length of time between performance of Required Actions is not an initiator to any accident previously evaluated. The consequences of any accident previously evaluated are the same during the Completion Time or during any extension of the Completion Time. As a result, the consequences of any accident previously evaluated are not significantly increased.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

   Response: No.

   The proposed change allows the Completion Time for periodic actions to be extended by 25%. This change will not involve physically altering the plant (i.e., no new or different type of equipment will be installed). In addition, the change does not involve any new or revised operator actions.

   Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

   Response: No.

   The proposed change allows the Completion Time for periodic actions to be extended by 25%. The 25% extension allowance is provided for scheduling convenience and is not expected to have significant effect on the average time between Required Actions. As a result, the Required Action will continue to provide appropriate compensatory measures for the subject Condition.

   Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified.

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.0, LCO AND SR APPLICABILITY

10 CFR 50.92 EVALUATION
FOR
LESS RESTRICTIVE CHANGE L03

Florida Power & Light Company (FPL) is converting St. Lucie Plant (PSL) Unit 1 and Unit 2 to the Improved Technical Specifications (ITS) as outlined in NUREG-1432, Rev. 5, "Standard Technical Specifications, Combustion Engineering Plants." The proposed change involves making the Current Technical Specifications (CTS) Less Restrictive. Below is the description of this less restrictive change and the determination of No Significant Hazards Considerations for conversion to NUREG-1432.

The proposed change revises Sections 3.0, "LCO Applicability" and "SR Applicability" of the Technical Specifications (TS) to clarify the use and application of the TS usage rules and revise the application of Surveillance Requirement (SR) 3.0.3. CTS TS 4.0.3 is revised to allow application of ITS SR 3.0.3 when an SR has not been previously performed.

FPL has evaluated whether a significant hazards consideration is involved with the proposed generic change by focusing on the three standards set forth in 10 CFR 50.92, "Issuance of amendment," as discussed below:

1. Does the proposed change involve a significant increase in the probability or consequences of an accident previously evaluated?

   Response: No.

   The proposed change to SR 3.0.3 states that the allowance may only be used when there is a reasonable expectation the surveillance will be met when performed. Since the proposed changes does not significantly affect system Operability, the proposed change will have no significant effect on the initiating events for accidents previously evaluated and will have no significant effect on the ability of the systems to mitigate accidents previously evaluated.

   Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the proposed change create the possibility of a new or different kind of accident from any accident previously evaluated?

   Response: No.

   The proposed change to the TS usage rules does not affect the design or function of any plant systems. The proposed change does not change the Operability requirements for plant systems or the actions taken when plant systems are not operable.

   Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the proposed change involve a significant reduction in a margin of safety?

   Response: No.

   The proposed change revised CTS TS 4.0.3 to allow application of ITS SR 3.0.3 when an SR has not been previously performed if there is reasonable expectation that the SR will be met when performed. This expands the use of SR 3.0.3 while ensuring the affected system is capable of performing its safety function. As a result, plant safety is either improved or unaffected..

   Therefore, the proposed change does not involve a significant reduction in a margin of safety.

Based on the above, FPL concludes that the proposed change does not involve a significant hazards consideration under the standards set forth in 10 CFR 50.92(c), and, accordingly, a finding of "no significant hazards consideration" is justified

See ITS 3.4.12

DISCUSSION OF CHANGES
ITS 3.1.1, SHUTDOWN MARGIN (SDM)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.1.1.1 provides the SHUTDOWN MARGIN (SDM) requirement in MODES 1, 2, 3, and 4 (i.e., $T_{avg} > 200°F$). CTS 3.1.1.2 provides the SDM requirement in MODE 5 (i.e., $T_{avg} \leq 200°F$). ITS 3.1.1 provides the SDM requirement in MODES 3, 4, and 5. This changes the CTS by combining the SDM requirements in MODES 3, 4, and 5. The Applicability for MODES 1 and 2 are described in ITS 3.1.6, “Regulating Control Element Assembly (CEA) Insertion Limits.”

This change is acceptable because the requirements have not changed. Combining the Specifications is an editorial change. Any technical changes resulting from this combination are discussed in other DOCs. This change is designated as administrative because it does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.1.1.1.1.e and CTS 4.1.1.2.b require determination that the SDM is within limits, and specifically requires the consideration of the following factors: reactor coolant system boron concentration, CEA position, reactor coolant system average temperature, fuel burnup based on gross thermal energy generation, xenon concentration and samarium concentration. ITS SR 3.1.1.1 requires a determination that the SDM is within limits, but does not describe the factors that must be considered in the calculation. This information is moved to the Bases. This changes the CTS by removing details on how the SDM calculation is performed from the Specification and placing the information in the Bases.

The removal of these details for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement that the SDM be within limits. The detail of how SDM is calculated does not need to appear in the specification in order for the requirement to apply. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 3 – Relaxation of Completion Time)* CTS 3.1.1.1 ACTION states when the SDM is less than the applicable limit, boration must be initiated immediately. ITS 3.1.1 ACTION states when SDM is not within limits, boration must be initiated within 15 minutes. This changes the CTS by relaxing the Completion Time from "immediately" to 15 minutes.

The purpose of CTS 3.1.1.1 ACTION is to restore the SDM to within its limit promptly. This change is acceptable because the Completion Time is consistent with safe operation under the specific Condition, considering the operability status of the redundant systems of required features, the capacity and capability of remaining features, and the low probability of a DBA occurring during the allowed Completion Time. This ITS Completion Time of 15 minutes is adequate for an operator to correctly align and start the required systems and components. In addition, the ITS Bases for the ACTION states that boration must be initiated promptly. This change is designated as less restrictive because additional time is allowed to restore parameters to within the LCO limits than was allowed in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.1.1.1 ACTION states when the SDM is not within limits, boration must be initiated and continued at ≥ 40 gpm of a solution containing greater than or equal to 1900 ppm boron or equivalent until the required SDM is restored. ITS 3.1.1 ACTION A states that when the SDM is not within limits to initiate boration to restore SDM to within limits. This changes the CTS by eliminating the specific values of flow rate and the boron concentration used to restore compliance with the LCO.

The purpose of CTS 3.1.1.1 ACTION is to restore the SDM to within its limit. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the operability status of the specified redundant systems of required features, the capacity and capability of remaining features, a reasonable time for repairs or replacement of required

features, and the low probability of a DBA occurring during the allowed Completion Time. Removing the specific values of flow rate and boron concentration from the CTS ACTION provides flexibility in the restoration of the SDM and eliminates conflicts between the SDM value and the specific boration values in the CTS ACTION. As stated, in the ITS Bases for ACTION A, "In the determination of the required combination of boration flow rate and boron concentration, there is no unique requirement that must be satisfied. Since it is imperative to raise the boron concentration of the RCS as soon as possible, the boron concentration should be a highly concentrated solution, such as that normally found in the boric acid makeup tank, or the refueling water tank. The operator should borate with the best source available for the plant conditions." Specifying a minimum flow rate and concentration in the ACTION may not accomplish the objective of raising the RCS boron concentration as soon as possible. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 *(Category 5 – Deletion of Surveillance Requirement)* CTS 4.1.1.1.1.d requires verification that the SDM is within limit, "Prior to initial operation above 5% RATED THERMAL POWER after each fuel loading, by consideration of the factors of e below [CTS 4.1.1.1.1.e], with the CEA groups at the power dependent insertion limits of Specification 3.1.3.6." The ITS does not contain a similar requirement. This changes the CTS by deleting Surveillance Requirement 4.1.1.1.1.d.

The purpose of CTS 4.1.1.1.1.d is to verify core design predictions by determining the SDM with the CEAs at the insertion limits. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify the LCO is within limit. The core design predictions, such as rod worth, boron worth, and critical boron concentration, are verified in a manner and at a Frequency necessary to give confidence that these predicted values are within limit in accordance with ITS SR 3.1.2.1. ITS SR 3.1.2.1 has a conditional Frequency similar to that of CTS 4.1.1.1.d requiring performance prior to entering MODE 1 (> 5% RTP) after fuel loading. To ensure the SDM is within limits during reactor startup the critical boron concentration is verified during the startup physics test program. Thereafter SDM is confirmed by performance of ITS SR 3.1.4.1 (CEA alignment verification), SR 3.1.5.1(shutdown CEA withdrawn verification), and SR 3.1.6.1 (regulating CEA group position verification). Thus, the SDM continues to be verified in a manner and at a Frequency necessary to give confidence that the parameter is within limit. Therefore, the core design parameters upon which SDM relies are verified before exceeding 5% RATED THERMAL POWER after each fuel loading. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~ 1

B 3.1.1 SHUTDOWN MARGIN (SDM) ~~(Analog)~~

BASES

BACKGROUND

The reactivity control systems must be redundant and capable of holding the reactor core subcritical when shut down under cold conditions, in accordance with GDC 26 (Ref. 1). Maintenance of the SHUTDOWN MARGIN (SDM) ensures that postulated reactivity events will not damage the fuel. SDM requirements provide sufficient reactivity margin to ensure that acceptable fuel design limits will not be exceeded for normal shutdown and anticipated operational occurrences (AOOs). As such, the SDM defines the degree of subcriticality that would be obtained immediately following the insertion of all control element assemblies (CEAs), assuming the single CEA of highest reactivity worth is fully withdrawn.

The system design requires that two independent reactivity control systems be provided, and that one of these systems be capable of maintaining the core subcritical under cold conditions. These requirements are provided by the use of movable CEAs and soluble boric acid in the Reactor Coolant System (RCS). The CEA System provides the SDM during power operation and is capable of making the core subcritical rapidly enough to prevent exceeding acceptable fuel damage limits, assuming that the CEA of highest reactivity worth remains fully withdrawn.

The soluble boron system can compensate for fuel depletion during operation and all xenon burnout reactivity changes, and maintain the reactor subcritical under cold conditions.

During power operation, SDM control is ensured by operating with the shutdown CEAs fully withdrawn and the regulating CEAs within the limits of LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits." When the unit is in the shutdown and refueling modes, the SDM requirements are met by means of adjustments to the RCS boron concentration.

APPLICABLE SAFETY ANALYSES

The minimum required SDM is assumed as an initial condition in safety analysis. The safety analysis (Ref. 2) establishes an SDM that ensures specified acceptable fuel design limits are not exceeded for normal operation and AOOs, with the assumption of the highest worth CEA stuck out following a reactor trip. For MODE 5, the primary safety analysis that relies on the SDM limits is the boron dilution analysis.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The acceptance criteria for the SDM requirements are that specified acceptable fuel design limits are maintained. This is done by ensuring that:

a. The reactor can be made subcritical from all operating conditions, transients, and Design Basis Events,

b. The reactivity transients associated with postulated accident conditions are controllable within acceptable limits (departure from nucleate boiling ratio (DNBR), fuel centerline temperature limit AOOs, and ≤ 2~~8~~0 cal/gm energy deposition for the CEA ejection accident), and 3 2

c. The reactor will be maintained sufficiently subcritical to preclude inadvertent criticality in the shutdown condition.

The most limiting accident for the SDM requirements are based on a main steam line break (MSLB), as described in the accident analysis (Ref. 2). The increased steam flow resulting from a pipe break in the main steam system causes an increased energy removal from the affected steam generator (SG), and consequently the RCS. This results in a reduction of the reactor coolant temperature. The resultant coolant shrinkage causes a reduction in pressure. In the presence of a negative moderator temperature coefficient, this cooldown causes an increase in core reactivity. As RCS temperature decreases, the severity of an MSLB decreases until the MODE 5 value is reached. The most limiting MSLB, with respect to potential fuel damage before a reactor trip occurs, is a guillotine break of a main steam line inside containment initiated at the end of core life. The positive reactivity addition from the moderator temperature decrease will terminate when the affected SG boils dry, thus terminating RCS heat removal and cooldown. Following the MSLB, a post trip return to power may occur; however, no fuel damage occurs as a result of the post trip return to power, and THERMAL POWER does not violate the Safety Limit (SL) requirement of SL 2.1.1.

In addition to the limiting MSLB transient, the SDM requirement for MODES 3 and 4 must also protect against:

BASES

APPLICABLE SAFETY ANALYSES (continued)

a. Inadvertent boron dilution,

b. An uncontrolled CEA withdrawal from a subcritical condition,

~~c. Startup of an inactive reactor coolant pump (RCP),~~ and

c

~~d~~. CEA ejection. 2

Each of these events is discussed below.

In the boron dilution analysis, the required SDM defines the reactivity difference between an initial subcritical boron concentration and the corresponding critical boron concentration. These values, in conjunction with the configuration of the RCS and the assumed dilution flow rate, directly affect the results of the analysis. This event is most limiting at the beginning of core life when critical boron concentrations are highest.

The withdrawal of CEAs from subcritical conditions adds reactivity to the reactor core, causing both the core power level and heat flux to increase with corresponding increases in reactor coolant temperatures and pressure. The withdrawal of CEAs also produces a time dependent redistribution of core power.

Depending on the system initial conditions and reactivity insertion rate, the uncontrolled CEA withdrawal transient is terminated by either a high power trip or a high pressurizer pressure trip. In all cases, power level, RCS pressure, linear heat rate, and the DNBR do not exceed allowable limits.

~~The startup of an inactive RCP will not result in a "cold water" criticality, even if the maximum difference in temperature exists between the SG and the core. The maximum positive reactivity addition that can occur due to an inadvertent RCP start is less than half the minimum required SDM. An idle RCP cannot, therefore, produce a return to power from the hot standby condition.~~

SDM satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

2

The ejection of a CEA rapidly adds reactivity to the reactor core, causing both the core power level and heat flux to increase with corresponding increases in reactor coolant temperatures and pressure. The ejection of a CEA also produces a time dependent redistribution of core power.

BASES

LCO

The MSLB (Ref. 2) and the boron dilution (Ref. 3) accidents are the most limiting analyses that establish the SDM value of the LCO. For MSLB accidents, if the LCO is violated, there is a potential to exceed the DNBR limit and to exceed 10 CFR ~~100, "Reactor Site Criteria~~," limits (Ref. 4). For the boron dilution accident, if the LCO is violated, then the minimum required time assumed for operator action to terminate dilution may no longer be applicable.

50.67, "Accident source term 2

SDM is a core physics design condition that can be ensured through CEA positioning (regulating and shutdown CEA) and through the soluble boron concentration.

APPLICABILITY

In MODES 3, 4, and 5, the SDM requirements are applicable to provide sufficient negative reactivity to meet the assumptions of the safety analyses discussed above. In MODES 1 and 2, SDM is ensured by complying with LCO 3.1.5, "Shutdown Control Element Assembly (CEA) Insertion Limits," and LCO 3.1.6. In MODE 6, the shutdown reactivity requirements are given in LCO 3.9.1, "Boron Concentration."

ACTIONS

A.1

If the SDM requirements are not met, boration must be initiated promptly. A Completion Time of 15 minutes is adequate for an operator to correctly align and start the required systems and components. It is assumed that boration will be continued until the SDM requirements are met.

In the determination of the required combination of boration flow rate and boron concentration, there is no unique requirement that must be satisfied. Since it is imperative to raise the boron concentration of the RCS as soon as possible, the boron concentration should be a highly concentrated solution, such as that normally found in the boric acid makeup ~~storage~~ tank or the ~~borated~~ water ~~storage~~ tank. The operator should borate with the best source available for the plant conditions.

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~ 1

B 3.1.1 SHUTDOWN MARGIN (SDM) ~~(Analog)~~

BASES

BACKGROUND

The reactivity control systems must be redundant and capable of holding the reactor core subcritical when shut down under cold conditions, in accordance with GDC 26 (Ref. 1). Maintenance of the SHUTDOWN MARGIN (SDM) ensures that postulated reactivity events will not damage the fuel. SDM requirements provide sufficient reactivity margin to ensure that acceptable fuel design limits will not be exceeded for normal shutdown and anticipated operational occurrences (AOOs). As such, the SDM defines the degree of subcriticality that would be obtained immediately following the insertion of all control element assemblies (CEAs), assuming the single CEA of highest reactivity worth is fully withdrawn.

The system design requires that two independent reactivity control systems be provided, and that one of these systems be capable of maintaining the core subcritical under cold conditions. These requirements are provided by the use of movable CEAs and soluble boric acid in the Reactor Coolant System (RCS). The CEA System provides the SDM during power operation and is capable of making the core subcritical rapidly enough to prevent exceeding acceptable fuel damage limits, assuming that the CEA of highest reactivity worth remains fully withdrawn.

The soluble boron system can compensate for fuel depletion during operation and all xenon burnout reactivity changes, and maintain the reactor subcritical under cold conditions.

During power operation, SDM control is ensured by operating with the shutdown CEAs fully withdrawn and the regulating CEAs within the limits of LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits." When the unit is in the shutdown and refueling modes, the SDM requirements are met by means of adjustments to the RCS boron concentration.

APPLICABLE SAFETY ANALYSES

The minimum required SDM is assumed as an initial condition in safety analysis. The safety analysis (Ref. 2) establishes an SDM that ensures specified acceptable fuel design limits are not exceeded for normal operation and AOOs, with the assumption of the highest worth CEA stuck out following a reactor trip. For MODE 5, the primary safety analysis that relies on the SDM limits is the boron dilution analysis.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The acceptance criteria for the SDM requirements are that specified acceptable fuel design limits are maintained. This is done by ensuring that:

a. The reactor can be made subcritical from all operating conditions, transients, and Design Basis Events,

b. The reactivity transients associated with postulated accident conditions are controllable within acceptable limits (departure from nucleate boiling ratio (DNBR), fuel centerline temperature limit AOOs, and ≤ 2~~8~~80 cal/gm energy deposition for the CEA ejection accident), and 3 2

c. The reactor will be maintained sufficiently subcritical to preclude inadvertent criticality in the shutdown condition.

The most limiting accident for the SDM requirements are based on a main steam line break (MSLB), as described in the accident analysis (Ref. 2). The increased steam flow resulting from a pipe break in the main steam system causes an increased energy removal from the affected steam generator (SG), and consequently the RCS. This results in a reduction of the reactor coolant temperature. The resultant coolant shrinkage causes a reduction in pressure. In the presence of a negative moderator temperature coefficient, this cooldown causes an increase in core reactivity. As RCS temperature decreases, the severity of an MSLB decreases until the MODE 5 value is reached. The most limiting MSLB, with respect to potential fuel damage before a reactor trip occurs, is a guillotine break of a main steam line inside containment initiated at the end of core life. The positive reactivity addition from the moderator temperature decrease will terminate when the affected SG boils dry, thus terminating RCS heat removal and cooldown. Following the MSLB, a post trip return to power may occur; however, no fuel damage occurs as a result of the post trip return to power, and THERMAL POWER does not violate the Safety Limit (SL) requirement of SL 2.1.1.

In addition to the limiting MSLB transient, the SDM requirement for MODES 3 and 4 must also protect against:

BASES

APPLICABLE SAFETY ANALYSES (continued)

a. Inadvertent boron dilution,

b. An uncontrolled CEA withdrawal from a subcritical condition,

~~c. Startup of an inactive reactor coolant pump (RCP),~~ and

c

~~d~~. CEA ejection. 2

Each of these events is discussed below.

In the boron dilution analysis, the required SDM defines the reactivity difference between an initial subcritical boron concentration and the corresponding critical boron concentration. These values, in conjunction with the configuration of the RCS and the assumed dilution flow rate, directly affect the results of the analysis. This event is most limiting at the beginning of core life when critical boron concentrations are highest.

The withdrawal of CEAs from subcritical conditions adds reactivity to the reactor core, causing both the core power level and heat flux to increase with corresponding increases in reactor coolant temperatures and pressure. The withdrawal of CEAs also produces a time dependent redistribution of core power.

Depending on the system initial conditions and reactivity insertion rate, the uncontrolled CEA withdrawal transient is terminated by either a high power trip or a high pressurizer pressure trip. In all cases, power level, RCS pressure, linear heat rate, and the DNBR do not exceed allowable limits.

~~The startup of an inactive RCP will not result in a "cold water" criticality, even if the maximum difference in temperature exists between the SG and the core. The maximum positive reactivity addition that can occur due to an inadvertent RCP start is less than half the minimum required SDM. An idle RCP cannot, therefore, produce a return to power from the hot standby condition.~~

SDM satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

2

The ejection of a CEA rapidly adds reactivity to the reactor core, causing both the core power level and heat flux to increase with corresponding increases in reactor coolant temperatures and pressure. The ejection of a CEA also produces a time dependent redistribution of core power.

BASES

LCO

The MSLB (Ref. 2) and the boron dilution (Ref. 3) accidents are the most limiting analyses that establish the SDM value of the LCO. For MSLB accidents, if the LCO is violated, there is a potential to exceed the DNBR limit and to exceed 10 CFR ~~100, "Reactor Site Criteria~~," limits (Ref. 4). For the boron dilution accident, if the LCO is violated, then the minimum required time assumed for operator action to terminate dilution may no longer be applicable.

50.67, "Accident source term 2

SDM is a core physics design condition that can be ensured through CEA positioning (regulating and shutdown CEA) and through the soluble boron concentration.

APPLICABILITY

In MODES 3, 4, and 5, the SDM requirements are applicable to provide sufficient negative reactivity to meet the assumptions of the safety analyses discussed above. In MODES 1 and 2, SDM is ensured by complying with LCO 3.1.5, "Shutdown Control Element Assembly (CEA) Insertion Limits," and LCO 3.1.6. In MODE 6, the shutdown reactivity requirements are given in LCO 3.9.1, "Boron Concentration."

ACTIONS

A.1

If the SDM requirements are not met, boration must be initiated promptly. A Completion Time of 15 minutes is adequate for an operator to correctly align and start the required systems and components. It is assumed that boration will be continued until the SDM requirements are met.

In the determination of the required combination of boration flow rate and boron concentration, there is no unique requirement that must be satisfied. Since it is imperative to raise the boron concentration of the RCS as soon as possible, the boron concentration should be a highly concentrated solution, such as that normally found in the boric acid makeup ~~storage~~ tank or the ~~borated~~ water ~~storage~~ tank. The operator should borate with the best source available for the plant conditions.

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.1 BASES, SHUTDOWN MARGIN (SDM)

1. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Westinghouse vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. Editorial changes made for enhanced clarity/consistency or grammatical error corrected.

5. As stated, the ISTS Bases discussion regarding the required boration flow rate and time necessary to recover 1% $\Delta k/k$ of SDM is provided for the purpose of offering a specific example. St. Lucie Plant operating procedures provide guidance to determine the necessary flow rate and boron concentration to recover SDM based on plant conditions. Therefore, the example provided in the ISTS 3.1.1 Bases is not included in the plant-specific ITS 3.1.1 Bases.

6. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

ACTION:

Add proposed ACTIONS A and B

L02

With the SHUTDOWN MARGIN outside the COLR limits, immediately initiate and continue boration at greater than or equal to 40 gpm of a solution containing greater than or equal to 1900 ppm boron or equivalent until the required SHUTDOWN MARGIN is restored.

See ITS 3.1.1

SURVEILLANCE REQUIREMENTS

See ITS 3.1.1

4.1.1.1.1 The SHUTDOWN MARGIN shall be determined to be within the COLR limits:

See ITS 3.1.4

a. Within one hour after detection of an inoperable CEA(s) and at least once per 12 hours thereafter while the CEA(s) is inoperable. If the inoperable CEA is not fully inserted, and is immovable as a result of excessive friction or mechanical interference or is known to be untrippable, the above required SHUTDOWN MARGIN shall be verified acceptable with an increased allowance for the withdrawn worth of the immovable or untrippable CEA(s).

See ITS 1.1

b. When in MODE 1 or MODE 2 with Keff greater than or equal to 1.0, in accordance with the Surveillance Frequency Control Program by verifying that CEA group withdrawal is within the Power Dependent Insertion Limits of Specification 3.1.3.6.

See ITS 3.1.6

c. When in MODE 2 with Keff less than 1.0, within 4 hours prior to achieving reactor criticality by verifying that the predicted critical CEA position is within the limits of Specification 3.1.3.6.

* See Special Test Exception 3.10.1.

DISCUSSION OF CHANGES
ITS 3.1.2, REACTIVITY BALANCE

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 4.1.1.1.2 requires the overall core reactivity balance to be compared to predicted values to demonstrate agreement within ± 1000 pcm. However, this Surveillance is currently part of the SHUTDOWN MARGIN Specification. Additionally, CTS 3.1.1.1 is titled SHUTDOWN MARGIN – T_{avg} > 200°F. A new LCO, ITS LCO 3.1.2, requires the measured core reactivity balance to be within ± 1% Δk/k of predicted values. Furthermore, ITS 3.1.2 is titled Reactivity Balance. This changes the CTS by having a separate Specification for the core reactivity requirement and changing the title. This change also changes the units of 1000 pcm to 1% Δk/k which are equivalent units of reactivity.

This change is acceptable because the requirements have not changed. Converting the requirement from a Surveillance in the SHUTDOWN MARGIN specification to an LCO is consistent with the ITS format and content guidance. Any technical changes resulting from this change are discussed in other DOCs. This change is designated as administrative because it does not result in a technical change to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS 4.1.1.1.2 requires comparison of the actual and predicted core reactivity balance and specifically requires consideration of at least those factors stated in Specification 4.1.1.1.1.e. CTS 4.1.1.1.1.e requires determination of SDM and requires the consideration of the following factors: reactor coolant system boron concentration, control element assembly (CEA) position, reactor coolant system average temperature, fuel burnup based on gross thermal energy generation, xenon concentration, and samarium concentration when in MODES 3 or 4. ITS SR 3.1.2.1 requires overall core

reactivity balance to be within the predicted values, but does not describe the factors that must be considered in the calculation. This information is relocated to the Bases. This changes the CTS by removing details on how the core reactivity balance comparison calculation is performed from the CTS and placing the information in the Bases.

The removal of these details for performing Surveillance Requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. ITS 3.1.2 still retains the requirement that the core reactivity balance comparison be within ± 1% $\Delta k/k$ in MODES 1 and 2. Refer to Discussion of Change L02 associated with deletion of MODES 3 and 4 from Applicability of CTS 4.1.1.1.2.

The details of how this comparison is calculated do not need to appear in the Specification in order for the requirement to apply. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the CTS.

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* CTS 4.1.1.1.2 is applicable in MODES 1, 2, 3, and 4. ITS 3.1.2 is applicable in MODES 1 and 2. This changes the CTS by reducing the applicable MODES in which the core reactivity requirement must be met.

The purpose of CTS Surveillance 4.1.1.1.2 is to verify the core design by comparing the actual and predicted core reactivity. This change is acceptable because the requirements continue to ensure that the process variables are maintained in the MODES and other specified conditions assumed in the safety analysis and licensing basis. The core reactivity balance can only be determined when the reactor is critical (MODES 1 and 2). Reducing the applicable MODES from MODES 1, 2, 3, and 4 to MODES 1 and 2 does not result in a reduction of the verification of this important measure of core design accuracy. This change is designated as less restrictive because the LCO requirements are applicable in fewer operating conditions than in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.1.1.1 does not contain ACTIONS to follow if the core reactivity balance Surveillance is not met. If the core reactivity balance Surveillance is not met, CTS 3.0.3 would be entered. CTS 3.0.3 requires action to be initiated within 1 hour and the unit to be in hot standby (MODE 3) within the next 6 hours, hot shutdown (MODE 4) within the following 6 hours, and cold shutdown (MODE 5) within the subsequent 24 hours. ITS 3.1.2 contains ACTIONS to follow if the core reactivity balance LCO is not met. If the LCO is not met, 7 days are provided to re-evaluate the core design

and safety analysis, to determine that the reactor core is acceptable for continued operation, and to establish appropriate operating restrictions and SRs. If these actions are not completed within the 7 days, the plant must be placed in MODE 3 within 6 hours. This changes the CTS by providing 7 days to evaluate and provide compensatory measures for not meeting the core reactivity balance requirement and then requiring entry into MODE 3 instead of requiring a unit shutdown and entry into MODE 5.

The purpose of CTS 4.1.1.1.2 is to verify the accuracy of the core design by comparing the predicted and actual core reactivity throughout core life. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABILITY status of the redundant systems of required features, the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of a DBA occurring during the repair period. Should the core reactivity balance requirement not be met, time is required to determine the cause of the disagreement and what adjustments may be needed to the operating conditions of the core. The startup physics testing program is used to verify most of the critical core design parameters, such as CEA worth, boron worth, and moderator temperature coefficient. In addition, there is considerable conservatism in the application of these values in the accident analyses. Therefore, allowing a time to evaluate the difference and make any adjustments to the operational controls is acceptable. The 7 day Completion time is reasonable considering the complexity of the evaluations and the time to meet administrative requirements, such as 10 CFR 50.59 safety evaluation preparation and approval. If it cannot be determined within 7 days that the core is acceptable for continued operation, the unit must be shutdown. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.1.1.1.2 requires comparison of the actual and predicted core reactivity balance in accordance with the Surveillance Frequency Control Program. CTS 4.1.1.1.2 also requires the predicted reactivity values to be adjusted (normalized) to correspond to the actual core conditions prior to exceeding a fuel burnup of 60 EFPD after each fuel loading. ITS SR 3.1.2.1 requires verifying the overall core reactivity balance is within ± 1 % Δ k/k of the predicted values prior to entering MODE 1 after each refueling and in accordance with the Surveillance Frequency Control Program after 60 EFPD. Note 2 to ITS SR 3.1.2.1 states that the Surveillance is not required to be performed prior to entry into MODE 2. This changes the CTS by not requiring the periodic, at-power core reactivity comparison until core burnup reaches 60 EFPD. Additionally, it allows the initial verification following fuel loading to be performed after entering MODE 2 and prior to MODE 1.

The purpose of CTS 4.1.1.1.2 is to verify the agreement between the actual and predicted core reactivity. The CTS requires and the ITS may require the predicted core reactivity values to be normalized to the actual values prior to exceeding 60 EFPD of core burnup. This allows sufficient time for core

conditions to reach steady state, but prevents operation for a large fraction of the fuel cycle without establishing a benchmark for the design calculations. The change allowing the required subsequent periodic Frequency in accordance with the Surveillance Frequency Control Program to be performed after entering MODE 2 and following the initial 60 EFPD after fuel loading, is acceptable, based on the slow rate of core reactivity changes resulting from fuel depletion and the presence of other indicators (AZIMUTHAL POWER TILT, AXIAL SHAPE INDEX, etc.) for prompt indication of an anomaly. This change has been designated as less restrictive because the Surveillance will be performed in a different MODE of operation under the ITS than under the CTS.

L04 *(Category 6 – Relaxation of Surveillance Requirement Acceptance Criteria)*
CTS 4.1.1.1.2 requires, in part, that the predicted reactivity values shall be adjusted (normalized) to correspond to the actual core conditions prior to exceeding a fuel burnup of 60 Effective Full Power Days after each fuel loading. ITS SR 3.1.2.1 Note 1 states the adjustment "may" be performed prior to exceeding a fuel burnup of 60 EFPD after each fuel loading. This changes the CTS by stating that the normalization may be performed prior to 60 EFPD after each fuel loading.

The purpose of adjusting the predicted reactivity values to the core conditions is to allow benchmarking of the design calculations. Making this adjustment closer to a fuel burnup of 60 EFPD of operation allows sufficient time for the core conditions to reach steady state. This change is acceptable because the expectation is to perform the adjusting of the predicted reactivity values to the core conditions. ITS SR 3.1.2.1 still allows the adjustment to take place prior to the 60 EFPD after each fuel loading. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~

1

B 3.1.2 Reactivity Balance ~~(Analog)~~

BASES

BACKGROUND

According to GDC 26, GDC 28, and GDC 29 (Ref. 1), reactivity shall be controllable, such that, subcriticality is maintained under cold conditions, and acceptable fuel design limits are not exceeded during normal operation and anticipated operational occurrences. Therefore, reactivity balance is used as a measure of the predicted versus measured core reactivity during power operation. The periodic confirmation of core reactivity is necessary to ensure that Design Basis Accident (DBA) and transient safety analyses remain valid. A large reactivity difference could be the result of unanticipated changes in fuel, control element assembly (CEA) worth, or operation at conditions not consistent with those assumed in the predictions of core reactivity, and could potentially result in a loss of SDM or violation of acceptable fuel design limits. Comparing predicted versus measured core reactivity validates the nuclear methods used in the safety analysis and supports the SDM demonstrations (LCO 3.1.1, "SHUTDOWN MARGIN (SDM)") in ensuring the reactor can be brought safely to cold, subcritical conditions.

When the reactor core is critical or in normal power operation, a reactivity balance exists and the net reactivity is zero. A comparison of predicted and measured reactivity is convenient under such a balance, since parameters are being maintained relatively stable under steady state power conditions. The positive reactivity inherent in the core design is balanced by the negative reactivity of the control components, thermal feedback, neutron leakage, and materials in the core that absorb neutrons, such as burnable absorbers producing zero net reactivity. Excess reactivity can be inferred from the critical boron curve, which provides an indication of the soluble boron concentration in the Reactor Coolant System (RCS) versus cycle burnup. Periodic measurement of the RCS boron concentration for comparison with the predicted value with other variables fixed (such as CEA height, temperature, pressure, and power) provides a convenient method of ensuring that core reactivity is within design expectations, and that the calculational models used to generate the safety analysis are adequate.

In order to achieve the required fuel cycle energy output, the uranium enrichment in the new fuel loading and in the fuel remaining from the previous cycle, provides excess positive reactivity beyond that required to sustain steady state operation throughout the cycle. When the reactor is critical at RTP and moderator temperature, the excess positive reactivity is compensated by burnable absorbers (if any), CEAs, whatever neutron poisons (mainly xenon and samarium) are present in the fuel, and the RCS boron concentration.

BASES

BACKGROUND (continued)

When the core is producing THERMAL POWER, the fuel is being depleted and excess reactivity is decreasing. As the fuel depletes, the RCS boron concentration is reduced to decrease negative reactivity and maintain constant THERMAL POWER. The critical boron curve is based on steady state operation at RTP. Therefore, deviations from the predicted critical boron curve may indicate deficiencies in the design analysis, deficiencies in the calculational models, or abnormal core conditions, and must be evaluated.

APPLICABLE SAFETY ANALYSES

Accurate prediction of core reactivity is either an explicit or implicit assumption in the accident analysis evaluations. Every accident evaluation (Ref. 2) is, therefore, dependent upon accurate evaluation of core reactivity. In particular, SDM and reactivity transients, such as CEA withdrawal accidents or CEA ejection accidents, are very sensitive to accurate prediction of core reactivity. These accident analysis evaluations rely on computer codes that have been qualified against available test data, operating plant data, and analytical benchmarks. Monitoring reactivity balance additionally ensures that the nuclear methods provide an accurate representation of the core reactivity.

Design calculations and safety analyses are performed for each fuel cycle for the purpose of predetermining reactivity behavior and the RCS boron concentration requirements for reactivity control during fuel depletion.

The comparison between measured and predicted initial core reactivity provides a normalization for calculational models used to predict core reactivity. If the measured and predicted RCS boron concentrations for identical core conditions at beginning of cycle (BOC) do not agree, then the assumptions used in the reload cycle design analysis or the calculational models used to predict soluble boron requirements may not be accurate. If reasonable agreement between measured and predicted core reactivity exists at BOC, then the prediction may be normalized to the measured boron concentration. Thereafter, any significant deviations in the measured boron concentration from the predicted critical boron curve that develop during fuel depletion may be an indication that the calculational model is not adequate for core burnups beyond BOC, or that an unexpected change in core conditions has occurred.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The normalization of predicted RCS boron concentration to the measured value is typically performed after reaching RTP following startup from a refueling outage, with the CEAs in their normal positions for power operation. The normalization is performed at BOC conditions, so that core reactivity relative to predicted values can be continually monitored and evaluated as core conditions change during the cycle.

The reactivity balance satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The reactivity balance limit is established to ensure plant operation is maintained within the assumptions of the safety analyses. Large differences between actual and predicted core reactivity may indicate that the assumptions of the DBA and transient analyses are no longer valid, or that the uncertainties in the nuclear design methodology are larger than expected. A limit on the reactivity balance of ± 1% $\Delta k/k$ has been established, based on engineering judgment. A 1% deviation in reactivity from that predicted is larger than expected for normal operation and should therefore be evaluated.

When measured core reactivity is within 1% $\Delta k/k$ of the predicted value at steady state thermal conditions, the core is considered to be operating within acceptable design limits. Since deviations from the limit are normally detected by comparing predicted and measured steady state RCS critical boron concentrations, the difference between measured and predicted values would be approximately 100 ppm (depending on the boron worth) before the limit is reached. These values are well within the uncertainty limits for analysis of boron concentration samples, so that spurious violations of the limit due to uncertainty in measuring the RCS boron concentration are unlikely.

APPLICABILITY

The limits on core reactivity must be maintained during MODES 1 and 2 because a reactivity balance must exist when the reactor is critical or producing THERMAL POWER. As the fuel depletes, core conditions are changing, and confirmation of the reactivity balance ensures the core is operating as designed. This Specification does not apply in MODES 3, 4, and 5 because the reactor is shut down and the reactivity balance is not changing.

In MODE 6, fuel loading results in a continually changing core reactivity. Boron concentration requirements (LCO 3.9.1, "Boron Concentration") ensure that fuel movements are performed within the bounds of the safety analysis. An SDM demonstration is required during the first startup following operations that could have altered core reactivity (e.g., fuel movement, or CEA replacement, or shuffling).

BASES

ACTIONS

A.1 and A.2

Should an anomaly develop between measured and predicted core reactivity, an evaluation of the core design and safety analysis must be performed. Core conditions are evaluated to determine their consistency with input to design calculations. Measured core and process parameters are evaluated to determine that they are within the bounds of the safety analysis, and safety analysis calculational models are reviewed to verify that they are adequate for representation of the core conditions. The required Completion Time of 7 days is based on the low probability of a DBA occurring during this period, and allows sufficient time to assess the physical condition of the reactor and complete the evaluation of the core design and safety analysis.

Following evaluations of the core design and safety analysis, the cause of the reactivity anomaly may be resolved. If the cause of the reactivity anomaly is a mismatch in core conditions at the time of RCS boron concentration sampling, then a recalculation of the RCS boron concentration requirements may be performed to demonstrate that core reactivity is behaving as expected. If an unexpected physical change in the condition of the core has occurred, it must be evaluated and corrected, if possible. If the cause of the reactivity anomaly is in the calculation technique, then the calculational models must be revised to provide more accurate predictions. If any of these results are demonstrated, and it is concluded that the reactor core is acceptable for continued operation, then the boron letdown curve may be renormalized, and power operation may continue. If operational restrictions or additional SRs are necessary to ensure the reactor core is acceptable for continued operation, then they must be defined.

The required Completion Time of 7 days is adequate for preparing whatever operating restrictions or Surveillances that may be required to allow continued reactor operation.

B.1

If the core reactivity cannot be restored to within the 1% $\Delta k/k$ limit, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. If the SDM for MODE 3 is not met, then boration required by SR 3.1.1.1 would occur. The allowed Completion Time is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.1.2.1

Core reactivity is verified by periodic comparisons of measured and predicted RCS boron concentrations. The comparison is made considering that other core conditions are fixed or stable including CEA position, ~~moderator~~ RCS boron concentration, RCS average temperature, ~~fuel temperature,~~ fuel depletion, xenon concentration, and samarium concentration. The Surveillance is performed prior to entering MODE 1 as an initial check on core conditions and design calculations at BOC. The SR is modified by three Notes. Note 1 in the Surveillance column indicates that the normalization of predicted core reactivity to the measured value ~~must~~ take place within the first 60 effective full power days (EFPD) after each fuel loading. This allows sufficient time for core conditions to reach steady state, but prevents operation for a large fraction of the fuel cycle without establishing a benchmark for the design calculations. ~~[The required subsequent Frequency of 31 EFPD following the initial 60 EFPD after entering MODE 1, is acceptable, based on the slow rate of core changes due to fuel depletion and the presence of other indicators (e.g., QPTR, etc.) for prompt indication of an anomaly.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

A second Note, "only required after 60 EFPD," is added to the Frequency column to allow this. Note 2 in the Surveillance column indicates that the performance of SR 3.1.2.1 is not required prior to entering MODE 2. This Note is required to allow a MODE 2 entry to verify core reactivity, because LCO Applicability is for MODES 1 and 2.

B 3.1.2 Reactivity Balance ~~(Analog)~~

BASES

BACKGROUND

According to GDC 26, GDC 28, and GDC 29 (Ref. 1), reactivity shall be controllable, such that, subcriticality is maintained under cold conditions, and acceptable fuel design limits are not exceeded during normal operation and anticipated operational occurrences. Therefore, reactivity balance is used as a measure of the predicted versus measured core reactivity during power operation. The periodic confirmation of core reactivity is necessary to ensure that Design Basis Accident (DBA) and transient safety analyses remain valid. A large reactivity difference could be the result of unanticipated changes in fuel, control element assembly (CEA) worth, or operation at conditions not consistent with those assumed in the predictions of core reactivity, and could potentially result in a loss of SDM or violation of acceptable fuel design limits. Comparing predicted versus measured core reactivity validates the nuclear methods used in the safety analysis and supports the SDM demonstrations (LCO 3.1.1, "SHUTDOWN MARGIN (SDM)") in ensuring the reactor can be brought safely to cold, subcritical conditions.

When the reactor core is critical or in normal power operation, a reactivity balance exists and the net reactivity is zero. A comparison of predicted and measured reactivity is convenient under such a balance, since parameters are being maintained relatively stable under steady state power conditions. The positive reactivity inherent in the core design is balanced by the negative reactivity of the control components, thermal feedback, neutron leakage, and materials in the core that absorb neutrons, such as burnable absorbers producing zero net reactivity. Excess reactivity can be inferred from the critical boron curve, which provides an indication of the soluble boron concentration in the Reactor Coolant System (RCS) versus cycle burnup. Periodic measurement of the RCS boron concentration for comparison with the predicted value with other variables fixed (such as CEA height, temperature, pressure, and power) provides a convenient method of ensuring that core reactivity is within design expectations, and that the calculational models used to generate the safety analysis are adequate.

In order to achieve the required fuel cycle energy output, the uranium enrichment in the new fuel loading and in the fuel remaining from the previous cycle, provides excess positive reactivity beyond that required to sustain steady state operation throughout the cycle. When the reactor is critical at RTP and moderator temperature, the excess positive reactivity is compensated by burnable absorbers (if any), CEAs, whatever neutron poisons (mainly xenon and samarium) are present in the fuel, and the RCS boron concentration.

BASES

BACKGROUND (continued)

When the core is producing THERMAL POWER, the fuel is being depleted and excess reactivity is decreasing. As the fuel depletes, the RCS boron concentration is reduced to decrease negative reactivity and maintain constant THERMAL POWER. The critical boron curve is based on steady state operation at RTP. Therefore, deviations from the predicted critical boron curve may indicate deficiencies in the design analysis, deficiencies in the calculational models, or abnormal core conditions, and must be evaluated.

APPLICABLE SAFETY ANALYSES

Accurate prediction of core reactivity is either an explicit or implicit assumption in the accident analysis evaluations. Every accident evaluation (Ref. 2) is, therefore, dependent upon accurate evaluation of core reactivity. In particular, SDM and reactivity transients, such as CEA withdrawal accidents or CEA ejection accidents, are very sensitive to accurate prediction of core reactivity. These accident analysis evaluations rely on computer codes that have been qualified against available test data, operating plant data, and analytical benchmarks. Monitoring reactivity balance additionally ensures that the nuclear methods provide an accurate representation of the core reactivity.

Design calculations and safety analyses are performed for each fuel cycle for the purpose of predetermining reactivity behavior and the RCS boron concentration requirements for reactivity control during fuel depletion.

The comparison between measured and predicted initial core reactivity provides a normalization for calculational models used to predict core reactivity. If the measured and predicted RCS boron concentrations for identical core conditions at beginning of cycle (BOC) do not agree, then the assumptions used in the reload cycle design analysis or the calculational models used to predict soluble boron requirements may not be accurate. If reasonable agreement between measured and predicted core reactivity exists at BOC, then the prediction may be normalized to the measured boron concentration. Thereafter, any significant deviations in the measured boron concentration from the predicted critical boron curve that develop during fuel depletion may be an indication that the calculational model is not adequate for core burnups beyond BOC, or that an unexpected change in core conditions has occurred.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The normalization of predicted RCS boron concentration to the measured value is typically performed after reaching RTP following startup from a refueling outage, with the CEAs in their normal positions for power operation. The normalization is performed at BOC conditions, so that core reactivity relative to predicted values can be continually monitored and evaluated as core conditions change during the cycle.

The reactivity balance satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The reactivity balance limit is established to ensure plant operation is maintained within the assumptions of the safety analyses. Large differences between actual and predicted core reactivity may indicate that the assumptions of the DBA and transient analyses are no longer valid, or that the uncertainties in the nuclear design methodology are larger than expected. A limit on the reactivity balance of ± 1% $\Delta k/k$ has been established, based on engineering judgment. A 1% deviation in reactivity from that predicted is larger than expected for normal operation and should therefore be evaluated.

When measured core reactivity is within 1% $\Delta k/k$ of the predicted value at steady state thermal conditions, the core is considered to be operating within acceptable design limits. Since deviations from the limit are normally detected by comparing predicted and measured steady state RCS critical boron concentrations, the difference between measured and predicted values would be approximately 100 ppm (depending on the boron worth) before the limit is reached. These values are well within the uncertainty limits for analysis of boron concentration samples, so that spurious violations of the limit due to uncertainty in measuring the RCS boron concentration are unlikely.

APPLICABILITY

The limits on core reactivity must be maintained during MODES 1 and 2 because a reactivity balance must exist when the reactor is critical or producing THERMAL POWER. As the fuel depletes, core conditions are changing, and confirmation of the reactivity balance ensures the core is operating as designed. This Specification does not apply in MODES 3, 4, and 5 because the reactor is shut down and the reactivity balance is not changing.

In MODE 6, fuel loading results in a continually changing core reactivity. Boron concentration requirements (LCO 3.9.1, "Boron Concentration") ensure that fuel movements are performed within the bounds of the safety analysis. An SDM demonstration is required during the first startup following operations that could have altered core reactivity (e.g., fuel movement, or CEA replacement, or shuffling).

BASES

ACTIONS

A.1 and A.2

Should an anomaly develop between measured and predicted core reactivity, an evaluation of the core design and safety analysis must be performed. Core conditions are evaluated to determine their consistency with input to design calculations. Measured core and process parameters are evaluated to determine that they are within the bounds of the safety analysis, and safety analysis calculational models are reviewed to verify that they are adequate for representation of the core conditions. The required Completion Time of 7 days is based on the low probability of a DBA occurring during this period, and allows sufficient time to assess the physical condition of the reactor and complete the evaluation of the core design and safety analysis.

Following evaluations of the core design and safety analysis, the cause of the reactivity anomaly may be resolved. If the cause of the reactivity anomaly is a mismatch in core conditions at the time of RCS boron concentration sampling, then a recalculation of the RCS boron concentration requirements may be performed to demonstrate that core reactivity is behaving as expected. If an unexpected physical change in the condition of the core has occurred, it must be evaluated and corrected, if possible. If the cause of the reactivity anomaly is in the calculation technique, then the calculational models must be revised to provide more accurate predictions. If any of these results are demonstrated, and it is concluded that the reactor core is acceptable for continued operation, then the boron letdown curve may be renormalized, and power operation may continue. If operational restrictions or additional SRs are necessary to ensure the reactor core is acceptable for continued operation, then they must be defined.

The required Completion Time of 7 days is adequate for preparing whatever operating restrictions or Surveillances that may be required to allow continued reactor operation.

B.1

If the core reactivity cannot be restored to within the 1% $\Delta k/k$ limit, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. If the SDM for MODE 3 is not met, then boration required by SR 3.1.1.1 would occur. The allowed Completion Time is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

SR 3.1.2.1

Core reactivity is verified by periodic comparisons of measured and predicted RCS boron concentrations. The comparison is made considering that other core conditions are fixed or stable including CEA position, ~~moderator~~ RCS boron concentration, RCS average temperature, ~~fuel temperature,~~ fuel depletion, xenon concentration, and samarium concentration. The Surveillance is performed prior to entering MODE 1 as an initial check on core conditions and design calculations at BOC. The SR is modified by three Notes. Note 1 in the Surveillance column indicates that the normalization of predicted core reactivity to the measured value ~~must~~ take place within the first 60 effective full power days (EFPD) after each fuel loading. This allows sufficient time for core conditions to reach steady state, but prevents operation for a large fraction of the fuel cycle without establishing a benchmark for the design calculations. ~~[The required subsequent Frequency of 31 EFPD following the initial 60 EFPD after entering MODE 1, is acceptable, based on the slow rate of core changes due to fuel depletion and the presence of other indicators (e.g., QPTR, etc.) for prompt indication of an anomaly.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

A second Note, "only required after 60 EFPD," is added to the Frequency column to allow this. Note 2 in the Surveillance column indicates that the performance of SR 3.1.2.1 is not required prior to entering MODE 2. This Note is required to allow a MODE 2 entry to verify core reactivity, because LCO Applicability is for MODES 1 and 2.

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.2 BASES, REACTIVITY BALANCE

1. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. Changes are made (additions, deletions, and/or changes) to the ISTS Bases that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

4. Changes are made to be consistent with the requirements of the Specification.

5. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

DISCUSSION OF CHANGES
ITS 3.1.3, MODERATOR TEMPERATURE COEFFICIENT (MTC)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.1.1.4 states, in part, that the maximum positive limit shall be less positive than +7 pcm/°F whenever THERMAL POWER is ≤ 70% of RATED THERMAL POWER, and less positive than +2 pcm/°F whenever THERMAL POWER is > 70% of RATED THERMAL POWER. Unit 1 ITS 3.1.3 states, in part, that the maximum positive limit shall be +7 pcm/°F when THERMAL POWER is ≤ 70% RTP, and +2 pcm/°F when THERMAL POWER is > 70% RTP. This changes the Unit 1 CTS by eliminating the wording “less positive than,” prior to listing the maximum positive MTC limit. This change is acceptable because the Unit 1 LCO requires a maximum value not a variable maximum value. The first sentence of the LCO requires the MTC to be maintained within the limits specified in the COLR and the second sentence is intended to ensure the upper MTC value specified in the COLR does not exceed a maximum positive MTC as stated in the LCO. In addition, Unit 1 and Unit 2 CTS 4.1.1.4.1, which requires verification that MTC is within the upper MTC limit, is changed to reference the COLR instead of the LCO, which references the maximum positive (i.e., upper) MTC limit. The limiting upper MTC specified in the COLR may be more restrictive than the maximum positive limit specified in the LCO. Therefore, ITS SR 3.1.3.1 requires verifying the MTC is within the upper limit specified in the COLR, which would encompass verifying the MTC is within the positive upper limit specified in the LCO. These changes are designated as administrative because they represent a presentation preference and do not represent a technical change to the CTS.

A03 The Applicability of CTS 3.1.1.4 is modified by footnote # stating "See Special Test Exception 3.10.2 (and 3.10.5 for Unit 2 only)." ITS 3.1.3 Applicability does not contain the footnote or a reference to the Special Test Exception. This changes the CTS by not including footnote # in the ITS.

The purpose of the footnote reference is to alert the user that a Special Test Exception exists that may modify the Applicability of the Specification. It is an ITS convention to not include these types of footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

A04 CTS 4.1.1.4.2 requires verification that the lower MTC is within the limits of the COLR. ****Note states that this Surveillance is only required if the MTC determined in SR 4.1.1.4.1 is not within ± 1.6 pcm/°F of the corresponding design value. ITS SR 3.1.3.2 contains a similar note (Note 1), which states, “Only required to be performed if MTC determined during performance of SR 3.2.3.1 is

not within 1.6 pcm/°F of the predicted MTC value." This changes the CTS by revising the Note to clarify the intent that the 1.6 pcm/°F criterion is based on the difference between the MTC determined during the performance of CTS 4.1.1.4.1 (ITS SR 3.1.3.1) and the predicted MTC at the point in core life when the Surveillance is performed.

In September 2016, the CTS **** Note was added in Amendments 235 and 185 for PSL Units 1 and 2, respectively, to waive performance of the MTC end of cycle measurement at or near 2/3 of expected core burn up if the MTC determined during performance of CTS 4.1.1.4.1 is within 1.6 pcm/°F of the predicted value (NRC ADAMS Accession No. ML16183A138). This change in presentation is designated as administrative because it only provides clarification to the original intent as approved in Amendments 235 (Unit 1) and 185 (Unit 2) and does not represent a technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.1.1.4 is applicable in MODES 1 and 2 with an * Note that states, "With K_{eff} ≥ 1.0 (Unit 1 CTS)," and "With K_{eff} greater than or equal to 1.0 (Unit 2 CTS." ITS 3.1.3 is applicable in MODES 1 and 2. This changes the CTS by requiring MTC to be maintained within limits in MODE 2 when k_{eff} is < 1.0.

MTC is an input assumption in the PSL accident analyses, particularly core overheating and core overcooling events. MTC is also an input assumption in startup and subcritical events, such as the uncontrolled CEA withdrawal from a subcritical or low power startup condition. Therefore, MTC must be maintained within limits during MODE 2, whether the reactor is critical or subcritical. This change is consistent with the Applicability of the ISTS and is designated as more restrictive because the Applicability of the CTS LCO requirements is expanded to include subcritical conditions while in MODE 2.

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.3, MODERATOR TEMPERATURE COEFFICIENT (MTC)

1. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. ISTS 3.1.3 contains Figure 3.1.3-1 for Allowable Positive MTC Vs Percent of RTP. This figure is not maintained in ITS 3.1.3. ITS 3.1.3 lists the maximum upper limit value based on THERMAL POWER level in the LCO. Therefore, ISTS Figure 3.1.3-1 is not required and has been deleted.

3. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, or licensing basis description.

4. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant specific information/value is inserted to reflect the current licensing basis.

5. ISTS SR 3.1.3.2 contains one Note. ITS SR 3.1.3.2 retains the Note but also adds a Note (Note 1) that states, "Only required to be performed if MTC determined during performance of SR 3.1.3.1 is not within 1.6 pcm/°F of predicted MTC." This Note is consistent with CTS and was approved in License Amendments 235 and 185, dated September 19, 2016, for PSL Units 1 and 2, respectively, as supported by Combustion Engineering Owners Group Topical Report CE NPSD-911-A and Amendment 1-A. The Note waives performance of the MTC end of cycle measurement if the measured MTC during performance of SR 3.1.3.1 is within 1.6 pcm/°F of the predicted value (NRC ADAMS Accession No. ML16183A138). Concomitant changes are made to reflect two Notes in the ITS.

6. The first Frequency of ISTS SR 3.1.3.2 states, "Each fuel cycle within 7 EFPD of reaching 40 EFPD core burnup." In September 2014, PSL modified the MTC surveillance requirements associated with the implementation of Westinghouse Topical Report WCAP-16011-P-A, "Startup Test Activity Reduction (STAR) Program." In the license amendment request supporting the change, PSL stated that proposed Surveillance 4.1.1.4.2 does not include a requirement for MTC measurements within 7 EFPD of reaching 40 EFPD core burnup to be extrapolated for comparison to the lower MTC limit because performing the surveillance at 2/3 of core burnup will be performed and available for extrapolation to verify the lower MTC limit. The extrapolation of MTC measured within 7 EFPD of reaching 40 EFPD core burnup will not add any additional technical value for comparison to the MTC lower limit and therefore the elimination of this frequency is considered acceptable. CTS 4.1.1.4.2, without the Frequency of 7 EFPD of reaching 40 EFPD core burnup, was approved in License Amendments 219 and 168, dated September 16, 2014, for PSL Units 1 and 2, respectively (NRC ADAMS Accession No. ML14218A180). Therefore, ITS SR 3.1.3.2 does not include this Frequency consistent with CTS.

Improved Standard Technical Specifications (ISTS) Bases Markup and Bases Justification for Deviations (JFDs)

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~

B 3.1.3 Moderator Temperature Coefficient (MTC) ~~(Analog)~~

BASES

BACKGROUND

According to GDC 11 (Ref. 1), the reactor core and its interaction with the Reactor Coolant System (RCS) must be designed for inherently stable power operation, even in the possible event of an accident. In particular, the net reactivity feedback in the system must compensate for any unintended or rapid reactivity increases.

The MTC relates a change in core reactivity to a change in reactor coolant temperature. A positive MTC means that reactivity increases with increasing moderator temperature; conversely, a negative MTC means that reactivity decreases with increasing moderator temperature. The reactor is designed to operate with a negative MTC over the largest possible range of fuel cycle operation. Therefore, a coolant temperature increase will cause a reactivity decrease, so that the coolant temperature tends to return toward its initial value. Reactivity increases that cause a coolant temperature increase will thus be self limiting, and stable power operation will result.

MTC values are predicted at selected burnups during the safety evaluation analysis and are confirmed to be acceptable by measurements. Both initial and reload cores are designed so that the beginning of cycle (BOC) MTC is less positive than that allowed by the LCO. The actual value of the MTC is dependent on core characteristics, such as fuel loading and reactor coolant soluble boron concentration. The core design may require additional fixed distributed poisons (lumped burnable poison assemblies) to yield an MTC at the BOC within the range analyzed in the plant accident analysis. The end of cycle (EOC) MTC is also limited by the requirements of the accident analysis. Fuel cycles that are designed to achieve high burnups or that have changes to other characteristics are evaluated to ensure that the MTC does not exceed the EOC limit.

APPLICABLE SAFETY ANALYSES

The acceptance criteria for the specified MTC are:

a. The MTC values must remain within the bounds of those used in the accident analysis (Ref. 2) and

b. The MTC must be such that inherently stable power operations result during normal operation and during accidents, such as overheating and overcooling events.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Reference 2 contains analyses of accidents that result in both overheating and overcooling of the reactor core. MTC is one of the controlling parameters for core reactivity in these accidents. Both the most positive value and most negative value of the MTC are important to safety, and both values must be bounded. Values used in the analyses consider worst case conditions, such as very large soluble boron concentrations, to ensure the accident results are bounding ~~(Ref. 3)~~. 2

Accidents that cause core overheating, either by decreased heat removal or increased power production, must be evaluated for results when the MTC is positive. Reactivity accidents that cause increased power production include the control element assembly (CEA) withdrawal transient from either zero or full THERMAL POWER. The limiting overheating event relative to plant response is based on the maximum difference between core power and steam generator heat removal during a transient. The most limiting event with respect to a positive MTC is ~~a~~ an uncontrolled CEA withdrawal accident from zero power~~, also referred to as a startup accident~~ (Ref. ~~4~~). 2 2

Accidents that cause core overcooling must be evaluated for results when the MTC is most negative. The event that produces the most rapid cooldown of the RCS, and is therefore the most limiting event with respect to the negative MTC, is a steam line break (SLB) event. Following the reactor trip for the postulated EOC SLB event, the large moderator temperature reduction combined with the large negative MTC may produce reactivity increases that are as much as the shutdown reactivity. When this occurs, a substantial fraction of core power is produced with all CEAs inserted, except the most reactive one, which is assumed withdrawn. Even if the reactivity increase produces slightly subcritical conditions, a large fraction of core power may be produced through the effects of subcritical neutron multiplication.

MTC values are bounded in reload safety evaluations assuming steady state conditions at BOC and EOC. A middle of cycle (MOC) measurement is conducted at conditions when the RCS boron concentration reaches approximately 300 ppm. The measured value may be extrapolated to project the EOC value, in order to confirm reload design predictions.

The MTC satisfies Criterion 2 of ~~the NRC Policy Statement~~ 10 CFR 50.36(c)(2)(ii). 2

BASES

LCO

LCO 3.1.3 requires the MTC to be within the positive and negative limits specified in the COLR to ensure the core operates within the assumptions of the accident analysis. During the reload core safety evaluation, the MTC is analyzed to determine that its values remain within the bounds of the original accident analysis during operation. The positive MTC limit in the COLR ensures that core overheating accidents will not violate the accident analysis assumptions. The negative MTC limit for EOC specified in the COLR ensures that core overcooling accidents will not violate the accident analysis assumptions.

the LCO

The MTC limit in ~~Figure 3.1.3-1~~ is the maximum positive MTC value approved in the plant's licensing basis and ensures that the reactor operates with a negative MTC over the largest possible range of fuel cycle operation. The cycle-specific MTC limit specified in the COLR must be equal to or less positive than the MTC limit specified in ~~Figure 3.1.3-1~~.

the LCO

3

MTC is a core physics parameter determined by the fuel and fuel cycle design and cannot be easily controlled once the core design is fixed. Limited control of MTC can be achieved by adjusting CEA position and boron concentration. During operation the LCO can be ensured through measurement and adjustments to CEA position and boron concentration. The surveillance checks at BOC and MOC on an MTC provide confirmation that the MTC is behaving as anticipated, so that the acceptance criteria are met.

APPLICABILITY

In MODE 1, the limits on the MTC must be maintained to ensure that any accident initiated from THERMAL POWER operation will not violate the design assumptions of the accident analysis. In MODE 2, the limits must also be maintained to ensure startup and subcritical accidents, such as the uncontrolled CEA or group withdrawal, will not violate the assumptions of the accident analysis. In MODES 3, 4, 5, and 6, this LCO is not applicable, since no Design Basis Accidents (DBAs) using the MTC as an analysis assumption are initiated from these MODES. However, the variation of the MTC, with temperature in MODES 3, 4, and 5, for DBAs initiated in MODES 1 and 2, is accounted for in the subject accident analysis. The variation of the MTC, with temperature assumed in the safety analysis, is accepted as valid once the BOC and MOC measurements are used for normalization.

ACTIONS

A.1

MTC is a function of the fuel and fuel cycle designs, and cannot be controlled directly once the designs have been implemented in the core. If MTC exceeds its limits, the reactor must be placed in MODE 3. This eliminates the potential for violation of the accident analysis bounds. The

BASES

ACTIONS (continued)

associated Completion Time of 6 hours is reasonable, considering the probability of an accident occurring during the time period that would require an MTC value within the LCO limits, and the time for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.3.1 and SR 3.1.3.2

The SRs for measurement of the MTC at the beginning and middle of each fuel cycle provide for confirmation of the limiting MTC values. The MTC changes smoothly from most positive (least negative) to most negative value during fuel cycle operation, as the RCS boron concentration is reduced to compensate for fuel depletion.

~~---------- REVIEWER'S NOTE ----------~~
~~The following Bases and the second Frequency of SR 3.1.3.1 are only applicable to plants that adopt WCAP-16011 (Reference 5).~~
~~----------~~ 4

[For fuel cycles that meet the applicability requirements in Reference ~~5~~, and specifically the acceptance criteria that must be met in order to substitute the measured value of MTC at hot zero power (HZP) with an alternate MTC value, SR 3.1.3.1 may be met prior to entering MODE 1 after each fuel loading by confirmation that the predicted MTC, when adjusted for the measured RCS boron concentration, is within the most positive (least negative) MTC limit specified in the COLR. If this adjusted predicted MTC value is used to meet the SR prior to entering MODE 1, a confirmation by measurement that MTC is within the upper MTC limit must be performed in MODE 1 within 7 Effective Full Power Days (EFPD) after reaching 40 EFPD of core burnup. The applicability requirements in Reference ~~5~~ ensure core designs are not significantly different from those used to benchmark predictions and require that the measured RCS boron concentration meets specific test criteria. This provides assurance that the MTC obtained from the adjusted predicted MTC is accurate. 5 3 3 2 3 2

For fuel cycles that do not meet the applicability requirements in Reference ~~5~~, the verification of MTC required prior to entering MODE 1 after each fuel loading is performed by calculation of the MTC based on measurement of the isothermal temperature coefficient. In this case, measurement of MTC within 7 EFPD after reaching 40 EFPD of core burnup is not required.] 3 2 5 3

BASES

SURVEILLANCE REQUIREMENTS (continued)

The requirement for measurement prior to operation > 5% RTP satisfies the confirmatory check on the most positive (least negative) MTC value.

The requirement for measurement, within 7 EFPD after reaching ~~40 EFPD at and~~ 2/3 core burnup, satisfies the confirmatory check of the most negative MTC value. The measurement is performed at any THERMAL POWER, so that the projected EOC MTC may be evaluated before the reactor actually reaches the EOC condition. MTC values may be extrapolated and compensated to permit direct comparison to the MTC limits specified in the COLR. 3

Insert 1 2 3

SR 3.1.3.2 is modified by ~~a Note, which~~ indicates that if the extrapolated MTC is more negative than the EOC limit specified in the COLR, the Surveillance may be repeated, and that shutdown must occur prior to exceeding the minimum allowable boron concentration at which MTC is projected to exceed the lower limit. An engineering evaluation is performed if the extrapolated value of MTC exceeds the Specification limits.

INSERT 1 (2) (3)

two Notes. Note 1 waives performance of the MTC EOC verification if the MTC determined during performance of SR 3.1.3.1 is within 1.6 pcm/°F of the predicted value. This allowance is based on the methodology described in Topical Report CE NPSD-911-A and Amendment 1-A (Ref. 4). Each cycle, the core is designed using this CE methodology such that the best estimate MTC includes a design margin to the BOC and EOC limits. The design margin is determined to be 1.6 pcm/°F at all times in core life. Therefore, if the BOC MTC values are within 1.6 pcm/°F of the best estimate prediction, then it can be assumed that the EOC MTC values will also be within 1.6 pcm/°F of the prediction and its verification is not required. Note 2

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~

B 3.1.3 Moderator Temperature Coefficient (MTC) ~~(Analog)~~

BASES

BACKGROUND

According to GDC 11 (Ref. 1), the reactor core and its interaction with the Reactor Coolant System (RCS) must be designed for inherently stable power operation, even in the possible event of an accident. In particular, the net reactivity feedback in the system must compensate for any unintended or rapid reactivity increases.

The MTC relates a change in core reactivity to a change in reactor coolant temperature. A positive MTC means that reactivity increases with increasing moderator temperature; conversely, a negative MTC means that reactivity decreases with increasing moderator temperature. The reactor is designed to operate with a negative MTC over the largest possible range of fuel cycle operation. Therefore, a coolant temperature increase will cause a reactivity decrease, so that the coolant temperature tends to return toward its initial value. Reactivity increases that cause a coolant temperature increase will thus be self limiting, and stable power operation will result.

MTC values are predicted at selected burnups during the safety evaluation analysis and are confirmed to be acceptable by measurements. Both initial and reload cores are designed so that the beginning of cycle (BOC) MTC is less positive than that allowed by the LCO. The actual value of the MTC is dependent on core characteristics, such as fuel loading and reactor coolant soluble boron concentration. The core design may require additional fixed distributed poisons (lumped burnable poison assemblies) to yield an MTC at the BOC within the range analyzed in the plant accident analysis. The end of cycle (EOC) MTC is also limited by the requirements of the accident analysis. Fuel cycles that are designed to achieve high burnups or that have changes to other characteristics are evaluated to ensure that the MTC does not exceed the EOC limit.

APPLICABLE SAFETY ANALYSES

The acceptance criteria for the specified MTC are:

a. The MTC values must remain within the bounds of those used in the accident analysis (Ref. 2) and

b. The MTC must be such that inherently stable power operations result during normal operation and during accidents, such as overheating and overcooling events.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Reference 2 contains analyses of accidents that result in both overheating and overcooling of the reactor core. MTC is one of the controlling parameters for core reactivity in these accidents. Both the most positive value and most negative value of the MTC are important to safety, and both values must be bounded. Values used in the analyses consider worst case conditions, such as very large soluble boron concentrations, to ensure the accident results are bounding ~~(Ref. 3)~~. 2

Accidents that cause core overheating, either by decreased heat removal or increased power production, must be evaluated for results when the MTC is positive. Reactivity accidents that cause increased power production include the control element assembly (CEA) withdrawal transient from either zero or full THERMAL POWER. The limiting overheating event relative to plant response is based on the maximum difference between core power and steam generator heat removal during a transient. The most limiting event with respect to a positive MTC is ~~a~~ CEA withdrawal accident from zero power~~, also referred to as a startup accident~~ (Ref. ~~4~~). 2

2 an uncontrolled

2

2

Accidents that cause core overcooling must be evaluated for results when the MTC is most negative. The event that produces the most rapid cooldown of the RCS, and is therefore the most limiting event with respect to the negative MTC, is a steam line break (SLB) event. Following the reactor trip for the postulated EOC SLB event, the large moderator temperature reduction combined with the large negative MTC may produce reactivity increases that are as much as the shutdown reactivity. When this occurs, a substantial fraction of core power is produced with all CEAs inserted, except the most reactive one, which is assumed withdrawn. Even if the reactivity increase produces slightly subcritical conditions, a large fraction of core power may be produced through the effects of subcritical neutron multiplication.

MTC values are bounded in reload safety evaluations assuming steady state conditions at BOC and EOC. A middle of cycle (MOC) measurement is conducted at conditions when the RCS boron concentration reaches approximately 300 ppm. The measured value may be extrapolated to project the EOC value, in order to confirm reload design predictions.

The MTC satisfies Criterion 2 of ~~the NRC Policy Statement~~. 10 CFR 50.36(c)(2)(ii) 2

BASES

LCO

LCO 3.1.3 requires the MTC to be within the positive and negative limits specified in the COLR to ensure the core operates within the assumptions of the accident analysis. During the reload core safety evaluation, the MTC is analyzed to determine that its values remain within the bounds of the original accident analysis during operation. The positive MTC limit in the COLR ensures that core overheating accidents will not violate the accident analysis assumptions. The negative MTC limit for EOC specified in the COLR ensures that core overcooling accidents will not violate the accident analysis assumptions.

the LCO

The MTC limit in ~~Figure 3.1.3-1~~ is the maximum positive MTC value approved in the plant's licensing basis and ensures that the reactor operates with a negative MTC over the largest possible range of fuel cycle operation. The cycle-specific MTC limit specified in the COLR must be equal to or less positive than the MTC limit specified in ~~Figure 3.1.3-1~~.

the LCO

3

MTC is a core physics parameter determined by the fuel and fuel cycle design and cannot be easily controlled once the core design is fixed. Limited control of MTC can be achieved by adjusting CEA position and boron concentration. During operation the LCO can be ensured through measurement and adjustments to CEA position and boron concentration. The surveillance checks at BOC and MOC on an MTC provide confirmation that the MTC is behaving as anticipated, so that the acceptance criteria are met.

APPLICABILITY

In MODE 1, the limits on the MTC must be maintained to ensure that any accident initiated from THERMAL POWER operation will not violate the design assumptions of the accident analysis. In MODE 2, the limits must also be maintained to ensure startup and subcritical accidents, such as the uncontrolled CEA or group withdrawal, will not violate the assumptions of the accident analysis. In MODES 3, 4, 5, and 6, this LCO is not applicable, since no Design Basis Accidents (DBAs) using the MTC as an analysis assumption are initiated from these MODES. However, the variation of the MTC, with temperature in MODES 3, 4, and 5, for DBAs initiated in MODES 1 and 2, is accounted for in the subject accident analysis. The variation of the MTC, with temperature assumed in the safety analysis, is accepted as valid once the BOC and MOC measurements are used for normalization.

ACTIONS

A.1

MTC is a function of the fuel and fuel cycle designs, and cannot be controlled directly once the designs have been implemented in the core. If MTC exceeds its limits, the reactor must be placed in MODE 3. This eliminates the potential for violation of the accident analysis bounds. The

BASES

ACTIONS (continued)

associated Completion Time of 6 hours is reasonable, considering the probability of an accident occurring during the time period that would require an MTC value within the LCO limits, and the time for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.3.1 and SR 3.1.3.2

The SRs for measurement of the MTC at the beginning and middle of each fuel cycle provide for confirmation of the limiting MTC values. The MTC changes smoothly from most positive (least negative) to most negative value during fuel cycle operation, as the RCS boron concentration is reduced to compensate for fuel depletion.

~~---------- REVIEWER'S NOTE ----------~~
~~The following Bases and the second Frequency of SR 3.1.3.1 are only applicable to plants that adopt WCAP-16011 (Reference 5).~~
~~----------~~ 4

[For fuel cycles that meet the applicability requirements in Reference ~~5~~, and specifically the acceptance criteria that must be met in order to substitute the measured value of MTC at hot zero power (HZP) with an alternate MTC value, SR 3.1.3.1 may be met prior to entering MODE 1 after each fuel loading by confirmation that the predicted MTC, when adjusted for the measured RCS boron concentration, is within the most positive (least negative) MTC limit specified in the COLR. If this adjusted predicted MTC value is used to meet the SR prior to entering MODE 1, a confirmation by measurement that MTC is within the upper MTC limit must be performed in MODE 1 within 7 Effective Full Power Days (EFPD) after reaching 40 EFPD of core burnup. The applicability requirements in Reference ~~5~~ ensure core designs are not significantly different from those used to benchmark predictions and require that the measured RCS boron concentration meets specific test criteria. This provides assurance that the MTC obtained from the adjusted predicted MTC is accurate. 5 3 3 2 3 2

For fuel cycles that do not meet the applicability requirements in Reference ~~5~~, the verification of MTC required prior to entering MODE 1 after each fuel loading is performed by calculation of the MTC based on measurement of the isothermal temperature coefficient. In this case, measurement of MTC within 7 EFPD after reaching 40 EFPD of core burnup is not required.] 3 2 5 3

BASES

SURVEILLANCE REQUIREMENTS (continued)

The requirement for measurement prior to operation > 5% RTP satisfies the confirmatory check on the most positive (least negative) MTC value.

The requirement for measurement, within 7 EFPD after reaching ~~40 EFPD at and~~ 2/3 core burnup, satisfies the confirmatory check of the most negative MTC value. The measurement is performed at any THERMAL POWER, so that the projected EOC MTC may be evaluated before the reactor actually reaches the EOC condition. MTC values may be extrapolated and compensated to permit direct comparison to the MTC limits specified in the COLR. 3

Insert 1 2 3

SR 3.1.3.2 is modified by ~~a Note, which~~ indicates that if the extrapolated MTC is more negative than the EOC limit specified in the COLR, the Surveillance may be repeated, and that shutdown must occur prior to exceeding the minimum allowable boron concentration at which MTC is projected to exceed the lower limit. An engineering evaluation is performed if the extrapolated value of MTC exceeds the Specification limits.

3/4.1 REACTIVITY CONTROL SYSTEMS

3/4.1.1 BORATION CONTROL

See ITS 3.1.1

SHUTDOWN MARGIN - T_{avg} GREATER THAN 200°F

LIMITING CONDITION FOR OPERATION

3.1.1.1 The SHUTDOWN MARGIN shall be within the limits specified in the COLR.

APPLICABILITY: MODES 1, 2*, 3 and 4.

See ITS 3.1.6

ACTION:

With the SHUTDOWN MARGIN outside the COLR limits, immediately initiate and continue boration at greater than or equal to 40 gpm of a solution containing greater than or equal to 1900 ppm boron or equivalent until the required SHUTDOWN MARGIN is restored.

See ITS 3.1.1

SURVEILLANCE REQUIREMENTS

4.1.1.1.1 The SHUTDOWN MARGIN shall be determined to be within the COLR limits:

L01

a. ~~Within one hour after detection of an inoperable CEA(s) and at least once per 12 hours thereafter while the CEA(s) is inoperable.~~ If the inoperable CEA is not fully inserted, and is immovable as a result of excessive friction or mechanical interference or is known to be untrippable, the above required SHUTDOWN MARGIN shall be verified acceptable with an increased allowance for the withdrawn worth of the immovable or untrippable CEA(s).

See ITS 1.1

b. When in MODE 1 or MODE 2 with Keff greater than or equal to 1.0, in accordance with the Surveillance Frequency Control Program by verifying that CEA group withdrawal is within the Power Dependent Insertion Limits of Specification 3.1.3.6.

See ITS 3.1.6

c. When in MODE 2 with Keff less than 1.0, within 4 hours prior to achieving reactor criticality by verifying that the predicted critical CEA position is within the limits of Specification 3.1.3.6.

* See Special Test Exception 3.10.1.

See ITS 3.1.6

A01

ITS 3.1.4

REACTIVITY CONTROL SYSTEMS

SHUTDOWN MARGIN - T_{avg} LESS THAN OR EQUAL TO 200°F

LIMITING CONDITION FOR OPERATION

3.1.1.2 The SHUTDOWN MARGIN shall be within the limits specified in the COLR.

APPLICABILITY: MODE 5.

See ITS 3.1.1

ACTION:

With the SHUTDOWN MARGIN outside the COLR limits, immediately initiate and continue boration at greater than or equal to 40 gpm of a solution containing greater than or equal to 1900 ppm boron or equivalent until the required SHUTDOWN MARGIN is restored.

SURVEILLANCE REQUIREMENTS

4.1.1.2 The SHUTDOWN MARGIN shall be determined to be within the COLR limits:

a. ~~Within 1 hour after detection of an inoperable CEA(s) and at least once per 12 hours thereafter while the CEA(s) is inoperable.~~ If the inoperable CEA is immovable or untrippable, the above required SHUTDOWN MARGIN shall be increased by an amount at least equal to the withdrawn worth of the immovable or untrippable CEA(s).

L01

See ITS 1.1

b. In accordance with the Surveillance Frequency Control Program by consideration of the following factors:

1. Reactor coolant system boron concentration,
2. CEA position,
3. Reactor coolant system average temperature,
4. Fuel burnup based on gross thermal energy generation,
5. Xenon concentration, and
6. Samarium concentration.

See ITS 3.1.1

c. At least once per 24 hours, when the Reactor Coolant System is drained below the hot leg centerline, by consideration of the factors in 4.1.1.2b and by verifying at least two charging pumps are rendered inoperable by racking out their motor circuit breakers.

See ITS 3.4.12

DISCUSSION OF CHANGES
ITS 3.1.4, CONTROL ELEMENT ASSEMBLY (CEA) ALIGNMENT

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS). These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.1.3.1 LCO, Actions a, d, e, f, g, 4.1.3.1.1, and 4.1.3.1.2 include the descriptor “full length” in reference to CEA(s). Unit 2 CTS 3.1.3.1 LCO, Actions a, c, d, e, f, 4.1.3.1.1, and 4.1.3.1.2 include the descriptor “full length” in reference to CEA(s).

The purpose of the CTS 3.1.3.1 descriptor is to distinguish between full length and partial length CEA(s). Unit 1 and Unit 2 no longer use partial length CEA(s). Therefore, since partial length CEA(s) are no longer a design feature for Unit 1 and Unit 2, the “full length” descriptors used for CEA(s) are deleted. These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A03 Unit 1 CTS 3.1.3.1 Applicability is MODES 1 and 2 with a footnote (footnote *) for MODE 1 and MODE 2 stating "See Special Test Exception 3.10.2 and 3.10.5.” Unit 2 CTS 3.1.3.1 Applicability is MODES 1 and 2 with a footnote (footnote *) for MODE 1 and MODE 2 stating "See Special Test Exception 3.10.2, 3.10.4, and 3.10.5.” ITS 3.1.4 does not contain the footnote or a reference to the Special Test Exceptions. This changes the CTS by not including footnote * in the ITS.

The purpose of the footnote references is to alert the user that conditions exist that may modify the Applicability of the Specification. ITS LCO 3.0.7 provides guidance on the use of special test exceptions. It is an ITS convention to not include reference only type footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

A04 Unit 1 CTS 3.1.3.1 ACTION b.1 states, in part, that “With one CEA position indicator per group inoperable, take action per Specification 3.1.3.3.” Unit 2 CTS 3.1.3.1 ACTION b.1 states, in part, that “With one CEA position indicator per group inoperable, take action per Specification 3.1.3.2.” ITS 3.1.4 does not provide a reference to ITS 3.1.6. This changes the CTS by deleting the reference to another Specification.

The purpose of the CTS 3.1.3.1 statement, “with one CEA position indicator per group inoperable, take action per Specification…” is to provide a reference to another Specification that may apply under these conditions. This changes the CTS by not including the cross-reference in the ITS. It is an ITS convention to not include footnotes or cross-references to comply with other Specification LCO and actions. CTS 3.0.1 (ITS LCO 3.0.1) requires LCOs to be met during the MODES or other specified conditions in the Applicability, except as provided in

LCO 3.0.2. CTS 3.0.2 (ITS LCO 3.0.2) requires, in part, upon discovery of a failure to meet an LCO, the Actions to be met. Therefore, it is unnecessary to reference or duplicate the requirements of another Specification. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

A05 Unit 1 CTS 3.1.3.1 ACTION h. and Unit 2 CTS ACTION g. each state that with one full length CEA inoperable due to causes other than addressed by ACTION a above, and inserted beyond the long term steady state insertion limits but within its above specified alignment requirements, operation in MODES 1 and 2 may continue pursuant to the requirements of Specification 3.1.3.6. ITS 3.1.4 does not provide a reference to ITS 3.1.6 (CTS 3.1.3.6). This changes the CTS by deleting the reference to Specification 3.1.3.6.

Unit 1 CTS 3.1.3.1 ACTION c. and Unit 2 CTS ACTION h. each state that with one full length CEA inoperable due to causes other than addressed by Action a above, but within its above specified alignment requirements and either fully withdrawn or within the long term steady state insertion limits if in CEA group 7 (for Unit 1) and if in CEA group 5 (for Unit 2), operation in MODES 1 and 2 may continue. Though specific reference to other Specifications is not made, reference to Specifications 3.1.3.5 and 3.1.3.6 is implied and requirements from these Specifications and the COLR are duplicated within this statement. ITS 3.1.4 does not include duplicative requirements from other Specifications. This changes the CTS by deleting a statement that contains duplicative requirements from other Specifications.

The purpose of the CTS statements is to associate requirements from other Specifications that may apply under these conditions with a CEA that is "trippable." This changes the CTS by not including these statements in the ITS. It is an ITS convention to not include these type of references or duplicative requirements from other Specifications. CTS 3.0.1 (ITS LCO 3.0.1) requires LCOs to be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2. CTS 3.0.2 (ITS LCO 3.0.2) requires, in part, upon discovery of a failure to meet an LCO, the Actions to be met. Therefore, it is unnecessary to reference or duplicate the requirements of another Specification. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

A06 Unit 1 CTS 3.1.3.1 Action d, and Unit 2 Action f, each allow, when one or more CEAs are misaligned by more than the LCO limit, but < 15 inches for Unit 1 and ≤ 15 inches for Unit 2, operation to continue in MODES 1 and 2 provided within 1 hour action is taken per d.1 or d.2 (Unit 1) and f.1 or f.2 (Unit 2).

Unit 1 CTS 3.1.3.1 Actions d.2 and f.2, and Unit 2 Actions e.2 and f.2, each state that after declaring the CEA inoperable, operation in MODES 1 and 2 may continue pursuant to the requirements of Specification 3.1.3.6 provided within 1 hour the remainder of the CEAs in the group with the inoperable CEA shall be aligned to within the LCO tolerance of the inoperable CEA while maintaining the allowable CEA sequence and insertion limits shown on COLR Figure 3.1-2; the THERMAL POWER level shall be restricted pursuant to Specification 3.1.3.6 during subsequent operation.

The purpose of the CTS statement is to provide time to restore the CEA to within alignment limits. CTS 3.1.3.1 Unit 1 Action d, and Unit 2 Action f specifically allow one hour to either align the CEA (i.e., move the misaligned CEA to align with the CEA group) or declare the CEA inoperable and provide an additional hour to move the other CEAs within the group to align with the misaligned CEA while maintaining allowable CEA sequence and insertion limits specified in the referenced COLR figure and THERMAL POWER restriction specified in Specification 3.1.3.6. In effect, the CTS Actions provide a total of 2 hours to align a CEA to within limits in this condition. This changes CTS by combining the 1 hour to restore the CEA alignment and additional 1 hour to restore CEA alignment.

CTS 3.1.3.1 Unit 1 Action f, and Unit 2 Action e require, in part, THERMAL POWER to be reduced ≤ 70 RTP prior to performing Action f.2 (Unit 1) and Action e.2 (Unit 2). The time to reduce THERMAL POWER has been defined as one hour (See DOC M02). After the power reduction, Action f.2 (Unit 1) and Action e.2 (Unit 2) require declaring the CEA inoperable and provide an additional hour to move the other CEAs within the group to align with the misaligned CEA while maintaining allowable CEA sequence and insertion limits specified in the referenced COLR figure and THERMAL POWER restriction specified in Specification 3.1.3.6. In effect, the CTS Actions provide time to reduce THERMAL POWER (i.e., 1 hour per ITS 3.1.4, Required Action C.1) and an additional hour (i.e., total of 2 hours from Condition entry) to align a CEA to within limits in this condition. This changes CTS by combining the 1 hour to reduce THERMAL POWER and additional 1 hour to restore CEA alignment.

ITS Section 1.2 provides guidance on logical connectors and ITS Section 1.3 provides guidance on Completion Times. When two actions are connected by the logical connector “or” either action can be performed within the required Completion Time. Thus, a total of 2 hours is provided in ITS to align the CEA regardless of the method of restoring the alignment (i.e., moving the CEA to align or moving the CEA group to align).

Also, CTS 3.1.3.6 LCO includes reference to limits specified in the COLR that include the COLR figure specifying the CEA sequence and insertion limits and THERMAL POWER level. This changes the CTS by not including the reference to the COLR figure and Specification 3.1.3.6 in the ITS. It is an ITS convention to not include these type of references and duplicative requirements from other Specifications. CTS 3.0.1 (ITS LCO 3.0.1) requires LCOs to be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2. CTS 3.0.2 (ITS LCO 3.0.2) requires, in part, upon discovery of a failure to meet an LCO, the ACTIONS to be met. Therefore, it is unnecessary to reference or duplicate the requirements of another Specification.

This change is designated as administrative as it combines the 1 hour and additional 1 hour to restore CEA alignment into a single 2 hour Completion Time and removes reference to other Specification requirements with no technical change to the CTS.

A07 **Unit 1 only:** CTS 3.1.3.1 ACTION d.2 states that with one or more CEAs misaligned from any other CEAs in its group by more than 7.5 inches but less than 15 inches, after declaring the CEA inoperable, operation in MODES 1 and 2 may continue pursuant to the requirements of Specification 3.1.3.6 "for up to 7 days per occurrence with a total accumulated time of ≤ 14 days per calendar year." Additionally, CTS 3.1.3.1 ACTION d.2.a) requires that within 1 hour, the remainder of the CEAs in the group with the inoperable CEA shall be aligned to within 7.5 inches of the inoperable CEA (i.e., within 1 hour, meet the LCO requirements of CTS 3.1.3.1). ITS 3.1.4 ACTIONS do not include the operational limit "for up to 7 days per occurrence with a total accumulated time of ≤ 14 days per calendar year." This changes the CTS by deleting the operational limit "for up to 7 days per occurrence with a total accumulated time of ≤ 14 days per calendar year." ITS 3.1.4 retains appropriate CTS 3.1.3.1 actions associated with a CEA outside alignment limits, as modified per the Discussion of Changes provided herein.

The purpose of the CTS requirement is to limit the time to operate, once CEA alignment limits are restored, with regulating CEAs not within the applicable insertion and withdraw sequence limits. The CTS 3.1.3.1 ACTION d.2 operational limit "for up to 7 days per occurrence with a total accumulated time of ≤ 14 days per calendar year," is inconsistent with the requirements of CTS 3.0.2 (ITS LCO 3.0.2). CTS 3.0.2 states, in part, "If the LCO is met or is no longer applicable prior to expiration of the specified time interval(s), completion of the ACTIONS is not required, unless otherwise stated." Once the CEA alignment limits have been restored, LCO 3.1.3.1 (ITS LCO 3.1.4) is met and, therefore, the remaining action limiting operation to, "7 days per occurrence with a total accumulated time of ≤ 14 days per calendar year," is no longer required since there is no note requiring completion of this action following restoration of the LCO. This change is designated as administrative and has no technical impact because the operational limit "for up to 7 days per occurrence with a total accumulated time of ≤ 14 days per calendar year," is an action that is never applicable since the CTS (and ITS) ACTIONS require the CEA Alignment LCO to be met prior to the applicable action requirement becoming limiting.

A08 CTS 4.1.3.1.4.a states that the CEA Block Circuit be demonstrated OPERABLE prior to each entry into MODE 2 from MODE 3, except that such verification need not be performed more often than once per 92 days. The associated footnote (*) states that the licensee shall be excepted from compliance during the initial startup test program for an entry into MODE 2 from MODE 3 made in association with a measurement of power defect.

The purpose of the CTS statement is to provide an exception to performance of the CEA Block Circuit Surveillance at less than a 92 day Frequency. CTS 4.0.4 (ITS SR 3.0.4) requires LCO's Surveillances have been met within their specified frequency prior to entry into a MODE or other specified condition in the Applicability of an LCO, except as provided by CTS 4.0.3 (ITS SR 3.0.3). Therefore, the requirement to perform the Surveillance prior to each entry into MODE 2 from MODE 3, except that such verification need not be performed more often than once per 92 days, is duplicative and unnecessary. CTS 4.1.3.1.4.a (ITS SR 3.1.4.2) will continue to be performed prior to entry into

MODE 2 from MODE 3 and within the Frequency specified in the Surveillance Frequency Control Program.

The purpose of the CTS footnote (*) is to provide a special test exception (STE). CTS 3.10.2, Group Height, Insertion and Power Distribution Limits (STE) provide provision for suspension of certain Specifications, including CTS 3.1.3.1, for startup testing. In addition, ITS LCO 3.0.7 provides guidance on the use of special test exceptions. It is an ITS convention to not include duplicative requirements from other Specifications. ITS 3.1.8 retains the CTS 3.10.2 requirements, therefore, the CTS footnote (*) is unnecessary and deleted.

This changes the CTS by deleting the statement to perform the Surveillance prior to entry into MODE 2 from MODE 3, except performance of the CEA Block Circuit Surveillance at less than a 92 day Frequency is not required, and deleting the footnote (*) that provides a special test exception. This change is designated as administrative as it removes duplicative requirements to Section 3.0 usage requirements and other Specifications with no technical change to the CTS.

A09 Unit 1 CTS 3.1.3.4 Action a. states “With the drop time of any full length CEA determined to exceed the above limit, restore the CEA drop time to within the above limit prior to proceeding to MODE 1 or 2.” Unit 2 CTS 3.1.3.4 Action a.2 states “If in MODE 3, 4, or 5, restore the CEA drop time to within the above limit prior to proceeding to MODE 1 or 2.” In both cases, the “above limit’ refers to the CEA drop time specified in CTS 3.1.3.4. CTS 3.0.4 (ITS LCO 3.0.4) states that when an LCO is not met, entry into a MODE or other specified condition in the Applicability shall only be made under certain conditions. The purpose of CTS 3.1.3.4 is to ensure the CEA drop times are determined within limits prior to entering MODES 1 and 2. Since a plant shutdown (i.e., be in MODE 3 within 6 hours) is required when one or more CEAs is not within the CEA drop time, CTS 3.1.3.4 Actions (ITS 3.1.4 ACTIONS) do not meet any of the LCO 3.0.4 conditions, and therefore, the LCO must be met prior to entry into the MODE of applicability. These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A10 CTS 3.1.3.4 ACTION b provides an allowance for drop times to be determined at less than full reactor coolant flow provided THERMAL POWER is restricted to less than or equal to the maximum THERMAL POWER level allowable for the reactor coolant pump combination operating at the time of the CEA Drop time. ITS 3.1.4 does not contain a similar allowance. This changes the CTS by not allowing continued operation at reduced power when the CEA drop times are determined with only 3 reactor coolant pumps operating. This change is designated as administrative change and is acceptable because they do not result in technical changes to the CTS.

The purpose of CTS 3.1.3.4 is to ensure the CEAs insert within the CEA drop criteria. This change is acceptable because ITS SR 3.1.4.5 requires verification of the CEA drop times be performed with all of the Reactor coolant pumps operating. In accordance with CTS 3.4.1.1 and ITS 3.4.1, Unit 1 and Unit 2 only operate in MODES 1 and 2 with both reactor coolant loops and both reactor coolant pumps in each loop in operation. Therefore, ITS 3.1.4 will not allow the CEA drop times to be determined with only 3 reactor coolant pumps operating.

This change is designated as administrative change and is acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 4.1.3.1.1 states that with the CEA Deviation Circuit and/or the CEA Block Circuit inoperable, verification of the individual CEA positions is required once per 4 hours. However, there is no explicit requirement for the CEA Deviation Circuit to be OPERABLE and no periodic Surveillance is specified to verify the CEA Deviation Circuit is OPERABLE. ITS LCO 3.1.4 requires, in part, that the CEA deviation circuit be OPERABLE and ITS SR 3.1.4.3 requires verification that the deviation circuit is OPERABLE with a Frequency in accordance with the Surveillance Frequency Control Program (SFCP). This changes the CTS by explicitly requiring the deviation circuit be OPERABLE and adding a Surveillance Requirement to verify the deviation circuit is OPERABLE with a Frequency in accordance with the SFCP.

The purpose of the CEA Deviation Circuit is to ensure improper CEA alignments are identified before unacceptable flux distributions occur. CTS 4.1.3.1.1 implies that the CEA deviation circuit is required to be OPERABLE. This change is acceptable because OPERABILITY requirements, implicit in the CTS, and a periodic Surveillance are added to the ITS. FPL adopted an SFCP in Amendments 223 and 173 for PSL Units 1 and 2, respectively (ADAMS Accession No. ML15127A066). Therefore, the Frequency of ITS SR 3.4.1.3 will be in accordance with the SFCP with an initial periodic frequency of 92 days consistent with the Frequency specified in ISTS SR 3.1.4.3. This Frequency considers other information continuously available to the operator in the control room, so that during CEA movement, deviations can be detected, and protection can be provided by the CEA motion inhibit.

This change has been designated as more restrictive because it explicitly adds an LCO operability requirement and Surveillance Requirement to the CTS.

M02 CTS 3.1.3.1 Unit 1 Action f, and Unit 2 Action e require, in part, THERMAL POWER to be reduced ≤ 70 RTP prior to performing Actions f.1 or f.2 (Unit 1) and Action e.1 or e.2 (Unit 2). After the power reduction, Action f.1 (Unit 1) and Action e.1 (Unit 2) require restoring the CEA to within the required alignment limits. The time to reduce THERMAL POWER and the time to restore CEA alignment limit in Action f.1 (Unit 1) and Action e.1 (Unit 2) are not defined in CTS. ITS 3.1.4, Required Action C.1 requires 1 hour to reduce THERMAL POWER to ≤ 70 RTP and Required Action C.2 requires a total of 2 hours (combining the 1 hour to reduce power and 1 hour to restore CEA alignment) to restore the CEA to within the required alignment limits. This changes CTS by adding a specific Completion Time to reduce THERMAL POWER and restore CEA alignment to within limits.

The purpose of CTS 3.1.3.1 actions, in part, is to ensure, when a major CEA alignment deviation occurs, that the CEA alignment be restored in a reasonable period of time to ensure core power distributions are maintained and thermal limits are not exceeded. Xenon redistribution in the core starts to occur as soon

as a CEA becomes misaligned. If the alignment cannot be restored within one hour, a power reduction is required to minimize the effects of the xenon redistribution, while allowing additional time to restore the CEA alignment consistent with the time provided in CTS 3.1.3.1 Unit 1 Action f.2 and Unit 2 Action e.2.

ITS 3.1.4, ACTION C requires THERMAL POWER to be reduced ≤ 70% RTP within 1 hour and the CEA to be restored to within the alignment limits within 2 hours. The Completion Time of Required Action C.1 provides the operator sufficient time to accomplish an orderly power reduction without challenging the Reactor Protection System. The Completion Time of C.2 is sufficient to take appropriate corrective action to realign the CEA following the power reduction while recognizing the importance of minimizing the effects of xenon redistribution.

This change has been designated as more restrictive because it adds to the CTS actions an explicit time to complete the THERMAL POWER reduction and time to restore the CEA to within the required limit following the power reduction.

M03 CTS 4.1.3.1.1 states that with the CEA Deviation Circuit and/or the CEA Block Circuit inoperable, verification of the individual CEA positions is required once per 4 hours. ITS 3.1.4 ACTION D and ACTION E require, with the CEA block circuit or the CEA deviation circuit inoperable, ITS SR 3.1.4.1 (verification of the individual CEA positions) must be performed within 1 hour and once per 4 hours thereafter. This changes the CTS by requiring the initial verification of the individual CEA positions be performed within 1 hour.

The purpose of CTS 4.1.3.1.1 CEA Block Circuit is to permit CEA motion within the requirements of LCO 3.1.6, "Regulating Control Element Assembly Insertion Limits," and prevents regulating CEAs from being misaligned from other CEAs in the group. The purpose of CTS 4.1.3.1.1 CEA Deviation Circuit is to ensure improper CEA alignments are identified before unacceptable flux distributions occur. Performing ITS SR 3.1.4.1 within 1 hour and every 4 hours thereafter, is considered acceptable since it takes into account other information continuously available to the operator in the control room, so that during CEA movement, deviations can be detected, and the protection provided by the CEA block and deviation circuit is not required. This change has been designated as more restrictive because it reduces the amount of time to perform the initial verification of CEA positions.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.1.3.1 Action a. requires that with one or more full-length CEAs inoperable due to being immovable as a result of excessive friction or mechanical interference or known to be untrippable, determine that the

SHUTDOWN MARGIN requirement of Specification 3.1.1.1 is satisfied within 1 hour and be in at least HOT STANDBY within 6 hours. This changes the CTS by relocating details for CEA operability. The details for CEA inoperability due to being immovable as a result of excessive friction or mechanical interference or known to be untrippable is relocated to the ITS Bases. The removal of these details that are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for CEA operability. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.1.3.1 Unit 1 Action e and Unit 2 Action d state that a misaligned CEA be positioned within the LCO alignment limit of other CEAs in its group in accordance with the time constraints shown in COLR Figure 3.1-1a. ITS 3.1.4 Required Action B.1 requires that the CEA alignment be restored "in accordance with the COLR" when one CEA is misaligned more than the maximum allowable alignment deviation. This changes the CTS by relocating details of the specific location in the COLR where the Completion Time value is provided. The details of the COLR figure number where a time restraints are provided based on the measured F_r^T value prior to the misalignment are relocated to the ITS Bases.

The purpose of CTS 3.1.3.1 Unit 1 Actions e and f and Unit 2 Actions d and e is to ensure CEA alignment is restored in a reasonable period of time to ensure core power distributions are maintained and thermal limits are not exceeded. Xenon redistribution in the core starts to occur as soon as a CEA becomes misaligned.

The removal of these details that are related to a specific document reference, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement to restore a misaligned CEA to within the required alignment limit with a Completion Time in accordance with the COLR. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications

LA03 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 4.1.3.1.3 requires the CEA Block Circuit to be demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program by a functional test which verifies that the circuit prevents any CEA from being | R1

misaligned from all other CEAs in its group by more than the required limit (indicated position).

CTS 4.1.3.1.4 requires the CEA Block Circuit to be demonstrated OPERABLE by a functional test which verifies that the circuit maintains the CEA group overlap and sequencing requirements of Specification 3.1.3.6 and that the circuit prevents the regulating CEAs from being inserted beyond the Power Dependent Insertion Limit of COLR Figure 3.1-2.

ITS SR 3.1.4.2 does not retain this detail. This changes the CTS by relocating the details that a functional test that verifies the CEA Block Circuit prevents any CEA from being misaligned from all other CEAs in its group by more than the LCO limit (indicated position), and verifies the CEA Block Circuit circuit maintains the CEA group overlap and sequencing requirements of Specification 3.1.3.6 (ITS 3.1.6) and the CEA Block Circuit prevents the regulating CEAs from being inserted beyond the Power Dependent Insertion Limit of COLR Figure 3.1-2 to the Bases.

The removal of these details, that are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the Surveillance requirement that the CEA Block Ciruit be OPERABLE. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA04 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.1.3.4 requires the individual (shutdown and regulating) CEA drop time from the fully withdrawn position shall be less than or equal to 3.1 seconds (Unit 1) and less than or equal to 3.25 seconds (Unit 2) from when the electrical power is interrupted to the CEA drive mechanism until the CEA reaches the 90% insertion position with T_{avg} greater than or equal to 515°F and all reactor coolant pumps operating. This changes the CTS by relocating details for the CEA drop time surveillance. The CEA drop time of less than or equal to 3.1 seconds is provided in Unit 1 ITS SR 3.1.4.5, and the CEA drop time of less than or equal to 3.25 seconds is provided in Unit 2 ITS SR 3.1.4.5, rather than the ITS 3.1.4 Bases description for SR 3.1.4.5. Because Units 1 and 2 only operate with four reactor coolant pumps, this detail is deleted and not included in the CEA drop time details provided in the ITS 3.1.4 Bases description for SR 3.1.4.5.

The removal of these details that are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for performing CEA drop time testing from the fully withdrawn position. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the

Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.1.3.1 ACTION a. states that with a CEA inoperable due to being immovable as a result of excessive friction or mechanical interference or known to be untrippable, satisfy the SHUTDOWN MARGIN (SDM) requirements of Specification 3.1.1.1 within 1 hour. Unit 1 CTS 3.1.3.1 ACTION d.2., d.2.b., f.2., f.2.b., state that with a misaligned CEA not restored to alignment requirements within 1 hour, declare the CEA inoperable and satisfy SDM requirements of Specification 3.1.1.1. Additionally, the SDM requirement of Specification 3.1.1.1 and 3.1.1.2 is determined at least once per 12 hours thereafter while the CEA(s) are inoperable in accordance with CTS 4.1.1.1.1.a and CTS 4.1.1.2.a, respectively.

Unit 2 CTS 3.1.3.1 ACTION a. states that with a CEA inoperable due to being immovable as a result of excessive friction or mechanical interference or known to be untrippable, satisfy the SDM requirements of Specification 3.1.1.1 within 1 hour. Unit 2 CTS 3.1.3.1 ACTION e.2., e.2.b., f.2., f.2.b., state that with a misaligned CEA not restored to alignment requirements within 1 hour, declare the CEA inoperable and satisfy SDM requirements of Specification 3.1.1.1. Additionally, the SDM requirement of Specification 3.1.1.1 and 3.1.1.2 is determined at least once per 12 hours thereafter while the CEA(s) are inoperable in accordance with CTS 4.1.1.1.1.a and CTS 4.1.1.2.a, respectively.

CTS 3.1.1.1, SDM requirements are applicable in MODES 1, 2, 3, and 4. ITS 3.1.4 does not require a SDM verification when one or more CEAs are inoperable. This changes the CTS Actions by not requiring SDM verification within 1 hour and once per 12 hours thereafter with one or more inoperable CEAs.

The purpose of CTS 4.1.1.1.1.a and CTS 4.1.1.2.a is to provide the appropriate compensatory measures to determine SDM when CEAs are inoperable during operations in MODES 1, 2, 3, 4, and 5. The purpose of the ITS 3.1.4 ACTIONS are to provide the appropriate compensatory actions for inoperable CEAs in MODES 1 and 2. ITS 3.1.5 and 3.1.6 provide requirements for shutdown and regulating CEA insertion limits in MODES 1 and 2. These insertion limits ensure SDM is maintained while the unit is at power. The purpose of ITS SR 3.1.1.1 is to periodically verify SDM regardless of the status of the CEAs in MODES 3, 4, and 5. ITS SR 3.1.1.1 requires SDM verification in accordance with the Surveillance Frequency Control Program. When the plant is operating in MODES 1 and 2, with one or more CEAs inoperable, the unit cannot continue operation and must be placed in MODE 3 within 6 hours. After reaching MODE 3, ITS 3.1.4 no longer applies therefore it is inappropriate to specify additional actions after the unit is outside the Applicability of the Specification. Nevertheless, SDM is periodically verified in accordance with ITS SR 3.1.1.1 in

MODES 3, 4, and 5 in accordance with the frequency specified in the Surveillance Frequency Control Program.

This SDM verification must also compensate for the reactivity worth of the CEA as specified in the definition of SDM. This change is acceptable since SDM will still be required to be monitored at a frequency in accordance with the Surveillance Frequency Control Program, and based on the definition of SDM, the reactivity worth of CEA not capable of being fully inserted must be accounted for in the determination of SDM. Since the proposed actions continue to require a plant shutdown to at least MODE 3 and a verification of SDM must account for the reactivity worth of an inoperable CEA, sufficient remedial measures continue to be provided to allow safe operation pursuant the requirements of 10 CFR 50.36(c)(2). SDM continues to be monitored in a manner and at a Frequency necessary to give confidence that the assumptions in the safety analyses are protected. The frequency currently established for the SDM margin verification in accordance with the Surveillance Frequency Control Program is 24 hours. This change is designated as less restrictive because an Action to perform a Surveillance which is required in the CTS will not be explicitly required in the ITS.

L02 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.1.3.1 Action b and b.2 states, in part, with the CEA Block Circuit inoperable, within 6 hours, with the group overlap and/or sequencing interlocks inoperable, maintain CEAs groups 3, 4, 5 and 6 fully withdrawn and withdraw the CEAs in group 7 to less than 5% insertion and place and maintain the CEA drive system mode switch in either the "Manual" or "Off" position. Unit 2 CTS 3.1.3.1 Action b and b.2 states, in part, with the CEA Block Circuit inoperable, within 6 hours, with the group overlap and/or sequencing interlocks inoperable, maintain CEA groups 1, 2, 3 and 4 fully withdrawn and the CEAs in group 5 to less than 15% insertion and place and maintain the CEA drive system in either the "Manual" or "Off" position. ITS 3.1.4 Required Action D.2.2 retains the CTS requirement, however, the ITS adds a Note that states that Required Action D.2.2 shall not be performed when in conflict with either Required Action C.1, C.2, or E.1. The Note is less restrictive by not requiring performance of Required Action D.2.2 when in conflict with reduction in THERMAL POWER to ≤ 70% RTP per Required Action C.1, restoring CEA alignment to within limits per Required Action C.2, or when performing the deviation circuit Surveillance (SR 3.1.4.1) per Required Action E.1. This changes the CTS by relaxing the requirements for an Action.

The purpose of Unit 1 CTS 3.1.3.1 Actions is to ensure acceptable power distributions are maintained and core thermal limits are not exceeded. This change is acceptable because the actions in the Note are consistent with safe operation under the specific Condition, considering the actions of lowering THERMAL POWER, restoring CEA alignment to within limits, or verifying the deviation circuit is OPERABLE by performance of the Surveillance, are sufficient remedial actions to ensure thermal limits are not exceeded and, therefore, should not be prevented by Required Action D.2.2. This change is designated as less restrictive because the requirements for an Action are relaxed.

L03 *(Category 5 – Deletion of Surveillance Requirement)* CTS 4.1.3.4.b requires the CEA drop time of CEAs shall be demonstrated through measurement prior to reactor criticality for specifically affected individual CEAs following any

maintenance on or modification to the CEA control system which could affect the drop time of those specific CEAs. ITS 3.1.4 does not contain this testing requirement. This changes the CTS by not explicitly requiring post-maintenance testing on CEAs.

The purpose of CTS 4.1.3.4.b is to verify OPERABILITY of the CEAs following maintenance that could alter their operation. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify that the equipment used to meet the LCO can perform its required functions. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to give confidence that the equipment can perform its assumed safety function. Any time the OPERABILITY of a system or component has been affected by repair, maintenance, modification, or replacement of a component, post-maintenance testing is required to demonstrate the OPERABILITY of the system or component. This is described in the Bases for ITS SR 3.0.1 and required under ITS SR 3.0.1. The OPERABILITY requirements for the CEA control system are described in the Bases for ITS 3.1.4. In addition, the requirements of 10 CFR 50, Appendix B, Section XI (Test Control) provide adequate controls for test programs to ensure that testing incorporates applicable acceptance criteria. Compliance with 10 CFR 50, Appendix B, is required under the unit operating license. As a result, post-maintenance testing will continue to be performed and an explicit requirement in the Technical Specifications is not necessary. This change is designated as less restrictive because Surveillances which are required in the CTS will not be required in the ITS.

L04 *(Category 5 – Deletion of Surveillance Requirement)* CTS 4.1.3.4 requires drop testing of CEAs to be demonstrated through measurement prior to reactor criticality following each removal of the reactor vessel head and in accordance with the Surveillance Frequency Control Program, which is at least once per 18 months. ITS SR 3.1.4.5 requires the test to be performed prior to criticality after each removal of the reactor head. This changes the CTS by deleting the requirement to perform this test at least once per 18 months. | R1

The purpose of CTS 4.1.3.4 is to ensure the CEA insert within the CEA drop criteria. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify that the equipment used to meet the LCO can perform its safety function. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to give confidence the equipment can perform its assumed safety function. The requirements in the CTS to perform the test following each removal of the reactor vessel head and at least once per 18 months normally coincide with one another. The head is removed once per 18 months unless there is a need to remove the head prior to the end of the cycle. This change is designated as less restrictive because a Surveillance that was required in the CTS will not be performed in the ITS.

L05 **Unit 2 only:** *(Category 4 – Relaxation of Required Action)* When a CEA is declared inoperable when misaligned by more than 15 inches and beyond the time constraints specified in the COLR figure, CTS 3.1.3.1 e.2 footnote (*) requires that if the pre-misalignment AXIAL SHAPE INDEX (ASI) was more negative than –0.15, power must be reduced to < 70% of RATED THERMAL POWER or 70% of the THERMAL POWER level prior to the misalignment,

whichever is less, prior to completing ACTION e.2.a) and e.2.b). ITS 3.1.4 does not include this additional power reduction requirement based on ASI. This changes the CTS by eliminating the requirement to reduce power to 70% of the THERMAL POWER level prior to the misalignment.

The purpose of the CTS 3.1.3.1 e.2 footnote (*) is to ensure adequate margin to thermal limits are maintained during recovery from a major CEA alignment deviation with a negative ASI value. CTS 3.2.5 (ITS 3.2.4) provides the appropriate remedial actions for conditions when ASI is outside limits specified in the COLR to ensure thermal limits are not exceeded. This change is acceptable because the CTS 3.2.5 action requirements, retained in ITS 3.2.4, provide the appropriate remedial actions for conditions when ASI is outside limits specified in the COLR to ensure thermal limits are not exceeded. The time to restore ASI to within limits specified in ITS 3.2.4 ACTION A is considered sufficiently short that the xenon distribution in the core cannot change significantly and the action to reduce THERMAL POWER in ITS 3.2.4 ACTION B provides reasonable assurance that the core is operating farther from thermal limits and places the core in a conservative condition. This change is designated as less restrictive because the requirements for an Action are relaxed.

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.4, CONTROL ELEMENT ASSEMBLY (CEA) ALIGNMENT

1. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering (CE) vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. ACTIONS A and B are added in the PSL Unit 1 and Unit 2 ITS. ITS ACTION A provides an action to restore the CEA alignment to within the limit in the condition of a minor CEA alignment deviation. For a major CEA alignment deviation, ITS ACTION B first allows time to restore the CEA alignment to within limits prior to the power reduction with a Completion Time of "in accordance with the COLR." These changes are consistent with the CTS Actions. The CTS Action requirement for a minor CEA alignment deviation does not require a THERMAL POWER reduction. For a major CEA alignment deviation, the CTS Actions allow time to restore CEA alignment prior to requiring a THERMAL POWER reduction, provided the time constraints in the specified COLR figure are not exceeded. This allowance was approved in License Amendments 150 and 92 for Unit 1 and Unit 2, respectively (ADAMS Accession No. ML17229A288 (U1) and ML013600531 (U2)) and is considered acceptable because the Completion Time in accordance with the COLR is dependent upon the F_r^T prior to the major CEA alignment deviation. A worst case analysis has previously shown that a DNB fuel design limit violation may occur during this condition but is eliminated by limiting the time operation is permitted at full power before a power reduction is required. Changes to the time constraint specified in the COLR are controlled by an NRC-approved methodology. This change to the ISTS is also similar to the ITS 3.1.4 ACTIONS of another analog type CE plant; Calvert Cliff Nuclear Power Plant, Units 1 and 2 (ADAMS Accession No. ML052720276). ISTS 3.1.4, Condition A (ITS 3.1.4., Condition C) is revised to state, "Required Action and associated Completion Time of Condition B not met. ISTS Required Action A.2 (ITS Required Action C.2) is revised to be consistent with the wording in Required Action A.1 of new ITS ACTION A and is considered editorial. The Completion Time for ISTS Required Actions A.1 and A.2 (ITS Required Actions C.1 and C.2) remain unchanged and are consistent with the Calvert Cliffs ITS 3.1.4 ACTION C Completion Times. Subsequent Conditions, Required Actions, and references to Required Actions are renumbered to reflect this change.

4. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

5. ISTS SR 3.1.4.5 is deleted and subsequent Surveillance is renumbered. PSL developed ITS 3.1.7, Control Element Assembly (CEA) Position Indication, and requires performance of ITS SR 3.1.7.1 to determine operability of the reed switch position indicating channels and the pulse counting position indicating channels in accordance with the Surveillance Frequency Control Program.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~

1

B 3.1.4 Control Element Assembly (CEA) Alignment ~~(Analog)~~

BASES

BACKGROUND

The OPERABILITY (i.e., trippability) of the shutdown and regulating Control Element Assemblies (CEAs) is an initial assumption in all safety analyses that assume CEA insertion upon reactor trip. Maximum CEA misalignment is an initial assumption in the safety analysis that directly affects core power distributions and assumptions of available SDM.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10 and GDC 26 (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Plants" (Ref. 2).

Mechanical or electrical failures may cause a CEA to become inoperable or to become misaligned from its group. CEA inoperability or misalignment may cause increased power peaking, due to the asymmetric reactivity distribution and a reduction in the total available CEA worth for reactor shutdown. Therefore, CEA alignment and OPERABILITY are related to core operation in design power peaking limits and the core design requirement of a minimum SDM.

Limits on CEA alignment and OPERABILITY have been established, and all CEA positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

CEAs are moved by their control element drive mechanisms (CEDMs)~~. Each CEDM moves its CEA~~ one step (approximately ¾ inch) at a time~~, but at varying rates (steps per minute) depending on the signal output from the Control Element Drive Mechanism Control System (CEDMCS)~~.

2

The CEAs are arranged into groups that are radially symmetric. Therefore, movement of the CEAs does not introduce radial asymmetries in the core power distribution. The shutdown and regulating CEAs provide the required reactivity worth for immediate reactor shutdown upon a reactor trip. The regulating CEAs also provide reactivity (power level) control during normal operation and transients. ~~Their movement may be automatically controlled by the Reactor Regulating System.~~

2

The axial position of shutdown and regulating CEAs is indicated by two separate and independent systems, which are the ~~Plant Computer CEA~~ Position Indication System and the Reed Switch Position Indication System.

3

Pulse Counting

3

1

BASES

BACKGROUND (continued)

Pulse Counting

The ~~Plant Computer CEA~~ Position Indication System counts the commands sent to the CEA gripper coils from the CEDM Control System that moves the CEAs. There is a one step counter for each ~~group of~~ CEA~~s~~. Individual CEAs in a group all receive the same signal to move and should, therefore, all be at the same position indicated by the group step counter for that group. ~~Plant Computer CEA~~ Position Indication System is considered highly precise (± 1 step or ± ¾ inch). ~~If a CEA does not move one step for each command signal, the step counter will still count the command and incorrectly reflect the position of the CEA.~~

3

An individual CEA may be moved in the Manual Individual Mode. The Pulse Counting

A step is counted after the Step Complete signal is received.

3 4

4

The Reed Switch Position Indication System provides a highly accurate indication of actual CEA position, but at a lower precision than the step counters. This system is based on ~~inductive analog~~ signals from a series of reed switch~~es~~ spaced ~~along a tube with a center to center distance of~~ 1.5 inch~~es~~, which is two steps. ~~To increase the reliability of the system, there are redundant reed switches at each position.~~

magnetically actuated

position transmitters

at

intervals

4

3

APPLICABLE SAFETY ANALYSES

CEA misalignment accidents are analyzed in the safety analysis (Ref. 3). The accident analysis defines CEA misoperation as an~~y~~ event~~, with the exception of sequential group withdraws,~~ which could result from a single malfunction in the reactivity control systems. ~~For example, CEA misalignment may be caused by a malfunction of the CEDM, CEDMCS, or by operator error. A stuck CEA may be caused by mechanical jamming of the CEA fingers or of the gripper. Inadvertent withdrawal of a single CEA may be caused by the opening of the electrical circuit of the CEDM holding coil for a full length or part length CEA. A dropped CEA could be caused by an electrical failure in the CEA coil power programmers~~.

5

The acceptance criteria for addressing CEA inoperability or misalignment are that:

a. There shall be no violations of either:

   1. Specified acceptable fuel design limits or

   2. Reactor Coolant System (RCS) pressure boundary integrity and

b. The core must remain subcritical after accident transients.

3

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~Three types of~~ misalignment are distinguished in the safety analysis (Ref. 1). ~~During movement of a group, one CEA may stop moving while the other CEAs in the group continue. This condition may cause excessive power peaking. The second type of~~ misalignment occurs if one CEA fails to insert upon a reactor trip and remains stuck fully withdrawn. This condition requires an evaluation to determine that sufficient reactivity worth is held in the remaining CEAs to meet the SDM requirement with the maximum worth CEA stuck fully withdrawn. If a CEA is stuck in the fully withdrawn position, its worth is added to the SDM requirement, since the safety analysis does not take two stuck CEAs into account. ~~The third type of~~ misalignment occurs when one CEA drops partially or fully into the reactor core. This event causes an initial power reduction followed by a return towards the original power, due to positive reactivity feedback from the negative moderator temperature coefficient. Increased peaking during the power increase may result in excessive local linear heat rates (LHRs).

~~Two types of~~ analyses are performed in regard to static CEA misalignment (Ref. ~~4~~). With CEA banks at their insertion limits, one type of analysis considers the case when any one CEA is inserted ~~[~~ ~~]~~ inches into the core. The second type of analysis considers the case of a single CEA withdrawn ~~[~~ ~~]~~ inches from a bank inserted into its insertion limit. Satisfying limits on departure from nucleate boiling ratio (DNBR) in both of these cases bounds the situation when a CEA is misaligned from its group by ~~[7~~ inches~~]~~.

Another type of misalignment occurs if one CEA fails to insert upon a reactor trip and remains stuck fully withdrawn. This condition is assumed in the evaluation to determine that the required SDM is met with the maximum worth CEA also fully withdrawn (Ref. ~~5~~).

Since the CEA drop incidents result in the most rapid approach to specified acceptable fuel design limits (SAFDLs) caused by a CEA misoperation, the accident analysis analyzed a single full length CEA drop. The most rapid approach to the DNBR SAFDL may be caused by a single full length CEA drop or a CEA subgroup drop, depending upon initial conditions.

~~All of the above CEA misoperations will result in an automatic reactor trip.~~ In the case of the full length CEA drop, a prompt decrease in core average power and a distortion in radial power are initially produced, which, when conservatively coupled, result in a local power and heat flux increase, and a decrease in DNBR parameters.

1

BASES

APPLICABLE SAFETY ANALYSES (continued)

The results of the CEA misoperation analysis show that during the most limiting misoperation events, no violations of the SAFDLs, fuel centerline temperature, or RCS pressure occur.

CEA alignment limits and OPERABILITY requirements satisfy Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The limits on shutdown and regulating CEA alignments ensure that the assumptions in the safety analysis will remain valid. The requirements on CEA OPERABILITY ensure that upon reactor trip, the CEAs will be available and will be inserted to provide enough negative reactivity to shut down the reactor. The CEA OPERABILITY requirements (i.e., trippability) are separate from alignment requirements which ensure that the CEA banks maintain the correct power distribution and CEA alignment. The CEA OPERABILITY requirement is satisfied provided the CEA will fully insert in the required CEA drop time assumed in the safety analysis. CEA control malfunctions that result in the inability to move a CEA (e.g., CEA lift rod failures), but do not impact trippability, do not result in CEA inoperability.

7.5

The requirement is to maintain the CEA alignment to within ~~[7~~ inches~~]~~ between any CEA and its group. The minimum misalignment assumed in safety analysis is ~~[~~15 inches~~]~~, and in some cases, a total misalignment from fully withdrawn to fully inserted is assumed.

6

Failure to meet the requirements of this LCO may produce unacceptable power peaking factors and LHRs, or unacceptable SDMS, all of which may constitute initial conditions inconsistent with the safety analysis.

APPLICABILITY

The requirements on CEA OPERABILITY and alignment are applicable in MODES 1 and 2 because these are the only MODES in which neutron (or fission) power is generated, and the OPERABILITY (i.e., trippability) and alignment of CEAs have the potential to affect the safety of the plant. In MODES 3, 4, 5, and 6, the alignment limits do not apply because the CEAs are bottomed, and the reactor is shut down and not producing fission power. In the shutdown Modes, the OPERABILITY of the shutdown and regulating CEAs has the potential to affect the required SDM, but this effect can be compensated for by an increase in the boron concentration of the RCS. See LCO 3.1.1, "SHUTDOWN MARGIN (SDM)," for SDM in MODES 3, 4, and 5, and LCO 3.9.1, "Boron Concentration," for boron concentration requirements during refueling.

3

BASES

ACTIONS

A.1 ~~and A.2~~

If one or more CEAs (regulating or shutdown) are misaligned by > ~~[~~7 inches~~]~~ and ≤ [15 inches~~]~~, ~~or one CEA is misaligned by > [15 inches], continued operation in MODES 1 and 2 may continue, provided, within 1 hour, the power is reduced to ≤ 70% RTP, and within~~ 2 hours ~~CEA alignment is restored~~. Regulating CEA alignment can be restored by either aligning the misaligned CEA(s) to within ~~[~~7 inches~~]~~ of its group or aligning the misaligned CEA's group to within ~~[~~7 inches~~]~~ of the misaligned CEA. Shutdown CEA alignment can be restored by aligning the misaligned CEA(s) to within ~~[~~7 inches~~]~~ of its group.

~~Xenon redistribution in the core starts to occur as soon as a CEA becomes misaligned. Reducing THERMAL POWER in accordance with Figure 3.1.4-1 (in the associated LCO) ensures acceptable power distributions are maintained (Ref. 6).~~ For ~~small misalignments~~ (< ~~[~~15 inches~~]~~) of the CEAs, there is:

a. A small effect on the time dependent long term power distributions relative to those used in generating LCOs and limiting safety system settings (LSSS) setpoints,

b. A negligible effect on the available SDM, and

c. A small effect on the ejected CEA worth used in the accident analysis.

~~With a large CEA misalignment (≥ [15 inches]), however, this misalignment would cause distortion of the core power distribution. This distortion may, in turn, have a significant effect on the time dependent, long term power distributions relative to those used in generating LCOs and LSSS setpoints. The effect on the available SDM and the ejected CEA worth used in the accident analysis remain small. Therefore, this condition is limited to a single CEA misalignment, while still allowing 2 hours for recovery.~~

~~In both cases, a~~ 2 hour~~s~~ ~~time period~~ is sufficient to:

a. Identify cause of a misaligned CEA, ~~and~~

b. Take appropriate corrective action to realign the CEAs~~, and~~

~~c. Minimize the effects of xenon redistribution~~.

Bases Insert 1

8

BASES INSERT 1

B.1

If one CEA is misaligned from its group by ≥ 15 inches, CEA alignment must be restored to < 15 inches in 1 hour. Regulating CEA alignment can be restored by either aligning the misaligned CEA to < 15 inches of its group or aligning the misaligned CEA's group to < 15 inches of the misaligned CEA. Shutdown CEA alignment can be restored by aligning the misaligned CEA to < 15 inches of its group.

Xenon redistribution in the core starts to occur as soon as a CEA becomes misaligned. With a major CEA alignment deviation (≥ 15 inches), misalignment could cause distortion of the core power distribution. This distortion may, in turn, have a significant effect on the time dependent, long term power distributions relative to those used in generating LCOs and LSSS setpoints. The effect on the available SDM and the ejected CEA worth used in the accident analysis remain small. Therefore, this condition is limited to a single major CEA alignment deviation and the time constraints provided in the applicable COLR figure for recovery. A higher total integrated peaking factor (F_r^T) prior to the misalignment could result in a shorter time constraint, further limiting the Completion Time before requiring a power reduction.

The Completion Time in accordance with the COLR is dependent upon the F_r^T prior to the major CEA alignment deviation. A worst case analysis has shown that a DNBR SAFDL violation may occur during this condition. This potential DNBR SAFDL violation is eliminated by limiting the time operation is permitted at full power before a power reduction is required.

C.1 and C.2

If the Required Action and associated Completion Time of Condition B cannot be met, operation in MODES 1 and 2 may continue provided power is promptly reduced to ≤ 70% RTP within 1 hour and the CEA is restored to within alignment limits in one additional hour. Operation with THERMAL POWER ≤ 70% RTP provides additional margin to offset the increase in F_r^T, thereby avoiding violation of the fuel design limits.

The Completion Time of Required Action C.1 provides the operator sufficient time to accomplish an orderly power reduction without challenging the Reactor Protection System. The Completion Time of C.2 to restore the CEA to within alignment limits is sufficient to take appropriate corrective action to realign the CEA following the power reduction while recognizing the importance of minimizing the effects of xenon redistribution.

BASES

ACTIONS (continued)

~~B~~.1, ~~B~~.2.1, and ~~B~~.2.2

The CEA ~~motion inhibit~~ permits CEA motion within the requirements of LCO 3.1.6, "Regulating Control Element Assembly Insertion Limits," and prevents regulating CEAs from being misaligned from other CEAs in the group.

Performing SR 3.1.4.1 within 1 hour and every 4 hours thereafter, is considered acceptable in view of other information continuously available to the operator in the control room.

With the CEA ~~motion inhibit~~ inoperable, a Completion Time of 6 hours is allowed for restoring the CEA ~~motion inhibit~~ to OPERABLE status, or placing and maintaining the CEA drive switch in either the "off" or "manual" position~~.~~, fully withdrawing the CEAs in groups ~~3 and 4~~, and withdrawing all CEAs in group ~~5~~ to < 5% insertion~~.~~,

Placing the CEA drive switch in the "off" or "manual" position ensures the CEAs will not move ~~in response to Reactor Regulating System automatic motion commands~~. Withdrawal of the CEAs to the positions required in the Required Action ~~B~~.2.2 ensures that core perturbations in local burnup, peaking factors, and SDM will not be more adverse than the Conditions assumed in the safety analyses and LCO setpoint determination (Ref. ~~6~~).

The 6 hour Completion Time takes into account Required Action ~~B~~.1, the protection afforded by the CEA deviation circuits, and other information continuously available to the operator in the control room, so that during actual CEA motion, deviations can be detected.

Required Action ~~B~~.2.2 is modified by a Note indicating that this Required Action shall not be performed when in conflict with either Required Action ~~A~~.1, ~~A~~.2, or ~~C~~.1.

BASES

ACTIONS (continued)

~~C~~.1

When the CEA deviation circuit is inoperable, performing SR 3.1.4.1, within 1 hour and every 4 hours thereafter, ensures improper CEA alignments are identified before unacceptable flux distributions occur. The specified Completion Times take into account other information continuously available to the operator in the control room, so that during CEA movement, deviations can be detected, and the protection provided by the CEA inhibit and deviation circuit is not required.

~~D~~.1

If the Required Action or associated Completion Time of Condition A, ~~Condition B, or Condition~~ C is not met, one or more regulating or shutdown CEAs are inoperable, or two or more CEAs are misaligned by ~~>~~ [15 inches], the unit is required to be brought to MODE 3. By being brought to MODE 3, the unit is brought outside its MODE of applicability. Continued operation is not allowed in the case of more than one CEA misaligned from any other CEA in its group by ~~>~~ [15 inches], or one or more CEAs inoperable. This is because these cases are indicative of a loss of SDM and power distribution, and a loss of safety function, respectively.

When a Required Action cannot be completed within the required Completion Time, a controlled shutdown should be commenced. The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.4.1

Verification is required that individual CEA positions are within [~~7~~ inches] (indicated reed switch positions) of all other CEAs in the group within 1 hour of any CEA movement of > 7.5 inches. The CEA position verification after each movement of > 7.5 inches ensures that the CEAs in that group are properly aligned at the time when CEA misalignments are most likely to have occurred. ~~[The 12 hour Frequency allows the operator to detect a CEA that is beginning to deviate from its expected position. The specified Frequency takes into account other CEA position information that is continuously available to the operator in the control room, so that during CEA movement, deviations can be detected, and protection can be provided by the CEA motion inhibit and deviation circuits.~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

Between required performances of SR 3.1.4.4, if a CEA(s) is discovered to be immovable, but remains trippable, the CEA is considered to be OPERABLE. At any time, if a CEA(s) is immovable, a determination of the trippability (OPERABILITY) of the CEA(s) must be made, and appropriate action taken.

3

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.1.4.5

~~Performance of a CHANNEL FUNCTIONAL TEST of each reed switch position transmitter channel ensures the channel is OPERABLE and capable of indicating CEA position over the entire length of the CEA's travel. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. [Since this Surveillance must be performed when the reactor is shut down, an 18 month Frequency to be coincident with refueling outage was selected. Operating experience has shown that these components usually pass this Surveillance when performed at a Frequency of once every 18 months. Furthermore, the Frequency takes into account other surveillances being performed at shorter Frequencies, which determine the OPERABILITY of the CEA Reed Switch Indication System.~~

11

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~

1

B 3.1.4 Control Element Assembly (CEA) Alignment ~~(Analog)~~

BASES

BACKGROUND

The OPERABILITY (i.e., trippability) of the shutdown and regulating Control Element Assemblies (CEAs) is an initial assumption in all safety analyses that assume CEA insertion upon reactor trip. Maximum CEA misalignment is an initial assumption in the safety analysis that directly affects core power distributions and assumptions of available SDM.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10 and GDC 26 (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Plants" (Ref. 2).

Mechanical or electrical failures may cause a CEA to become inoperable or to become misaligned from its group. CEA inoperability or misalignment may cause increased power peaking, due to the asymmetric reactivity distribution and a reduction in the total available CEA worth for reactor shutdown. Therefore, CEA alignment and OPERABILITY are related to core operation in design power peaking limits and the core design requirement of a minimum SDM.

Limits on CEA alignment and OPERABILITY have been established, and all CEA positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

CEAs are moved by their control element drive mechanisms (CEDMs). ~~Each CEDM moves its CEA~~ one step (approximately ¾ inch) at a time~~, but at varying rates (steps per minute) depending on the signal output from the Control Element Drive Mechanism Control System (CEDMCS)~~.

2

The CEAs are arranged into groups that are radially symmetric. Therefore, movement of the CEAs does not introduce radial asymmetries in the core power distribution. The shutdown and regulating CEAs provide the required reactivity worth for immediate reactor shutdown upon a reactor trip. The regulating CEAs also provide reactivity (power level) control during normal operation and transients. ~~Their movement may be automatically controlled by the Reactor Regulating System.~~

2

The axial position of shutdown and regulating CEAs is indicated by two separate and independent systems, which are the ~~Plant Computer CEA~~ Position Indication System and the Reed Switch Position Indication System.

APPLICABLE SAFETY ANALYSES

CEA misalignment accidents are analyzed in the safety analysis (Ref. 3). The accident analysis defines CEA misoperation as an~~y~~ event~~, with the exception of sequential group withdraws,~~ which could result from a single malfunction in the reactivity control systems. ~~For example, CEA misalignment may be caused by a malfunction of the CEDM, CEDMCS, or by operator error. A stuck CEA may be caused by mechanical jamming of the CEA fingers or of the gripper. Inadvertent withdrawal of a single CEA may be caused by the opening of the electrical circuit of the CEDM holding coil for a full length or part length CEA. A dropped CEA could be caused by an electrical failure in the CEA coil power programmers.~~

5

The acceptance criteria for addressing CEA inoperability or misalignment are that:

a. There shall be no violations of either:

   1. Specified acceptable fuel design limits or

   2. Reactor Coolant System (RCS) pressure boundary integrity and

b. The core must remain subcritical after accident transients.

BASES

APPLICABLE SAFETY ANALYSES (continued)

~~Three types of~~ misalignment are distinguished in the safety analysis (Ref. 1). ~~During movement of a group, one CEA may stop moving while the other CEAs in the group continue. This condition may cause excessive power peaking. The second type of~~ misalignment occurs if one CEA fails to insert upon a reactor trip and remains stuck fully withdrawn. This condition requires an evaluation to determine that sufficient reactivity worth is held in the remaining CEAs to meet the SDM requirement with the maximum worth CEA stuck fully withdrawn. If a CEA is stuck in the fully withdrawn position, its worth is added to the SDM requirement, since the safety analysis does not take two stuck CEAs into account. ~~The third type of~~ misalignment occurs when one CEA drops partially or fully into the reactor core. This event causes an initial power reduction followed by a return towards the original power, due to positive reactivity feedback from the negative moderator temperature coefficient. Increased peaking during the power increase may result in excessive local linear heat rates (LHRs).

~~Two types of~~ analyses are performed in regard to static CEA misalignment (Ref. ~~4~~). With CEA banks at their insertion limits, one type of analysis considers the case when any one CEA is inserted ~~[~~ ~~]~~ inches into the core. The second type of analysis considers the case of a single CEA withdrawn ~~[~~ ~~]~~ inches from a bank inserted into its insertion limit. Satisfying limits on departure from nucleate boiling ratio (DNBR) in both of these cases bounds the situation when a CEA is misaligned from its group by ~~[~~7 inches~~]~~.

Another type of misalignment occurs if one CEA fails to insert upon a reactor trip and remains stuck fully withdrawn. This condition is assumed in the evaluation to determine that the required SDM is met with the maximum worth CEA also fully withdrawn (Ref. ~~5~~).

Since the CEA drop incidents result in the most rapid approach to specified acceptable fuel design limits (SAFDLs) caused by a CEA misoperation, the accident analysis analyzed a single full length CEA drop. The most rapid approach to the DNBR SAFDL may be caused by a single full length CEA drop or a CEA subgroup drop, depending upon initial conditions.

~~All of the above CEA misoperations will result in an automatic reactor trip.~~ In the case of the full length CEA drop, a prompt decrease in core average power and a distortion in radial power are initially produced, which, when conservatively coupled, result in a local power and heat flux increase, and a decrease in DNBR parameters.

1

BASES

APPLICABLE SAFETY ANALYSES (continued)

The results of the CEA misoperation analysis show that during the most limiting misoperation events, no violations of the SAFDLs, fuel centerline temperature, or RCS pressure occur.

CEA alignment limits and OPERABILITY requirements satisfy Criteria 2 and 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The limits on shutdown and regulating CEA alignments ensure that the assumptions in the safety analysis will remain valid. The requirements on CEA OPERABILITY ensure that upon reactor trip, the CEAs will be available and will be inserted to provide enough negative reactivity to shut down the reactor. The CEA OPERABILITY requirements (i.e., trippability) are separate from alignment requirements which ensure that the CEA banks maintain the correct power distribution and CEA alignment. The CEA OPERABILITY requirement is satisfied provided the CEA will fully insert in the required CEA drop time assumed in the safety analysis. CEA control malfunctions that result in the inability to move a CEA (e.g., CEA lift rod failures), but do not impact trippability, do not result in CEA inoperability.

The requirement is to maintain the CEA alignment to within ~~[~~7 inches~~]~~ between any CEA and its group. The minimum misalignment assumed in safety analysis is ~~[~~15 inches~~]~~, and in some cases, a total misalignment from fully withdrawn to fully inserted is assumed.

6

Failure to meet the requirements of this LCO may produce unacceptable power peaking factors and LHRs, or unacceptable SDMS, all of which may constitute initial conditions inconsistent with the safety analysis.

APPLICABILITY

The requirements on CEA OPERABILITY and alignment are applicable in MODES 1 and 2 because these are the only MODES in which neutron (or fission) power is generated, and the OPERABILITY (i.e., trippability) and alignment of CEAs have the potential to affect the safety of the plant. In MODES 3, 4, 5, and 6, the alignment limits do not apply because the CEAs are bottomed, and the reactor is shut down and not producing fission power. In the shutdown Modes, the OPERABILITY of the shutdown and regulating CEAs has the potential to affect the required SDM, but this effect can be compensated for by an increase in the boron concentration of the RCS. See LCO 3.1.1, "SHUTDOWN MARGIN (SDM)," for SDM in MODES 3, 4, and 5, and LCO 3.9.1, "Boron Concentration," for boron concentration requirements during refueling.

3

BASES

ACTIONS

A.1 ~~and A.2~~

If one or more CEAs (regulating or shutdown) are misaligned by > [7 inches] and ≤ [15 inches], ~~or one CEA is misaligned by > [15 inches], continued operation in MODES 1 and 2 may continue, provided, within 1 hour, the power is reduced to ≤ 70% RTP, and within~~ 2 hours ~~CEA alignment is restored~~. Regulating CEA alignment can be restored by either aligning the misaligned CEA(s) to within [7 inches] of its group or aligning the misaligned CEA's group to within [7 inches] of the misaligned CEA. Shutdown CEA alignment can be restored by aligning the misaligned CEA(s) to within [7 inches] of its group.

~~Xenon redistribution in the core starts to occur as soon as a CEA becomes misaligned. Reducing THERMAL POWER in accordance with Figure 3.1.4-1 (in the associated LCO) ensures acceptable power distributions are maintained (Ref. 6).~~ For ~~small misalignments~~ (~~<~~ [15 inches]) of the CEAs, there is:

a. A small effect on the time dependent long term power distributions relative to those used in generating LCOs and limiting safety system settings (LSSS) setpoints,

b. A negligible effect on the available SDM, and

c. A small effect on the ejected CEA worth used in the accident analysis.

~~With a large CEA misalignment (≥ [15 inches]), however, this misalignment would cause distortion of the core power distribution. This distortion may, in turn, have a significant effect on the time dependent, long term power distributions relative to those used in generating LCOs and LSSS setpoints. The effect on the available SDM and the ejected CEA worth used in the accident analysis remain small. Therefore, this condition is limited to a single CEA misalignment, while still allowing 2 hours for recovery.~~

~~In both cases, a~~ 2 hour~~s~~ ~~time period~~ is sufficient to:

a. Identify cause of a misaligned CEA, ~~and~~

b. Take appropriate corrective action to realign the CEAs~~, and~~

~~c. Minimize the effects of xenon redistribution~~.

Bases Insert 1

8

BASES INSERT 1

B.1

If one CEA is misaligned from its group by > 15 inches, CEA alignment must be restored to ≤ 15 inches in 1 hour. Regulating CEA alignment can be restored by either aligning the misaligned CEA to ≤ 15 inches of its group or aligning the misaligned CEA's group to ≤ 15 inches of the misaligned CEA. Shutdown CEA alignment can be restored by aligning the misaligned CEA to ≤ 15 inches of its group.

Xenon redistribution in the core starts to occur as soon as a CEA becomes misaligned. With a major CEA alignment deviation (> 15 inches), misalignment could cause distortion of the core power distribution. This distortion may, in turn, have a significant effect on the time dependent, long term power distributions relative to those used in generating LCOs and LSSS setpoints. The effect on the available SDM and the ejected CEA worth used in the accident analysis remain small. Therefore, this condition is limited to a single major CEA alignment deviation and the time constraints provided in the applicable COLR figure for recovery. A higher total integrated peaking factor (F_r^T) prior to the misalignment could result in a shorter time constraint, further limiting the Completion Time before requiring a power reduction.

The Completion Time in accordance with the COLR is dependent upon the F_r^T prior to the major CEA alignment deviation. A worst case analysis has shown that a DNBR SAFDL violation may occur during this condition. This potential DNBR SAFDL violation is eliminated by limiting the time operation is permitted at full power before a power reduction is required.

C.1 and C.2

If the Required Action and associated Completion Time of Condition B cannot be met, operation in MODES 1 and 2 may continue provided power is promptly reduced to ≤ 70% RTP within 1 hour and the CEA is restored to within alignment limits in one additional hour. Operation with THERMAL POWER ≤ 70% RTP provides additional margin to offset the increase in F_r^T, thereby avoiding violation of the fuel design limits.

The Completion Time of Required Action C.1 provides the operator sufficient time to accomplish an orderly power reduction without challenging the Reactor Protection System. The Completion Time of C.2 to restore the CEA to within alignment limits is sufficient to take appropriate corrective action to realign the CEA following the power reduction while recognizing the importance of minimizing the effects of xenon redistribution.

BASES

ACTIONS (continued)

~~B~~.1, ~~B~~.2.1, and ~~B~~.2.2

The CEA ~~motion inhibit~~ permits CEA motion within the requirements of LCO 3.1.6, "Regulating Control Element Assembly Insertion Limits," and prevents regulating CEAs from being misaligned from other CEAs in the group.

Performing SR 3.1.4.1 within 1 hour and every 4 hours thereafter, is considered acceptable in view of other information continuously available to the operator in the control room.

With the CEA ~~motion inhibit~~ inoperable, a Completion Time of 6 hours is allowed for restoring the CEA ~~motion inhibit~~ to OPERABLE status, or placing and maintaining the CEA drive switch in either the "off" or "manual" position, fully withdrawing the CEAs in groups 3 and 4, and withdrawing all CEAs in group 5 to < ~~5~~% insertion~~.~~,

Placing the CEA drive switch in the "off" or "manual" position ensures the CEAs will not move ~~in response to Reactor Regulating System automatic motion commands~~. Withdrawal of the CEAs to the positions required in the Required Action ~~B~~.2.2 ensures that core perturbations in local burnup, peaking factors, and SDM will not be more adverse than the Conditions assumed in the safety analyses and LCO setpoint determination (Ref. ~~6~~).

The 6 hour Completion Time takes into account Required Action ~~B~~.1, the protection afforded by the CEA deviation circuits, and other information continuously available to the operator in the control room, so that during actual CEA motion, deviations can be detected.

Required Action ~~B~~.2.2 is modified by a Note indicating that this Required Action shall not be performed when in conflict with either Required Action ~~A~~.1, ~~A~~.2, or ~~C~~.1.

1

BASES

ACTIONS (continued)

E → ~~C~~.1

8

When the CEA deviation circuit is inoperable, performing SR 3.1.4.1, within 1 hour and every 4 hours thereafter, ensures improper CEA alignments are identified before unacceptable flux distributions occur. The specified Completion Times take into account other information continuously available to the operator in the control room, so that during CEA movement, deviations can be detected, and the protection provided by the CEA inhibit and deviation circuit is not required.

F → ~~D~~.1

8

If the Required Action or associated Completion Time of Condition A, ~~Condition B, or Condition~~ C, D, or E is not met, one or more regulating or shutdown CEAs are inoperable, or two or more CEAs are misaligned by > ~~[~~15 inches~~]~~, the unit is required to be brought to MODE 3. By being brought to MODE 3, the unit is brought outside its MODE of applicability. Continued operation is not allowed in the case of more than one CEA misaligned from any other CEA in its group by > ~~[~~15 inches~~]~~, or one or more CEAs inoperable. This is because these cases are indicative of a loss of SDM and power distribution, and a loss of safety function, respectively.

6

6

When a Required Action cannot be completed within the required Completion Time, a controlled shutdown should be commenced. The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.4.1

Verification is required that individual CEA positions are within ~~[~~7 inches~~]~~ (indicated reed switch positions) of all other CEAs in the group within 1 hour of any CEA movement of > 7~~.5~~ inches. The CEA position verification after each movement of > 7~~.5~~ inches ensures that the CEAs in that group are properly aligned at the time when CEA misalignments are most likely to have occurred. ~~[The 12 hour Frequency allows the operator to detect a CEA that is beginning to deviate from its expected position. The specified Frequency takes into account other CEA position information that is continuously available to the operator in the control room, so that during CEA movement, deviations can be detected, and protection can be provided by the CEA motion inhibit and deviation circuits.~~

~~]~~

6

SR 3.1.4.3

Demonstrating the CEA deviation circuit is OPERABLE verifies the circuit is functional. ~~[The 92 day Frequency takes into account other information continuously available to the operator in the control room, so that during CEA movement, deviations can be detected, and protection can be provided by the CEA motion inhibit.~~

6

3

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

SR 3.1.4.4

Verifying each CEA is trippable would require that each CEA be tripped. In MODES 1 and 2, tripping each CEA would result in radial or axial power tilts, or oscillations. Therefore, individual CEAs are exercised to provide increased confidence that all CEAs continue to be trippable, even if they are not regularly tripped. A movement of [~~5~~ inches] is adequate to demonstrate motion without exceeding the alignment limit when only one CEA is being moved. ~~[The 92 day Frequency takes into consideration other information available to the operator in the control room and other surveillances being performed more frequently, which add to the determination of OPERABILITY of the CEAs.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

Between required performances of SR 3.1.4.4, if a CEA(s) is discovered to be immovable, but remains trippable, the CEA is considered to be OPERABLE. At any time, if a CEA(s) is immovable, a determination of the trippability (OPERABILITY) of the CEA(s) must be made, and appropriate action taken.

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.1.4.5

~~Performance of a CHANNEL FUNCTIONAL TEST of each reed switch position transmitter channel ensures the channel is OPERABLE and capable of indicating CEA position over the entire length of the CEA's travel. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. [Since this Surveillance must be performed when the reactor is shut down, an 18 month Frequency to be coincident with refueling outage was selected. Operating experience has shown that these components usually pass this Surveillance when performed at a Frequency of once every 18 months. Furthermore, the Frequency takes into account other surveillances being performed at shorter Frequencies, which determine the OPERABILITY of the CEA Reed Switch Indication System.~~

11

~~OR~~

~~The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.~~

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

~~SR 3.1.4.6~~

and installation

3

Verification of CEA drop times determined that the maximum CEA drop time permitted is consistent with the assumed drop time used in that safety analysis (Ref. ~~7~~). Measuring drop times prior to reactor criticality, after reactor vessel head removal, ensures that reactor internals and CEDM will not interfere with CEA motion or drop time and that no degradation in these systems has occurred that would adversely affect CEA motion or drop time. Individual CEAs whose drop times are greater than safety analysis assumptions are not OPERABLE. This SR is

3

The individual (shutdown and regulating) CEA drop time from the fully withdrawn position shall be determined from when the electrical power is interrupted to the CEA drive mechanism until the CEA reaches the 90% insertion position with Tavg greater than or equal to 515°F.

12

3

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

performed prior to criticality, based on the need to perform this Surveillance under the conditions that apply during a unit outage and because of the potential for an unplanned unit transient if the Surveillance were performed with the reactor at power.

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.4, BASES, CONTROL ELEMENT ASSEMBLY (CEA) ALIGNMENT

1. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

2. The ISTS Bases states that the CEAs may be moved at varying rates (steps per minute), and that the CEA movement may be automatically controlled by the Reactor Regulating System. Moving CEA(s) at varying rates and automatic control of CEA(s) is not a design feature for PSL Unit 1 and Unit 2 due to the incorporation of the ARCH (Advanced Rod Control Hybrid) system that controls CEA movement. Therefore, the associated text is deleted.

3. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

4. ISTS Bases is changed to incorporate ARCH (Advanced Rod Control Hybrid) system design features installed at PSL Unit 1 and PSL Unit 2. For ARCH, an individual CEA may be moved in the Manual Individual Mode, therefore, the description is added. ISTS states that if a CEA does not move one step for each command signal, the step counter will still count the command and incorrectly reflect the position of the CEA. For ARCH, a step is counted only after the Step Complete signal is received. The associated text is changed. The ISTS states that the system is based on analog signals. For ARCH, the system uses a resistance voltage divider network. Therefore, the associated text “inductive analog” is deleted. The ISTS states that during movement of a group, one CEA may stop moving while the other CEAs in the group continue. This condition may cause excessive power peaking. For ARCH, this is not a valid failure mode. Therefore, this text is deleted.

5. ISTS includes numerous examples of failure modes for CEA alignment accidents. These examples are unnecessary information in the Applicable Safety Analysis and are deleted. The deleted examples do not affect the subsequent description for the Applicable Safety Analysis.

6. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

7. The ISTS alignment limits are changed to the PSL Unit 1 current licensing basis. PSL Unit 2 current licensing basis is also retained and matches the ISTS without change.

8. ACTIONS A and B are added to ITS 3.1.4 and ISTS 3.1.4, Condition A (ITS 3.1.4, Condition C) is modified to reflect PSL CTS 3.1.3.1 Actions as modified by the CTS Discussion of Changes. The ISTS Bases changes reflect the changes associated with the ISTS Specification.

9. Changes made to the PSL ITS Bases to correct a grammatical error in the ISTS Bases or align the text with the PSL ITS Specification.

10. Surveillance Requirement details removed from CTS 4.1.3.1.3 and CTS 4.1.3.1.4 and relocated to the ITS Bases of SR 3.1.4.2. See CTS DOC LA03.

11. ISTS SR 3.1.4.5 is deleted and subsequent Surveillance is renumbered. PSL developed ITS 3.1.7, Control Element Assembly (CEA) Position Indication, and requires performance of ITS SR 3.1.7.1 to determine OPERABILITY of the reed switch position indicating channels and the pulse counting position indicating channels in accordance with the Surveillance Frequency Control Program.

12. CTS 3.1.3.4 requires the individual (shutdown and regulating) CEA drop time from the fully withdrawn position shall be less than or equal to 3.1 seconds (PSL Unit 1) and less than or equal to 3.25 seconds (PSL Unit 2) from when the electrical power is interrupted to the CEA drive mechanism until the CEA reaches the 90% insertion position with Tavg greater than or equal to 515°F. These details for the CEA drop time surveillance are relocated to the ITS 3.1.4 Bases. See DOC LA04.

DISCUSSION OF CHANGES
ITS 3.1.5, SHUTDOWN CONTROL ELEMENT ASSEMBLY (CEA) INSERTION LIMITS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.1.3.5 Applicability is MODES 1 and 2 with a footnote (footnote *) for MODE 2 stating "See Special Test Exception 3.10.2," and a footnote (footnote #) for MODE 2 stating "With $K_{eff} \geq 1.0$." ITS 3.1.5 does not contain the footnotes or a reference to the Special Test Exception or reference to the K_{eff}. This changes the CTS by not including footnote * and footnote # in the ITS.

The purpose of the footnote references is to alert the user that conditions exist that may modify the Applicability of the Specification. It is an ITS convention to not include these types of footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS. See DOC M01 for additional discussion of change for the footnote # for MODE 2 stating "With $K_{eff} \geq 1.0$."

MORE RESTRICTIVE CHANGES

M01 CTS 3.1.3.5 is applicable in MODES 1 and 2 with $k_{eff} \geq 1.0$. MODE 2 is modified by CTS 3.1.3.5 footnote #. ITS 3.1.5 is applicable in MODES 1 and 2. This changes the CTS by expanding the Applicability from MODE 2 with the reactor critical to all of MODE 2.

The purpose of CTS 3.1.3.5 is to ensure that the shutdown CEAs are fully withdrawn prior to withdrawing the regulating CEAs to ensure that there is sufficient shutdown margin available to quickly shutdown the reactor. This change is acceptable because applying the requirement prior to moving the CEAs and bringing the reactor critical ensures that the shutdown margin is available and is consistent with plant operation, in that the shutdown CEAs are withdrawn to at least 129.0 inches before beginning to withdraw the regulating CEAs and approaching criticality. This change is designated as more restrictive because it increases the conditions under which Technical Specification controls will be applied.

RELOCATED SPECIFICATIONS

None

DISCUSSION OF CHANGES
ITS 3.1.5, SHUTDOWN CONTROL ELEMENT ASSEMBLY (CEA) INSERTION LIMITS

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 (*Category 4 – Relaxation of Required Action)* CTS 3.1.3.5 ACTION states that with one shutdown CEA withdrawn to less than 129.0 inches, then withdraw the CEA to at least 129.0 inches within 1 hour. ITS 3.1.5 Required Action A.1 requires that the shutdown CEA be withdrawn to at least 129.0 inches within 2 hours. This changes the CTS by changing the Completion Time from one hour to two hours.

The purpose of CTS 3.1.3.5 ACTION is to restore a shutdown CEA not withdrawn to at least 129.0 inches, to within limits within 1 hour. Prior to entering this Condition, the shutdown CEAs were fully withdrawn. If a shutdown CEA is then inserted into the core, its potential negative reactivity is added to the core as it is inserted. The 2 hour Completion Time allows the operator adequate time to adjust the CEA(s) in an orderly manner and is consistent with the Completion Times in LCO 3.1.4, “Control Element Assembly (CEA) Alignment.” This change is acceptable because the Completion Time is consistent with safe operation under the specified Condition, the capacity and capability of remaining features, and the low probability of a DBA occurring during the allowed Completion Time. The Completion Time of 2 hours gives the operator sufficient time to adjust the CEA(s) in an orderly manner. This change is designated as less restrictive because additional time is allowed to restore parameters to within the LCO limits than was allowed in the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.1.3.5 ACTION a. and ACTION B provide compensatory actions for a maximum of one shutdown CEA withdrawn to less than 129.0 inches. The actions require within one hour either restore the CEA to at least 129.0 inches or declare the CEA inoperable and apply ACTION Specification 3.1.3.1. For more than one shutdown CEA not withdrawn to at least 129.0 inches, CTS 3.1.3.5 does not contain a specific requirement; therefore, entry into CTS 3.0.3 is required. ITS 3.1.5 ACTION A and ACTION B provide Required Actions for one or more shutdown CEAs not within limits. ITS 3.1.5 Required Action A.1 requires restoring the shutdown CEA(s) to within the limit within 2 hours. Additionally, ITS 3.1.5 Required Action B.1 requires if any Required Action and associated Completion Time is not met, the unit must be in MODE 3 within 6 hours. This changes the CTS by allowing more than one shutdown CEA to be outside the limits specified in the LCO, eliminates the allowance to declare the CEA inoperable and to take the ACTIONS of Specification 3.1.3.1, and eliminates the requirement to enter CTS 3.0.3 if more than one shutdown CEA is not within the limits specified in the LCO, or if any Required Action and associated Completion Time is not met.

The purpose of CTS 3.1.3.5 ACTION a. is to ensure the shutdown CEAs are withdrawn to at least 129.0 inches to ensure that there is sufficient margin available to quickly shutdown the reactor. This change is acceptable because

the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering that only a small amount of time is provided to establish the required features, and the low probability of a DBA occurring during the repair period. Allowing an additional hour to restore one or more shutdown CEAs to within the limit is appropriate allows the operator adequate time to adjust the CEA(s) in an orderly manner and is consistent with the Completion Times in LCO 3.1.4, "Control Element Assembly (CEA) Alignment." .

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 *(Category 5 – Deletion of Surveillance Requirement)* CTS 4.1.3.5.a requires verification that each shutdown CEA is within the limit specified in the LCO within 15 minutes prior to withdrawal of any CEAs in the regulating groups during an approach to reactor criticality. ITS 3.1.5 does not require verification that each shutdown CEA is within the limit specified in the LCO within 15 minutes prior to withdrawal of any CEAs in the regulating groups during an approach to reactor criticality. This changes the CTS by eliminating the requirement that each CEA is within the limit specified in the LCO within 15 minutes prior to withdrawal of any CEAs in the regulating groups during an approach to reactor criticality.

The purpose of CTS 4.1.3.5.a is to verify the shutdown CEAs are withdrawn to at least 129.0 inches prior to withdrawing the regulating CEAs. This change is acceptable because the deleted Surveillance Requirement is not necessary to verify the equipment being used to meet the LCO can perform its required function. Thus, appropriate equipment continues to be tested in a manner and at a Frequency necessary to give confidence the equipment can perform its assumed safety function. Under the ITS Applicability of MODE 2 and the requirement of ITS LCO 3.0.4, the shutdown CEAs must be withdrawn to at least 129.0 inches prior to entering the ITS Applicability of MODE 2. However, it is not required to verify compliance within a specified time prior to initial withdrawal of regulating CEAs. Specifying a time is not necessary to ensure the shutdown CEAs are withdrawn to at least 129.0 inches prior to initial withdrawal of regulating CEA withdrawal if the shutdown CEAs are withdrawn to at least 129.0 before withdrawing the regulating CEAs.

This change is designated as less restrictive because a Surveillance which was required in CTS will not be required in the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.5, SHUTDOWN CONTROL ELEMENT ASSEMBLY (CEA) INSERTION LIMITS

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~ 4

B 3.1.5 Shutdown Control Element Assembly (CEA) Insertion Limits ~~(Analog)~~

BASES

BACKGROUND

The insertion limits of the shutdown Control Element Assemblies (CEAs) are initial assumptions in all safety analyses that assume CEA insertion upon reactor trip. The insertion limits directly affect core power distributions and assumptions of available SDM, ejected CEA worth, and initial reactivity insertion rate.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, "Reactor Design," and GDC 26, "Reactivity Limits" (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors" (Ref. 2). Limits on shutdown CEA insertion have been established, and all CEA positions are monitored and controlled during power operation to ensure that the reactivity limits, ejected CEA worth, and SDM limits are preserved.

The shutdown CEAs are arranged into groups that are radially symmetric. Therefore, movement of the shutdown CEAs does not introduce radial asymmetries in the core power distribution. The shutdown and regulating CEAs provide the required reactivity worth for immediate reactor shutdown upon a reactor trip.

The design calculations are performed with the assumption that the shutdown CEAs are withdrawn prior to the regulating CEAs. The shutdown CEAs can be fully withdrawn without the core going critical. This provides available negative reactivity for SDM in the event of boration errors. The shutdown CEAs are controlled manually ~~or automatically~~ by the control room operator. During normal unit operation, the shutdown CEAs are fully withdrawn. The shutdown CEAs must be completely withdrawn from the core prior to withdrawing any regulating CEAs during an approach to criticality. The shutdown CEAs are then left in this position until the reactor is shut down. They affect core power, burnup distribution, and add negative reactivity to shut down the reactor upon receipt of a reactor trip signal. 3

APPLICABLE SAFETY ANALYSES

Accident analysis assumes that the shutdown CEAs are fully withdrawn any time the reactor is critical. This ensures that:

a. The minimum SDM is maintained and

b. The potential effects of a CEA ejection accident are limited to acceptable limits.

BASES

APPLICABLE SAFETY ANALYSES (continued)

CEAs are considered fully withdrawn at 129 inches, since this position places them outside the active region of the core.

On a reactor trip, all CEAs (shutdown and regulating), except the most reactive CEA, are assumed to insert into the core. The shutdown and regulating CEAs shall be at their insertion limits and available to insert the maximum amount of negative reactivity on a reactor trip signal. The regulating CEAs may be partially inserted in the core as allowed by LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits." The shutdown CEA insertion limit is established to ensure that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM (see LCO 3.1.1, "SHUTDOWN MARGIN (SDM)") following a reactor trip from full power. The combination of regulating CEAs and shutdown CEAs (less the most reactive CEA, which is assumed to be fully withdrawn) is sufficient to take the reactor from full power conditions at rated temperature to zero power, and to maintain the required SDM at rated no load temperature (Ref. 3). The shutdown CEA insertion limit also limits the reactivity worth of an ejected shutdown CEA.

The acceptance criteria for addressing shutdown CEA as well as regulating CEA insertion limits and inoperability or misalignment are that:

a. There be no violation of either:

   1. Specified acceptable fuel design limits or

   2. Reactor Coolant System pressure boundary damage and

b. The core remains subcritical after accident transients.

As such, the shutdown CEA insertion limits affect safety analyses involving core reactivity, ejected CEA worth, and SDM (Ref. 3).

The shutdown CEA insertion limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The shutdown CEAs must be within their insertion limits any time the reactor is critical or approaching criticality. This ensures that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM following a reactor trip.

BASES

APPLICABILITY

The shutdown CEAs must be within their insertion limits, with the reactor in MODES 1 and 2. The Applicability in MODE 2 begins anytime any regulating CEA is not fully inserted. This ensures that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM following a reactor trip. In MODE 3, 4, 5, or 6, the shutdown CEAs are fully inserted in the core and contribute to the SDM. Refer to LCO 3.1.1, "SHUTDOWN MARGIN (SDM)," for SDM requirements in MODES 3, 4, and 5. LCO 3.9.1, "Boron Concentration," ensures adequate SDM in MODE 6.

This LCO has been modified by a Note indicating the LCO requirement is suspended during SR 3.1.4.4. This SR verifies the freedom of the CEAs to move, and requires the shutdown CEAs to move below the LCO limits, which would normally violate the LCO.

ACTIONS

A.1

Prior to entering this condition, the shutdown CEAs were fully withdrawn. If a shutdown CEA(s) is then inserted into the core, its potential negative reactivity is added to the core as it is inserted.

~~If the CEA(s) is not restored to within limits within 1 hour, then an additional 1 hour is allowed for restoring the CEA(s) to within limits.~~ The 2 hour total Completion Time allows the operator adequate time to adjust the CEA(s) in an orderly manner and is consistent with the required Completion Times in LCO 3.1.4, "Control Element Assembly (CEA) Alignment." 1

B.1

When Required Action A.1 ~~or A.2~~ cannot be met or completed within the required Completion Time, a controlled shutdown should be commenced. The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems. 1

SURVEILLANCE REQUIREMENTS

SR 3.1.5.1

Verification that the shutdown CEAs are within their insertion limits prior to an approach to criticality ensures that when the reactor is critical, or being taken critical, the shutdown CEAs will be available to shut down the reactor, and the required SDM will be maintained following a reactor trip. This SR and Frequency ensure that the shutdown CEAs are withdrawn before the regulating CEAs are withdrawn during a unit startup.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[Since the shutdown CEAs are positioned manually by the control room operator, verification of shutdown CEA position at a Frequency of 12 hours is adequate to ensure that the shutdown CEAs are within their insertion limits. Also, the 12 hour Frequency takes into account other information available to the operator in the control room for the purpose of monitoring the status of the shutdown CEAs.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

B 3.1.5 Shutdown Control Element Assembly (CEA) Insertion Limits ~~(Analog)~~

BASES

BACKGROUND

The insertion limits of the shutdown Control Element Assemblies (CEAs) are initial assumptions in all safety analyses that assume CEA insertion upon reactor trip. The insertion limits directly affect core power distributions and assumptions of available SDM, ejected CEA worth, and initial reactivity insertion rate.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, "Reactor Design," and GDC 26, "Reactivity Limits" (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors" (Ref. 2). Limits on shutdown CEA insertion have been established, and all CEA positions are monitored and controlled during power operation to ensure that the reactivity limits, ejected CEA worth, and SDM limits are preserved.

The shutdown CEAs are arranged into groups that are radially symmetric. Therefore, movement of the shutdown CEAs does not introduce radial asymmetries in the core power distribution. The shutdown and regulating CEAs provide the required reactivity worth for immediate reactor shutdown upon a reactor trip.

The design calculations are performed with the assumption that the shutdown CEAs are withdrawn prior to the regulating CEAs. The shutdown CEAs can be fully withdrawn without the core going critical. This provides available negative reactivity for SDM in the event of boration errors. The shutdown CEAs are controlled manually ~~or automatically~~ by the control room operator. During normal unit operation, the shutdown CEAs are fully withdrawn. The shutdown CEAs must be completely withdrawn from the core prior to withdrawing any regulating CEAs during an approach to criticality. The shutdown CEAs are then left in this position until the reactor is shut down. They affect core power, burnup distribution, and add negative reactivity to shut down the reactor upon receipt of a reactor trip signal. 3

APPLICABLE SAFETY ANALYSES

Accident analysis assumes that the shutdown CEAs are fully withdrawn any time the reactor is critical. This ensures that:

a. The minimum SDM is maintained and

b. The potential effects of a CEA ejection accident are limited to acceptable limits.

BASES

APPLICABLE SAFETY ANALYSES (continued)

CEAs are considered fully withdrawn at 129 inches, since this position places them outside the active region of the core.

On a reactor trip, all CEAs (shutdown and regulating), except the most reactive CEA, are assumed to insert into the core. The shutdown and regulating CEAs shall be at their insertion limits and available to insert the maximum amount of negative reactivity on a reactor trip signal. The regulating CEAs may be partially inserted in the core as allowed by LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits." The shutdown CEA insertion limit is established to ensure that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM (see LCO 3.1.1, "SHUTDOWN MARGIN (SDM)") following a reactor trip from full power. The combination of regulating CEAs and shutdown CEAs (less the most reactive CEA, which is assumed to be fully withdrawn) is sufficient to take the reactor from full power conditions at rated temperature to zero power, and to maintain the required SDM at rated no load temperature (Ref. 3). The shutdown CEA insertion limit also limits the reactivity worth of an ejected shutdown CEA.

The acceptance criteria for addressing shutdown CEA as well as regulating CEA insertion limits and inoperability or misalignment are that:

a. There be no violation of either:

   1. Specified acceptable fuel design limits or

   2. Reactor Coolant System pressure boundary damage and

b. The core remains subcritical after accident transients.

As such, the shutdown CEA insertion limits affect safety analyses involving core reactivity, ejected CEA worth, and SDM (Ref. 3).

The shutdown CEA insertion limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The shutdown CEAs must be within their insertion limits any time the reactor is critical or approaching criticality. This ensures that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM following a reactor trip.

BASES

APPLICABILITY

The shutdown CEAs must be within their insertion limits, with the reactor in MODES 1 and 2. The Applicability in MODE 2 begins anytime any regulating CEA is not fully inserted. This ensures that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM following a reactor trip. In MODE 3, 4, 5, or 6, the shutdown CEAs are fully inserted in the core and contribute to the SDM. Refer to LCO 3.1.1, "SHUTDOWN MARGIN (SDM)," for SDM requirements in MODES 3, 4, and 5. LCO 3.9.1, "Boron Concentration," ensures adequate SDM in MODE 6.

This LCO has been modified by a Note indicating the LCO requirement is suspended during SR 3.1.4.4. This SR verifies the freedom of the CEAs to move, and requires the shutdown CEAs to move below the LCO limits, which would normally violate the LCO.

ACTIONS

A.1

Prior to entering this condition, the shutdown CEAs were fully withdrawn. If a shutdown CEA(s) is then inserted into the core, its potential negative reactivity is added to the core as it is inserted.

~~If the CEA(s) is not restored to within limits within 1 hour, then an additional 1 hour is allowed for restoring the CEA(s) to within limits.~~ The 2 hour total Completion Time allows the operator adequate time to adjust the CEA(s) in an orderly manner and is consistent with the required Completion Times in LCO 3.1.4, "Control Element Assembly (CEA) Alignment." 1

B.1

When Required Action A.1 ~~or A.2~~ cannot be met or completed within the required Completion Time, a controlled shutdown should be commenced. The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems. 1

SURVEILLANCE REQUIREMENTS

SR 3.1.5.1

Verification that the shutdown CEAs are within their insertion limits prior to an approach to criticality ensures that when the reactor is critical, or being taken critical, the shutdown CEAs will be available to shut down the reactor, and the required SDM will be maintained following a reactor trip. This SR and Frequency ensure that the shutdown CEAs are withdrawn before the regulating CEAs are withdrawn during a unit startup.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[Since the shutdown CEAs are positioned manually by the control room operator, verification of shutdown CEA position at a Frequency of 12 hours is adequate to ensure that the shutdown CEAs are within their insertion limits. Also, the 12 hour Frequency takes into account other information available to the operator in the control room for the purpose of monitoring the status of the shutdown CEAs.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

ITS

3/4.1 REACTIVITY CONTROL SYSTEMS

3/4.1.1 BORATION CONTROL

SHUTDOWN MARGIN - T_{avg} GREATER THAN 200°F

LIMITING CONDITION FOR OPERATION

3.1.1.1 The SHUTDOWN MARGIN shall be within the limits specified in the COLR.

Applicability **APPLICABILITY:** MODES 1, 2*, 3 and 4.

See ITS 3.1.1

ACTION:

With the SHUTDOWN MARGIN outside the COLR limits, immediately initiate and continue boration at greater than or equal to 40 gpm of a solution containing greater than or equal to 1900 ppm boron or equivalent until the required SHUTDOWN MARGIN is restored.

SURVEILLANCE REQUIREMENTS

4.1.1.1.1 The SHUTDOWN MARGIN shall be determined to be within the COLR limits:

See ITS 3.1.4

a. Within one hour after detection of an inoperable CEA(s) and at least once per 12 hours thereafter while the CEA(s) is inoperable. If the inoperable CEA is not fully inserted, and is immovable as a result of excessive friction or mechanical interference or is known to be untrippable, the above required SHUTDOWN MARGIN shall be verified acceptable with an increased allowance for the withdrawn worth of the immovable or untrippable CEA(s).

See ITS 1.1

SR 3.1.6.1

b. ~~When in MODE 1 or MODE 2 with Keff greater than or equal to 1.0,~~ in accordance with the Surveillance Frequency Control Program by verifying that CEA group withdrawal is within the Power Dependent Insertion Limits of Specification 3.1.3.6.

L03

c. ~~When in MODE 2 with Keff less than 1.0, within 4 hours prior to achieving reactor criticality by verifying that the predicted critical CEA position is within the limits of Specification 3.1.3.6.~~

~~* See Special Test Exception 3.10.1.~~

A02

3/4.2 POWER DISTRIBUTION LIMITS

See ITS 3.2.1

3/4 2.1 LINEAR HEAT RATE

LIMITING CONDITION FOR OPERATION

3.2.1 The linear heat rate shall not exceed the limits specified in the COLR.

APPLICABILITY: MODE 1.

ACTION:

With the linear heat rate exceeding its limits, as indicated by four or more coincident incore channels or by the AXIAL SHAPE INDEX outside of the power dependent control limits of COLR Figure 3.2-2, within 15 minutes initiate corrective action to reduce the linear heat rate to within the limits and either:

a. Restore the linear heat rate to within its limits within 1 hour, or

b. Be in at least HOT STANDBY within the next 6 hours.

SURVEILLANCE REQUIREMENTS

4.2.1.1 The provisions of Specification 4.0.4 are not applicable.

4.2.1.2 The linear heat rate shall be determined to be within its limits by continuously monitoring the core power distribution with either the excore detector monitoring system or with the incore detector monitoring system.

4.2.1.3 Excore Detector Monitoring System – The excore detector monitoring system may be used for monitoring the linear heat rate by:

SR 3.1.6.1
SR 3.1.6.2

a. Verifying in accordance with the Surveillance Frequency Control Program that the ~~full-length~~ CEAs are withdrawn to and maintained at or beyond the Long Term Steady State Insertion Limit of Specification 3.1.3.6.

A05

b. Verifying in accordance with the Surveillance Frequency Control Program that the AXIAL SHAPE INDEX alarm setpoints are adjusted to within the limits shown on COLR Figure 3.2-2.

DISCUSSION OF CHANGES
ITS 3.1.6, REGULATING CONTROL ELEMENT ASSEMBLY (CEA) INSERTION LIMITS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.1.3.6 Applicability is MODES 1 and 2 with a footnote (footnote *) for MODE 2 stating "See Special Test Exception 3.10.2 and 3.10.5," and a footnote (footnote #) for MODE 2 stating "With $K_{eff} \geq 1.0$." CTS 3.1.1.1 Applicability is, in part, MODE 2 with a footnote (footnote *) stating "See Special Test Exception 3.10.1," and Unit 1 CTS 4.1.1.1.1.b and c contain footnotes (footnotes # and ##) for MODE 2 stating "With $K_{eff} \geq 1.0$," and "With $K_{eff} < 1.0$," respectively. ITS 3.1.6 does not contain the footnotes or a reference to the Special Test Exception or reference to the K_{eff}. This changes the CTS by not including footnote * and footnotes # and ## in the ITS.

The purpose of the footnote references is to alert the user that conditions exist that may modify the Applicability of the Specification. It is an ITS convention to not include these types of footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS. See DOC M01 for additional discussion of change for the footnote # for MODE 2 stating "With $K_{eff} \geq 1.0$.''

A03 **Unit 1 only:** PSL Unit 1 CTS 3.1.3.6 ACTION b. states, in part, that power operation may proceed provided ACTIONS b.1or b.2 are met, "except during operation pursuant to the provisions of ACTION items c. and d. of Specification 3.1.3.1." PSL Unit 1 CTS 3.1.3.6 ACTION c. states, in part, that power operation may proceed provided ACTIONS c.1 or c.2 are met, "except during operation pursuant to the provisions of ACTION items c. and d. of Specification 3.1.3.1." ITS 3.1.6 does not provide a reference to ITS 3.1.4.

The purpose of the CTS statement "except during operation pursuant to the provisions of ACTION items c. and d. of Specification 3.1.3.1." is to provide a reference to another Specification that may apply under these conditions. This changes the CTS by not including the cross-reference in the ITS. It is an ITS convention to not include these types of footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

A04 CTS 4.1.3.6 states that with the Power Dependent Insertion Limits (PDIL) alarm circuit inoperable, verification of the individual CEA positions is required once per 4 hours. However, the PDIL alarm circuit operability is not specifically addressed. CTS does not require that the PDIL alarm circuit be OPERABLE in the LCO statement, and CTS does not provide a Surveillance to verify the PDIL

alarm circuit is OPERABLE. ITS 3.1.6 LCO requires the PDIL alarm circuit be OPERABLE, and ITS SR 3.1.6.3 verifies the PDIL alarm circuit is OPERABLE. | R1

The purpose of CTS 4.1.3.6 is to ensure that with the Power Dependent Insertion Limits (PDIL) alarm circuit is OPERABLE, since CTS requires ACTIONS be taken if the PDIL alarm circuit is inoperable. To ensure the position of the individual CEA positions is within limits to avoid improper CEA alignment, it is necessary to initially verify the individual CEA positions within one hour. These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A05 PSL Unit 1 CTS 4.2.1.3.a and PSL Unit 2 CTS 4.2.1.3.a include the descriptor "full length" in reference to CEA(s). The purpose of the CTS 3.1.3.1 descriptor is to distinguish between full length and partial length CEA(s). PSL Unit 1 and PSL Unit 2 no longer use partial length CEA(s). Therefore, since partial length CEA(s) are no longer a design feature for PSL Unit 1 and PSL Unit 2, the "full length" descriptors used for CEA(s) are deleted.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 3.1.3.6 is applicable in MODES 1 and 2 with $k_{eff} \geq 1.0$. MODE 2 is modified by CTS 3.1.3.6 footnote #. ITS 3.1.6 is applicable in MODES 1 and 2. This changes the CTS by expanding the Applicability from MODE 2 with the reactor critical to all of MODE 2.

The purpose of CTS 3.1.3.6 is to maintain the regulating CEA sequence, overlap, and physical insertion limits with the reactor in MODES 1 and 2 with the reactor critical. These limits must be maintained, since they preserve power distribution, ejected CEA worth, SDM, and reactivity rate insertion assumptions. This change is acceptable because applying the requirement prior to bringing the reactor critical ensures The limits on regulating CEAs sequence, overlap, and physical insertion, as defined in the COLR, are maintained and serve the function of preserving power distribution, ensuring that the SDM is maintained, ensuring that ejected CEA worth is maintained, and ensuring adequate negative reactivity insertion on trip. This change is designated as more restrictive because it increases the conditions under which Technical Specification controls will be applied.

M02 CTS 4.1.3.6 states that with the Power Dependent Insertion Limits (PDIL) alarm circuit inoperable, verification of the individual CEA positions is required once per 4 hours. ITS 3.1.6 ACTION D requires with the PDIL alarm circuit inoperable, verification of the individual CEA positions must be completed within 1 hour and once per 4 hours thereafter. This changes the CTS by requiring the initial verification of the individual CEA positions be performed within 1 hour.

The purpose of CTS 4.1.3.6 is to ensure that with the Power Dependent Insertion Limits (PDIL) alarm circuit inoperable, improper CEA alignments are identified before unacceptable flux distributions occur. To ensure the position of the individual CEA positions is within limits to avoid improper CEA alignment, it is necessary to initially verify the individual CEA positions within one hour. This change is designated as more restrictive because it increases the conditions under which Technical Specification controls will be applied.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 (Type 1 – Removing Details of System Design and System Description, Including Design Limits) CTS 3.1.3.6 LCO states that regulating CEAs are considered to be fully withdrawn when withdrawn to at least 129.0 inches. ITS LCO 3.1.6 does not retain this detail. This changes the CTS by relocating the details that regulating CEAs are considered to be fully withdrawn when withdrawn to at least 129.0 inches to the Bases.

The removal of these details, that are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for the regulating CEA groups to be limited to the withdrawal sequence and to the insertion limits specified in the COLR) with CEA insertion between the Long Term Steady State Insertion Limits and the Power Dependent Insertion Limits. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 3 – Relaxation of Completion Time)* CTS 3.1.3.6 ACTION b. states that with the regulating CEA groups inserted between the Long Term Steady State Insertion Limits and the Power Dependent Insertion Limits for intervals > 4 hours per 24 hour interval, operation may proceed provided either (CTS ACTION b.1) the Short Term Steady State Insertion Limits are not exceeded, or (CTS ACTION b.2) any subsequent increase in THERMAL POWER is restricted to < 5% of RATED THERMAL POWER per hour. The CTS completion time is assumed to be “immediately” since a Completion Time for ACTION b. is not provided. ITS 3.1.6, Required Action B.1 requires verification within 15 minutes

that the Short Term Steady State Insertion Limits are not exceeded. ITS 3.1.6 Required Action B.2 requires that within 15 minutes any subsequent increase in THERMAL POWER is restricted to < 5% of RATED THERMAL POWER per hour. This changes the CTS by relaxing the Completion Time from "immediately" to 15 minutes.

The purpose of CTS 3.1.2.6 ACTION b. is to ensure peaking factors remain within limits with the regulating CEA groups inserted between the Long Term Steady State Insertion Limits and the Power Dependent Insertion Limits for extended intervals. If the CEAs are inserted between the long term steady state insertion limits and the transient insertion limits for intervals > 4 hours per 24 hour period, and the short term steady state insertions are exceeded, peaking factors can develop that are of immediate concern. Fifteen minutes provides adequate time for the operator to verify if the short term steady state insertion limits are exceeded. Experience has shown that rapid power increases in areas of the core, in which the flux has been depressed, can result in fuel damage, as the LHR in those areas rapidly increases. Restricting the rate of THERMAL POWER increases to ≤ 5% RTP per hour, following CEA insertion beyond the long term steady state insertion limits, ensures the power transients experienced by the fuel will not result in fuel failure

This change is acceptable because the Completion Time is consistent with safe operation under the specific Condition, considering the operability status of the redundant systems of required features, the capacity and capability of remaining features, and the low probability of a DBA occurring during the allowed Completion Time. This ITS Completion Time of 15 minutes is adequate for an operator to perform the verification and implement measures to restrict the rate of THERMAL POWER increases.

This change is designated as less restrictive because additional time is allowed to restore parameters to within the LCO limits than was allowed in the CTS.

L02 *(Category 7 – Relaxation of Surveillance Frequency)* CTS 4.1.3.6 requires verification of regulating CEA groups position and regulating CEA groups time Inside Long Term Steady State Insertion Limits in accordance with the Surveillance Frequency Control Program (SFCP). The SFCP frequencies are at least once per 12 hours and at least per 24 hours, respectively. ITS SR 3.1.6.1 provides a Note that states “Not required to be performed until 12 hours after entry into MODE 2” indicating that entry is allowed into MODE 2 for 12 hours without having performed the SR. This is necessary, since the unit must be in the applicable MODES in order to perform Surveillances that demonstrate the LCO limits are met. CTS does not contain this Note. CTS SR 4.0.4 and CTS LCO 3.0.4 allow entry into 3.1.3.6 ACTION a to allow 2 hours to complete the Surveillance in MODE 2. | R1

The purpose of CTS 4.1.3.6 is to verify regulating CEA groups position and regulating CEA groups time Inside Long Term Steady State Insertion Limits in accordance with the Surveillance Frequency Control Program (SFCP). ITS 3.1.6 Note indicates that entry is allowed into MODE 2 for 12 hours without having performed the SR. This is necessary, since the unit must be in MODE 2 in order

to perform the Surveillance that verifies each regulating CEA group position is within its insertion limits. CTS does not contain this Note. CTS SR 4.0.4 and CTS LCO 3.0.4 allow entry into 3.1.3.6 ACTION a to allow 2 hours to complete the Surveillance in MODE 2. | R1

This change is designated as less restrictive because additional time is allowed to perform the Surveillances in MODE 2 in the ITS that was not allowed in the CTS. | R1

L03 (*Category 5 – Deletion of Surveillance Requirement*) CTS 4.1.1.1.1.c requires verification of SDM, when in MODE 2 with keff < 1.0, at least once during CEA withdrawal and in accordance with the Surveillance Frequency Control Program until the reactor is critical. ITS 3.1.6 does not require an explicit requirement to verify SDM in MODE 2 with keff < 1.0. This changes the CTS by eliminating the explicit statement that a SDM verification is required to be performed in MODE 2 with keff < 1.0.

The purpose of CTS 4.1.1.1.1.c is to verify SDM is within the required limit more frequently from entry into MODE 2 until the reactor is critical. Limits on shutdown and regulating CEA insertion ensure SDM limits are preserved. This change is acceptable because the shutdown CEAs must be withdrawn to ≥ 129 inches and the regulating CEAs are required to be within the insertion limits specified in the COLR upon entry into MODE 2 per the requirements of CTS 3.0.1 (ITS LCO 3.0.1) and CTS 3.0.4 (ITS LCO 3.0.4). Therefore, it is unnecessary to verify SDM more frequently in MODE 2 until the reactor is critical. ITS SR 3.1.1.1 requires SDM to verified in accordance with the Surveillance Frequency Control Program while in MODE 3 and, prior to entry into MODE 2, SR 3.1.5.1 and 3.1.6.1 (i.e., verifying shutdown and regulating CEAs are within the required insertion limits) must be met per ITS SR 3.0.4. Thus, there is continued confidence that SDM will be within limits during a plant startup in MODE 2 until the reactor is critical. The surveillance testing associated with SDM and CEA insertion limits is considered adequate to assure, pursuant to the requirements of 10 CFR 50.36(c)(3), that facility operation will be within safety limits and that the limiting condition for operation associated with the shutdown and regulating CEA insertion limits will be met. This change is designated as less restrictive because a Surveillance that was required in the CTS will not be performed in the ITS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.6, REGULATING CONTROL ELEMENT ASSEMBLY (CEA) INSERTION LIMITS

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

6

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~

6

B 3.1.6 Regulating Control Element Assembly (CEA) Insertion Limits ~~(Analog)~~

BASES

BACKGROUND

The insertion limits of the regulating Control Element Assemblies (CEAs) are initial assumptions in all safety analyses that assume CEA insertion upon reactor trip. The insertion limits directly affect core power distributions, assumptions of available SDM, and initial reactivity insertion rate. The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, "Reactor Design," and GDC 26, "Reactivity Limits" (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors" (Ref. 2).

Limits on regulating CEA insertion have been established, and all CEA positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking, ejected CEA worth, reactivity insertion rate, and SDM limits are preserved.

The regulating CEA groups operate with a predetermined amount of position overlap, in order to approximate a linear relation between CEA worth and CEA position (integral CEA worth). The regulating CEA groups are withdrawn and operate in a predetermined sequence. The group sequence and overlap limits are specified in the COLR.

The regulating CEAs are used for precise reactivity control of the reactor. The positions of the regulating CEAs are manually controlled. They are capable of adding reactivity very quickly (compared to borating or diluting).

The power density at any point in the core must be limited to maintain specified acceptable fuel design limits, including limits that preserve the criteria specified in 10 CFR 50.46 (Ref. 2). Together, LCO 3.1.6, LCO 3.2.~~4~~, "AZIMUTHAL POWER TILT (Tq)," and LCO 3.2.~~5~~, "AXIAL SHAPE INDEX (ASI)," provide limits on control component operation and on monitored process variables to ensure the core operates within the linear heat rate (LCO 3.2.1, "Linear Heat Rate (LHR)"), ~~total planar radial peaking factor (F_{XY}^T) (LCO 3.2.2, "Total Planar Radial Peaking Factor (F_{XY}^T)"),~~ and total integrated radial peaking factor (F_r^T) (LCO 3.2.3, "Total Integrated Radial Peaking Factor (F_r^T)") limits in the COLR. Operation within the LHR limits given in the COLR prevents power peaks that would exceed the loss of coolant accident (LOCA) limits derived by the Emergency Core Cooling System analysis. Operation within the ~~F_{XY}^T and~~

3 4 3 3 3

1

6

BASES

BACKGROUND (continued)

F_r^T limits given in the COLR prevents departure from nucleate boiling (DNB) during a loss of forced reactor coolant flow accident. In addition to the LHR~~, F_{XY}^T,~~ and F^T_r limits, certain reactivity limits are preserved by regulating CEA insertion limits. The regulating CEA insertion limits also restrict the ejected CEA worth to the values assumed in the safety analysis and preserve the minimum required SDM in MODES 1 and 2.

3

The establishment of limiting safety system settings and LCOs requires that the expected long and short term behavior of the radial peaking factors be determined. The long term behavior relates to the variation of the steady state radial peaking factors with core burnup and is affected by the amount of CEA insertion assumed, the portion of a burnup cycle over which such insertion is assumed, and the expected power level variation throughout the cycle. The short term behavior relates to transient perturbations to the steady state radial peaks, due to radial xenon redistribution. The magnitudes of such perturbations depend upon the expected use of the CEAs during anticipated power reductions and load maneuvering. Analyses are performed, based on the expected mode of operation of the Nuclear Steam Supply System (base loaded, maneuvering, etc.). From these analyses, CEA insertions are determined and a consistent set of radial peaking factors defined. The long term steady state and short term insertion limits are determined, based upon the assumed mode of operation used in the analyses, and provide a means of preserving the assumption on CEA insertions used. The long and short term insertion limits of LCO 3.1.6 are specified for the plant, which has been designed primarily for base loaded operation, but has the ability to accommodate a limited amount of load maneuvering.

The regulating CEA insertion and alignment limits are process variables that together characterize and control the three dimensional power distribution of the reactor core. Additionally, the regulating bank insertion limits control the reactivity that could be added in the event of a CEA ejection accident, and the shutdown and regulating bank insertion limits ensure the required SDM is maintained.

Operation within the subject LCO limits will prevent fuel cladding failures that would breach the primary fission product barrier and release fission products to the reactor coolant in the event of a LOCA, loss of flow, ejected CEA, or other accident requiring termination by a Reactor Protection System trip function.

1

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition I) and anticipated operational occurrences (Condition II). The acceptance criteria for the regulating CEA insertion, ASI, and T_q LCOs are such as to preclude core power distributions from occurring that would violate the following fuel design criteria:

a. During a large break LOCA, the peak cladding temperature must not exceed a limit of 2200°F, 10 CFR 50.46 (Ref. 2),

b. During a loss of forced reactor coolant flow accident, there must be at least a 95% probability at a 95% confidence level (the 95/95 DNB criterion) that the hot fuel CEA in the core does not experience a DNB condition,

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. 3), and

d. The CEAs must be capable of shutting down the reactor with a minimum required SDM, with the highest worth CEA stuck fully withdrawn, GDC 26 (Ref. 1).

Regulating CEA position, ASI, and T_q are process variables that together characterize and control the three dimensional power distribution of the reactor core.

Fuel cladding damage does not occur when the core is operated outside these LCOs during normal operation. However, fuel cladding damage could result, should an accident occur with simultaneous violation of one or more of these LCOs. Changes in the power distribution can cause increased power peaking and corresponding increased local LHRs.

The SDM requirement is ensured by limiting the regulating and shutdown CEA insertion limits, so that the allowable inserted worth of the CEAs is such that sufficient reactivity is available to shut down the reactor to hot zero power. SDM assumes the maximum worth CEA remains fully withdrawn upon trip (Ref. 4).

The most limiting SDM requirements for MODE 1 and 2 conditions at BOC are determined by the requirements of several transients, e.g., loss of flow, seized rotor, etc. However, the most limiting SDM requirements for MODES 1 and 2 at EOC come from just one transient, Steam Line Break (SLB). The requirements of the SLB event at EOC for both the full power and no load conditions are significantly larger than those of any other event at that time in cycle and, also, considerably larger than the most limiting requirements at BOC.

6

BASES

APPLICABLE SAFETY ANALYSES (continued)

Although the most limiting SDM requirements at EOC are much larger than those at BOC, the available SDMs obtained via the scramming of the CEAs are also substantially larger due to the much lower boron concentration at EOC. To verify that adequate SDMs are available throughout the cycle to satisfy the changing requirements, calculations are performed at both BOC and EOC. It has been determined that calculations at these two times in cycle are sufficient since the differences between available SDMs and the limiting SDM requirements are the smallest at these times in cycle. The measurement of CEA bank worth performed as part of the Startup Testing Program demonstrates that the core has the expected shutdown capability. Consequently, adher~~a~~nce to LCOs 3.1.5 and 3.1.6 provides assurance that the available SDMs at any time in cycle will exceed the limiting SDM requirements at that time in cycle.

1

e

Operation at the insertion limits or ASI limits may approach the maximum allowable linear heat generation rate or peaking factor, with the allowed T_q present. Operation at the insertion limit may also indicate the maximum ejected CEA worth could be equal to the limiting value in fuel cycles that have sufficiently high ejected CEA worths.

The regulating and shutdown CEA insertion limits ensure that safety analyses assumptions for reactivity insertion rate, SDM, ejected CEA worth, and power distribution peaking factors are preserved (Ref. ~~5~~).

1

3

The regulating CEA insertion limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The limits on regulating CEAs sequence, overlap, and physical insertion, as defined in the COLR, must be maintained because they serve the function of preserving power distribution, ensuring that the SDM is maintained, ensuring that ejected CEA worth is maintained, and ensuring adequate negative reactivity insertion on trip. The overlap between regulating banks provides more uniform rates of reactivity insertion and withdrawal and is imposed to maintain acceptable power peaking during regulating CEA motion.

Regulating CEAs are considered to be fully withdrawn when withdrawn to at least 129.0 inches

4

The power dependent insertion limit (PDIL) alarm circuit is required to be OPERABLE for notification that the CEAs are outside the required insertion limits. When the PDIL alarm circuit is inoperable, the verification of CEA positions is increased to ensure improper CEA alignment is identified before unacceptable flux distribution occurs.

St. Lucie – Unit 1

Revision XXX

1

6

BASES

APPLICABILITY

The regulating CEA sequence, overlap, and physical insertion limits shall be maintained with the reactor in MODES 1 and 2. These limits must be maintained, since they preserve the assumed power distribution, ejected CEA worth, SDM, and reactivity rate insertion assumptions. Applicability in MODES 3, 4, and 5 is not required, since neither the power distribution nor ejected CEA worth assumptions would be exceeded in these MODES. SDM is preserved in MODES 3, 4, and 5 by adjustments to the soluble boron concentration.

This LCO has been modified by a Note indicating the LCO requirement is suspended during SR 3.1.4.4. This SR verifies the freedom of the CEAs to move, and requires the regulating CEAs to move below the LCO limits, which would normally violate the LCO. ~~The Note also allows the LCO to be not applicable during reactor power cutback operation, which inserts a selected CEA group (usually group 5) during loss of load events.~~

5

ACTIONS

A.1 and A.2

Operation beyond the transient insertion limit may result in a loss of SDM and excessive peaking factors. The transient insertion limit should not be violated during normal operation; this violation, however, may occur during transients when the operator is manually controlling the CEAs in response to changing plant conditions. When the regulating groups are inserted beyond the transient insertion limits, actions must be taken to either withdraw the regulating groups beyond the limits or to reduce THERMAL POWER to less than or equal to that allowed for the actual CEA insertion limit. Two hours provides a reasonable time to accomplish this, allowing the operator to deal with current plant conditions while limiting peaking factors to acceptable levels.

B.1 and B.2

If the CEAs are inserted between the long term steady state insertion limits and the transient insertion limits for intervals > 4 hours per 24 hour period, and the short term steady state insertions are exceeded, peaking factors can develop that are of immediate concern (Ref. ~~6~~ 3).

1

Verifying the short term steady state insertion limits are not exceeded ensures that the peaking factors that do develop are within those allowed for continued operation. Fifteen minutes provides adequate time for the operator to verify if the short term steady state insertion limits are exceeded.

1

6

BASES

ACTIONS (continued)

Experience has shown that rapid power increases in areas of the core, in which the flux has been depressed, can result in fuel damage, as the LHR in those areas rapidly increases. Restricting the rate of THERMAL POWER increases to ≤ 5% RTP per hour, following CEA insertion beyond the long term steady state insertion limits, ensures the power transients experienced by the fuel will not result in fuel failure (Ref. ~~7~~).

3

1

C.1

With the regulating CEAs inserted between the long term steady state insertion limit and the ~~transient~~ insertion limit, and with the core approaching the 5 effective full power days (EFPD) per 30 EFPD or 14 EFPD per 365 EFPD limits, the core approaches the acceptable limits placed on operation with flux patterns outside those assumed in the long term burnup assumptions (Ref. ~~8~~). In this case, the CEAs must be returned to within the long term steady state insertion limits, or the core must be placed in a condition in which the abnormal fuel burnup cannot continue. A Completion Time of 2 hours is allotted to return the CEAs to within the long term steady state insertion limits.

power dependent

3

1

1

The required Completion Time of 2 hours from initial discovery of a regulating CEA group outside the limits until its restoration to within the long term steady state limits, shown on the figures in the COLR, allows sufficient time for borated water to enter the Reactor Coolant System from the chemical addition and makeup systems, and ~~to cause~~ the regulating CEAs to ~~withdraw~~ to the acceptable region. It is reasonable to continue operation for 2 hours after it is discovered that the 5 day or 14 day EFPD limit has been exceeded. This Completion Time is based on limiting the potential xenon redistribution, the low probability of an accident, and the steps required to complete the action.

allowing

be withdrawn

1

D.1

When the PDIL alarm circuit is inoperable, performing SR 3.1.6.1 within 1 hour and once per 4 hours thereafter ensures improper CEA alignments are identified before unacceptable flux distributions occur.

1

6

BASES

ACTIONS (continued)

E.1

When a Required Action cannot be completed within the required Completion Time, a controlled shutdown should be commenced. The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.6.1

With the PDIL alarm circuit OPERABLE, verification of each regulating CEA group position is sufficient to detect CEA positions that may approach the acceptable limits, and to provide the operator with time to undertake the Required Action(s) should the sequence or insertion limits be found to be exceeded. ~~[The 12 hour Frequency also takes into account the indication provided by the PDIL alarm circuit and other information about CEA group positions available to the operator in the control room.~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

2

SR 3.1.6.1 is modified by a Note indicating that entry is allowed into MODE 2 for 12 hours without having performed the SR. This is necessary, since the unit must be in the applicable MODES in order to perform Surveillances that demonstrate the LCO limits are met.

SR 3.1.6.2

Verification of the accumulated time of CEA group insertion between the long term steady state insertion limits and the ~~transient~~ insertion limits ensures the cumulative time limits are not exceeded. ~~[The 24 hour Frequency ensures the operator identifies a time limit that is being approached before it is reached.~~

power dependent

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~

6

B 3.1.6 Regulating Control Element Assembly (CEA) Insertion Limits ~~(Analog)~~

BASES

BACKGROUND

The insertion limits of the regulating Control Element Assemblies (CEAs) are initial assumptions in all safety analyses that assume CEA insertion upon reactor trip. The insertion limits directly affect core power distributions, assumptions of available SDM, and initial reactivity insertion rate. The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, "Reactor Design," and GDC 26, "Reactivity Limits" (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors" (Ref. 2).

Limits on regulating CEA insertion have been established, and all CEA positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking, ejected CEA worth, reactivity insertion rate, and SDM limits are preserved.

The regulating CEA groups operate with a predetermined amount of position overlap, in order to approximate a linear relation between CEA worth and CEA position (integral CEA worth). The regulating CEA groups are withdrawn and operate in a predetermined sequence. The group sequence and overlap limits are specified in the COLR.

The regulating CEAs are used for precise reactivity control of the reactor. The positions of the regulating CEAs are manually controlled. They are capable of adding reactivity very quickly (compared to borating or diluting).

The power density at any point in the core must be limited to maintain specified acceptable fuel design limits, including limits that preserve the criteria specified in 10 CFR 50.46 (Ref. 2). Together, LCO 3.1.6, LCO 3.2.~~4~~, "AZIMUTHAL POWER TILT (Tq)," and LCO 3.2.~~5~~, "AXIAL SHAPE INDEX (ASI)," provide limits on control component operation and on monitored process variables to ensure the core operates within the linear heat rate (LCO 3.2.1, "Linear Heat Rate (LHR)"), ~~total planar radial peaking factor (F^T_{XY}) (LCO 3.2.2, "Total Planar Radial Peaking Factor (F^T_{XY})"),~~ and total integrated radial peaking factor (F^T_r) (LCO 3.2.3, "Total Integrated Radial Peaking Factor (F^T_r)") limits in the COLR. Operation within the LHR limits given in the COLR prevents power peaks that would exceed the loss of coolant accident (LOCA) limits derived by the Emergency Core Cooling System analysis. Operation within the ~~F^T_{XY} and~~

3 4 3 3 3

1

6

BASES

BACKGROUND (continued)

F_r^T limits given in the COLR prevents departure from nucleate boiling (DNB) during a loss of forced reactor coolant flow accident. In addition to the LHR~~, F_{XY}^T,~~ and F^T_r limits, certain reactivity limits are preserved by regulating CEA insertion limits. The regulating CEA insertion limits also restrict the ejected CEA worth to the values assumed in the safety analysis and preserve the minimum required SDM in MODES 1 and 2.

3

The establishment of limiting safety system settings and LCOs requires that the expected long and short term behavior of the radial peaking factors be determined. The long term behavior relates to the variation of the steady state radial peaking factors with core burnup and is affected by the amount of CEA insertion assumed, the portion of a burnup cycle over which such insertion is assumed, and the expected power level variation throughout the cycle. The short term behavior relates to transient perturbations to the steady state radial peaks, due to radial xenon redistribution. The magnitudes of such perturbations depend upon the expected use of the CEAs during anticipated power reductions and load maneuvering. Analyses are performed, based on the expected mode of operation of the Nuclear Steam Supply System (base loaded, maneuvering, etc.). From these analyses, CEA insertions are determined and a consistent set of radial peaking factors defined. The long term steady state and short term insertion limits are determined, based upon the assumed mode of operation used in the analyses, and provide a means of preserving the assumption on CEA insertions used. The long and short term insertion limits of LCO 3.1.6 are specified for the plant, which has been designed primarily for base loaded operation, but has the ability to accommodate a limited amount of load maneuvering.

The regulating CEA insertion and alignment limits are process variables that together characterize and control the three dimensional power distribution of the reactor core. Additionally, the regulating bank insertion limits control the reactivity that could be added in the event of a CEA ejection accident, and the shutdown and regulating bank insertion limits ensure the required SDM is maintained.

Operation within the subject LCO limits will prevent fuel cladding failures that would breach the primary fission product barrier and release fission products to the reactor coolant in the event of a LOCA, loss of flow, ejected CEA, or other accident requiring termination by a Reactor Protection System trip function.

1

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition I) and anticipated operational occurrences (Condition II). The acceptance criteria for the regulating CEA insertion, ASI, and T_q LCOs are such as to preclude core power distributions from occurring that would violate the following fuel design criteria:

a. During a large break LOCA, the peak cladding temperature must not exceed a limit of 2200°F, 10 CFR 50.46 (Ref. 2),

b. During a loss of forced reactor coolant flow accident, there must be at least a 95% probability at a 95% confidence level (the 95/95 DNB criterion) that the hot fuel CEA in the core does not experience a DNB condition,

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. 3), and

d. The CEAs must be capable of shutting down the reactor with a minimum required SDM, with the highest worth CEA stuck fully withdrawn, GDC 26 (Ref. 1).

Regulating CEA position, ASI, and T_q are process variables that together characterize and control the three dimensional power distribution of the reactor core.

Fuel cladding damage does not occur when the core is operated outside these LCOs during normal operation. However, fuel cladding damage could result, should an accident occur with simultaneous violation of one or more of these LCOs. Changes in the power distribution can cause increased power peaking and corresponding increased local LHRs.

The SDM requirement is ensured by limiting the regulating and shutdown CEA insertion limits, so that the allowable inserted worth of the CEAs is such that sufficient reactivity is available to shut down the reactor to hot zero power. SDM assumes the maximum worth CEA remains fully withdrawn upon trip (Ref. ~~4~~3).

The most limiting SDM requirements for MODE 1 and 2 conditions at BOC are determined by the requirements of several transients, e.g., loss of flow, seized rotor, etc. However, the most limiting SDM requirements for MODES 1 and 2 at EOC come from just one transient, Steam Line Break (SLB). The requirements of the SLB event at EOC for both the full power and no load conditions are significantly larger than those of any other event at that time in cycle and, also, considerably larger than the most limiting requirements at BOC.

6

BASES

APPLICABLE SAFETY ANALYSES (continued)

Although the most limiting SDM requirements at EOC are much larger than those at BOC, the available SDMs obtained via the scramming of the CEAs are also substantially larger due to the much lower boron concentration at EOC. To verify that adequate SDMs are available throughout the cycle to satisfy the changing requirements, calculations are performed at both BOC and EOC. It has been determined that calculations at these two times in cycle are sufficient since the differences between available SDMs and the limiting SDM requirements are the smallest at these times in cycle. The measurement of CEA bank worth performed as part of the Startup Testing Program demonstrates that the core has the expected shutdown capability. Consequently, adher~~a~~nce to LCOs 3.1.5 and 3.1.6 provides assurance that the available SDMs at any time in cycle will exceed the limiting SDM requirements at that time in cycle.

e

1

Operation at the insertion limits or ASI limits may approach the maximum allowable linear heat generation rate or peaking factor, with the allowed T_q present. Operation at the insertion limit may also indicate the maximum ejected CEA worth could be equal to the limiting value in fuel cycles that have sufficiently high ejected CEA worths.

The regulating and shutdown CEA insertion limits ensure that safety analyses assumptions for reactivity insertion rate, SDM, ejected CEA worth, and power distribution peaking factors are preserved (Ref. ~~5~~).

3

1

The regulating CEA insertion limits satisfy Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The limits on regulating CEAs sequence, overlap, and physical insertion, as defined in the COLR, must be maintained because they serve the function of preserving power distribution, ensuring that the SDM is maintained, ensuring that ejected CEA worth is maintained, and ensuring adequate negative reactivity insertion on trip. The overlap between regulating banks provides more uniform rates of reactivity insertion and withdrawal and is imposed to maintain acceptable power peaking during regulating CEA motion.

Regulating CEAs are considered to be fully withdrawn when withdrawn to at least 129.0 inches

4

The power dependent insertion limit (PDIL) alarm circuit is required to be OPERABLE for notification that the CEAs are outside the required insertion limits. When the PDIL alarm circuit is inoperable, the verification of CEA positions is increased to ensure improper CEA alignment is identified before unacceptable flux distribution occurs.

1

6

BASES

APPLICABILITY

The regulating CEA sequence, overlap, and physical insertion limits shall be maintained with the reactor in MODES 1 and 2. These limits must be maintained, since they preserve the assumed power distribution, ejected CEA worth, SDM, and reactivity rate insertion assumptions. Applicability in MODES 3, 4, and 5 is not required, since neither the power distribution nor ejected CEA worth assumptions would be exceeded in these MODES. SDM is preserved in MODES 3, 4, and 5 by adjustments to the soluble boron concentration.

This LCO has been modified by a Note indicating the LCO requirement is suspended during SR 3.1.4.4. This SR verifies the freedom of the CEAs to move, and requires the regulating CEAs to move below the LCO limits, which would normally violate the LCO. ~~The Note also allows the LCO to be not applicable during reactor power cutback operation, which inserts a selected CEA group (usually group 5) during loss of load events.~~

5

ACTIONS

A.1 and A.2

Operation beyond the transient insertion limit may result in a loss of SDM and excessive peaking factors. The transient insertion limit should not be violated during normal operation; this violation, however, may occur during transients when the operator is manually controlling the CEAs in response to changing plant conditions. When the regulating groups are inserted beyond the transient insertion limits, actions must be taken to either withdraw the regulating groups beyond the limits or to reduce THERMAL POWER to less than or equal to that allowed for the actual CEA insertion limit. Two hours provides a reasonable time to accomplish this, allowing the operator to deal with current plant conditions while limiting peaking factors to acceptable levels.

B.1 and B.2

If the CEAs are inserted between the long term steady state insertion limits and the transient insertion limits for intervals > 4 hours per 24 hour period, and the short term steady state insertions are exceeded, peaking factors can develop that are of immediate concern (Ref. ~~6~~ 3).

1

Verifying the short term steady state insertion limits are not exceeded ensures that the peaking factors that do develop are within those allowed for continued operation. Fifteen minutes provides adequate time for the operator to verify if the short term steady state insertion limits are exceeded.

1

6

BASES

ACTIONS (continued)

Experience has shown that rapid power increases in areas of the core, in which the flux has been depressed, can result in fuel damage, as the LHR in those areas rapidly increases. Restricting the rate of THERMAL POWER increases to ≤ 5% RTP per hour, following CEA insertion beyond the long term steady state insertion limits, ensures the power transients experienced by the fuel will not result in fuel failure (Ref. ~~7~~).

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.6, BASES, REGULATING CONTROL ELEMENT ASSEMBLY (CEA) INSERTION LIMITS

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The ISTS includes ISTS 3.2.1, Linear Heat Rate (LHR), ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^{T}), ISTS 3.2.3, Total Integrated Radial Peaking Factor (F_{r}^{T}), ISTS 3.2.4, Azimuthal Power Tilt (T_q), and ISTS 3.2.5, Axial Shape Index (ASI). CTS do not include a Specification for ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^{T}). The CTS and ISTS are renumbered. CTS 3.2.3, Total Integrated Radial Peaking Factor (F_{r}^{T}), CTS 3.2.4, Azimuthal Power Tilt (T_q), and CTS 3.2.5, Axial Shape Index (ASI), are renumbered as ITS 3.2.2, ITS 3.2.3, and ITS 3.2.4, respectively.

4. CTS 3.1.3.6 LCO states that regulating CEAs are considered to be fully withdrawn when withdrawn to at least 129.0 inches. ITS LCO 3.1.6 does not retain this detail. This changes the CTS by relocating the details that regulating CEAs are considered to be fully withdrawn when withdrawn to at least 129.0 inches to the Bases. See DOC LA01.

5. The ISTS Bases states “The Note also allows the LCO to be not applicable during reactor power cutback operation, which inserts a selected CEA group (usually group 5) during loss of load events.” Reactor power cutback design feature is not applicable to PSL Unit 1 and Unit 2. Therefore, this statement is deleted.

6. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

4.1.3.2 ~~Each position indicator channel shall be determined to be OPERABLE by~~ verify~~ing the~~ pulse counting position indicator channels and ~~the~~ reed switch position indicator channels agree within 5.0 inches in accordance with the Surveillance Frequency Control Program ~~except during time intervals~~ when ~~the~~ Deviation Circuit is inoperable~~, then compare the pulse counting position indicator and reed switch position indicator channels at least once per~~ 4 hours.

DISCUSSION OF CHANGES
ITS 3.1.7, CONTROL ELEMENT ASSEMBLY (CEA) POSITION INDICATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 Unit 1 CTS 3.1.3.3 ACTION b. covers the inoperability for a maximum of one reed switch position indicator channel per group (except as permitted by ACTION d.). Unit 1 CTS 3.1.3.3 ACTION d. covers the inoperability for one or more pulse counting position indicator channels inoperable and the maximum allowed inoperable reed switch position indicator channels per group to allow continued operation in MODES 1 and 2.

Unit 2 CTS 3.1.3.2 ACTION a. covers the inoperability for a maximum of one reed switch position indicator channel per group except as permitted by ACTION d.). Unit 2 CTS 3.1.3.2 ACTION c. covers the inoperability for one or more pulse counting position indicator channels inoperable and the maximum allowed inoperable reed switch position indicator channels per group to allow continued operation in MODES 1 and 2.

The purpose of the CTS “(except as permitted by ACTION d.)” statement is to alert the user to a limitation on inoperable reed switch position indicator channels per group, when one or more pulse counting indicator channels is inoperable. This changes the CTS by not including the cross-reference in the ITS. It is an ITS convention to not include these types of footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A03 Unit 1 CTS 3.1.3.3 ACTION b.3, and Unit 2 CTS 3.1.3.2 ACTION a.3, each state that THERMAL POWER be reduced to ≤ 70% of the maximum allowable THERMAL POWER level for the existing Reactor Coolant Pump combination, and if negative reactivity insertion is required to reduce THERMAL POWER, boration shall be used.

The purpose of the CTS is to provide the THERMAL POWER limit should it be necessary to reduce THERMAL POWER. The ITS retains this requirement but does not contain a method to be used to reduce THERMAL POWER. PSL only operates in the four reactor coolant pump combination; therefore, subsequent operation is allowable provided the THERMAL POWER is reduced to ≤ 70% RTP – the equivalent THERMAL POWER for the CTS four reactor coolant pump combination. Additionally, the method to be used to reduce THERMAL POWER is determined by Licensed Operators based upon plant conditions and without

challenging plant systems. This changes the CTS by changing the statement that THERMAL POWER be reduced to ≤ 70% of the maximum allowable THERMAL POWER level for the existing Reactor Coolant Pump combination to THERMAL POWER be reduced to ≤ 70% RTP, and by removing the method to be used to reduce THERMAL POWER. This changes the ITS by stating the specific THERMAL POWER limit should it be necessary to reduce THERMAL POWER.

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A04 Unit 1 CTS 3.1.3.3 ACTIONS b.3, b.3.a, b.3.b, c.3, and Unit 2 CTS 3.1.3.2 ACTIONS a.3, a.3.a, a.3.b, b.3, each contain statements in reference to CTS 3.1.3.6 requirements including; (b.3, a.3) operation at or below this reduced THERMAL POWER level may continue provided requirements in Specification 3.1.3.6 are maintained; (b.3.a, a.3.a) subsequent to fully withdrawing this CEA group(s), the THERMAL POWER level may be returned to a level consistent with all other applicable specifications; (b.3.b, a.3.b) subsequent operation shall be within the limits of Specification 3.1.3.6.; and (c.3, b.3) subsequent operation is within the limits of Specification 3.1.3.6. Each CTS statement is in reference to requirements in CTS 3.1.3.6, “Regulating CEA Insertion Limits.”

The purpose of the CTS is to provide reference to CTS 3.1.3.6 to determine if the CEA Insertion Limits are met. The ITS does not contain these references. This changes the CTS by not including the reference to the CEA insertion limits in the ITS. It is an ITS convention to not include these types of footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

A05 Unit 1 CTS 3.1.3.3 LCO states that shutdown and regulating CEA reed switch position indicator channels and CEA pulse counting position indicator channels shall be OPERABLE and capable of determining the absolute CEA positions within $\pm$ 2.25 inches. Similarly, Unit 2 CTS 3.1.3.2 LCO states that shutdown and regulating CEA reed switch position indicator channels and CEA pulse counting position indicator channels shall be OPERABLE and capable of determining the absolute CEA positions within $\pm$ 2.50 inches.

The purpose of the CTS is to provide acceptance criteria for the accuracy of the CEA reed switch position indicator channels and CEA pulse counting position indicator channels. The acceptance criteria are provided in the ITS 3.1.7 Bases. ITS 3.1.7 Bases LCO description states that for a CEA position indicator channel to be considered OPERABLE, the position indicator must be capable of determining the absolute CEA position within $\pm$ 2.25 inches for Unit 1, and $\pm$ 2.50 inches for Unit 2. ITS Bases Surveillance Requirements, SR 3.1.7.1, description states that CEA pulse counting indicator position channels and reed switch position indicator channels for the CEAs in each group agree within 4.5 inches for Unit 1, and within 5.0 inches for Unit 2. These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A06 Unit 1 CTS 3.1.3.3 Action c.2 states that the fully inserted CEA group(s) containing the inoperable position indicator channel is subsequently maintained fully inserted. Similarly, Unit 2 CTS 3.1.3.3 Action b.2 states that the fully inserted full-length CEA group(s) containing the inoperable position indicator channel is subsequently maintained fully inserted.

The purpose of the CTS is to provide Action to maintain a fully inserted CEA group(s) containing the inoperable position indicator channel in the fully inserted position. For ITS Condition A, with one or more CEA groups with one reed switch or one pulse counting position indicator channel inoperable, Required Actions A.1 and A.2 require fully withdrawing or fully inserting the CEA with the inoperable position indicator. These actions place the CEA in a condition where the position can be verified using the CEA Limits Indication System. The associated CEA "full out" or "full in" limit position indicator actuation provides assurance the CEA is at a known position. Once the CEA is fully withdrawn or fully inserted, Condition A no longer applies, and Condition B is entered.

For ITS Condition B, with one or more CEA groups with one reed switch or one pulse counting position indicator channel inoperable and the associated CEA is fully withdrawn or fully inserted, a verification is required to ensure that either the CEA "full out" or "full in" limit indicator is actuated immediately and every 12 hours thereafter. The associated CEA "full out" or "full in" limit position indicator actuation provides assurance the CEA is at a known position. Use of the CEA limit indicator is an acceptable method to determine CEA position since the CEA Limits Indication System is separate and independent from the reed switch and the pulse counting position indication systems. This change is designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.1.3.3 ACTION b. covers the inoperability for a maximum of one reed switch position indicator channel per group or a maximum of one pulse counting position indicator channel per group with the CEA partially inserted, and CTS 3.1.3.3 ACTION c.

covers the inoperability for a maximum of one rod position indicator channel per group with the CEA fully withdrawn or inserted.
Unit 2 CTS 3.1.3.2 ACTION a. covers the inoperability for a maximum of one reed switch position indicator channel per group or a maximum of one pulse counting position indicator channel per group with the CEA partially inserted, and CTS 3.1.3.2 ACTION b. covers the inoperability for a maximum of one rod position indicator channel per group with the CEA fully withdrawn or inserted.

ITS 3.1.7 ACTIONS are modified by Note 1 that states "Separate Condition entry is allowed for each CEA group." ITS 3.1.7 ACTION A covers inoperability for one or more CEA groups with one reed switch position indicator channel inoperable, or one or more CEA groups with one pulse counting position indicator channel inoperable with the CEA partially inserted. ITS 3.1.7 ACTION B covers inoperability for one or more CEA groups with one reed switch position indicator channel inoperable, or one or more CEA groups with one pulse counting position indicator channel inoperable with the CEA fully withdrawn or inserted.

The purpose of Unit 1 CTS 3.1.3.3 ACTION b. (Unit 2 CTS 3.1.3.2 ACTION a.) is to provide compensatory actions for a maximum of one rod position indicator per group. The purpose of Unit 1 CTS 3.1.3.3 ACTION c. (Unit 2 CTS 3.1.3.2 ACTION b.) is to provide compensatory actions for more than one rod position indicator per group with the CEA fully withdrawn or inserted. This change is acceptable because the Required Actions provide appropriate compensatory actions for one or more inoperable position indicator channels in each CEA group. The actions that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of a DBA occurring during the repair period.

This change will allow separate Condition entry for each inoperable CEA group while the CTS does not. The ITS will allow each inoperable CEA group with an inoperable reed rod position indicator or inoperable pulse counting position indicator to be tracked separately. This change is acceptable because the Required Actions for each Condition provide appropriate compensatory actions for inoperable CEA position indication.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 **Unit 1 only:** *(Category 4 – Relaxation of Required Action)* CTS 3.1.3.3 ACTION d. states “With one or more pulse counting position indicator channels inoperable, operation in MODES 1 and 2 may continue for up to 24 hours provided all of the reed switch position indicator channels are OPERABLE.” ITS 3.1.7 Required Action C.1 states “Verify no more than one reed switch position indicator channel per group is inoperable.” This changes the CTS by relaxing the allowable number of inoperable pulse counting position indicator channels and concurrent inoperable reed switch position indicator channels per group from “one or more pulse counting position indicator channels inoperable”

to “one or more CEA groups with two or more pulse counting position indicator channels inoperable”, and from “provided all of the reed switch position indicator channels are OPERABLE” to “no more than one reed switch position indicator channel per group is inoperable.”

The purpose of CTS 3.1.3.3 ACTION d. is to continue to determine CEA position using reed switch position indicator channels, with two or more inoperable pulse counting position indicator channels. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the operability status of the specified redundant systems of required features, the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of a DBA occurring during the allowed Completion Time.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 **Unit 1 only:** *(Category 3 – Relaxation of Completion Time)* CTS 3.1.3.3 ACTION d. states “With one or more pulse counting position indicator channels inoperable, operation in MODES 1 and 2 may continue for up to 24 hours provided all of the reed switch position indicator channels are OPERABLE.” ITS 3.1.7 Required Action C.2 states that the pulse counting position indicator channels be restored to OPERABLE status within 72 hours. This changes the CTS by relaxing the Completion Time from 24 hours to 72 hours.

This change is acceptable because the Completion Time is consistent with safe operation under the specific Condition, considering the operability status of the redundant systems of required features, the capacity and capability of remaining features, and the low probability of a DBA occurring during the allowed Completion Time. This ITS Completion Time of 72 hours is adequate time to restore the inoperable pulse counting position indicator channels to OPERABLE status, considering the reed switch position indicator channels will continue to provide indication of CEA position.

This change is designated as less restrictive because additional time is allowed to restore parameters to within the LCO limits than was allowed in the CTS.

L04 *(Category 4 – Relaxation of Required Action)* Unit 1 CTS 3.1.3.3 ACTION b. covers the inoperability for a maximum of one reed switch position indicator channel per group or a maximum of one pulse counting position indicator channel per group with the CEA partially inserted, and CTS 3.1.3.3 ACTION c. covers the inoperability for a maximum of one rod position indicator channel per group with the CEA fully withdrawn or inserted. Unit 2 CTS 3.1.3.2 ACTION a. covers the inoperability for a maximum of one reed switch position indicator channel per group or a maximum of one pulse counting position indicator channel per group with the CEA partially inserted, and CTS 3.1.3.2 ACTION b. covers the inoperability for a maximum of one rod position indicator channel per group with the CEA fully withdrawn or inserted.

ITS 3.1.7 adds Required Action A.1, which states “Fully withdraw CEA with inoperable position indicator channel” with a Completion Time or 6 hours, and adds Required Action A.2, which states “Fully insert CEA with inoperable position indicator channel” with a Completion Time or 6 hours. Unit 1 CTS 3.1.3.3 ACTION b. and Unit 2 CTS 3.1.3.2 ACTION a. are changed by adding an option to fully insert or fully withdraw the affected individual CEA, rather than the CEA group, provided the CEA alignment is maintained in accordance with LCO 3.1.4, “Control Element Assembly Alignment” as annotated in the ITS 3.1.7 Required Action A.1 and Required Action A.2 Note.

The purpose of the Unit 1 CTS 3.1.3.3 ACTION b. (Unit 2 CTS 3.1.3.2 ACTION a. and b.) is to provide compensatory actions for a maximum of one rod position indicator per group inoperable with the CEA partially inserted. The purpose of Unit 1 CTS 3.1.3.3 ACTION c. (Unit 2 CTS 3.1.3.2 ACTION b.) is to provide compensatory actions for a maximum of one rod position indicator channel per group inoperable with the CEA fully withdrawn or inserted. The CTS Required Actions are not affected. Rather, the individual CEA with the inoperable position indicator channel may be moved to the fully withdrawn or fully inserted position rather than moving its CEA group, provided the that contains the individual CEA with the inoperable position indicator channel is maintained in accordance with LCO 3.1.4, “Control Element Assembly Alignment.” The Completion Time is the same as the Completion Time allowed by CTS for alignment of the CEA group with an inoperable position indicator channel.

This change is acceptable because the ITS Required Actions A.1 and A.2 provide appropriate compensatory actions for an inoperable CEA position indication. ITS Required Action A.1 or A.2 may be taken when the CEA group is within the LCO 3.1.4 group alignment limit of the fully inserted or fully withdrawn position. These ACTIONS minimize CEA movements and reduce the likelihood that a reduction in THERMAL POWER. Upon Completion of Required Action A.1 or A.2, Condition A is exited, and Condition B is entered and ACTIONS consistent with the CTS ACTIONS are taken. When the CEA group with the inoperable position indicator channel is not within the LCO 3.1.4 group alignment limit of the fully inserted or fully withdrawn position, then the ITS 3.1.7 Required Action A.3.1 to reduce THERMAL POWER within 6 hours, and Required Action A.3.2.1 to fully withdraw the CEA group with the inoperable position indicator channel within 10 hours, or Required Action A.3.2.2 to fully insert the CEA group with the inoperable position indicator channel within 10 hours, are taken. ITS Required Actions A.1 and A.2 provide appropriate compensatory actions for one inoperable position indicator channel within a CEA group. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining features, a reasonable time for repairs or replacement of required features, and the low probability of a DBA occurring during the repair period.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.7, CONTROL ELEMENT ASSEMBLY (CEA) POSITION INDICATION

1. NUREG 1432, “Standard Technical Specifications, Combustion Engineering Plants”, Revision 5.0, ISTS 3.1.4 includes one Surveillance Requirement (SR) related to CEA position indication, ISTS SR 3.1.4.5. However, the LCO statement of ISTS 3.1.4 does not specifically delineate position indication as being required for a CEA. It only requires OPERABILITY of CEAs to be within the alignment limits. Furthermore, the LCO Section of the ISTS 3.1.4 Bases does not describe indication as a necessary feature for the CEA to be OPERABLE. However, the ISTS Bases for SR 3.1.4.5 provides a requirement that each reed switch position indication channel ensures the channel is OPERABLE and capable of indicating CEA position over the entire length of the CEA's travel. In addition, ISTS 3.1.4 does not provide any specific actions to take if one or more of the required CEA position indicators is inoperable. Consistent with the approach taken in NUREG 1431, “Standard Technical Specifications, Westinghouse Plants”, Revision 5.0, a new LCO has been provided for the CEA Position Indicators.

   PSL Unit 1 CTS 3.1.3.3 and PSL Unit 2 CTS 3.1.3.2 are adapted using NUREG 1431, ISTS 3.1.7, to develop the new LCO 3.1.7. PSL LCO 3.1.7 maintains the current licensing basis while adapting the new LCO to NUREG 1431 requirements. Specifically, PSL requires two CEA position indicator channels for each CEA to be OPERABLE; the reed switch position indicator channels and the pulse counting indicator channel. The ACTIONS are adapted from the ACTIONS in NUREG-1431. The Surveillance Requirement ensures the reed switch position indicator channels and the pulse counting indicator channels for a group agree within an allowable tolerance.

   Refer to the PSL Unit 1 CTS 3.1.3.3 and PSL Unit 2 CTS 3.1.3.2 markups and discussion of changes for the details of changes from CTS to ITS 3.1.7.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.7 Control Element Assembly (CEA) Position Indication

BASES

BACKGROUND

According to GDC 13 (Ref. 1), instrumentation to monitor variables and systems over their operating ranges during normal operation, anticipated operational occurrences, and accident conditions must be OPERABLE. The purpose of this LCO is to ensure OPERABILITY of the shutdown and regulating CEA position indicators so CEA position can be determined thereby ensuring compliance with the CEA alignment and insertion limits.

The OPERABILITY (i.e., trippability) of the shutdown and regulating CEAs is an initial assumption in the safety analyses that assume CEA insertion upon reactor trip. Maximum CEA misalignment is an initial assumption in the safety analysis that directly affects core power distributions and assumptions of available SDM.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10 and GDC 26 (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Plants" (Ref. 2).

Limits on CEA alignment and OPERABILITY have been established, and CEA positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

CEAs are moved by their control element drive mechanisms (CEDMs). Each CEDM moves its CEA one step (approximately 0.75 inches) at a time. Step in and step out signals are totalized within the CEA Control System to provide one of the means of determining CEA position.

The axial position of shutdown and regulating CEAs is indicated by two separate and independent systems: Pulse Counting Position Indication System and the Reed Switch Position Indication System. Additionally, the CEA Limits Indication System independently provides indication of a CEA that is fully withdrawn or fully inserted.

BASES

BACKGROUND (continued)

The Pulse Counting Position Indication System counts the pulses sent to the CEA gripper coils from the CEDM Control System that moves the CEAs. There is a step counter for each CEA. Individual CEAs in a group all receive the same signal to move and should, therefore, all be at the same position indicated by the pulse counter. The Pulse Counting Position Indication System is considered highly precise (± 1 step or ± 0.75 inches).

The Reed Switch Position Indication System provides an independent and diverse means of providing indication of actual CEA position, but at a lower precision than the step counters. This system is based on signals from a series of magnetically actuated reed switch position transmitters spaced at 1.5-inch intervals along the CEDM housing. The reed switch position transmitters provide voltage signals for CEA position monitoring in the control room. The reed switch position transmitters also provide signals for alarm information and CEA motion inhibit on CEA deviation within a group.

The CEA Limits Indication System provides indication of a fully withdrawn or fully inserted CEA from distinct contact closure signals from the reed switch position transmitter assembly. The limit reed switch position transmitter assembly, on each CEA, transmits an upper electrical limit signal when the CEA is fully withdrawn and transmits a lower electrical limit signal when the CEA is fully inserted. The CEA Limits Indication System is separate from the Reed Switch Position Indication System.

A detailed description of the CEA position indication systems is found in the UFSAR, Chapter 7 (Ref. 3)

APPLICABLE SAFETY ANALYSES

CEA misalignment accidents are analyzed in the safety analysis (Ref. 4). The accident analysis defines CEA misoperation as any event, with the exception of sequential group withdraws, which could result from a single malfunction in the reactivity control systems. For example, CEA misalignment may be caused by a malfunction of the CEDM, CEDM Control System, or by operator error. Therefore, the acceptance criteria for CEA position indication is that CEA positions must be known with sufficient accuracy in order to verify the core is operating within the limits of LCO 3.1.5, "Shutdown Control Element Assembly (CEA) Insertion Limits," and LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits". The CEA positions must also be known in order to verify the alignment limits are preserved (LCO 3.1.4, "Control Element Assembly (CEA) Alignment"). CEA positions are continuously monitored to provide operators with information that ensures the plant is operating within the bounds of the accident analysis assumptions.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The position of the CEAs satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii). The CEA position indication systems monitor CEA position, which is an initial condition of the accident.

LCO

OPERABILITY of the CEA reed switch and pulse counting position indicator channels ensure that the CEA alignment assumptions in the safety analysis will remain valid. The CEA alignment requirements specified in LCO 3.1.4 ensure that the CEA groups maintain the correct power distribution and CEA alignment.

OPERABILITY of the position indicator channels ensures that inoperable, misaligned, or mispositioned CEAs can be detected. Therefore, power peaking and SDM can be controlled within acceptable limits.

For a CEA position indicator channel to be considered OPERABLE, the position indicator must be capable of determining the absolute CEA position within $\pm$ 2.25 inches.

APPLICABILITY

The requirements on CEA position indicator channels are applicable in MODES 1 and 2 because these are the MODES power is generated, and the OPERABILITY and alignment of CEAs and CEA insertion limits have the potential to affect the safety of the plant. In the shutdown MODES, the OPERABILITY of the shutdown and regulating banks has the potential to affect the required SDM, but this effect can be compensated for by an increase in the boron concentration of the Reactor Coolant System.

ACTIONS

The ACTIONS Table is modified by a Note indicating that a separate Condition entry is allowed for each CEA group. This is acceptable because the Required Actions for each Condition provide appropriate compensatory actions for one or more inoperable position indicator channels in each CEA group.

Conditions A and B are modified by a Note. The Note to Condition A indicates that the Condition only applies when the inoperable position indicator channel is associated with a partially inserted CEA and the Note to Condition B indicates that the Condition only applies when the inoperable position indicator channel is associated with a fully withdrawn or fully inserted CEA. Because the actions are different for partially inserted CEAs and CEAs that are fully inserted or fully withdrawn, these

BASES

ACTIONS (continued

Notes identify the applicable Condition when a CEA reed switch or pulse counting position indicator channel in one or more CEA groups is inoperable.

A.1 and A.2

With one or more CEA groups with one reed switch or one pulse counting position indicator channel inoperable, Required Actions A.1 and A.2 require fully withdrawing or fully inserting the CEA with the inoperable position indicator. These actions place the CEA in a condition where the position can be verified using the CEA Limits Indication System. The associated CEA “full out” or “full in” limit position indicator actuation provides assurance the CEA is at a known position. Once the CEA is fully withdrawn or fully inserted, Condition A no longer applies and Condition B is entered. The Completion Time for Required Actions A 1 and A.2 is reasonable, based on operating experience, to fully withdraw or fully insert a CEA during power operation.

Required Actions A.1 and A.2 are modified by a Note to restrict these options to only be applicable if the CEA with the inoperable position indicator channel can be maintained within the group alignment limits required by LCO 3.1.4 when the CEA is fully withdrawn or fully inserted. Otherwise, the CEA group must be fully withdrawn or fully inserted in accordance with Required Actions A.3.1, A.3.2.1, and A.3.2.2.

A.3.1, A.3.2.1, and A.3.2.2

If the CEA with an inoperable position indicator channel cannot be maintained within the group alignment limits of LCO 3.1.4 when withdrawing or inserting the CEA, Required Actions A.3.1, A.3.2.1, and A.3.2.2 allow withdrawing or inserting the CEA group to the fully withdrawn or fully inserted position provided THERMAL POWER is reduced to ≤ 70% RTP.

Required Action A.3.1 requires the THERMAL POWER reduction to place the core in a condition where moving a controlling CEA group will not result in core peaking factors exceeding associated limits (Ref. 3).

Required Action A.3.2.1 and A.3.2.2 require either fully withdrawing or fully inserting the CEA group with the inoperable position indicator channel so the position of the affected CEA can be verified using the CEA Limits Indication System.

The Completion Time of Required Action A.3.1 is reasonable, based on operating experience, for reducing power to ≤ 70% RTP from full power conditions without challenging plant systems.

BASES

ACTIONS (continued

The Completion Time of Required Actions A.3.2.1 and A.3.2.2 takes into account the time to reduce THERMAL POWER and the additional time needed to fully withdraw or fully insert the associated CEA group.

Required Actions A.3.2.1 and A.3.2.2 are modified by a Note to only allow fully withdrawing or fully inserting a CEA group with the inoperable position indicator channel if the CEA group can be maintained within the CEA group withdrawal sequence and insertion limits specified in the COLR, as required by LCO 3.1.6.

B.1 and B2

With one or more CEA groups with one reed switch or one pulse counting position indicator channel inoperable and the associated CEA is fully withdrawn or fully inserted, a verification is required to ensure that either the CEA “full out” or “full in” limit indicator is actuated immediately and every 12 hours thereafter. The associated CEA “full out” or “full in” limit position indicator actuation provides assurance the CEA is at a known position. Use of the CEA limit indicator is an acceptable method to determine CEA position since the CEA Limits Indication System is separate and independent from the reed switch and the pulse counting position indication systems. Performing the verification immediately, and every 12 hours thereafter, is considered acceptable in view of other information available to the operator in the control room to determine CEA position and that the actual CEA position is not expected to change.

C.1 and C.2

With one or more CEA groups with two or more pulse counting position indicator channels inoperable, continued operation in MODES 1 and 2 may continue provided verification that no more than one reed switch position indicator channel per group is inoperable. Required Action C.1 ensures no more than one CEA per group has lost position indication. The Completion Time of immediately ensures that prompt action is taken to verify the status of the remaining CEA position indicator channels within the group.

Required Action C.2 requires the pulse counting position indicator channels be restored to OPERABLE status within 72 hours. The Completion Time of 72 hours is adequate time to restore the inoperable pulse counting position indicator channels to OPERABLE status, considering the reed switch position indicators will continue to provide indication of CEA position.

BASES

ACTIONS (continued)

D.1

If two or more reed switch position indicator channels are inoperable in one or more CEA groups, or the Required Actions cannot be completed within the associated Completion Times, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. The allowed Completion Time is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.7.1

This SR verifies that CEA pulse counting indicator position channels and reed switch position indicator channels for the CEAs in each group agree within 4.5 inches. This Surveillance is performed every 4 hours when the alignment deviation circuit is inoperable. Performing the verification every 4 hours when the alignment deviation circuit is inoperable, is considered acceptable in view of other information continuously available to the operator in the control room. The periodic Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.7 Control Element Assembly (CEA) Position Indication

BASES

BACKGROUND

According to GDC 13 (Ref. 1), instrumentation to monitor variables and systems over their operating ranges during normal operation, anticipated operational occurrences, and accident conditions must be OPERABLE. The purpose of this LCO is to ensure OPERABILITY of the shutdown and regulating CEA position indicators so CEA position can be determined thereby ensuring compliance with the CEA alignment and insertion limits.

The OPERABILITY (i.e., trippability) of the shutdown and regulating CEAs is an initial assumption in the safety analyses that assume CEA insertion upon reactor trip. Maximum CEA misalignment is an initial assumption in the safety analysis that directly affects core power distributions and assumptions of available SDM.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10 and GDC 26 (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Plants" (Ref. 2).

Limits on CEA alignment and OPERABILITY have been established, and CEA positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

CEAs are moved by their control element drive mechanisms (CEDMs). Each CEDM moves its CEA one step (approximately 0.75 inches) at a time. Step in and step out signals are totalized within the CEA Control System to provide one of the means of determining CEA position.

The axial position of shutdown and regulating CEAs is indicated by two separate and independent systems: Pulse Counting Position Indication System and the Reed Switch Position Indication System. Additionally, the CEA Limits Indication System independently provides indication of a CEA that is fully withdrawn or fully inserted.

BASES

BACKGROUND (continued)

The Pulse Counting Position Indication System counts the pulses sent to the CEA gripper coils from the CEDM Control System that moves the CEAs. There is a step counter for each CEA. Individual CEAs in a group all receive the same signal to move and should, therefore, all be at the same position indicated by the pulse counter. The Pulse Counting Position Indication System is considered highly precise (± 1 step or ± 0.75 inches).

The Reed Switch Position Indication System provides an independent and diverse means of providing indication of actual CEA position, but at a lower precision than the step counters. This system is based on signals from a series of magnetically actuated reed switch position transmitters spaced at 1.5-inch intervals along the CEDM housing. The reed switch position transmitters provide voltage signals for CEA position monitoring in the control room. The reed switch position transmitters also provide signals for alarm information and CEA motion inhibit on CEA deviation within a group.

The CEA Limits Indication System provides indication of a fully withdrawn or fully inserted CEA from distinct contact closure signals from the reed switch position transmitter assembly. The limit reed switch position transmitter assembly, on each CEA, transmits an upper electrical limit signal when the CEA is fully withdrawn and transmits a lower electrical limit signal when the CEA is fully inserted. The CEA Limits Indication System is separate from the Reed Switch Position Indication System.

A detailed description of the CEA position indication systems is found in the UFSAR, Chapter 7 (Ref. 3)

APPLICABLE SAFETY ANALYSES

CEA misalignment accidents are analyzed in the safety analysis (Ref. 4). The accident analysis defines CEA misoperation as any event, with the exception of sequential group withdraws, which could result from a single malfunction in the reactivity control systems. For example, CEA misalignment may be caused by a malfunction of the CEDM, CEDM Control System, or by operator error. Therefore, the acceptance criteria for CEA position indication is that CEA positions must be known with sufficient accuracy in order to verify the core is operating within the limits of LCO 3.1.5, "Shutdown Control Element Assembly (CEA) Insertion Limits," and LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits". The CEA positions must also be known in order to verify the alignment limits are preserved (LCO 3.1.4, "Control Element Assembly (CEA) Alignment"). CEA positions are continuously monitored to provide operators with information that ensures the plant is operating within the bounds of the accident analysis assumptions.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The position of the CEAs satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii). The CEA position indication systems monitor CEA position, which is an initial condition of the accident.

LCO

OPERABILITY of the CEA reed switch and pulse counting position indicator channels ensure that the CEA alignment assumptions in the safety analysis will remain valid. The CEA alignment requirements specified in LCO 3.1.4 ensure that the CEA groups maintain the correct power distribution and CEA alignment.

OPERABILITY of the position indicator channels ensures that inoperable, misaligned, or mispositioned CEAs can be detected. Therefore, power peaking and SDM can be controlled within acceptable limits.

For a CEA position indicator channel to be considered OPERABLE, the position indicator must be capable of determining the absolute CEA position within $\pm$ 2.50 inches.

APPLICABILITY

The requirements on CEA position indicator channels are applicable in MODES 1 and 2 because these are the MODES power is generated, and the OPERABILITY and alignment of CEAs and CEA insertion limits have the potential to affect the safety of the plant. In the shutdown MODES, the OPERABILITY of the shutdown and regulating banks has the potential to affect the required SDM, but this effect can be compensated for by an increase in the boron concentration of the Reactor Coolant System.

ACTIONS

The ACTIONS Table is modified by a Note indicating that a separate Condition entry is allowed for each CEA group. This is acceptable because the Required Actions for each Condition provide appropriate compensatory actions for one or more inoperable position indicator channels in each CEA group.

Conditions A and B are modified by a Note. The Note to Condition A indicates that the Condition only applies when the inoperable position indicator channel is associated with a partially inserted CEA and the Note to Condition B indicates that the Condition only applies when the inoperable position indicator channel is associated with a fully withdrawn or fully inserted CEA. Because the actions are different for partially inserted CEAs and CEAs that are fully inserted or fully withdrawn, these

BASES

ACTIONS (continued

Notes identify the applicable Condition when a CEA reed switch or pulse counting position indicator channel in one or more CEA groups is inoperable.

A.1 and A.2

With one or more CEA groups with one reed switch or one pulse counting position indicator channel inoperable, Required Actions A.1 and A.2 require fully withdrawing or fully inserting the CEA with the inoperable position indicator. These actions place the CEA in a condition where the position can be verified using the CEA Limits Indication System. The associated CEA “full out” or “full in” limit position indicator actuation provides assurance the CEA is at a known position. Once the CEA is fully withdrawn or fully inserted, Condition A no longer applies and Condition B is entered. The Completion Time for Required Actions A 1 and A.2 is reasonable, based on operating experience, to fully withdraw or fully insert a CEA during power operation.

Required Actions A.1 and A.2 are modified by a Note to restrict these options to only be applicable if the CEA with the inoperable position indicator channel can be maintained within the group alignment limits required by LCO 3.1.4 when the CEA is fully withdrawn or fully inserted. Otherwise, the CEA group must be fully withdrawn or fully inserted in accordance with Required Actions A.3.1, A.3.2.1, and A.3.2.2.

A.3.1, A.3.2.1, and A.3.2.2

If the CEA with an inoperable position indicator channel cannot be maintained within the group alignment limits of LCO 3.1.4 when withdrawing or inserting the CEA, Required Actions A.3.1, A.3.2.1, and A.3.2.2 allow withdrawing or inserting the CEA group to the fully withdrawn or fully inserted position provided THERMAL POWER is reduced to ≤ 70% RTP.

Required Action A.3.1 requires the THERMAL POWER reduction to place the core in a condition where moving a controlling CEA group will not result in core peaking factors exceeding associated limits (Ref. 3).

Required Action A.3.2.1 and A.3.2.2 require either fully withdrawing or fully inserting the CEA group with the inoperable position indicator channel so the position of the affected CEA can be verified using the CEA Limits Indication System.

The Completion Time of Required Action A.3.1 is reasonable, based on operating experience, for reducing power to ≤ 70% RTP from full power conditions without challenging plant systems.

BASES

ACTIONS (continued

The Completion Time of Required Actions A.3.2.1 and A.3.2.2 takes into account the time to reduce THERMAL POWER and the additional time needed to fully withdraw or fully insert the associated CEA group.

Required Actions A.3.2.1 and A.3.2.2 are modified by a Note to only allow fully withdrawing or fully inserting a CEA group with the inoperable position indicator channel if the CEA group can be maintained within the CEA group withdrawal sequence and insertion limits specified in the COLR, as required by LCO 3.1.6.

B.1 and B2

With one or more CEA groups with one reed switch or one pulse counting position indicator channel inoperable and the associated CEA is fully withdrawn or fully inserted, a verification is required to ensure that either the CEA “full out” or “full in” limit indicator is actuated immediately and every 12 hours thereafter. The associated CEA “full out” or “full in” limit position indicator actuation provides assurance the CEA is at a known position. Use of the CEA limit indicator is an acceptable method to determine CEA position since the CEA Limits Indication System is separate and independent from the reed switch and the pulse counting position indication systems. Performing the verification immediately, and every 12 hours thereafter, is considered acceptable in view of other information available to the operator in the control room to determine CEA position and that the actual CEA position is not expected to change.

C.1 and C.2

With one or more CEA groups with two or more pulse counting position indicator channels inoperable, continued operation in MODES 1 and 2 may continue provided verification that no more than one reed switch position indicator channel per group is inoperable. Required Action C.1 ensures no more than one CEA per group has lost position indication. The Completion Time of immediately ensures that prompt action is taken to verify the status of the remaining CEA position indicator channels within the group.

Required Action C.2 requires the pulse counting position indicator channels be restored to OPERABLE status within 72 hours. The Completion Time of 72 hours is adequate time to restore the inoperable pulse counting position indicator channels to OPERABLE status, considering the reed switch position indicators will continue to provide indication of CEA position.

BASES

ACTIONS (continued)

D.1

If two or more reed switch position indicator channels are inoperable in one or more CEA groups, or the Required Actions cannot be completed within the associated Completion Times, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. The allowed Completion Time is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.1.7.1

This SR verifies that CEA pulse counting indicator position channels and reed switch position indicator channels for the CEAs in each group agree within 5.0 inches. This Surveillance is performed every 4 hours when the alignment deviation circuit is inoperable. Performing the verification every 4 hours when the alignment deviation circuit is inoperable, is considered acceptable in view of other information continuously available to the operator in the control room. The periodic Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

JUSTIFICATION FOR DEVIATIONS
ITS 3.1.7, BASES, CONTROL ELEMENT ASSEMBLY (CEA) POSITION INDICATION

1. NUREG 1432, “Standard Technical Specifications, Combustion Engineering Plants”, Revision 5.0, ISTS 3.1.4 includes one Surveillance Requirement (SR) related to CEA position indication, ISTS SR 3.1.4.5. However, the LCO statement of ISTS 3.1.4 does not specifically delineate position indication as being required for a CEA. It only requires OPERABILITY of CEAs to be within the alignment limits. Furthermore, the LCO Section of the ISTS 3.1.4 Bases does not describe indication as a necessary feature for the CEA to be OPERABLE. However, the ISTS Bases for SR 3.1.4.5 provides a requirement that each reed switch position indication channel ensures the channel is OPERABLE and capable of indicating CEA position over the entire length of the CEA's travel. In addition, ISTS 3.1.4 does not provide any specific actions to take if one or more of the required CEA position indicators is inoperable. Consistent with the approach taken in NUREG 1431, “Standard Technical Specifications, Westinghouse Plants”, Revision 5.0, a new LCO has been provided for the CEA Position Indicators.

   PSL Unit 1 CTS 3.1.3.3 and PSL Unit 2 CTS 3.1.3.2 are adapted using NUREG 1431, ISTS 3.1.7 and ISTS 3.1.7 Bases, to develop the new LCO 3.1.7. PSL LCO 3.1.7 maintains the current licensing basis while adapting the new LCO to NUREG 1431 requirements. Specifically, PSL requires two CEA position indicator channels for each CEA to be OPERABLE; the reed switch position indicator channels and the pulse counting indicator channel. The ACTIONS are adapted from the ACTIONS in NUREG-1431. The Surveillance Requirement ensures the reed switch position indicator channels and the pulse counting indicator channels for a group agree within an allowable tolerance.

   Refer to the PSL Unit 1 CTS 3.1.3.3 and PSL Unit 2 CTS 3.1.3.2 markups and discussion of changes for the details of changes from CTS to ITS 3.1.7.

A02

DISCUSSION OF CHANGES
ITS 3.1.8, SPECIAL TEST EXCEPTIONS (STE) – MODES 1 and 2

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.10.2 and Unit 2 CTS 3.10.5 require the linear heat rate (LHR) limits of Specification 3.2.1 to be maintained and determined in accordance with the applicable Surveillances (CTS 4.10.2.2 and 4.10.5.2, respectively). These Surveillances require verifying LHR is within limits by monitoring continuously with the Incore Detector Monitoring System during PHYSICS TESTS above 5% RTP when the applicable LCOs are suspended. Additionally, Action a of CTS 3.10.2 and Unit 2 CTS 3.10.5 require reducing THERMAL POWER sufficiently to satisfy the requirements of Specification 3.2.1. Neither CTS 3.10.2 nor Unit 2 CTS 3.10.5 allow suspension of CTS 3.2.1 requirements. Therefore, it is unnecessary to state that the LHR requirements of Specification 3.2.1 be maintained and determined to be within limits because CTS 3.2.1 (ITS 3.2.1) will continue to be required in MODE 1 (i.e., above 5% RTP) irrespective of whether PHYSICS TESTS are in progress.

In addition, testing maintains THERMAL POWER within the test power plateau and limits THERMAL POWER to < 85% RTP as specified in CTS 3.10.2.a. ITS LCO 3.1.8 retains this requirement. Limiting THERMAL POWER to < 85% RTP ensures that LHRs are maintained within acceptable limits. Therefore, the limits specified in CTS 3.2.1 (ITS 3.2.1) will be maintained in MODE 1 during PHYSICS TESTS.

This change is acceptable because the requirement to restrict THERMAL POWER to the test power plateau and not to exceed 85% RTP ensures the LHR requirement of Specification 3.2.1 is maintained within the limits specified in the COLR. Therefore, explicitly stating this as a requirement is unnecessary. Additionally, ITS 3.1.8 Required Action A.1, which requires reducing THERMAL POWER to less than or equal to the test power plateau within 15 minutes when the test power plateau is exceeded, ensures THERMAL power will be sufficiently reduced to satisfy the requirements of Specification 3.2.1.

This change is designated as administrative because the ITS requirements achieve the same result as the CTS requirements; maintain the LHR requirements of CTS 3.2.1 within the limits specified in the COLR.

A03 Combines Unit 2 CTS 3.10.2 and CTS 3.10.5 into one Specification, ITS 3.1.8. The requirements of CTS 3.10.5 are encompassed in ITS 3.1.8 by allowing the CEA alignment limits and regulating CEA insertion limits to be suspended to

perform PHYSICS TESTS. Changes related to Unit 2 CTS 3.10.2 are discussed in other Discussion of Changes (DOCs) provided herein.

MORE RESTRICTIVE CHANGES

M01 CTS 3.10.2 and Unit 2 CTS 3.10.5 actions require the unit to be placed in Hot Standby within 6 hours when the limits of Specification 3.2.1 are exceeded while requirements are suspended during PHYSICS TESTS in MODE 1. ITS 3.1.8 requires the PHYSICS TESTS to be suspended within 1 hour when the Required Actions and associated Completion Times are not met. This changes the CTS by requiring the PHYSICS TESTS to be suspended within 1 hour instead of placing the unit in MODE 3 (Hot Standby) within 6 hours. Suspension of the PHYSICS TEST results in canceling the STE and application of the normal Technical Specifications. This change is designated as more restrictive because it requires a more restrictive action within a shorter Completion Time than CTS.

M02 **Unit 2 only:** CTS 3.10.5 allows CTS 3.1.3.1 and 3.1.3.6 to be suspended during performance of PHYSICS TESTS provided the limits of Specification 3.2.1 are maintained and determined as specified in Specification 4.10.5.2 with no explicit restriction on THERMAL POWER. ITS 3.1.8 also allows suspension of LCO 3.1.4 (CTS 3.1.3.1) and LCO 3.1.6 (CTS 3.1.3.6) requirements provided THERMAL POWER is restricted to the test power plateau, which shall not exceed 85% RTP. This changes the CTS by restricting THERMAL POWER to the test power plateau not to exceed 85% RTP while performing these PHYSICS TESTS. Restricting THERMAL POWER to the test power plateau with a maximum restriction of 85% RTP ensures that adequate LHR and DNB parameter margins are maintained while the applicable LCOs are suspended. Therefore, as discussed in DOC A02 herein, the limits specified in CTS 3.2.1 (ITS 3.2.1) will be maintained in MODE 1 during PHYSICS TESTS.

This change is designated as more restrictive because THERMAL POWER is restricted to the test power plateau with a maximum restriction of 85% RTP.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 **Unit 2 only** (*Type 1 – Removing Details of System Design and System Description, Including Design Limits*) Unit 2 CTS 3.10.5 states, in part, that the purpose of the STE is to "…determine the isothermal temperature coefficient, moderator temperature coefficient, and power coefficient..." ITS does not include the details of why the STE is used. This changes the CTS by eliminating the specific reason the STE is used. R1

The removal of these details, which are related to description of the STE, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate

protection of public health and safety. The ITS explicitly requires THERMAL POWER to be restricted to the test power plateau and not to exceed 85% RTP while performing PHYSICS TEST with the specified LCOs not met. Also, this change is acceptable because the removed information will be adequately controlled in the Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design (i.e., description of the purpose of the STE) is being removed from the Technical Specifications.

LA02 (*Type 5 – Removal of SR Frequency to the Surveillance Frequency Control Program*) CTS 4.10.5.1 requires verification that THERMAL POWER be determined at least once per hour during PHYSICS TESTS in which the requirements of Specifications 3.1.3.1 and 3.1.3.6 are suspended and shall be verified to be within the test power plateaus. ITS SR 3.1.8.1 requires a similar Surveillance and specifies a periodic Frequency of, "In accordance with the Surveillance Frequency Control Program." This changes the CTS by moving the specified periodic Frequency to the Surveillance Frequency Control Program. |R1

The removal of periodic Surveillance Requirement Frequencies is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement to periodically verify THERMAL POWER is within the test power plateau. The existing Surveillance Frequency is removed from Technical Specifications and placed under licensee control pursuant to the methodology described in NEI 04-10. The control of changes to Surveillance Frequencies is in accordance with the Surveillance Frequency Control Program requirements specified in ITS Chapter 5.0. This program ensures that Surveillance Requirements specified in the Technical Specifications are performed at intervals sufficient to assure the associated Limiting Conditions for Operation are met. This change is designated as a less restrictive removal of detail change because Surveillance Frequencies are being removed from the Technical Specifications.

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~

B 3.1.8 Special Test Exceptions (STE) - MODES 1 and 2 ~~(Analog)~~ 1

BASES

BACKGROUND

The primary purpose of these MODES 1 and 2 Special Test Exceptions (STE) is to permit relaxation of existing LCOs to allow the performance of certain PHYSICS TESTS. These tests are conducted to determine specific reactor core characteristics.

Section XI of 10 CFR 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Processing Plants" (Ref. 1), requires that a test program be established to ensure that structures, systems, and components will perform satisfactorily in service. All functions necessary to ensure that specified design conditions are not exceeded during normal operation and anticipated operational occurrences must be tested. Testing is required as an integral part of the design, fabrication, construction, and operation of the power plant. Requirements for notification of the NRC, for the purpose of conducting tests and experiments, are specified in 10 CFR 50.59, "Changes, Tests, and Experiments" (Ref. 2).

The key objectives of a test program are to (Ref. 3):

a. Ensure that the facility has been adequately designed,

b. Validate the analytical models used in design and analysis,

c. Verify assumptions used for predicting plant response,

d. Ensure that installation of equipment in the facility has been accomplished in accordance with design, and

e. Verify that operating and emergency procedures are adequate.

To accomplish these objectives, testing is required prior to initial criticality, after each refueling shutdown, and during startup, low power operation, power ascension, and at power operation. The PHYSICS TESTS requirements for reload fuel cycles ensure that the operating characteristics of the core are consistent with the design predictions, and that the core can be operated as designed (Ref. 4).

BASES

BACKGROUND (continued)

PHYSICS TESTS procedures are written and approved in accordance with established formats. The procedures include all information necessary to permit a detailed execution of testing required to ensure that design intent is met. PHYSICS TESTS are performed in accordance with these procedures and test results are approved prior to continued power escalation and long term power operation.

Examples of PHYSICS TESTS include determination of critical boron concentration, control element assembly (CEA) group worths, reactivity coefficients, flux symmetry, and core power distribution.

APPLICABLE SAFETY ANALYSES

It is acceptable to suspend certain LCOs for PHYSICS TESTS because fuel damage criteria are not exceeded. Even if an accident occurs during a PHYSICS TEST with one or more LCOs suspended, fuel damage criteria are preserved because the limits on power distribution and shutdown capability are maintained during PHYSICS TESTS.

Reference 5 define~~s~~d the requirements for initial testing of the facility, including PHYSICS TESTS. Requirements for reload fuel cycle PHYSICS TESTS are defined in ANSI/ANS-19.6.1-1985 (Ref. 4). Although these PHYSICS TESTS are generally accomplished within the limits of all LCOs, conditions may occur when one or more LCOs must be suspended to make completion of PHYSICS TESTS possible or practical. This is acceptable as long as the fuel design criteria are not violated. As long as the linear heat rate (LHR) remains within its limit, fuel design criteria are preserved. 2

In this test, the following LCOs are suspended:

LCO 3.1.3, "Moderator Temperature Coefficient (MTC),"
LCO 3.1.4, "Control Element Assembly (CEA) Alignment,"
LCO 3.1.5, "Shutdown Control Element Assembly (CEA) Insertion Limits,"
LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits,"
~~LCO 3.2.2, "Total Planar Radial Peaking Factor (F^T_{xy}),"~~ 3
LCO 3.2.~~3~~2, "Total Integrated Radial Peaking Factor (F^T_r)" and
LCO 3.2.~~4~~3, "AZIMUTHAL POWER TILT (T_q)."

The ~~safety analysis (Ref. 6) places~~ limits on allowable THERMAL POWER during PHYSICS TESTS ~~and requires~~ the LHR and the departure from nucleate boiling (DNB) parameter ~~to be~~ maintained within limits. The power plateau of < 85% RTP and the associated trip setpoints are required to ensure ~~[explain]~~. 2

ensure
are
adequate margin is provided to the LHR and DNB parameter limits so that fuel design limits are not violated during PHYSICS TESTS 4

BASES

APPLICABLE SAFETY ANALYSES (continued)

The individual LCOs governing CEA group height, insertion and alignment, ASI, ~~F^T_{XY}~~, F^T_r, and T_q preserve the LHR limits. Additionally, the LCOs governing Reactor Coolant System (RCS) flow, reactor inlet temperature (T_c), and pressurizer pressure contribute to maintaining DNB parameter limits. The initial condition criteria for accidents sensitive to core power distribution are preserved by the LHR and DNB parameter limits. The criteria for the loss of coolant accident (LOCA) are specified in 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors" (Ref. ~~7~~6). The criteria for the loss of forced reactor coolant flow accident are specified in Reference 7. Operation within the LHR limit preserves the LOCA criteria; operation within the DNB parameter limits preserves the loss of flow criteria. 3 2

During PHYSICS TESTS, one or more of the LCOs that normally preserve the LHR and DNB parameter limits may be suspended. The results of the accident analysis are not adversely impacted, however, if LHR and DNB parameters are verified to be within their limits while the LCOs are suspended. Therefore, SRs are placed as necessary to ensure that LHR and DNB parameters remain within limits during PHYSICS TESTS. Performance of these Surveillances allows PHYSICS TESTS to be conducted without decreasing the margin of safety.

PHYSICS TESTS include measurement of core parameters or exercise of control components that affect process variables. Among the process variables involved are ~~F^T_{XY}~~, F^T_r, T_q, and ASI, which represent initial condition input (power peaking) to the accident analysis. Also involved are the shutdown and regulating CEAs, which affect power peaking and are required for shutdown of the reactor. The limits for these variables are specified for each fuel cycle in the COLR. 3

As described in LCO 3.0.7, compliance with Special Test Exceptions LCOs is optional, and therefore no criteria of 10 CFR 50.36(c)(2)(ii) apply. Special Test Exception LCOs provide flexibility to perform certain operations by appropriately modifying requirements of other LCOs. A discussion of the criteria satisfied for the other LCOs is provided in their respective Bases.

BASES

LCO

This LCO permits individual CEAs to be positioned outside of their normal group heights and insertion limits during the performance of PHYSICS TESTS such as those required to:

a. Measure CEA worth,

b. Determine the reactor stability index and damping factor under xenon oscillation conditions,

c. Determine power distributions for nonnormal CEA configurations,

d. Measure rod shadowing factors, and

e. Measure temperature and power coefficients.

Additionally, it permits the center CEA to be misaligned during PHYSICS TESTS required to determine the isothermal temperature coefficient (ITC), MTC, and power coefficient.

The requirements of LCO 3.1.3, LCO 3.1.4, LCO 3.1.5, LCO 3.1.6, LCO 3.2.2, LCO 3.2.3 and ~~, and LCO 3.2.4~~ may be suspended during the performance of PHYSICS TESTS, provided THERMAL POWER is restricted to test power plateau, which shall not exceed 85% RTP. 3

APPLICABILITY

This LCO is applicable in MODES 1 and 2 because the reactor must be critical at various THERMAL POWER levels to perform the PHYSICS TESTS described in the LCO section. Limiting the test power plateau to < 85% RTP ensures that LHRs are maintained within acceptable limits.

ACTIONS

A.1

If THERMAL POWER exceeds the test power plateau, THERMAL POWER must be reduced to restore the additional thermal margin provided by the reduction. The 15 minute Completion Time ensures that prompt action shall be taken to reduce THERMAL POWER to within acceptable limits.

B.1 ~~and B.2~~ 3

If Required Action A.1 cannot be completed within the required Completion Time, PHYSICS TESTS must be suspended within 1 hour. Allowing 1 hour for suspending PHYSICS TESTS allows the operator sufficient time to change any abnormal CEA configuration back to within the limits of LCO 3.1.4, LCO 3.1.5, and LCO 3.1.6.

BASES

ACTIONS (continued)

Suspension of PHYSICS TESTS exceptions requires restoration of each of the applicable LCOs to within specification.

SURVEILLANCE REQUIREMENTS

SR 3.1.8.1

Verifying that THERMAL POWER is equal to or less than that allowed by the test power plateau, as specified in the PHYSICS TEST procedure and required by the safety analysis, ensures that adequate LHR and DNB parameter margins are maintained while LCOs are suspended. ~~[The 1 hour Frequency is sufficient, based on the slow rate of power change and increased operational controls in place during PHYSICS TESTS.~~ 4

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 5

B 3.1 REACTIVITY CONTROL SYSTEMS ~~(Analog)~~

B 3.1.8 Special Test Exceptions (STE) - MODES 1 and 2 ~~(Analog)~~ 1

BASES

BACKGROUND

The primary purpose of these MODES 1 and 2 Special Test Exceptions (STE) is to permit relaxation of existing LCOs to allow the performance of certain PHYSICS TESTS. These tests are conducted to determine specific reactor core characteristics.

Section XI of 10 CFR 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Processing Plants" (Ref. 1), requires that a test program be established to ensure that structures, systems, and components will perform satisfactorily in service. All functions necessary to ensure that specified design conditions are not exceeded during normal operation and anticipated operational occurrences must be tested. Testing is required as an integral part of the design, fabrication, construction, and operation of the power plant. Requirements for notification of the NRC, for the purpose of conducting tests and experiments, are specified in 10 CFR 50.59, "Changes, Tests, and Experiments" (Ref. 2).

The key objectives of a test program are to (Ref. 3):

a. Ensure that the facility has been adequately designed,

b. Validate the analytical models used in design and analysis,

c. Verify assumptions used for predicting plant response,

d. Ensure that installation of equipment in the facility has been accomplished in accordance with design, and

e. Verify that operating and emergency procedures are adequate.

To accomplish these objectives, testing is required prior to initial criticality, after each refueling shutdown, and during startup, low power operation, power ascension, and at power operation. The PHYSICS TESTS requirements for reload fuel cycles ensure that the operating characteristics of the core are consistent with the design predictions, and that the core can be operated as designed (Ref. 4).

BASES

BACKGROUND (continued)

PHYSICS TESTS procedures are written and approved in accordance with established formats. The procedures include all information necessary to permit a detailed execution of testing required to ensure that design intent is met. PHYSICS TESTS are performed in accordance with these procedures and test results are approved prior to continued power escalation and long term power operation.

Examples of PHYSICS TESTS include determination of critical boron concentration, control element assembly (CEA) group worths, reactivity coefficients, flux symmetry, and core power distribution.

APPLICABLE SAFETY ANALYSES

It is acceptable to suspend certain LCOs for PHYSICS TESTS because fuel damage criteria are not exceeded. Even if an accident occurs during a PHYSICS TEST with one or more LCOs suspended, fuel damage criteria are preserved because the limits on power distribution and shutdown capability are maintained during PHYSICS TESTS.

Reference 5 define~~s~~d the requirements for initial testing of the facility, including PHYSICS TESTS. Requirements for reload fuel cycle PHYSICS TESTS are defined in ANSI/ANS-19.6.1-1985 (Ref. 4). Although these PHYSICS TESTS are generally accomplished within the limits of all LCOs, conditions may occur when one or more LCOs must be suspended to make completion of PHYSICS TESTS possible or practical. This is acceptable as long as the fuel design criteria are not violated. As long as the linear heat rate (LHR) remains within its limit, fuel design criteria are preserved. 2

In this test, the following LCOs are suspended:

LCO 3.1.3, "Moderator Temperature Coefficient (MTC),"
LCO 3.1.4, "Control Element Assembly (CEA) Alignment,"
LCO 3.1.5, "Shutdown Control Element Assembly (CEA) Insertion Limits,"
LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits,"
~~LCO 3.2.2, "Total Planar Radial Peaking Factor (F^T_{xy}),"~~ 3
LCO 3.2.~~3~~2, "Total Integrated Radial Peaking Factor (F^T_r)" and
LCO 3.2.~~4~~3, "AZIMUTHAL POWER TILT (T_q)."

The ~~safety analysis (Ref. 6) places~~ limits on allowable THERMAL POWER during PHYSICS TESTS ~~and requires~~ the LHR and the departure from nucleate boiling (DNB) parameter ~~to be~~ maintained within limits. The power plateau of < 85% RTP and the associated trip setpoints are required to ensure ~~[explain]~~. 2

ensure
are
adequate margin is provided to the LHR and DNB parameter limits so that fuel design limits are not violated during PHYSICS TESTS 4

BASES

APPLICABLE SAFETY ANALYSES (continued)

The individual LCOs governing CEA group height, insertion and alignment, ASI, ~~F^T_{XY}~~, F^T_r, and T_q preserve the LHR limits. Additionally, the LCOs governing Reactor Coolant System (RCS) flow, reactor inlet temperature (T_c), and pressurizer pressure contribute to maintaining DNB parameter limits. The initial condition criteria for accidents sensitive to core power distribution are preserved by the LHR and DNB parameter limits. The criteria for the loss of coolant accident (LOCA) are specified in 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors" (Ref. ~~7~~6). The criteria for the loss of forced reactor coolant flow accident are specified in Reference 7. Operation within the LHR limit preserves the LOCA criteria; operation within the DNB parameter limits preserves the loss of flow criteria. 3 2

During PHYSICS TESTS, one or more of the LCOs that normally preserve the LHR and DNB parameter limits may be suspended. The results of the accident analysis are not adversely impacted, however, if LHR and DNB parameters are verified to be within their limits while the LCOs are suspended. Therefore, SRs are placed as necessary to ensure that LHR and DNB parameters remain within limits during PHYSICS TESTS. Performance of these Surveillances allows PHYSICS TESTS to be conducted without decreasing the margin of safety.

PHYSICS TESTS include measurement of core parameters or exercise of control components that affect process variables. Among the process variables involved are ~~F^T_{XY}~~, F^T_r, T_q, and ASI, which represent initial condition input (power peaking) to the accident analysis. Also involved are the shutdown and regulating CEAs, which affect power peaking and are required for shutdown of the reactor. The limits for these variables are specified for each fuel cycle in the COLR. 3

As described in LCO 3.0.7, compliance with Special Test Exceptions LCOs is optional, and therefore no criteria of 10 CFR 50.36(c)(2)(ii) apply. Special Test Exception LCOs provide flexibility to perform certain operations by appropriately modifying requirements of other LCOs. A discussion of the criteria satisfied for the other LCOs is provided in their respective Bases.

BASES

LCO

This LCO permits individual CEAs to be positioned outside of their normal group heights and insertion limits during the performance of PHYSICS TESTS such as those required to:

a. Measure CEA worth,

b. Determine the reactor stability index and damping factor under xenon oscillation conditions,

c. Determine power distributions for nonnormal CEA configurations,

d. Measure rod shadowing factors, and

e. Measure temperature and power coefficients.

Additionally, it permits the center CEA to be misaligned during PHYSICS TESTS required to determine the isothermal temperature coefficient (ITC), MTC, and power coefficient.

The requirements of LCO 3.1.3, LCO 3.1.4, LCO 3.1.5, LCO 3.1.6, LCO 3.2.2, LCO 3.2.3 and ~~, and LCO 3.2.4~~ may be suspended during the performance of PHYSICS TESTS, provided THERMAL POWER is restricted to test power plateau, which shall not exceed 85% RTP. 3

APPLICABILITY

This LCO is applicable in MODES 1 and 2 because the reactor must be critical at various THERMAL POWER levels to perform the PHYSICS TESTS described in the LCO section. Limiting the test power plateau to < 85% RTP ensures that LHRs are maintained within acceptable limits.

ACTIONS

A.1

If THERMAL POWER exceeds the test power plateau, THERMAL POWER must be reduced to restore the additional thermal margin provided by the reduction. The 15 minute Completion Time ensures that prompt action shall be taken to reduce THERMAL POWER to within acceptable limits.

B.1 ~~and B.2~~ 3

If Required Action A.1 cannot be completed within the required Completion Time, PHYSICS TESTS must be suspended within 1 hour. Allowing 1 hour for suspending PHYSICS TESTS allows the operator sufficient time to change any abnormal CEA configuration back to within the limits of LCO 3.1.4, LCO 3.1.5, and LCO 3.1.6.

BASES

ACTIONS (continued)

Suspension of PHYSICS TESTS exceptions requires restoration of each of the applicable LCOs to within specification.

SURVEILLANCE REQUIREMENTS

SR 3.1.8.1

Verifying that THERMAL POWER is equal to or less than that allowed by the test power plateau, as specified in the PHYSICS TEST procedure and required by the safety analysis, ensures that adequate LHR and DNB parameter margins are maintained while LCOs are suspended. ~~[The 1 hour Frequency is sufficient, based on the slow rate of power change and increased operational controls in place during PHYSICS TESTS.~~ 4

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

APPLICABILITY: ALL MODES.

ACTION:

With the flow rate of reactor coolant to the reactor pressure vessel < 3000 gpm, immediately suspend all operations involving a reduction in boron concentration of the Reactor Coolant System.

R01

SURVEILLANCE REQUIREMENTS

4.1.1.3 The flow rate of reactor coolant to the reactor pressure vessel shall be determined to be ≥ 3000 gpm within 1 hour prior to the start of and in accordance with the Surveillance Frequency Control Program during a reduction in the Reactor Coolant System boron concentration by either:

a. Verifying at least one reactor coolant pump is in operation, or

b. Verifying that at least one low pressure safety injection pump is in operation and supplying ≥ 3000 gpm to the reactor pressure vessel.

DISCUSSION OF CHANGES
CTS 3/4.1.1.3, BORON DILUTION

ADMINISTRATIVE CHANGES

None

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

R01 CTS 3/4.1.1.3 establishes a minimum flow rate to the reactor pressure vessel (RPV) of at least 3000 gpm whenever a reduction in Reactor Coolant System (RCS) boron concentration is being made. This minimum flowrate provides adequate mixing, prevents stratification, and ensures that reactivity changes will be gradual during boron concentration changes in the RCS.

A minimum boron dilution flow rate to the RPV is not assumed as an initial condition of a design basis accident (DBA) or transient analysis nor is it an assumed value to mitigate a DBA or transient (e.g., a boron dilution event). The ITS does not include this Specification. This changes the CTS by relocating this Specification to the Technical Requirements Manual (TRM).

This change is acceptable because the CTS 3/4.1.1.3.Specification does not meet the 10 CFR 50.36(c)(2)(ii) criteria for inclusion into the ITS.

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. The minimum boron dilution flow rate to the RPV is not an instrumentation system. Therefore, this Specification does not constitute an instrumentation system that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary.

2. The minimum boron dilution flow rate to the RPV is not a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier. This Specification specifies a minimum flowrate value that provides adequate mixing, prevents stratification, and ensures that reactivity changes in the core are gradual during boron concentration changes in the RCS. These limits, however, do not reflect initial condition assumptions in a DBA or transient.

3. The minimum boron dilution flow rate to the RPV is a parameter and not a structure, system, or component that is part of the primary success path and which functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The minimum boron dilution flow rate to the RPV is a parameter requirement and is not a structure, system, or component which operating experience or

probabilistic risk assessment has shown to be significant to public health and safety.

Since 10 CFR 50.36(c)(2)(ii) criteria have not been satisfied, the Boron Dilution Specification may be relocated to a licensee controlled document outside the Technical Specifications. Control element assembly insertion limits during power operation, shutdown margin requirements during shutdown, and boration concentration requirements during refueling are retained in separate Technical Specifications and ensure adequate excess negative core reactivity is available in the event of an inadvertent boron dilution event. Additionally, RCS circulation requirements to provide mixing and prevent stratification are retained in separate Technical Specifications (i.e., shutdown cooling specifications).

Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as relocation because the Specifications did not meet the criteria in 10 CFR 50.36(c)(2)(ii) and have been relocated to the TRM.

REACTIVITY CONTROL SYSTEMS

3/4.1.2 BORATION SYSTEMS

FLOW PATHS – SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.1.2.1 As a minimum, one of the following boron injection flow paths shall be OPERABLE and capable of being powered from an OPERABLE emergency power source.

a. A flow path from the boric acid makeup tank via either a boric acid pump or a gravity feed connection and any charging pump to the Reactor Coolant System if only the boric acid makeup tank in Specification 3.1.2.7a is OPERABLE, or

b. The flow path from the refueling water tank via either a charging pump or a high pressure safety injection pump* to the Reactor Coolant System if only the refueling water tank in Specification 3.1.2.7b is OPERABLE.

APPLICABILITY: MODES 5 and 6.

ACTION:

R01

With none of the above flow paths OPERABLE, suspend all operations involving CORE ALTERATIONS or positive reactivity changes** until at least one injection path is restored to OPERABLE status.

SURVEILLANCE REQUIREMENTS

4.1.2.1 At least one of the above required flow paths shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by verifying that each valve (manual, power operated or automatic) in the flow path that is not locked, sealed, or otherwise secured in position, is in its correct position.

---

* The flow path from the RWT to the RCS via a single HPSI pump shall only be established if: (a) the RCS pressure boundary does not exist, or (b) RCS pressure boundary integrity exists and no charging pumps are operable. In the latter case, all charging pumps shall be disabled.

** Plant temperature changes are allowed provided the temperature change is accounted for in the calculated SHUTDOWN MARGIN.

REACTIVITY CONTROL SYSTEMS

SURVEILLANCE REQUIREMENTS

R01

b. At least once per 24 hours, when the Reactor Auxiliary Building air temperature is less than 55°F, by verifying that the Boric Acid Makeup Tank solution temperature is greater than 55°F, when the flow path from the Boric Acid Makeup Tank is required to be OPERABLE.

REACTIVITY CONTROL SYSTEMS

FLOW PATHS – OPERATING

LIMITING CONDITION FOR OPERATION

3.1.2.2 At least two of the following three boron injection flow paths shall be OPERABLE:

a. One flow path from the boric acid makeup tank(s) with the tank meeting Specification 3.1.2.8 part a) or b), via a boric acid makeup pump through a charging pump to the Reactor Coolant System.

b. One flow path from the boric acid makeup tank(s) with the tank meeting Specification 3.1.2.8 part a) or b), via a gravity feed valve through a charging pump to the Reactor Coolant System.

c. The flow path from the refueling water storage tank via a charging pump to the Reactor Coolant System.

OR

R01

At least two of the following three boron injection flow paths shall be OPERABLE:

d. One flow path from each boric acid makeup tank with the combined tank contents meeting Specification 3.1.2.8 c), via both boric acid makeup pumps through a charging pump to the Reactor Coolant System.

e. One flow path from each boric acid makeup tank with the combined tank contents meeting Specification 3.1.2.8 c), via both gravity feed valves through a charging pump to the Reactor Coolant System.

f. The flow path from the refueling water storage tank, via a charging pump to the Reactor Coolant System.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

With only one of the above required boron injection flow paths to the Reactor Coolant System OPERABLE, restore at least two boron injection flow paths to the Reactor Coolant System to OPERABLE status within 72 hours or make the reactor subcritical within the next 2 hours and borate to a SHUTDOWN MARGIN equivalent to the requirements of Specification 3.1.1.2 at 200°F; restore at least two flow paths to OPERABLE status within the next 7 days or be in COLD SHUTDOWN within the next 30 hours.

REACTIVITY CONTROL SYSTEMS

SURVEILLANCE REQUIREMENTS

R01

4.1.2.2 At least two of the above required flow paths shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by verifying that each valve (manual, power operated or automatic) in the flow path that is not locked, sealed, or otherwise secured in position, is in its correct position.

b. In accordance with the Surveillance Frequency Control Program during shutdown by verifying that each automatic valve in the flow path actuates to its correct position on a Safety Injection Actuation Signal.

c. At least once per 24 hours when the Reactor Auxiliary Building air temperature is below 55°F by verifying that the solution temperature of the Boric Acid Makeup Tank(s) is above 55°F.

REACTIVITY CONTROL SYSTEMS

CHARGING PUMPS – SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.1.2.3 At least one charging pump or high pressure safety injection pump* in the boron injection flow path required OPERABLE pursuant to Specification 3.1.2.1 shall be OPERABLE and capable of being powered from an OPERABLE emergency bus.

APPLICABILITY: MODES 5 and 6.

ACTION:

With no charging pump or high pressure safety injection pump* OPERABLE, suspend all operations involving CORE ALTERATIONS or positive reactivity changes** until at least one of the required pumps is restored to OPERABLE status.

R01

SURVEILLANCE REQUIREMENTS

4.1.2.3 At least one of the above required pumps shall be demonstrated OPERABLE by verifying the charging pump develops a flow rate of greater than or equal to 40 gpm or the high pressure safety injection pump develops a total head of greater than or equal to 2571 ft. when tested pursuant to the INSERVICE TESTING PROGRAM.

---

* The flow path from the RWT to the RCS via a single HPSI pump shall be established only if: (a) the RCS pressure boundary does not exist, or (b) RCS pressure boundary integrity exists and no charging pumps are operable. In the latter case, all charging pumps shall be disabled.

** Plant temperature changes are allowed provided the temperature change is accounted for in the calculated SHUTDOWN MARGIN.

REACTIVITY CONTROL SYSTEMS

CHARGING PUMPS – OPERATING

LIMITING CONDITION FOR OPERATION

3.1.2.4 At least two charging pumps shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

With only one charging pump OPERABLE, restore at least two charging pumps to OPERABLE status within 72 hours or be in HOT STANDBY within the next 6 hours; restore at least two charging pumps to OPERABLE status within the next 48 hours or be in COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.1.2.4 At least two charging pumps shall be demonstrated OPERABLE by verifying that each pump develops a flow rate or greater than or equal to 40 gpm when tested pursuant to the INSERVICE TESTING PROGRAM.

R1

REACTIVITY CONTROL SYSTEMS

BORIC ACID PUMPS – SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.1.2.5 At least one boric acid pump shall be OPERABLE if only the flow path through the boric acid pump in Specification 3.1.2.1a above, is OPERABLE.

APPLICABILITY: MODES 5 and 6.

R01

ACTION:

With no boric acid pump OPERABLE as required to complete the flow path of Specification 3.1.2.1a, suspend all operations involving CORE ALTERATIONS or positive reactivity changes* until at least one boric acid pump is restored to OPERABLE status.

SURVEILLANCE REQUIREMENTS

4.1.2.5 The above required boric acid pump shall be demonstrated OPERABLE by verifying that the pump develops the specified discharge pressure when tested pursuant to the INSERVICE TESTING PROGRAM.

* Plant temperature changes are allowed provided the temperature change is accounted for in the calculated SHUTDOWN MARGIN.

REACTIVITY CONTROL SYSTEMS

BORIC ACID PUMPS – OPERATING

LIMITING CONDITION FOR OPERATION

3.1.2.6 At least the boric acid pump(s) in the boron injection flow path(s) required OPERABLE pursuant to Specification 3.1.2.2a shall be OPERABLE if the flow path through the boric acid pump in Specification 3.1.2.2a is OPERABLE.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

R01

With one boric acid pump required for boron injection flow path(s) pursuant to Specification 3.1.2.2a inoperable, restore the boric acid pump to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.1.2.6 The above required boric acid pump(s) shall be demonstrated OPERABLE by verifying that the pump(s) develop the specified discharge pressure when tested pursuant to the INSERVICE TESTING PROGRAM.

REACTIVITY CONTROL SYSTEMS

BORATED WATER SOURCES – SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.1.2.7 As a minimum, one of the following borated water sources shall be OPERABLE:

a. One boric acid makeup tank with a minimum borated water volume of 3650 gallons of 3.0 to 3.5 weight percent boric acid (5245 to 6119 ppm boron).

b. The refueling water tank with:

1. A minimum contained volume of 125,000 gallons,

2. A minimum boron concentration of 1900 ppm, and

3. A minimum solution temperature of 40°F.

APPLICABILITY: MODES 5 and 6.

ACTION:

With no borated water sources OPERABLE, suspend all operations involving positive reactivity changes* until at least one borated water source is restored to OPERABLE status.

R01

SURVEILLANCE REQUIREMENTS

4.1.2.7 The above required borated water source shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by:

1. Verifying the boron concentration of the water,

2. Verifying the water level of the tank, and.

b. At least once per 24 hours by verifying the RWT temperature when it is the source of borated water and the site ambient air temperature is < 40°F.

c. At least once per 24 hours when the Reactor Auxiliary Building air temperature is less than 55°F by verifying that the Boric Acid Makeup Tank solution temperature is greater than 55°F when that Boric Acid Makeup Tank is required to be OPERABLE.

* Plant temperature changes are allowed provided the temperature change is accounted for in the calculated SHUTDOWN MARGIN.

REACTIVITY CONTROL SYSTEMS

BORATED WATER SOURCES – OPERATING

LIMITING CONDITION FOR OPERATION

3.1.2.8 At least two of the following four borated water sources shall be OPERABLE:

a. Boric Acid Makeup Tank 1A in accordance with Figure 3.1-1.

b. Boric Acid Makeup Tank 1B in accordance with Figure 3.1-1.

c. Boric Acid Makeup Tanks 1A and 1B with a minimum combined contained borated water volume in accordance with Figure 3.1-1.

d. The refueling water tank with:

1. A minimum contained volume of 477,360 gallons of water,

2. A minimum boron concentration of 1900 ppm,

3. A maximum solution temperature of 100°F,

4. A minimum solution temperature of 55°F when in MODES 1 and 2, and

5. A minimum solution temperature of 40°F when in MODES 3 and 4.

R01

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

With only one borated water source OPERABLE, restore at least two borated water sources to OPERABLE status within 72 hours or make the reactor subcritical within the next 2 hours and borate to a SHUTDOWN MARGIN equivalent to the requirements of Specification 3.1.1.2 at 200°F; restore at least two borated water sources to OPERABLE status within the next 7 days or be in COLD SHUTDOWN within the next 30 hours.

SURVEILLANCE REQUIREMENTS

4.1.2.8 At least two borated water sources shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by:

1. Verifying the boron concentration of the water source,

REACTIVITY CONTROL SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

R01

2. Verifying the water level in each water source.

b. In accordance with the Surveillance Frequency Control Program by verifying the RWT temperature.

c. At least once per 24 hours by verifying that the Boric Acid Makeup Tank solution temperature is greater than 55°F when the Reactor Auxiliary Building air temperature is below 55°F.

REACTIVITY CONTROL SYSTEMS

3/4.1.2 BORATION SYSTEMS

FLOW PATHS – SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.1.2.1 As a minimum, one of the following boron injection flow paths shall be OPERABLE and capable of being powered from an OPERABLE emergency power source:

a. A flow path from the boric acid makeup tank via either a boric acid makeup pump or a gravity feed connection and any charging pump to the Reactor Coolant System if only the boric acid makeup tank in Specification 3.1.2.7a. is OPERABLE, or

b. The flow path from the refueling water tank via either a charging pump or a high pressure safety injection pump to the Reactor Coolant System if only the refueling water tank in Specification 3.1.2.7b. is OPERABLE.

APPLICABILITY: MODES 5 and 6.

ACTION:

R01

With none of the above flow paths OPERABLE or capable of being powered from an OPERABLE emergency power source, suspend all operations involving CORE ALTERATIONS or positive reactivity changes*.

SURVEILLANCE REQUIREMENTS

4.1.2.1 At least one of the above required flow paths shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by verifying that each valve (manual, power-operated, or automatic) in the flow path that is not locked, sealed, or otherwise secured in position, is in its correct position.

b. At least once per 24 hours when the Reactor Auxiliary Building air temperature is less than 55°F by verifying that the Boric Acid Makeup Tank solution temperature is greater than 55°F (when the flow path from the Boric Acid Makeup Tank is used).

* Plant temperature changes are allowed provided the temperature change is accounted for in the calculated SHUTDOWN MARGIN.

REACTIVITY CONTROL SYSTEMS

FLOW PATHS – OPERATING

LIMITING CONDITION FOR OPERATION

3.1.2.2 At least two of the following three boron injection flow paths shall be OPERABLE:

a. One flow path from the boric acid makeup tank(s) with the tank meeting Specification 3.1.2.8 part a) or b), via a boric acid makeup pump through a charging pump to the Reactor Coolant System.

b. One flow path from the boric acid makeup tank(s) with the tank meeting Specification 3.1.2.8 part a) or b), via a gravity feed valve through a charging pump to the Reactor Coolant System.

c. The flow path from the refueling water tank via a charging pump to the Reactor Coolant System.

OR

At least two of the following three boron injection flow paths shall be OPERABLE: R01

d. One flow path from each boric acid makeup tank with the combined tank contents meeting Specification 3.1.2.8 c), via both boric acid makeup pumps through a charging pump to the Reactor Coolant System.

e. One flow path from each boric acid makeup tank with the combined tank contents meeting Specification 3.1.2.8 c), via both gravity feed valves through a charging pump to the Reactor Coolant System.

f. The flow path from the refueling water tank, via a charging pump to the Reactor Coolant System.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

With only one of the above required boron injection flow paths to the Reactor Coolant System OPERABLE, restore at least two boron injection flow paths to the Reactor Coolant System to OPERABLE status within 72 hours or be in at least HOT STANDBY and borated to a SHUTDOWN MARGIN equivalent to its COLR limit at 200 °F within the next 6 hours; restore at least two flow paths to OPERABLE status within the next 7 days or be in COLD SHUTDOWN within the next 30 hours.

REACTIVITY CONTROL SYSTEMS

FLOW PATHS - OPERATING

SURVEILLANCE REQUIREMENTS

4.1.2.2 At least two of the above required flow paths shall be demonstrated OPERABLE:

R01

a. At least once per 24 hours, when the Reactor Auxiliary Building air temperature is below 55°F, by verifying that the solution temperature of the Boric Acid Makeup Tanks is above 55°F.

b. In accordance with the Surveillance Frequency Control Program by verifying that each valve (manual, power-operated or automatic) in the flow path that is not locked, sealed, or otherwise secured in position, is in its correct position.

c. In accordance with the Surveillance Frequency Control Program during shutdown by verifying that each automatic valve in the flow path actuates to its correct position on an SIAS test signal.

d. In accordance with the Surveillance Frequency Control Program by verifying that the flow path required by Specification 3.1.2.2a and 3.1.2.2b delivers at least ~~40~~ gpm to the Reactor Coolant System.

REACTIVITY CONTROL SYSTEMS

CHARGING PUMPS – SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.1.2.3 At least one charging pump or high pressure safety injection pump in the boron injection flow path required OPERABLE pursuant to Specification 3.1.2.1 shall be OPERABLE and capable of being powered from an OPERABLE emergency power source.

APPLICABILITY: MODES 5 and 6.

ACTION:

With no charging pump or high pressure safety injection pump OPERABLE or capable of being powered from an OPERABLE emergency power source, suspend all operations involving CORE ALTERATIONS or positive reactivity changes*.

R01

SURVEILLANCE REQUIREMENTS

4.1.2.3 At least the above required pumps shall be demonstrated OPERABLE by verifying the charging pump develops a flow rate of greater than or equal to 40 gpm or the high pressure safety injection pump develops a total head of greater than or equal to 2854 ft. when tested pursuant to the INSERVICE TESTING PROGRAM.

---

* Plant temperature changes are allowed provided the temperature change is accounted for in the calculated SHUTDOWN MARGIN.

REACTIVITY CONTROL SYSTEMS

CHARGING PUMPS – OPERATING

LIMITING CONDITION FOR OPERATION

3.1.2.4 At least two charging pumps shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

With only one charging pump OPERABLE, restore at least two charging pumps to OPERABLE status within 72 hours or be in at least HOT STANDBY and borated to a SHUTDOWN MARGIN equivalent to its COLR limit at 200°F within the next 6 hours; restore at least two charging pumps to OPERABLE status within the next 7 days or be in COLD SHUTDOWN within the next 30 hours.

R01

SURVEILLANCE REQUIREMENTS

4.1.2.4.1 At least two charging pumps shall be demonstrated OPERABLE by verifying that each pump develops a flow rate of greater than or equal to 40 gpm when tested pursuant to the INSERVICE TESTING PROGRAM.

4.1.2.4.2 In accordance with the Surveillance Frequency Control Program verify that each charging pump starts automatically on an SIAS test signal.

REACTIVITY CONTROL SYSTEMS

BORIC ACID MAKEUP PUMPS – SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.1.2.5 At least one boric acid makeup pump shall be OPERABLE and capable of being powered from an OPERABLE emergency bus if only the flow path through the boric acid pump in Specification 3.1.2.1a is OPERABLE.

APPLICABILITY: MODES 5 and 6.

ACTION:

With no boric acid pump OPERABLE as required to complete the flow path of Specification 3.1.2.1a, suspend all operations involving CORE ALTERATIONS or positive reactivity changes*.

R01

SURVEILLANCE REQUIREMENTS

4.1.2.5 The above required boric acid makeup pump shall be demonstrated OPERABLE by verifying that the pump develops the specified discharge pressure when tested pursuant to the INSERVICE TESTING PROGRAM.

* Plant temperature changes are allowed provided the temperature change is accounted for in the calculated SHUTDOWN MARGIN.

REACTIVITY CONTROL SYSTEMS

BORIC ACID MAKEUP PUMPS – OPERATING

LIMITING CONDITION FOR OPERATION

3.1.2.6 At least the boric acid makeup pump(s) in the boron injection flow path(s) required OPERABLE pursuant to Specification 3.1.2.2 shall be OPERABLE and capable of being powered from an OPERABLE emergency bus if the flow path through the boric acid pump(s) in Specification 3.1.2.2 is OPERABLE.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

With no boric acid makeup pump required for the boron injection flow path(s) pursuant to Specification 3.1.2.2 operable, restore the boric acid makeup pump to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours and borated to a SHUTDOWN MARGIN equivalent to its COLR limit at 200°F; restore the above required boric acid makeup pump(s) to OPERABLE status within the next 7 days or be in COLD SHUTDOWN within the next 30 hours.

R01

SURVEILLANCE REQUIREMENTS

4.1.2.6 The above required boric acid makeup pump(s) shall be demonstrated OPERABLE by verifying that the pump(s) develop the specified discharge pressure when tested pursuant to the INSERVICE TESTING PROGRAM.

REACTIVITY CONTROL SYSTEMS

BORATED WATER SOURCES – SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.1.2.7 As a minimum, one of the following borated water sources shall be OPERABLE:

a. One boric acid makeup tank with a minimum borated water volume of 3550 gallons of 3.1 to 3.5 weight percent boric acid (5420 to 6119 ppm boron).

b. The refueling water tank with:

1. A minimum contained borated water volume of 125,000 gallons,

2. A minimum boron concentration of 1900 ppm, and

3. A solution temperature between 40°F and 120°F.

R01

APPLICABILITY: MODES 5 and 6.

ACTION:

With no borated water sources OPERABLE, suspend all operations involving CORE ALTERATIONS or positive reactivity changes*.

SURVEILLANCE REQUIREMENTS

4.1.2.7 The above required borated water source shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by:

1. Verifying the boron concentration of the water,

2. Verifying the contained borated water volume of the tank, and

b. At least once per 24 hours by verifying the RWT temperature when it is the source of borated water and the outside air temperature is outside the range of 40°F and 120°F.

.

c. At least once per 24 hours when the Reactor Auxiliary Building air temperature is less than 55°F, by verifying that the boric acid makeup tank solution temperature is greater than 55°F when that boric acid makeup tank is required to be OPERABLE.

* Plant temperature changes are allowed provided the temperature change is accounted for in the calculated SHUTDOWN MARGIN.

REACTIVITY CONTROL SYSTEMS

BORATED WATER SOURCES – OPERATING

LIMITING CONDITION FOR OPERATION

3.1.2.8 At least two of the following four borated water sources shall be OPERABLE:

a. Boric Acid Makeup Tank 2A in accordance with Figure 3.1-1.

b. Boric Acid Makeup Tank 2B in accordance with Figure 3.1-1.

c. Boric Acid Makeup Tanks 2A and 2B with a minimum combined contained borated water volume in accordance with Figure 3.1-1.

d. The refueling water tank with:

1. A minimum contained borated water volume of 477,360 gallons,

2. A boron concentration of between 1900 and 2200 ppm of boron, and

3. A solution temperature of between 55°F and 100°F.

R01

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

a. With the above required boric acid makeup tank(s) inoperable, restore the tank(s) to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours and borated to a SHUTDOWN MARGIN equivalent to its COLR limit at 200°F; restore the above required boric acid makeup tank(s) to OPERABLE status within the next 7 days or be in COLD SHUTDOWN within the next 30 hours.

b. With the refueling water tank inoperable, restore the tank to OPERABLE status within 1 hour or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.1.2.8 At least two required borated water sources shall be demonstrated OPERABLE:

a. In accordance with the Surveillance Frequency Control Program by:

1. Verifying the boron concentration in the water and

2. Verifying the contained borated water volume of the water source.

b. At least once per 24 hours by verifying the RWT temperature when the outside air temperature is outside the range of 55°F and 100°F.

c. At least once per 24 hours when the Reactor Auxiliary Building air temperature is less than 55°F, by verifying that the boric acid makeup tank solution is greater than 55°F.

DISCUSSION OF CHANGES
CTS 3/4.1.2, BORATION SYSTEMS

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG - 1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

R01 CTS 3/4.1.2.1, 3/4.1.2.2, 3/4.1.2.3, 3/4.1.2.4, 3/4.1.2.5, 3/4.1.2.6, 3/4.1.2.7, and 3/4.1.2.8 provide boration system requirements and require a source of borated water, one or more flow paths to inject borated water into the RCS, and either a charging pump or high pressure safety injection pump to provide the necessary charging head.

The purpose of the boration system Technical Specifications is provide the means to control the chemical neutron absorber (boron) concentration in the Reactor Coolant System (RCS) and to help maintain the shutdown margin during normal operations. The RCS boration management system functions to control boron concentration and maintain shutdown margin are not assumed to be OPERABLE to mitigate the consequences of a DBA or transient. In the case of a malfunction of a component in the boration systems which causes a boron dilution event, the automatic response, or that required by the operator, is to close the appropriate valves in the reactor makeup system. The plant response to a boron dilution event also includes control rod assembly movement and reactor trip features to ensure shutdown margin is maintained. The boration capabilities of the boration systems are not assumed to mitigate the boron dilution event. The ITS does not include these Specifications. This changes the CTS by relocating these Specifications to the Technical Requirements Manual (TRM).

This change is acceptable because the CTS 3/4.1.2.boration system Specifications do not meet the 10 CFR 50.36(c)(2)(ii) criteria for inclusion into the ITS.

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. The boration systems do not constitute instrumentation systems that are used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary.

2. The boration systems are not process variables, design features, or operating restrictions that represent an initial condition of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier.

3. The RCS boration management system functions to control boron concentration and maintain shutdown margin do not represent a structure, system, or component that is part of the primary success path and which functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The St. Lucie Plant (PSL) at-power PRA has shown that the RCS boration management system functions are not significant risk contributors to core damage frequency and offsite releases. PSL does not have shutdown PRA model. However, operational experience has shown that the boration management system is not a constraint of prime importance in the mitigation of any accident or transient that results in challenging public health and safety. Therefore, the RCS boration management system functions to control boron concentration and maintain shutdown margin do not represent structures, systems, or components which operating experience or probabilistic risk assessment has shown to be significant to public health and safety

Since 10 CFR 50.36(c)(2)(ii) criteria have not been satisfied for the RCS boration management system functions to control boron concentration and maintain shutdown margin, the Boration System Specifications may be relocated to a licensee controlled document outside the Technical Specifications. RCS boration structures, systems, or components credited as the primary success path which function or actuate to mitigate a DBA or transient are retained in separate Technical Specifications (e.g., Emergency Core Cooling System). Additionally, shutdown margin requirements during shutdown, and boration concentration requirements during refueling are retained in separate Technical Specifications to ensure adequate excess negative core reactivity is available in the event of an inadvertent boron dilution event.

Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as relocation because the Specifications did not meet the criteria in 10 CFR 50.36(c)(2)(ii) and have been relocated to the TRM.

RELOCATED SPECIFICATIONS

R01 Unit 2 Current Technical Specifications (CTS) 3/4.1.3.3 provide control element assembly (CEA) position indication requirements when the reactor is shutdown and requires one CEA position indication channel for each withdrawn CEA to be OPERABLE when the reactor trip breakers are closed and one or more CEAs are withdrawn.

The purpose of this requirement is to provide the control room operator with indication of the position of a CEA when the CEA is not fully inserted and perform any related operations that are required. The CEA position indication channels do not provide any automatic function and no operator action assumed in accident or transient analyses (e.g., uncontrolled CEA withdrawal event) is initiated based on CEA position. Shutdown margin requirements ensure adequate excess negative reactivity is available to maintain the reactor subcritical when a CEA with the highest reactivity worth is withdrawn while the reactor is shutdown. The ITS does not include this Specification. This changes the CTS by relocating this Specification to the Technical Requirements Manual (TRM).

This change is acceptable because the Unit 2 CTS 3/4.1.3.3.Specification does not meet the 10 CFR 50.36(c)(2)(ii) criteria for inclusion into the ITS.

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. The CEA position monitoring system when the reactor is shutdown is not an instrumentation system that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary.

2. The CEA position monitoring system when the reactor is shutdown is not a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier.

3. The CEA position monitoring system when the reactor is shutdown is not a structure, system, or component that is part of the primary success path or which functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The CEA position monitoring system when the reactor is shutdown and the reactor trip breakers are closed is not addressed in the St. Lucie Plant Unit 2 PRA and does not represent a system which operating experience or probabilistic risk assessment has shown to be significant to public health and safety.

Since 10 CFR 50.36(c)(2)(ii) criteria have not been satisfied for the CEA position monitoring system when the reactor trip breakers are closed and one or more CEAs are withdrawn, the requirements of the CEA Position Indication – Shutdown Specification may be relocated to a licensee controlled document outside the Unit 2 Technical Specifications. Shutdown Margin requirements during shutdown are retained in separate Technical Specifications and ensure adequate excess negative core reactivity is available in the event of a CEA system malfunction during shutdown (e.g., uncontrolled CEA withdrawal event from a subcritical condition).

Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as relocation because the Specifications did not meet the criteria in 10 CFR 50.36(c)(2)(ii) and have been relocated to the TRM.

3/4.10 SPECIAL TEST EXCEPTIONS

SHUTDOWN MARGIN

LIMITING CONDITION FOR OPERATION

3.10.1 The SHUTDOWN MARGIN requirement of Specification 3.1.1.1 may be suspended for measurement of CEA worth and shutdown margin provided reactivity equivalent to at least the highest estimated CEA worth is available for trip insertion from OPERABLE CEA(s).

APPLICABILITY: MODE 2.

ACTION:

a. With any full length CEA not fully inserted and with less than the above reactivity equivalent available for trip insertion, immediately initiate and continue boration at ≥ 40 gpm of 1900 ppm boric acid solution or its equivalent until the SHUTDOWN MARGIN required by Specification 3.1.1.1 is restored.

b. With all full length CEAs inserted and the reactor subcritical by less than the above reactivity equivalent, immediately initiate and continue boration at ≥ 40 gpm of 1900 ppm boric acid solution or its equivalent until the SHUTDOWN MARGIN required by Specification 3.1.1.1 is restored.

SURVEILLANCE REQUIREMENTS

4.10.1.1 The position of each full length CEA required either partially or fully withdrawn shall be determined in accordance with the Surveillance Frequency Control Program.

4.10.1.2 Each CEA not fully inserted shall be demonstrated capable of full insertion when tripped from at least the 50% withdrawn position within 7 days prior to reducing the SHUTDOWN MARGIN to less than the limits of Specification 3.1.1.1.

M01

3/4.10 SPECIAL TEST EXCEPTIONS

3/4.10.1 SHUTDOWN MARGIN

LIMITING CONDITION FOR OPERATION

3.10.1 The SHUTDOWN MARGIN requirement of Specification 3.1.1.1 may be suspended for measurement of CEA worth, MTC, and SHUTDOWN MARGIN provided reactivity equivalent to at least the highest estimated CEA worth is available for trip insertion from OPERABLE CEA(s).

APPLICABILITY: MODES 2 and 3*.

ACTION:

a. With any full-length CEA not fully inserted and with less than the above reactivity equivalent available for trip insertion, immediately initiate and continue boration at greater than or equal to 40 gpm of a solution containing greater than or equal to 1900 ppm boron or its equivalent until the SHUTDOWN MARGIN required by Specification 3.1.1.1 is restored.

b. With all full-length CEAs inserted and the reactor subcritical by less than the above reactivity equivalent, immediately initiate and continue boration at greater than or equal to 40 gpm of a solution containing greater than or equal to 1900 ppm boron or its equivalent until the SHUTDOWN MARGIN required by Specification 3.1.1.1 is restored.

SURVEILLANCE REQUIREMENTS

4.10.1.1 The position of each full-length CEA required either partially or fully withdrawn shall be determined in accordance with the Surveillance Frequency Control Program.

4.10.1.2 Each CEA not fully inserted shall be demonstrated capable of full insertion when tripped from at least the 50% withdrawn position within 7 days prior to reducing the SHUTDOWN MARGIN to less than the limits of Specification 3.1.1.1.

* Operation in MODE 3 shall be limited to 6 consecutive hours.

DISCUSSION OF CHANGES
CTS 3/4.10.1, SHUTDOWN MARGIN

ADMINISTRATIVE CHANGES

None

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.10.1 provides an exception to the SHUTDOWN MARGIN (SDM) requirements of CTS 3.1.1.1 in MODE 2 and Unit 2 CTS 3.10.1 provides an exception to the SHUTDOWN MARGIN requirements of CTS 3.1.1.1 in MODES 2 and 3 for the purpose of measurement of control element assembly (CEA) worth and shutdown margin, and moderator temperature coefficient (MTC) for Unit 2, provided the reactivity equivalent to at least the highest estimated CEA worth is available for trip insertion from OPERABLE CEAs. According to the Bases, this special test exception provides that a minimum amount of CEA worth is immediately available for reactivity control when tests are performed for CEA measurement. This special test exception is required to permit the periodic verification of the actual versus predicted core reactivity condition occurring as a result of fuel burnup or fuel cycling operations. This changes the CTS by eliminating a special test exception.

This change is acceptable because SDM is maintained in MODE 2 by CEA alignment and insertion limits (CTS 3.1.3.1, 3.1.3.5, and 3.1.3.6), which are not suspended by CTS 3.10.1. In addition, verification of the actual versus predicted core reactivity condition is not required to be performed in MODE 3. ITS SR 3.1.2.1, Note 2 states that this Surveillance is not required to be performed prior to entry into MODE 2. As a result, the CTS 3.10.1 special test exception is not needed. Future PHYSICS TESTS, including CEA worth, SDM, and MTC measurements, may be performed under ITS 3.1.8, "Special Test Exceptions (STE) - MODES 1 and 2," or in accordance with the requirements of LCO 3.1.4, “Control Element Assembly (CEA) Alignment,” LCO 3.1.5, "Shutdown Control Element Assembly (CEA) Insertion Limits," and LCO 3.1.6, “Regulating Control Element Assembly (CEA) Insertion Limits.” This change is designated as more restrictive because a special test exception allowance is being deleted.

CENTER CEA MISALIGNMENT

LIMITING CONDITION FOR OPERATION

3.10.5 The requirements of Specifications 3.1.3.1 and 3.1.3.6 may be suspended during the performance of PHYSICS TESTS to determine the isothermal temperature coefficient and power coefficient provided:

a. Only the center CEA (CEA #1) is misaligned, and

b. The limits of Specification 3.2.1 are maintained and determined as specified in Specification 4.10.5.2 below.

APPLICABILITY: MODES 1 and 2.

ACTION:

With any of the limits of Specification 3.2.1 being exceeded while the requirements of Specifications 3.1.3.1 and 3.1.3.6 are suspended, either:

a. Reduce THERMAL POWER sufficiently to satisfy the requirements of Specification 3.2.1, or

b. Be in HOT STANDBY within 6 hours.

SURVEILLANCE REQUIREMENTS

4.10.5.1 The THERMAL POWER shall be determined in accordance with the Surveillance Frequency Control Program during PHYSICS TESTS in which the requirements of Specifications 3.1.3.1 and/or 3.1.3.6 are suspended and shall be verified to be within the test power plateau.

4.10.5.2 The linear heat rate shall be determined to be within the limits of Specification 3.2.1 by monitoring it continuously with the Incore Detector Monitoring System pursuant to the requirements of Specification 4.2.1.4 during PHYSICS TESTS above 5% of RATED THERMAL POWER in which the requirements of Specifications 3.1.3.1 and/or 3.1.3.6 are suspended.

SPECIAL TEST EXCEPTIONS

M01

3/4.10.4 CENTER CEA MISALIGNMENT

LIMITING CONDITION FOR OPERATION

3.10.4 The requirements of Specifications 3.1.3.1 and 3.1.3.6 may be suspended during the performance of PHYSICS TESTS to determine the isothermal temperature coefficient, moderator temperature coefficient and power coefficient provided:

a. Only the center CEA (CEA #1) is misaligned, and

b. The limits of Specification 3.2.1 are maintained and determined as specified in Specification 4.10.4.2 below.

APPLICABILITY: MODES 1 and 2.

ACTION:

With any of the limits of Specification 3.2.1 being exceeded while the requirements of Specifications 3.1.3.1 and 3.1.3.6 are suspended, either:

a. Reduce THERMAL POWER sufficiently to satisfy the requirements of Specification 3.2.1, or

b. Be in HOT STANDBY within 6 hours.

SURVEILLANCE REQUIREMENTS

4.10.4.1 The THERMAL POWER shall be determined at least once per hour during PHYSICS TESTS in which the requirements of Specifications 3.1.3.1 and/or 3.1.3.6 are suspended and shall be verified to be within the test power plateau.

4.10.4.2 The linear heat rate shall be determined to be within the limits of Specification 3.2.1 by monitoring it continuously with the Incore Detector Monitoring System pursuant to the requirements of Specification 4.2.1.4 during PHYSICS TESTS above 5% of RATED THERMAL POWER in which the requirements of Specifications 3.1.3.1 and/or 3.1.3.6 are suspended.

DISCUSSION OF CHANGES
UNIT 1 CTS 3/4.10.5, CENTER CEA MISALIGNMENT
UNIT 2 CTS 3/4.10.4, CENTER CEA MISALIGNMENT

ADMINISTRATIVE CHANGES

None

MORE RESTRICTIVE CHANGES

M01 Unit 1 Current Technical Specifications (CTS) 3/4.10.5 and Unit 2 CTS 3/4.10.5 provide an exception to CTS 3.1.3.3 and CTS 3.1.3.6 Specifications. This special test exception permits the center CEA to be misaligned during PHYSICS TESTS required to determine the isothermal temperature coefficient and power coefficient. The Improved Technical Specifications (ITS) do not contain this special test exception. This changes the CTS by eliminating a special test exception.

This change is acceptable because this type of PHYSICS TEST is no longer performed. Future PHYSICS TESTS will be performed under ITS 3.1.8, "Special Test Exceptions (STE) - MODES 1 and 2," or in accordance with the requirements of LCO 3.1.4, “Control Element Assembly (CEA) Alignment,” and LCO 3.1.6, “Regulating Control Element Assembly (CEA) Insertion Limits.” As a result, this CTS Special test exception is not needed. This change is designated as more restrictive because an exception to the CTS is being deleted.

1

B 3.1 REACTIVITY CONTROL SYSTEMS (Analog)

B 3.1.7 Special Test Exception (STE) - SHUTDOWN MARGIN (SDM) (Analog)

BASES

BACKGROUND The primary purpose of the SHUTDOWN MARGIN (SDM) Special Test Exception (STE) is to permit relaxation of existing LCOs to allow the performance of certain PHYSICS TESTS. These tests are constructed to determine the control element assembly (CEA) worth.

Section XI of 10 CFR 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Processing Plants" (Ref. 1), requires that a test program be established to ensure that structures, systems, and components will perform satisfactorily in service. All functions necessary to ensure that specified design conditions are not exceeded during normal operation and anticipated operational occurrences must be tested. Testing is required as an integral part of the design, fabrication, construction, and operation of the power plant. Requirements for notification of the NRC, for the purpose of conducting tests and experiments, are specified in 10 CFR 50.59, "Changes, Tests, and Experiments" (Ref. 2).

The key objectives of a test program are to (Ref. 3):

a. Ensure that the facility has been adequately designed,

b. Validate the analytical models used in design and analysis,

c. Verify assumptions used for predicting plant response,

d. Ensure that installation of equipment in the facility has been accomplished in accordance with the design, and

e. Verify that operating and emergency procedures are adequate.

To accomplish these objectives, testing is required prior to initial criticality, after each refueling shutdown, and during startup, low power operation, power ascension, and at power operation. The PHYSICS TESTS requirements for reload fuel cycles ensure that the operating characteristics of the core are consistent with the design predictions, and that the core can be operated as designed (Ref. 4).

1

BASES

BACKGROUND (continued)

PHYSICS TESTS procedures are written and approved in accordance with established formats. The procedures include all information necessary to permit a detailed execution of testing required to ensure that the design intent is met. PHYSICS TESTS are performed in accordance with these procedures, and test results are approved prior to continued power escalation and long term power operation. Examples of PHYSICS TESTS include determination of critical boron concentration, CEA group worths, reactivity coefficients, flux symmetry, and core power distribution.

APPLICABLE SAFETY ANALYSES

It is acceptable to suspend certain LCOs for PHYSICS TESTS because fuel damage criteria are not exceeded. Even if an accident occurs during PHYSICS TESTS with one or more LCOs suspended, fuel damage criteria are preserved because adequate limits on power distribution and shutdown capability are maintained during PHYSICS TESTS.

Reference 5 defines the requirements for initial testing of the facility, including PHYSICS TESTS. Requirements for reload fuel cycle PHYSICS TESTS are defined in ANSI/ANS-19.6.1-1985 (Ref. 4). Although these PHYSICS TESTS are generally accomplished within the limits of all LCOs, conditions may occur when one or more LCOs must be suspended to make completion of PHYSICS TESTS possible or practical. This is acceptable as long as the fuel design criteria are not violated. As long as the linear heat rate (LHR) remains within its limit, fuel design criteria are preserved.

In this test, the following LCOs are suspended:

a. LCO 3.1.1, "SHUTDOWN MARGIN (SDM)",

b. LCO 3.1.5, “Shutdown Control Element Assembly (CEA) Insertion Limits,” and

c. LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits."

Therefore, this LCO places limits on the minimum amount of CEA worth required to be available for reactivity control when CEA worth measurements are performed.

The individual LCOs cited above govern SDM CEA group height, insertion, and alignment. Additionally, the LCOs governing Reactor Coolant System (RCS) flow, reactor inlet temperature, and pressurizer pressure contribute to maintaining departure from nucleate boiling (DNB) parameter limits. The initial condition criteria for accidents sensitive to

APPLICABLE SAFETY ANALYSES (continued)

core power distribution are preserved by the LHR and DNB parameter limits. The criteria for the loss of coolant accident (LOCA) are specified in 10 CFR 50.46, "Acceptance Criteria for Emergency core Cooling Systems for Light Water Nuclear Power Reactors" (Ref. 6). The criteria for the loss of forced reactor coolant flow accident are specified in Reference 7. Operation within the LHR limit preserves the LOCA criteria; operation within the DNB parameter limits preserves the loss of flow criteria.

SRs are conducted as necessary to ensure that LHR and DNB parameters remain within limits during PHYSICS TESTS. Performance of these SRs allows PHYSICS TESTS to be conducted without decreasing the margin of safety.

Requiring that shutdown reactivity equivalent to at least the highest estimated CEA worth (of those CEAs actually withdrawn) be available for trip insertion from the OPERABLE CEA provides a high degree of assurance that shutdown capability is maintained for the most challenging postulated accident, a stuck CEA. Since LCO 3.1.1 is suspended, however, there is not the same degree of assurance during this test that the reactor would always be shut down if the highest worth CEA was stuck out and calculational uncertainties or the estimated highest CEA worth was not as expected (the single failure criterion is not met). This situation is judged acceptable, however, because specified acceptable fuel damage limits are still met. The risk of experiencing a stuck CEA and subsequent criticality is reduced during this PHYSICS TEST exception by the requirements to determine CEA positions every 2 hours; by the trip of each CEA to be withdrawn 24 hours prior to suspending the SDM; and by ensuring that shutdown reactivity is available, equivalent to the reactivity worth of the estimated highest worth withdrawn CEA (Ref. 5).

PHYSICS TESTS include measurement of core parameters or exercise of control components that affect process variables. Among the process variables involved are total planar radial peaking factor, total integrated radial peaking factor, T_q and ASI, which represent initial condition input (power peaking) to the accident analysis. Also involved are the shutdown and regulating CEAs, which affect power peaking and are required for shutdown of the reactor. The limits for these variables are specified for each fuel cycle in the COLR.

As described in LCO 3.0.7, compliance with Special Test Exception LCOs is optional, and therefore no criteria of 10 CFR 50.36(c)(2)(ii) apply. Special Test Exception LCOs provide flexibility to perform certain operations by appropriately modifying requirements of other LCOs. A discussion of the criteria satisfied for the other LCOs is provided in their respective Bases.

1

BASES

LCO

This LCO provides that a minimum amount of CEA worth is immediately available for reactivity control when CEA worth measurement tests are performed. The STE is required to permit the periodic verification of the actual versus predicted worth of the regulating and shutdown CEAs. The SDM requirements of LCO 3.1.1, the shutdown CEA insertion limits of LCO 3.1.5, and the regulating CEA insertion limits of LCO 3.1.6 may be suspended.

APPLICABILITY

This LCO is applicable in MODES 2 and 3. Although CEA worth testing is conducted in MODE 2, sufficient negative reactivity is inserted during the performance of these tests to result in temporary entry into MODE 3. Because the intent is to immediately return to MODE 2 to continue CEA worth measurements, the STE allows limited operation to 6 consecutive hours in MODE 3, as indicated by the Note, without having to borate to meet the SDM requirements of LCO 3.1.1.

ACTIONS

A.1

With any CEA not fully inserted and less than the minimum required reactivity equivalent available for insertion, or with all CEAs inserted and the reactor subcritical by less than the reactivity equivalent of the highest worth CEA, restoration of the minimum SDM requirements must be accomplished by increasing the RCS boron concentration. The required Completion Time of 15 minutes for initiating boration allows the operator sufficient time to align the valves and start the boric acid pumps and is consistent with the Completion Time of LCO 3.1.1.

SURVEILLANCE REQUIREMENTS

SR 3.1.7.1

Verification of the position of each partially or fully withdrawn full length or part length CEA is necessary to ensure that the minimum negative reactivity requirements for insertion on a trip are preserved. [A 2 hour Frequency is sufficient for the operator to verify that each CEA position is within the acceptance criteria.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------

Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.

----------]

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.1.7.2

Prior demonstration that each CEA to be withdrawn from the core during PHYSICS TESTS is capable of full insertion, when tripped from at least a 50% withdrawn position, ensures that the CEA will insert on a trip signal. The Frequency ensures that the CEAs are OPERABLE prior to reducing SDM to less than the limits of LCO 3.1.1.

The SR is modified by a Note which allows the SR to not be performed during initial power escalation following a refueling outage if SR 3.1.4.6 has been met during that refueling outage. This allows the CEA drop time test, which also proves the CEAs are trippable, to be credited for this SR.

DISCUSSION OF CHANGES
ITS 3.2.1, LINEAR HEAT RATE (LHR)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 4.2.1.1 states that the provisions of Specification 4.0.4 are not applicable, and thereby provides an allowance for entering the next higher MODE of Applicability when the Surveillance is not met. ITS 3.2.1 does not provide a Surveillance Note that states that the provisions of LCO 4.0.4 are not applicable. LCO 4.0.4 states that entry into a MODE or other specified condition in the Applicability of a Limiting Condition for Operation (LCO) shall only be made when the LCO's Surveillances have been met within their specified Frequency, except as provided by Surveillance Requirement 4.0.3. LCO 4.0.3 provides the provisions for a missed surveillance and does not apply to a surveillance known to not be met within its specified Frequency prior to entering the Mode of Applicability.

The purpose of CTS 4.2.2.1 is to provide an allowance for entering the MODE of applicability when any Surveillance is not met. This change is designated as more restrictive because the CTS 4.0.4 MODE change allowance is deleted and entry into MODE 1 shall only be made when the LCO's surveillances have been met within their specified Frequency. This changes CTS by allowing entry into the MODE of Applicability by only deferring the performance of the Surveillance Requirements instead of deferring compliance with the LCO.

ITS SR 3.2.1.2 and SR 3.2.1.3 each contain a note that states "Not required to be performed below 20% RTP. ITS SR 3.2.1.2 and SR 3.2.1.3 Surveillance Requirements Note will provide an allowance whereby, Surveillance performance is not required prior to entering MODE 1. This allows establishing the conditions at which the Surveillances can be performed. See DOC L03 discussion of change for ITS SR 3.2.1.2 Note and SR 3.2.1.3 Note.

M02 CTS 4.2.1.4.b does not explicitly state how often the incore detector low power density alarm setpoint is adjusted to less than or equal to the limits shown on COLR Figure 3.2.1. CTS 4.2.1.4.b is changed to include a Surveillance Frequency in accordance with the Surveillance Frequency Control Program (SFCP) consistent with the Frequency to update the core distribution map as specified in CTS 4.2.1.4.a. The Frequency of ITS 3.2.1.3 is "in accordance with the Surveillance Frequency Control Program."

PSL controls periodic Frequencies for Surveillances in accordance with the Surveillance Frequency Control Program (SFCP) per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Performance of SR 3.2.1.3 (CTS 4.2.1.4.b) verifies, in part, that the Incore Detector Monitoring System can accurately monitor LHR and is performed following the update of the core flux map, which is performed at a frequency specified in the SFCP. The change to the Frequency of CTS 4.2.1.4.a is discussed in FPL (PSL Unit 1 and Unit 2) "Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program" (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066). The initial frequency established in accordance with the SFCP will be 31 days consistent with the frequency established for ISTS SR 3.2.1.3 and considers the historical testing frequency of the reactor monitoring system.

This change is designated as more restrictive because a Surveillance Frequency has been added to ensure the incore detector local power density alarm setpoints are periodically verified to be within the limits of the COLR.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, QAP, CLRT Program, IST Program, ISI Program, or Surveillance Frequency Control Program)*

CTS 4.2.1.4 footnote # states that if the incore detector monitoring system becomes inoperable, reduce power to M x N within 4 hours and monitor linear heat rate in accordance with Specification 4.2.1.3. CTS 4.2.1.3.c provides the determination of M x N and directs which figures in the COLR to use for LHR verifications using the excore detection system. ITS 3.2.1 does not include this requirement. This changes the CTS by relocating the action to take when the incore detector monitoring system is inoperable to the Technical Requirements Manual (TRM).

The incore detector monitoring system monitors LHR. However, there are no requirements in CTS for this indication-only instrumentation system to be OPERABLE. Therefore, it is unnecessary to provide actions in the Technical Specifications that must be performed when this non-TS system is not functional. The removal of action requirements for indication-only instrumentation and alarms from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The requirement to determine LHR and actions to perform when LHR is not within limits remains in

the ITS. Either the incore detector monitoring system or the excore detector monitoring system is used to monitor LHR.

Normally, LHR is verified using the incore detector local power density alarm. The setpoint is maintained less than or equal to the COLR Figure 3.2-1 limits. When the incore detector monitoring system is discovered to be non-functional, the ASI alarm associated with the excore detector monitoring system is used to determine LHR. The ASI alarm setpoint is maintained within the COLR Figure 3.2-2 limits. A power reduction may be required to adjust the ASI alarm setpoint to correspond to the COLR figure limits, however, a power reduction may not be necessary based on plant conditions. If a power reduction is necessary to adjust the ASI alarm setpoints to within COLR limits, the power reduction is accomplished using normal plant operating procedures.

This change is acceptable because inoperability of the incore detector monitoring system alone does not indicate that LHR has exceeded the limit and the removed information will be adequately controlled in the TRM. Changes to the TRM are made under 10 CFR 50.59, thereby ensuring changes are properly evaluated. This change is designated as a less restrictive removal of detail change because action requirements for non-TS indication-only instrumentation and alarms is being removed from the Technical Specifications. R1

LESS RESTRICTIVE CHANGES

L01 *(Category 3 – Relaxation of Completion Time)* CTS 3.2.1 Action states that within 15 minutes initiate corrective action to reduce the linear heat rate (LHR) to within limits. ITS 3.2.1 Required Action A.1 and associated Completion Time states that LHR be restored to within limits with a Completion Time of 1 hour. This changes the CTS by not requiring that within 15 minutes corrective action be taken to reduce the LHR to within limits, rather only requiring that the LHR be restored to within limits within 1 hour, consistent with the ITS 3.2.1 Completion Time. Requiring corrective action be taken within 15 minutes does not necessarily restore LHR within limits within 1 hour.

The purpose of CTS 3.2.1 is to maintain LHR within the limits specified in the COLR. When the LCO is not met, both CTS 3.2.1 and ITS 3.2.1 require that the LHR be restored to within limits within 1 hour. With the LHR exceeding its limit, fuel damage could occur following an accident. In this Condition, prompt action must be taken to restore the LHR to within the specified limits. One hour to restore the LHR to within its specified limits is reasonable and ensures that the core does not continue to operate in this Condition. The 1 hour Completion Time also allows the operator sufficient time for evaluating core conditions and for initiating proper corrective actions. This change is acceptable because the CTS 3.2.1 Completion Time and ITS 3.2.1 Completion Time are both 1 hour.

This change is designated as less restrictive because the CTS requirement to within 15 minutes initiate corrective action to reduce the linear heat rate (LHR) to within limits is deleted.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.2.1 Action b. states that with the linear heat rate (LHR) not within limits within 1 hour, to be in HOT STANDBY within the next 6 hours. ITS 3.2.1 Action B states that with the LHR not within limits within 1 hour, then be in MODE 2 with a Completion Time of 6 hours. This changes the CTS by only requiring entry into MODE 2 within 6 hours. Once in MODE 2, LCO 3.0.2 allows the LCO to be exited since the Applicability is MODE 1, and completing the Required Actions is not required when an LCO is met or is no longer applicable, unless otherwise stated in the individual Specifications.

The purpose of CTS 3.2.1 Action b. and ITS 3.2.1 Action B is to reduce THERMAL POWER. Exiting the Mode of Applicability provides reasonable assurance that the core is operating within its thermal limits and places the core in a conservative condition. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the repair period.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 *(Category 7 – Relaxation Of Surveillance Frequency)* CTS 4.2.1.1 states that the provisions of Specification 4.0.4 are not applicable, and thereby provides an allowance for entering the next higher MODE of Applicability when the Surveillance is not met. ITS 3.2.1 does not provide a Surveillance Note that states that the provisions of LCO 4.0.4 are not applicable. See DOC M01. ITS SR 3.2.1.2 and SR 3.2.1.3 each contain a note that states “Not required to be performed below 20% RTP.” ITS SR 3.2.1.2 and SR 3.2.1.3 Surveillance Requirements Note will provide an allowance whereby, Surveillance performance is not required prior to entering MODE 1. This allows establishing the conditions at which the Surveillances can be performed. CTS 4.0.1. states that Surveillance Requirements shall be applicable during the OPERATIONAL MODES or other conditions specified for individual LCOs unless otherwise stated in an individual Surveillance Requirement. Similarly, ITS SR 3.0.1 states that SRs shall be met during the MODES or other specified conditions in the Applicability for individual LCOs, unless otherwise stated in the SR. This changes the CTS by providing a Surveillance Note which states “Not required to be performed below 20% RTP.”

The purpose of CTS 4.2.1.1 is to provide a note that states that the provisions of Specification 4.0.4 are not applicable, and thereby provides an allowance for entering the next higher MODE of Applicability when the Surveillance is not met. ITS 3.2.1 does not provide a Surveillance Note that states that the provisions of LCO 4.0.4 are not applicable.

This change is acceptable because the note added to ITS SR 3.2.1.2 and SR 3.2.1.3 will provide an allowance whereby, Surveillance performance is not

met prior to entering MODE 1. This allows establishing the conditions at which the Surveillances can be performed. This change is designated as less restrictive because Surveillances will be performed after entering MODE 1 rather than being performed prior to entry into MODE 1.

JUSTIFICATION FOR DEVIATIONS
ITS 3.2.1, LINEAR HEAT RATE (LHR)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The ISTS SR 3.2.1.2 statement "which shall be updated at least once per 31 days of accumulated operation in MODE 1" is deleted. ITS SR 3.2.1.2, including update of the core power distribution map, is in accordance with the Surveillance Frequency Control Program (SFCP). The SFCP Frequency is at least once per 31 days.

4. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

5

B 3.2 POWER DISTRIBUTION LIMITS ~~(Analog)~~

5

B 3.2.1 Linear Heat Rate (LHR) ~~(Analog)~~

BASES

(Linear Heat Rate (LHR))

1

BACKGROUND

The purpose of this LCO is to limit the core power distribution to the initial values assumed in the accident analyses. Operation within the limits imposed by this LCO either limits or prevents potential fuel cladding failures that could breach the primary fission product barrier and release fission products to the reactor coolant in the event of a loss of coolant accident (LOCA), loss of flow accident, ejected control element assembly (CEA) accident, or other postulated accident requiring termination by a Reactor Protection System trip function. This LCO limits the amount of damage to the fuel cladding during an accident by ensuring that the plant is operating within acceptable bounding conditions at the onset of a transient.

Methods of controlling the power distribution include:

a. Using CEAs to alter the axial power distribution,

b. Decreasing CEA insertion by boration, thereby improving the radial power distribution, and

c. Correcting off optimum conditions (e.g., a CEA drop or misoperation of the unit) that cause margin degradations.

The core power distribution is controlled so that, in conjunction with other core operating parameters (e.g., CEA insertion and alignment limits), the power distribution does not result in violation of ~~satisfies~~ this LCO. The limiting safety system settings and this LCO are based on the accident analyses (Ref~~s~~. 1 ~~and 2~~), so that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences (AOOs), and the limits of acceptable consequences are not exceeded for other postulated accidents.

1

Limiting power distribution skewing over time also minimizes the xenon distribution skewing, which is a significant factor in controlling the axial power distribution.

Power distribution is a product of multiple parameters, various combinations of which may produce acceptable power distributions. Operation within the design limits of power distribution is accomplished by generating operating limits on linear heat rate (LHR) and departure from nucleate boiling (DNB).

1

BASES

BACKGROUND (continued)

The limits on LHR, ~~Total Planar Radial Peaking Factor (F^T_{XY}),~~ Total Integrated Radial Peaking Factor (F^T_r), T_q, and ASI represent limits within which the LHR algorithms are valid. These limits are obtained directly from the core reload analysis.

Either of the two core power distribution monitoring systems, the Excore Detector Monitoring System or the Incore Detector Monitoring System, provides adequate monitoring of the core power distribution and is capable of verifying that the LHR is within its limits. The Excore Detector Monitoring System performs this function by continuously monitoring ASI with the OPERABLE quadrant symmetric excore neutron flux detectors and verifying that the ASI is maintained within the allowable limits specified in the COLR.

In conjunction with the use of the Excore Detector Monitoring System and in establishing ASI limits, the following ~~assumptions~~ are ~~made~~:

a. The CEA insertion limits of LCO 3.1.5, "Shutdown CEA Insertion Limits," and LCO 3.1.6, "Regulating CEA Insertion Limits," are satisfied,

b. The T_q restrictions of LCO 3.2.~~4~~ are satisfied, and

c. ~~F^T_{xy}~~ is within the limits of LCO 3.2.2.

The Incore Detector Monitoring System continuously provides a more direct measure of the peaking factors and alarms ~~that have been~~ established for the individual incore detector segments~~,~~ ensuring that the peak LHRs are maintained within the limits specified in the COLR. The setpoints for these alarms include tolerances~~, set in conservative directions, for:~~

~~a. A measurement calculational uncertainty factor of 1.062,~~

~~b. An engineering uncertainty factor of 1.03,~~

~~c. An allowance of 1.002 for axial fuel densification and thermal expansion, and~~

~~d. A THERMAL POWER measurement uncertainty factor of 1.02.~~

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition 1) and AOOs (Condition 2) (Ref. ~~3~~, GDC 10). The power distribution and CEA insertion and alignment LCOs preclude core power distributions that violate the following fuel design criteria:

a. During a LOCA, peak cladding temperature must not exceed 2200°F (Ref. ~~4~~),

b. During a loss of flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB condition (Ref. ~~3~~, GDC 10),

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. [ ]), and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. ~~3~~, GDC 26).

The power density at any point in the core must be limited to maintain the fuel design criteria (Ref. ~~4~~). This is accomplished by maintaining the power distribution and reactor coolant conditions so that the peak LHR and DNB parameters are within operating limits supported by accident analyses (Ref. 1), with due regard for the correlations between measured quantities, the power distribution, and uncertainties in determining the power distribution.

Fuel cladding failure during a LOCA is limited by restricting the maximum linear heat generation rate so that the peak cladding temperature does not exceed 2200°F (Ref. ~~4~~). High peak cladding temperatures are assumed to cause severe cladding failure by oxidation due to a Zircaloy water reaction.

The LCOs governing LHR, ASI, and the Reactor Coolant System ensure that these criteria are met as long as the core is operated within the ASI~~,~~ ~~F^T_{XY}~~, F^T_r ~~, and T_q~~ limits specified in the COLR. The latter are process variables that characterize the three dimensional power distribution of the reactor core. Operation within the limits for these variables ensures that their actual values are within the ranges used in the accident analyses.

5

BASES

APPLICABLE SAFETY ANALYSES (continued)

reactor

1

Fuel cladding damage does not normally occur while the ~~unit~~ is operating at conditions outside the limits of these LCOs during normal operation. Fuel cladding damage could result, however, if an accident or AOO occurs from initial conditions outside the limits of these LCOs. ~~The~~ This potential for fuel cladding damage exists because changes in the power distribution can cause increased power peaking and can correspondingly increase local LHR.

1

The LHR satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The power distribution LCO limits are based on correlations between power peaking and certain measured variables used as inputs to the LHR and DNB ratio operating limits. The power distribution LCO limits, except T_q, are provided in the COLR. The limitation on the LHR ensures that, in the event of a LOCA, the peak temperature of the fuel cladding does not exceed 2200°F.

APPLICABILITY

In MODE 1, power distribution must be maintained within the limits assumed in the accident analysis to ensure that fuel damage does not result following an AOO. In other MODES, this LCO does not apply because ~~there~~ is not sufficient THERMAL POWER to require a limit on the core power distribution.

1

ACTIONS

A.1

With the LHR exceeding its limit, excessive fuel damage could occur following an accident. In this Condition, prompt action must be taken to restore the LHR to within the specified limits. One hour to restore the LHR to within its specified limits is reasonable and ensures that the core does not continue to operate in this Condition. The 1 hour Completion Time also allows the operator sufficient time for evaluating core conditions and for initiating proper corrective actions.

B.1

If the LHR cannot be returned to within its specified limits, THERMAL POWER must be reduced. The change to MODE 2 provides reasonable assurance that the core is operating within its thermal limits and places the core in a conservative condition. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 2 from full power MODE 1 conditions in an orderly manner and without challenging plant systems.

1

5

BASES

SURVEILLANCE REQUIREMENTS

A Note was added to the SRs to require LHR to be determined by either the Excore Detector Monitoring System or the Incore Detector Monitoring System.

SR 3.2.1.1

Performance of this SR verifies that the Excore Detector Monitoring System can accurately monitor the LHR. Therefore, this SR is only applicable when the Excore Detector Monitoring System is being used to determine the LHR. ~~[The 31 day Frequency is appropriate for this SR because it is consistent with the requirements of SR 3.3.1.3 for calibration of the excore detectors using the incore detectors.~~

2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

2

The SR is modified by a Note that states that the SR is only required to be met when the Excore Detection Monitoring System is being used to determine LHR. The reason for the Note is that the excore detectors input neutron flux information into the ASI calculation.

SR 3.2.1.2 and SR 3.2.1.3

Continuous monitoring of the LHR is provided by the Incore Detector Monitoring System and the Excore Detector Monitoring System. Either of these two core power distribution monitoring systems provides adequate monitoring of the core power distribution and is capable of verifying that the LHR does not exceed its specified limits.

Performance of these SRs verifies that the Incore Detector Monitoring System can accurately monitor LHR. Therefore, they are only applicable when the Incore Detector Monitoring System is being used to determine the LHR.

1

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[A 31 day Frequency is consistent with the historical testing frequency of the reactor monitoring system.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

The SRs are modified by two Notes. Note 1 allows the SRs to be met only when the Incore Detector Monitoring System is being used to determine LHR. Note 2 states that the SRs are not required to be performed when THERMAL POWER is < 20% RTP. The accuracy of the neutron flux information from the incore detectors is not reliable at ~~THERMAL POWER < 20% RTP~~.

REFERENCES

1. FSAR, Chapter ~~[~~15~~]~~.
2. ~~FSAR, Chapter [6].~~ NUREG 0800, Section 4.2, Appendix B

low power levels . Note 2 allows entry into and operation in MODE 1 prior to performing the SRs in order to establish a power level that provides more accurate neutron flux information . Consistent with the requirements of SR 3.0.1 and SR 3.0.2, as specified in Example 1.4-5 of Section 1.4, "Frequency," the Surveillances must be performed within the Frequency requirements of the Surveillance Frequency Control Program prior to exceeding 20% RTP.

5

B 3.2 POWER DISTRIBUTION LIMITS ~~(Analog)~~

5

B 3.2.1 Linear Heat Rate (LHR) ~~(Analog)~~

BASES

(Linear Heat Rate (LHR))

1

BACKGROUND

The purpose of this LCO is to limit the core power distribution to the initial values assumed in the accident analyses. Operation within the limits imposed by this LCO either limits or prevents potential fuel cladding failures that could breach the primary fission product barrier and release fission products to the reactor coolant in the event of a loss of coolant accident (LOCA), loss of flow accident, ejected control element assembly (CEA) accident, or other postulated accident requiring termination by a Reactor Protection System trip function. This LCO limits the amount of damage to the fuel cladding during an accident by ensuring that the plant is operating within acceptable bounding conditions at the onset of a transient.

Methods of controlling the power distribution include:

a. Using CEAs to alter the axial power distribution,

b. Decreasing CEA insertion by boration, thereby improving the radial power distribution, and

c. Correcting off optimum conditions (e.g., a CEA drop or misoperation of the unit) that cause margin degradations.

The core power distribution is controlled so that, in conjunction with other core operating parameters (e.g., CEA insertion and alignment limits), the power distribution does not result in violation of ~~satisfies~~ this LCO. The limiting safety system settings and this LCO are based on the accident analyses (Ref~~s~~. 1 ~~and 2~~), so that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences (AOOs), and the limits of acceptable consequences are not exceeded for other postulated accidents.

1

Limiting power distribution skewing over time also minimizes the xenon distribution skewing, which is a significant factor in controlling the axial power distribution.

Power distribution is a product of multiple parameters, various combinations of which may produce acceptable power distributions. Operation within the design limits of power distribution is accomplished by generating operating limits on linear heat rate (LHR) and departure from nucleate boiling (DNB).

1

BASES

BACKGROUND (continued)

The limits on LHR, ~~Total Planar Radial Peaking Factor (F^T_{XY}),~~ Total Integrated Radial Peaking Factor (F^T_r), T_q, and ASI represent limits within which the LHR algorithms are valid. These limits are obtained directly from the core reload analysis.

Either of the two core power distribution monitoring systems, the Excore Detector Monitoring System or the Incore Detector Monitoring System, provides adequate monitoring of the core power distribution and is capable of verifying that the LHR is within its limits. The Excore Detector Monitoring System performs this function by continuously monitoring ASI with the OPERABLE quadrant symmetric excore neutron flux detectors and verifying that the ASI is maintained within the allowable limits specified in the COLR.

In conjunction with the use of the Excore Detector Monitoring System and in establishing ASI limits, the following ~~assumptions~~ are ~~made~~:

a. The CEA insertion limits of LCO 3.1.5, "Shutdown CEA Insertion Limits," and LCO 3.1.6, "Regulating CEA Insertion Limits," are satisfied,

b. The T_q restrictions of LCO 3.2.~~4~~ are satisfied, and

c. ~~F^T_{xy}~~ is within the limits of LCO 3.2.2.

The Incore Detector Monitoring System continuously provides a more direct measure of the peaking factors and alarms ~~that have been~~ established for the individual incore detector segments~~,~~ ensuring that the peak LHRs are maintained within the limits specified in the COLR. The setpoints for these alarms include tolerances~~, set in conservative directions, for:~~

~~a. A measurement calculational uncertainty factor of 1.062,~~

~~b. An engineering uncertainty factor of 1.03,~~

~~c. An allowance of 1.002 for axial fuel densification and thermal expansion, and~~

~~d. A THERMAL POWER measurement uncertainty factor of 1.02.~~

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition 1) and AOOs (Condition 2) (Ref. ~~3~~, GDC 10). The power distribution and CEA insertion and alignment LCOs preclude core power distributions that violate the following fuel design criteria:

a. During a LOCA, peak cladding temperature must not exceed 2200°F (Ref. ~~4~~),

b. During a loss of flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB condition (Ref. ~~3~~, GDC 10),

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. [ ]), and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. ~~3~~, GDC 26).

The power density at any point in the core must be limited to maintain the fuel design criteria (Ref. ~~4~~). This is accomplished by maintaining the power distribution and reactor coolant conditions so that the peak LHR and DNB parameters are within operating limits supported by accident analyses (Ref. 1), with due regard for the correlations between measured quantities, the power distribution, and uncertainties in determining the power distribution.

Fuel cladding failure during a LOCA is limited by restricting the maximum linear heat generation rate so that the peak cladding temperature does not exceed 2200°F (Ref. ~~4~~). High peak cladding temperatures are assumed to cause severe cladding failure by oxidation due to a Zircaloy water reaction.

The LCOs governing LHR, ASI, and the Reactor Coolant System ensure that these criteria are met as long as the core is operated within the ASI~~,~~ ~~F^T_{XY},~~ F^T_r ~~, and T_q~~ limits specified in the COLR. The latter are process variables that characterize the three dimensional power distribution of the reactor core. Operation within the limits for these variables ensures that their actual values are within the ranges used in the accident analyses.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Fuel cladding damage does not normally occur while the ~~unit~~ reactor is operating at conditions outside the limits of these LCOs during normal operation. Fuel cladding damage could result, however, if an accident or AOO occurs from initial conditions outside the limits of these LCOs. ~~The~~ This potential for fuel cladding damage exists because changes in the power distribution can cause increased power peaking and can correspondingly increase local LHR.

The LHR satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The power distribution LCO limits are based on correlations between power peaking and certain measured variables used as inputs to the LHR and DNB ratio operating limits. The power distribution LCO limits, except T_q, are provided in the COLR. The limitation on the LHR ensures that, in the event of a LOCA, the peak temperature of the fuel cladding does not exceed 2200°F.

APPLICABILITY

In MODE 1, power distribution must be maintained within the limits assumed in the accident analysis to ensure that fuel damage does not result following an AOO. In other MODES, this LCO does not apply because ~~there~~ is not sufficient THERMAL POWER to require a limit on the core power distribution.

ACTIONS

A.1

With the LHR exceeding its limit, excessive fuel damage could occur following an accident. In this Condition, prompt action must be taken to restore the LHR to within the specified limits. One hour to restore the LHR to within its specified limits is reasonable and ensures that the core does not continue to operate in this Condition. The 1 hour Completion Time also allows the operator sufficient time for evaluating core conditions and for initiating proper corrective actions.

B.1

If the LHR cannot be returned to within its specified limits, THERMAL POWER must be reduced. The change to MODE 2 provides reasonable assurance that the core is operating within its thermal limits and places the core in a conservative condition. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 2 from full power MODE 1 conditions in an orderly manner and without challenging plant systems.

BASES

SURVEILLANCE REQUIREMENTS

A Note was added to the SRs to require LHR to be determined by either the Excore Detector Monitoring System or the Incore Detector Monitoring System.

SR 3.2.1.1

Performance of this SR verifies that the Excore Detector Monitoring System can accurately monitor the LHR. Therefore, this SR is only applicable when the Excore Detector Monitoring System is being used to determine the LHR. ~~[The 31 day Frequency is appropriate for this SR because it is consistent with the requirements of SR 3.3.1.3 for calibration of the excore detectors using the incore detectors.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2

~~]~~

The SR is modified by a Note that states that the SR is only required to be met when the Excore Detection Monitoring System is being used to determine LHR. The reason for the Note is that the excore detectors input neutron flux information into the ASI calculation.

SR 3.2.1.2 and SR 3.2.1.3

Continuous monitoring of the LHR is provided by the Incore Detector Monitoring System and the Excore Detector Monitoring System. Either of these two core power distribution monitoring systems provides adequate monitoring of the core power distribution and is capable of verifying that the LHR does not exceed its specified limits.

Performance of these SRs verifies that the Incore Detector Monitoring System can accurately monitor LHR. Therefore, they are only applicable when the Incore Detector Monitoring System is being used to determine the LHR.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~[A 31 day Frequency is consistent with the historical testing frequency of the reactor monitoring system.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

The SRs are modified by two Notes. Note 1 allows the SRs to be met only when the Incore Detector Monitoring System is being used to determine LHR. Note 2 states that the SRs are not required to be performed when THERMAL POWER is < 20% RTP. The accuracy of the neutron flux information from the incore detectors is not reliable at ~~THERMAL POWER < 20% RTP~~.

REFERENCES

1. FSAR, Chapter ~~[~~15~~]~~.

low power levels . Note 2 allows entry into and operation in MODE 1 prior to performing the SRs in order to establish a power level that provides more accurate neutron flux information . Consistent with the requirements of SR 3.0.1 and SR 3.0.2, as specified in Example 1.4-5 of Section 1.4, "Frequency," the Surveillances must be performed within the Frequency requirements of the Surveillance Frequency Control Program prior to exceeding 20% RTP.

JUSTIFICATION FOR DEVIATIONS
ITS 3.2.1, BASES, LINEAR HEAT RATE (LHR)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The ISTS contains tolerances to be applied to the incore detector alarm setpoints. PSL Unit 1 UFSAR, Section 13.8, Licensee-Controlled Technical Specification Requirements, and PSL Unit 2 UFSAR, Section 13.7, Licensee-Controlled Technical Specification Requirements, each contain these tolerances to be applied to the incore detector alarm setpoints. Additionally, these tolerances will be provided in the Technical Requirements Manual. Therefore, the tolerances to be applied to the incore detector alarm setpoints are deleted.

4. The ISTS includes ISTS 3.2.1, Linear Heat Rate (LHR), ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^{T}), ISTS 3.2.3, Total Integrated Radial Peaking Factor (F_{r}^{T}), ISTS 3.2.4, Azimuthal Power Tilt (T_q), and ISTS 3.2.5, Axial Shape Index (ASI). CTS do not include a Specification for ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^{T}). The CTS and ISTS are renumbered. CTS 3.2.3, Total Integrated Radial Peaking Factor (F_{r}^{T}), CTS 3.2.4, Azimuthal Power Tilt (T_q), and CTS 3.2.5, Axial Shape Index (ASI), are renumbered as ITS 3.2.2, ITS 3.2.3, and ITS 3.2.4, respectively.

5. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

6. Changes made to clarify the SR Frequency and Note 2 consistent with the generic Surveillance requirements specified in ISTS Section 3.0, “LCO and SR Applicability,” as specified in ISTS Section 1.4, “Frequency.”

Specific No Significant Hazards Considerations (NSHCs)

DISCUSSION OF CHANGES
ITS 3.2.2, TOTAL INTEGRATED RADIAL PEAKING FACTOR - F_r^T

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 4.2.3.2.c states that CTS 4.2.3.2 be performed within 4 hours if the Azimuthal Power Tilt (Tq) is > 0.03. CTS 3.2.4 Action a. states that with the Tq > 0.03 the F_r^T be verified within limits within 4 hours if the Tq is not restored. CTS 4.2.3.2.c is redundant to CTS 3.2.4 Action a. and is deleted.

This change is designated as an administrative change and is acceptable because the change does not result in technical changes to the CTS.

A03 CTS 3.2.3 Applicability is MODE 1 with a footnote (footnote *) for MODE 1 stating "See Special Test Exception 3.10.2." ITS 3.2.2 does not contain the footnote or a reference to the Special Test Exceptions. This changes the CTS by not including footnote * in the ITS.

The purpose of the footnote references is to alert the user that a Special Test Exception exists that may modify the Applicability of the Specification. It is an ITS convention to not include these types of footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 4.2.3.1 states that the provisions of Specification 4.0.4 are not applicable, and thereby provides an allowance for entering the next higher MODE of Applicability when the Surveillance is not met. ITS 3.2.2 does not provide a Surveillance Note that states that the provisions of LCO 4.0.4 are not applicable. LCO 4.0.4 states that entry into a MODE or other specified condition in the Applicability of a Limiting Condition for Operation (LCO) shall only be made when the LCO's Surveillances have been met within their specified Frequency, except as provided by Surveillance Requirement 4.0.3. LCO 4.0.3 provides the provisions for a missed surveillance and does not apply to a surveillance known to not be met within its specified Frequency prior to entering the Mode of Applicability.

The purpose of CTS 4.2.3.1 is to provide an allowance for entering the MODE of applicability when any Surveillance is not met.

This change is designated as more restrictive because the CTS 4.0.4 MODE change allowance is deleted and entry into MODE 1 shall only be made when the LCO's surveillances have been met within their specified Frequency.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements)* CTS 3.2.3 Action b. states, in part, establish a revised upper THERMAL POWER level limit, and provides the COLR details used for this determination. ITS 3.2.2 Required Action A.3 states "Establish a revised upper THERMAL POWER limit as specified in the COLR." This changes the CTS by relocating the details for making the revised upper THERMAL POWER limit determination to the COLR.

The removal of these details for performing actions from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement to establish a revised upper THERMAL POWER limit as specified in the COLR. Also, this change is acceptable because these types of procedural details will be adequately controlled in the COLR. Changes to the COLR are made under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements)* CTS 4.2.3.2 and CTS 4.2.3.4 state details for calculating F_r^T with a non-full core power distribution analysis code and with a full core power distribution analysis code. ITS SR 3.2.2.1 and ITS SR 3.2.2.3 do not provide details for calculating F_r^T. This changes the CTS by relocating the details for calculating F_r^T to the ITS Bases. The ITS still retains the requirement to verify the value of F_r and to verify the value of Tq.

The removal of these details for performing actions from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. Also, this change is acceptable because these types of procedural details will be adequately controlled in the ITS Bases. The Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled.

This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 4 – Relaxation of Required Action)* CTS 3.2.3 Action a. states that with F_r^T not within limits, within 6 hours be in at least HOT STANDBY within the next 6 hours as an alternative to CTS Action b. ITS 3.2.2 Action B states that with the Required Actions and associated Completion Times (of Condition A) not met, then be in MODE 2 with a Completion Time of 6 hours. This changes the CTS by only requiring that MODE 2 be entered. Once in MODE 2, LCO 3.0.2 allows the LCO to be exited since the Applicability is MODE 1, and completing the Required Actions is not required when an LCO is met or is no longer applicable, unless otherwise stated in the individual Specifications. R1

The purpose of CTS 3.2.3 Action a. and ITS 3.2.2 Action B is to reduce THERMAL POWER. Exiting the Mode of Applicability provides reasonable assurance that the core is operating within its thermal limits and places the core in a conservative condition. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the repair period. R1

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 *(Category 3 – Relaxation of Completion Time)* CTS 3.2.3 Action a. states that with F_r^T not within limits, within 6 hours be in at least HOT STANDBY as an alternative to CTS Action b. ITS 3.2.2 Action B states that with the Required Actions and associated Completion Times (of Condition A) not met, then be in MODE 2 with a Completion Time of 6 hours. The ITS 3.2.2 Completion Time for Required Action A.1, A.2, and A.3 is 6 hours. Therefore, up to 12 hours may be allowed to be in MODE 2. This changes the CTS by allowing 6 hours to restore F_r^T to within limits before requiring that MODE 2 be entered within 6 hours. See DOC L01 for a discussion of change from MODE 3 (CTS) to MODE 2 (ITS). R1

The purpose of CTS 3.2.3 Action a. and ITS 3.2.2 Action B is to exit the Mode of Applicability should the LCO not be restored or the Required Actions not be completed within the associated Completion Times. A Note modifying ITS 3.2.2 Condition A requires Required Actions A.1, A.2, and A.3 to be completed if the Condition is entered. This ensures that corrective action is taken prior to unrestricted operation. The limitations on F_r^T provided in the COLR ensure that the assumptions used in the analysis for establishing the ASI, LCO, and LSSS R1

remain valid during operation at the various allowable CEA group insertion limits. If F_r^T exceeds its basic limitation, operation may continue under the additional restrictions imposed by the Required Actions (reducing THERMAL POWER, withdrawing CEAs to or beyond the long term steady state insertion limits of LCO 3.1.6, and establishing a revised upper THERMAL POWER limit) because these additional restrictions provide adequate provisions to ensure the assumptions used in establishing the LHR, LCO, and LSSS remain valid. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. This includes the capacity and capability of remaining systems or features, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the repair period.

This change is designated as less restrictive because the ITS allows up to 6 hours longer to exit the Mode of Applicability should the LCO not be restored or the Required Actions not be completion within the associated Completion Times.

JUSTIFICATION FOR DEVIATIONS
ITS 3.2.2, TOTAL INTEGRATED RADIAL PEAKING FACTOR (F_r^T)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. ISTS SR 3.2.2.1 Note, deletes the term "full length" as related to control element assemblies (CEAs). Part length CEAs are not used at PSL Unit 1 and PSL Unit 2.

4. The ISTS includes ISTS 3.2.1, Linear Heat Rate (LHR), ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^T), ISTS 3.2.3, Total Integrated Radial Peaking Factor (F_r^T), ISTS 3.2.4, Azimuthal Power Tilt (T_q), and ISTS 3.2.5, Axial Shape Index (ASI). CTS do not include a Specification for ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^T). The CTS and ISTS are renumbered. CTS 3.2.3, Total Integrated Radial Peaking Factor (F_r^T), CTS 3.2.4, Azimuthal Power Tilt (T_q), and CTS 3.2.5, Axial Shape Index (ASI), are renumbered as ITS 3.2.2, ITS 3.2.3, and ITS 3.2.4, respectively.

5. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

B 3.2.~~3~~ (2) Total Integrated Radial Peaking Factor (F_r^T) ~~(F_{XY}^T) (Analog)~~

BASES

BACKGROUND

The purpose of this LCO (Total Integrated Radial Peaking Factor (F^T_r)) is to limit the core power distribution to the initial values assumed in the accident analyses. Operation within the limits imposed by this LCO either limits or prevents potential fuel cladding failures that could breach the primary fission product barrier and release fission products to the reactor coolant in the event of a loss of coolant accident (LOCA), loss of flow accident, ejected control element assembly (CEA) accident, or other postulated accident requiring termination by a Reactor Protection System trip function. This LCO limits the amount of damage to the fuel cladding during an accident by ensuring that the plant is operating within acceptable bounding conditions at the onset of a transient.

Methods of controlling the power distribution include:

a. The use of CEAs to alter the axial power distribution,

b. Decreasing CEA insertion by boration, thereby improving the radial power distribution, and

c. Correcting off optimum conditions (e.g., a CEA drop or misoperation of the unit) that cause margin degradations.

The core power distribution is controlled so that, in conjunction with other core operating parameters (e.g., CEA insertion and alignment limits), the power distribution does not result in violation of this LCO. The limiting safety system settings (LSSS) and this LCO are based on the accident analyses (Ref~~s~~. 1 ~~and 2~~), so that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences (AOOs), and the limits of acceptable consequences are not exceeded for other postulated accidents.

Limiting power distribution skewing over time also minimizes the xenon distribution skewing, which is a significant factor in controlling the axial power distribution.

Power distribution is a product of multiple parameters, various combinations of which may produce acceptable power distributions. Operation within the design limits of power distribution is accomplished by generating operating limits on the linear heat rate (LHR) and departure from nucleate boiling (DNB).

BACKGROUND (continued)

LINEAR HEAT RATE ( ) AZIMUTHAL POWER TILT ( )
AXIAL SHAPE INDEX ( )

The limits on LHR, ~~Total Planar Radial Peaking Factor (F_{XY}^T),~~ F_r^T, T_q, and ASI represent limits within which the LHR algorithms are valid. These limits are obtained directly from the core reload analysis. 4 1

Either of the two core power distribution monitoring systems, the Excore Detector Monitoring System or the Incore Detector Monitoring System, provide adequate monitoring of the core power distribution and ~~are~~ is capable of verifying that the LHR does not exceed its limits. The Excore Detector Monitoring System performs this function by continuously monitoring ~~the~~ ASI with the OPERABLE quadrant symmetric excore neutron flux detectors and verifying that the ASI is maintained within the allowable limits specified in the COLR. 1

In conjunction with the use of the Excore Detector Monitoring System and in establishing the ASI limits, the following conditions are assumed:

a. The CEA insertion limits of LCO 3.1.5, "Shutdown CEA Insertion Limits," and LCO 3.1.6, "Regulating CEA Insertion Limits," are satisfied,

b. The T_q restrictions of LCO 3.2.~~4~~ 3 are satisfied, and

c. ~~F_{xy}^T~~ F_r^T does not exceed the limits of LCO 3.2.2. 4

The Incore Detector Monitoring System continuously provides a more direct measure of the peaking factors, and the alarms established for the individual incore detector segments ensure that the peak LHRs are maintained within the limits specified in the COLR. The setpoints for these alarms include tolerances~~, set in conservative directions, for:~~ described in Reference 3. 3

~~a. A measurement calculational uncertainty factor of 1.062,~~

~~b. An engineering uncertainty factor of 1.03,~~

~~c. An allowance of 1.002 for axial fuel densification and thermal expansion, and~~

~~d. A THERMAL POWER measurement uncertainty factor of 1.02~~.

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition 1) and AOOs (Condition 2) (Ref. ~~3~~, GDC 10). The power distribution and CEA insertion and alignment LCOs preclude core power distributions that violate the following fuel design criteria: 4 1

a. During a LOCA, peak cladding temperature must not exceed 2200°F (Ref. ~~4~~), 1 5

b. During a loss of flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB condition (Ref. ~~3~~, GDC 10), 1 4

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. ~~[~~ ~~]~~), and 2 3 2

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. ~~3~~, GDC 26). 1 4

The power density at any point in the core must be limited to maintain the fuel design criteria (Ref. ~~4~~). This is accomplished by maintaining the power distribution and reactor coolant conditions so that the peak LHR and DNB parameters are within operating limits supported by the accident analyses (Ref. 1), with due regard for the correlations between measured quantities, the power distribution, and uncertainties in the determination of power distribution. 1 5

Fuel cladding failure during a LOCA is limited by restricting the maximum linear heat generation rate so that the peak cladding temperature does not exceed 2200°F (Ref. ~~4~~). High peak cladding temperatures are assumed to cause severe cladding failure by oxidation due to a Zircaloy water reaction. 1 5

The LCOs governing LHR, ASI, and the Reactor Coolant System ensure that these criteria are met as long as the core is operated within the ASI, ~~F_{XY}^T~~, and F_r^T limits specified in the COLR, and within the T_q limits. The latter are process variables that characterize the three dimensional power distribution of the reactor core. Operation within the limits for these variables ensures that their actual values are within the range used in the accident analysis. 4

BASES

APPLICABLE SAFETY ANALYSES (continued)

Fuel cladding damage does not normally occur while the reactor is operating at conditions outside the limits of these LCOs during normal operation. Fuel cladding damage could result, however, if an accident or AOO occurs from initial conditions outside the limits of these LCOs. This potential for fuel cladding damage exists because changes in the power distribution cause increased power peaking and correspondingly increased local LHR. 1

F^T_r satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO limits for certain power distribution are based on correlations between power peaking and measured variables used as inputs to LHR and DNB ratio operating limits. The LCO limits for power distribution, except T_q, are provided in the COLR. The limitation on the LHR ensures that, in the event of a LOCA, the peak temperature of the fuel cladding does not exceed 2200°F. 1

APPLICABILITY

In MODE 1, power distribution must be maintained within the limits assumed in the accident analysis to ensure that fuel damage does not result following an AOO. In other MODES, this LCO does not apply because ~~there~~ is not sufficient THERMAL POWER to require a limit on the core power distribution. 1

ACTIONS

A.1, A.2, and A.3

A Note modifying Condition A requires Required Actions A.1, A.2, and A.3 to be completed if the Condition is entered. This ensures that corrective action is taken prior to unrestricted operation.

The limitations on F_r^T provided in the COLR ensure that the assumptions used in the analysis for establishing the ASI, LCO, and LSSS remain valid during operation at the various allowable CEA group insertion limits. If F_r^T exceeds its basic limitation, operation may continue under the additional restrictions imposed by the Required Actions (reducing THERMAL POWER, withdrawing CEAs to or beyond the long term steady state insertion limits of LCO 3.1.6, and establishing a revised upper THERMAL POWER limit) because these additional restrictions provide adequate provisions to ensure that the assumptions used in establishing the LHR, LCO, and LSSS remain valid. Six hours to return F_r^T to within its limits by adjusting the ASI limits based on maximum power allowed for F^T_r ~~F^T_{XY}~~ is reasonable and ensures that all CEAs meet the long term steady state insertion limits of LCO 3.1.6. 4

ACTIONS (continued)

B.1

If F_r^T cannot be returned to within its limit, THERMAL POWER must be reduced. A change to MODE 2 provides reasonable assurance that the core is operating within its thermal limits and places the core in a conservative condition. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 2 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.~~3~~.1 (2) 5

The periodic Surveillance to determine the calculated F_r^T ensures that F_r^T remains within the range assumed in the analysis throughout the fuel cycle. Determining the measured F_r^T once after each fuel loading prior to exceeding 70% RTP ensures that the core is properly loaded.

~~[Performance of the Surveillance every 31 days of accumulated operation in MODE 1 provides reasonable assurance that unacceptable changes in the F_r^T are promptly detected.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~----------]~~

The power distribution map can only be obtained after THERMAL POWER exceeds 20% RTP because the incore detectors are not reliable below 20% RTP.

The SR is modified by a Note that requires SR 3.2.3.2 and SR 3.2.3.3 be completed each time SR 3.2.3.1 is completed. This procedure is required because the values computed by these SRs are required to perform this SR.

F_r^T is calculated by the expression $F_r^T = Fr\,(1 + Tq)$ when Fr is calculated with a non-full core power distribution analysis code and is calculated by the expression $F_r^T = Fr$ when calculations are performed with a full core power distribution analysis code. 6

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.2.~~3~~.2 and SR 3.2.~~3~~.3

Measuring the values of $F_r^{~~X~~}$ and T_q each time a value of F_r^T is calculated ensures that the calculated value of F_r^T accurately reflects the condition of the core.

The Frequency for these Surveillances is in accordance with the requirements of SR 3.2.~~3~~.1 because these SRs provide information to complete SR 3.2.2.1.

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition 1) and AOOs (Condition 2) (Ref. ~~3~~, GDC 10). The power distribution and CEA insertion and alignment LCOs preclude core power distributions that violate the following fuel design criteria: 4 1

a. During a LOCA, peak cladding temperature must not exceed 2200°F (Ref. ~~4~~), 1
5

b. During a loss of flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB condition (Ref. ~~3~~, GDC 10), 1
4

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. ~~[~~ ~~]~~), and 2
3 2

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. ~~3~~, GDC 26). 1
4

The power density at any point in the core must be limited to maintain the fuel design criteria (Ref. ~~4~~). This is accomplished by maintaining the power distribution and reactor coolant conditions so that the peak LHR and DNB parameters are within operating limits supported by the accident analyses (Ref. 1), with due regard for the correlations between measured quantities, the power distribution, and uncertainties in the determination of power distribution. 1
5

Fuel cladding failure during a LOCA is limited by restricting the maximum linear heat generation rate so that the peak cladding temperature does not exceed 2200°F (Ref. ~~4~~). High peak cladding temperatures are assumed to cause severe cladding failure by oxidation due to a Zircaloy water reaction. 1
5

The LCOs governing LHR, ASI, and the Reactor Coolant System ensure that these criteria are met as long as the core is operated within the ASI, ~~F_{XY}^T~~, and F_r^T limits specified in the COLR, and within the T_q limits. The latter are process variables that characterize the three dimensional power distribution of the reactor core. Operation within the limits for these variables ensures that their actual values are within the range used in the accident analysis. 4

BASES

APPLICABLE SAFETY ANALYSES (continued)

Fuel cladding damage does not normally occur while the reactor is operating at conditions outside the limits of these LCOs during normal operation. Fuel cladding damage could result, however, if an accident or AOO occurs from initial conditions outside the limits of these LCOs. This potential for fuel cladding damage exists because changes in the power distribution cause increased power peaking and correspondingly increased local LHR.

F^T_r satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO limits for certain power distribution are based on correlations between power peaking and measured variables used as inputs to LHR and DNB ratio operating limits. The LCO limits for power distribution, except T_q, are provided in the COLR. The limitation on the LHR ensures that, in the event of a LOCA, the peak temperature of the fuel cladding does not exceed 2200°F.

APPLICABILITY

In MODE 1, power distribution must be maintained within the limits assumed in the accident analysis to ensure that fuel damage does not result following an AOO. In other MODES, this LCO does not apply because ~~there~~ is not sufficient THERMAL POWER to require a limit on the core power distribution.

ACTIONS

A.1, A.2, and A.3

A Note modifying Condition A requires Required Actions A.1, A.2, and A.3 to be completed if the Condition is entered. This ensures that corrective action is taken prior to unrestricted operation.

The limitations on F_r^T provided in the COLR ensure that the assumptions used in the analysis for establishing the ASI, LCO, and LSSS remain valid during operation at the various allowable CEA group insertion limits. If F_r^T exceeds its basic limitation, operation may continue under the additional restrictions imposed by the Required Actions (reducing THERMAL POWER, withdrawing CEAs to or beyond the long term steady state insertion limits of LCO 3.1.6, and establishing a revised upper THERMAL POWER limit) because these additional restrictions provide adequate provisions to ensure that the assumptions used in establishing the LHR, LCO, and LSSS remain valid. Six hours to return F_r^T to within its limits by adjusting the ASI limits based on maximum power allowed for F_r^T ~~F^T_{XY}~~ is reasonable and ensures that all CEAs meet the long term steady state insertion limits of LCO 3.1.6.

BASES

ACTIONS (continued)

B.1

If F_r^T cannot be returned to within its limit, THERMAL POWER must be reduced. A change to MODE 2 provides reasonable assurance that the core is operating within its thermal limits and places the core in a conservative condition. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The ISTS contains tolerances to be applied to the incore detector alarm setpoints. PSL Unit 1 UFSAR, Section 13.8, Licensee-Controlled Technical Specification Requirements, and PSL Unit 2 UFSAR, Section 13.7, Licensee-Controlled Technical Specification Requirements, each contain these tolerances to be applied to the incore detector alarm setpoints. Additionally, these tolerances will be provided in the Technical Requirements Manual. Therefore, the tolerances to be applied to the incore detector alarm setpoints are deleted.

4. The ISTS includes ISTS 3.2.1, Linear Heat Rate (LHR), ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^T), ISTS 3.2.3, Total Integrated Radial Peaking Factor (F_r^T), ISTS 3.2.4, Azimuthal Power Tilt (T_q), and ISTS 3.2.5, Axial Shape Index (ASI). CTS do not include a Specification for ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^T). The CTS and ISTS are renumbered. CTS 3.2.3, Total Integrated Radial Peaking Factor (F_r^T), CTS 3.2.4, Azimuthal Power Tilt (T_q), and CTS 3.2.5, Axial Shape Index (ASI), are renumbered as ITS 3.2.2, ITS 3.2.3, and ITS 3.2.4, respectively.

5. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

6. CTS 4.2.3.2 and CTS 4.2.3.4 state details for calculating F_r^T with a non-full core power distribution analysis code and with a full core power distribution analysis code. ITS SR 3.2.2.1 and ITS SR 3.2.2.3 do not provide details for calculating F_r^T. This changes the CTS by relocating the details for calculating F_r^T to the ITS Bases. This change is acceptable since procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications and relocating these details to the ITS Bases.

DISCUSSION OF CHANGES
ITS 3.2.3, AZIMUTHAL POWER TILT (T_q)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS 3.2.4 Applicability is MODE 1 with a footnote (footnote *) for MODE 1 stating "See Special Test Exception 3.10.2." ITS 3.2.3 does not contain the footnote or a reference to the Special Test Exceptions. This changes the CTS by not including footnote * in the ITS.

The purpose of the footnote references is to alert the user that a Special Test Exception exists that may modify the Applicability of the Specification. It is an ITS convention to not include these types of footnotes or cross-references. This change is designated as administrative as it incorporates an ITS convention with no technical change to the CTS.

MORE RESTRICTIVE CHANGES

M01 CTS 4.2.4.1 states that the provisions of Specification 4.0.4 are not applicable, and thereby provides an allowance for entering the next higher MODE of Applicability when the Surveillance is not met. ITS 3.2.3 does not provide a Surveillance Note that states that the provisions of LCO 4.0.4 are not applicable. LCO 4.0.4 states that entry into a MODE or other specified condition in the Applicability of a Limiting Condition for Operation (LCO) shall only be made when the LCO's Surveillances have been met within their specified Frequency, except as provided by Surveillance Requirement 4.0.3. LCO 4.0.3 provides the provisions for a missed surveillance and does not apply to a surveillance known to not be met within its specified Frequency prior to entering the Mode of Applicability.

The purpose of CTS 4.2.4.1 is to provide an allowance for entering the MODE of applicability when any Surveillance is not met. The ITS MODE change is changed from MODE 1 to MODE 1 with THERMAL POWER > 50% RTP. See DOC L01 for a discussion of change regarding the MODE change from MODE 1, to MODE 1 with THERMAL POWER > 50% RTP. This change allows the performance of ITS 3.2.3.1 after entry into MODE 1 and up to 50% RTP. The ITS MODE change to MODE 1 with THERMAL POWER > 50% is less restrictive; however, the deletion of CTS 4.0.4 is solely a more restrictive change.

This change is designated as more restrictive because the CTS 4.0.4 MODE change allowance is deleted and entry into MODE 1 shall only be made when the LCO's surveillances have been met within their specified Frequency.

DISCUSSION OF CHANGES
ITS 3.2.3, AZIMUTHAL POWER TILT (T_q)

M02 CTS 3.2.4.a states that T_q be corrected within 2 hours or F_r^T be verified within limits within the next 2 hours and at least once per subsequent 8 hours. ITS 3.2.3 Condition A states that T_q be restored to ≤ 0.03 within 2 hours or F_r^T be verified within the limits of LCO 3.2.2 within 2 hours and once per 8 hours thereafter. CTS requires the first verification that F_r^T is within limits be completed within 4 hours. ITS requires the first verification that F_r^T is within limits be completed within 2 hours.

The purpose of CTS/ITS is to provide reasonable assurance that the core is operating within its thermal limits during power operation beyond 2 hours by verifying that F_r^T is within limits if T_q is not corrected. The change requires that for operation to continue beyond 2 hours with T_q > 0.03 and ≤ 0.10, F_r^T must be verified within limits within 2 hours. Two hours is sufficient time to allow the operator to reposition CEAs, and significant radial xenon redistribution cannot occur within this time. This change is consistent with the ISTS Required Action A.2 Completion Time.

This change is designated as more restrictive as it requires that with T_q > 0.03 and ≤ 0.10, the first verification that F_r^T is within limits be completed within 2 hours.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* CTS 3.2.4 states that the Applicability is MODE 1. ITS 3.2.3 states that the Applicability is MODE 1 with THERMAL POWER > 50% RTP. This changes the CTS by relaxing the Applicability to MODE 1 with THERMAL POWER > 50% RTP.

The purpose of CTS 3.2.4 Applicability is to state the MODE in which Tq must be maintained within the limits assumed in accident analysis to ensure that fuel damage does not result following an AOO. ITS 3.2.3 relaxes the Applicability to MODE 1 with THERMAL POWER > 50% RTP. CTS 4.2.4.1 states that the provisions of Specification 4.0.4 are not applicable, and thereby provides an allowance for entering the next higher MODE of Applicability with surveillances not met. ITS 3.2.3 Applicability of MODE 1 with THERMAL POWER > 50% RTP allows entry into MODE 1 with surveillances not met. See DOC M01 for the discussion of change for the MODE change.

This change limits the applicability of T_q to power operations with THERMAL POWER > 50% RTP. This change clarifies the applicability of the T_q, Azimuthal Power Tilt, consistent with the industry Standard Technical Specification (STS), approved by the NRC for generic use as NUREG-1432, Rev. 5.0, "Standard Technical Specifications - Combustion Engineering Plants" (ISTS). This change is acceptable because the LCO requirements applied in ITS MODE 1 continue to ensure process variables, structures, systems, and components are maintained in the conditions assumed in the safety analyses and licensing basis, and the proposed TS has been generically approved for industry usage.

In MODE 1 with THERMAL POWER > 50% RTP, T_q must be maintained within the limits assumed in accident analysis to ensure that fuel damage does not result following an anticipated operational occurrence (AOO). In other MODES, this LCO does not apply because THERMAL POWER is not sufficient to require a limit on T_q, and xenon transients generated within the lower power level range are not severe. In addition, significant margin to thermal limits exists at lower power levels and therefore thermal limits are not significantly challenged.

The power distribution and CEA insertion and alignment LCOs preclude core power distributions that violate the fuel design criteria. The core power distribution is controlled so that, in conjunction with other core operating parameters (e.g., CEA insertion and alignment limits), the power distribution does not result in violation of the power distribution LCOs, including ITS 3.2.3, T_q. This is accomplished by maintaining the power distribution and reactor coolant conditions so that the peak LHR and DNB parameters are within operating limits supported by the accident analysis.

PSL controls the AXIAL SHAPE INDEX (ASI) during startup, steady-state, and transients such as a dropped CEA. ASI COLR bands are applicable above 40% RTP while fuel conditioning ASI bands are applicable above 50% RTP. Axial shape control establishes and maintains axial shape within the fuel conditioning control bands prior to exceeding 50% RTP. The intent of the fuel preconditioning guidelines is to minimize fuel pellet / clad interaction and maximize fuel rod integrity. When THERMAL POWER is ≥ 50 RTP, boration or dilution is the primary means to compensate for changes in power level and transient xenon. Using boration/dilution to compensate for power changes subjects the fuel rods to uniform and smooth power transients. Regulating Group CEAs are used to respond deviations of ASI from its target equilibrium shape index.

This change is designated as less restrictive because the LCO requirements will not be applied under plant conditions in which they would be applied under the CTS.

L02 *(Category 4 – Relaxation of Required Action)* CTS 3.2.4 Action b. states, in part, “with in the indicated Azimuthal Power Tilt determined to be > 0.10 operation may proceed for up to 2 hours”. CTS 3.2.4 CTS 3.2.4.b states, in part, the subsequent operation be “≤ 20% of the maximum allowable THERMAL POWER level for the existing Reactor Coolant Pump combination.” PSL only operates in the four reactor coolant pump combination; therefore, subsequent operation is allowable provided the THERMAL POWER is reduced to ≤ 20% RTP – the

equivalent THERMAL POWER for the CTS. ITS Required Action B.2 states "Restore T_q to ≤ 0.10 within 2 hours. If T_q is not restored to ≤ 0.10 within 2 hours, Required Action C.1 requires reducing THERMAL POWER to the ≤ 50% RTP within 4 hours. See DOC L01 for a discussion of change regarding the ITS MODE change from MODE 1, to MODE 1 with THERMAL POWER > 50% RTP.

The purpose of CTS 3.2.4 Action b. is to reduce THERMAL POWER to ≤ 20% if T_q is not restored to ≤ 0.10 within 2 hours. ITS requires that with T_q not restored to ≤ 0.10 within 2 hours, reduce THERMAL POWER to the ≤ 50% RTP within 4 hours.

This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.2.3, AZIMUTHAL POWER TILT (T_q)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The ISTS includes ISTS 3.2.1, Linear Heat Rate (LHR), ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^T), ISTS 3.2.3, Total Integrated Radial Peaking Factor (F_r^T), ISTS 3.2.4, Azimuthal Power Tilt (T_q), and ISTS 3.2.5, Axial Shape Index (ASI). CTS do not include a Specification for ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^T). The CTS and ISTS are renumbered. CTS 3.2.3, Total Integrated Radial Peaking Factor (F_r^T), CTS 3.2.4, Azimuthal Power Tilt (T_q), and CTS 3.2.5, Axial Shape Index (ASI), are renumbered as ITS 3.2.2, ITS 3.2.3, and ITS 3.2.4, respectively.

4. ISTS Condition B is renumbered as ITS Condition C, and ISTS Condition C is renumbered as ITS Condition B. ITS Condition C deletes the verbiage "of Condition A" so ITS Condition C and Required Action C.1 apply to both ITS Condition A and ITS Condition B.

5. CTS 3.2.4.b allows operation for up to 2 hours with $T_q > 0.10$ provided F_r^T is verified within limits. ISTS Required Action C.3 (renumbered as ITS Required Action B.2) is changed to restore T_q to ≤ 0.10 with a Completion Time of 2 hours. ISTS Required Action C.2 is deleted since this action is moved to ITS Condition C and ITS Required Action C.1. This change is like Calvert Cliffs – Unit 1, Calvert Cliffs – Unit 2 Improved Technical Specifications (ADAMS Accession No. ML052720276). JFD-4 changes ISTS Condition B to Condition C.

   If the Required Actions and associated Completion Times of ITS Condition A or Condition B are not met, Condition C must be entered. ITS Required Action C.1 requires a reduction in THERMAL POWER to ≤ 50% RTP within 4 hours. If the T_q cannot be restored to within its specified limit, THERMAL POWER must be reduced. The reduction in THERMAL POWER to ≤ 50% RTP provides reasonable assurance that the core is operating within its thermal limits and places the core in a conservative condition.

6. ISTS Condition C Required Actions are modified by a Note that requires all subsequent actions to be performed once power reduction commences after entering the Condition if Tq is not restored to < 0.10. This Note is deleted.

   ISTS Required Action C.3 is modified with a Note to indicate that the cause of the out of limit condition must be corrected prior to increasing THERMAL POWER, and that subsequent power operation may proceed provided that the measured Tq is verified within its limit at least once per hour for 12 hours, or until verified at 95% RTP. This Note is deleted.

If ITS Required Action B.1 or Required Action B.2 is not met within its associated Completion Time, ITS Required Action C.1 requires a reduction in THERMAL POWER to ≤ 50% RTP within 4 hours. If F_r^T is verified within limits within 1 hour, and T_q is restored to ≤ 0.10 with 2 hours, Condition A is entered, and the Required Actions are taken. If the Condition A Required Actions are not met, ITS Required Action C.1 requires a reduction in THERMAL POWER to ≤ 50% RTP within 4 hours. The reduction in THERMAL POWER to ≤ 50% RTP provides reasonable assurance that the core is operating within its thermal limits and places the core in a conservative condition.

7. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.2 POWER DISTRIBUTION LIMITS ~~(Analog)~~

B 3.2.~~4~~ AZIMUTHAL POWER TILT (T_q) ~~(Analog)~~

BASES

BACKGROUND

The purpose of this LCO (AZIMUTHAL POWER TILT (T_q)) is to limit the core power distribution to the initial values assumed in the accident analyses. Operation within the limits imposed by this LCO limits or prevents potential fuel cladding failures that could breach the primary fission product barrier and release fission products to the reactor coolant in the event of a loss of coolant accident (LOCA), loss of flow accident, ejected control element assembly (CEA) accident, or other postulated accident requiring termination by a Reactor Protection System trip function. This LCO limits the amount of damage to the fuel cladding during an accident by ensuring that the plant is operating within acceptable bounding conditions at the onset of a transient.

Methods of controlling the power distribution include:

a. Using CEAs to alter the axial power distribution,

b. Decreasing CEA insertion by boration, thereby improving the radial power distribution, and

c. Correcting off optimum conditions (e.g., a CEA drop or misoperation of the unit) that cause margin degradations.

The core power distribution is controlled so that, in conjunction with other core operating parameters (e.g., CEA insertion and alignment limits), the power distribution does not result in violation of this LCO. The limiting safety system settings and this LCO are based on the accident analyses (Ref~~s~~. 1 ~~and 2~~), so that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences (AOOs), and the limits of acceptable consequences are not exceeded for other postulated accidents.

Limiting power distribution skewing over time also minimizes the xenon distribution skewing, which is a significant factor in controlling the axial power distribution.

Power distribution is a product of multiple parameters, various combinations of which may produce acceptable power distributions. Operation within the design limits of power distribution is accomplished by generating operating limits for linear heat rate (LHR) and departure from nucleate boiling (DNB).

BACKGROUND (continued)

The limits on LHR, ~~Total Planar Radial Peaking Factor (F_{XY}^T),~~ Total Integrated Radial Peaking Factor (F_r^T), T_q, and ASI represent limits within which the LHR algorithms are valid. These limits are obtained directly from the core reload analysis.

Either of the two core power distribution monitoring systems, the Excore Detector Monitoring System or the Incore Detector Monitoring System, provides adequate monitoring of the core power distribution and is capable of verifying that the LCO limits are not exceeded. The Excore Detector Monitoring System performs this function by continuously monitoring ASI with OPERABLE quadrant symmetric excore neutron detectors and by verifying ASI is maintained within the limits specified in the COLR.

In conjunction with the use of the Excore Detector Monitoring System and in establishing the ASI limits, the following assumptions are made:

a. The CEA insertion limits of LCO 3.1.5, "Shutdown CEA Insertion Limits," and LCO 3.1.6, "Regulating CEA Insertion Limits," are satisfied,

b. The T_q restrictions of LCO 3.2.~~4~~ are satisfied, and

c. ~~F_{xy}^T~~ F_r^T does not exceed the limits of LCO 3.2.2.

The Incore Detector Monitoring System continuously provides a more direct measure of the peaking factors, and the alarms ~~that have been~~ established for the individual incore detector segments ensure that the peak LHRs are maintained within the limits specified in the COLR. The setpoints for these alarms include tolerances~~, set in conservative directions, for:~~ described in Reference 3.

~~a. A measurement calculational uncertainty factor of 1.062,~~

~~b. An engineering uncertainty factor of 1.03,~~

~~c. An allowance of 1.002 for axial fuel densification and thermal expansion, and~~

~~d. A THERMAL POWER measurement uncertainty factor of 1.02~~.

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition 1) or AOOs (Condition 2) (Ref. ~~3~~, GDC 10). The power distribution and CEA insertion and alignment LCOs preclude core power distributions that violate the following fuel design criteria:

a. During a LOCA, peak cladding temperature must not exceed 2200°F (Ref. ~~4~~),

b. During a loss of flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB condition (Ref. ~~3~~, GDC 10),

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. ~~[ ]~~), and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. ~~3~~, GDC 26).

The power density at any point in the core must be limited to maintain the fuel design criteria (Ref. ~~4~~). This process is accomplished by maintaining the power distribution and reactor coolant conditions so that the peak LHR and DNB parameters are within operating limits supported by the accident analysis (Ref. 1) with due regard for the correlations between measured quantities, the power distribution, and uncertainties in determining the power distribution.

Fuel cladding failure during a LOCA is limited by restricting the maximum linear heat generation rate ~~(LHGR)~~ so that the peak cladding temperature does not exceed 2200°F (Ref. ~~4~~). High peak cladding temperatures are assumed to cause severe cladding failure by oxidation due to a Zircaloy water reaction.

The LCOs governing LHR, ASI, and the Reactor Coolant System ensure that these criteria are met as long as the core is operated within the ASI~~,~~ ~~F_{XY}^T~~, and F_r^T limits specified in the COLR, and within the T_q limits. The latter are process variables that characterize the three dimensional power distribution of the reactor core. Operation within the limits for these variables ensures that their actual values are within the range used in the accident analyses.

BASES

APPLICABLE SAFETY ANALYSES (continued)

This potential for fuel cladding damage exists because

Fuel cladding damage does not normally occur while the reactor is operating at conditions outside these LCOs during ~~otherwise~~ normal operation. Fuel cladding damage could result, however, if an accident or AOO occurs from initial conditions outside the limits of these LCOs. Changes in the power distribution cause increased power peaking and correspondingly increased local LHRs.

The T_q satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

certain

The power distribution LCO limits are based on correlations between power peaking and ~~the~~ measured variables used as inputs to the LHR and DNB operating limits. The power distribution LCO limits, except T_q, are provided in the COLR. The limits on LHR ensure that in the event of a LOCA, the peak temperature of the fuel cladding does not exceed 2200°F.

APPLICABILITY

In MODE 1 with THERMAL POWER > 50% RTP, T_q must be maintained within the limits assumed in accident analysis to ensure that fuel damage does not result following an AOO. In other MODES, this LCO does not apply because THERMAL POWER is not sufficient to require a limit on T_q.

ACTIONS

A.1 and A.2

≤

within 2 hours

If the measured T_q is > ~~[~~0.03~~]~~ and ~~<~~ 0.10, the calculation of T_q may be nonconservative. T_q must be restored within 2 hours or F^T_{XY} ~~and~~ F^T_r must be determined to be within the limits of LCO 3.2.2 ~~and LCO 3.2.3~~, and determined to be within these limits every 8 hours thereafter, as long as T_q is out of limits. Two hours is sufficient time to allow the operator to reposition CEAs, and significant radial xenon redistribution cannot occur within this time. The 8 hour Completion Time ensures changes in F^T_{XY} ~~and~~ F^T_r can be identified before the limits of LCO 3.2.2 ~~and LCO 3.2.3, respectively,~~ are exceeded.

C

~~B~~.1

conservative protection from increased peaking due to potential xenon redistribution and

or B

If Required Actions and associated Completion Times of Condition A are not met, THERMAL POWER must be reduced to ≤ 50% RTP. This requirement provides reasonable assurance that the core is operating within its thermal limits ~~and places the core in a conservative condition~~. Four hours is a reasonable time to reach 50% RTP in an orderly manner and without challenging plant systems.

BASES

ACTIONS (continued)

~~C~~.1, ~~C.2,~~ and ~~C.3~~

With T_q > 0.10, ~~F^T_{XY} and~~ F^T_r must be within ~~their~~ specified limits to ensure that acceptable flux peaking factors are maintained. Based on operating experience, 1 hour is sufficient time for the operator to evaluate these factors. If ~~F^T_{XY} and~~ F^T_r ~~are~~ within limits, operation may proceed for a total of 2 hours after the Condition is entered while attempts are made to restore T_q to within its limit.

If T_q ≤ 0.10 cannot be achieved, power must be reduced to ≤ 50% RTP within ~~2~~ hours. ~~If the tilt is generated due to a CEA misalignment, operating at ≤ 50% RTP allows for the recovery of the CEA. Except as a result of CEA misalignment, T_q > 0.10 is not expected; if it occurs, continued operation of the reactor may be necessary to discover the cause of the tilt. If this procedure is followed, operation is restricted to only those conditions required to identify the cause of the tilt. It is necessary to account explicitly for power asymmetries because the radial power peaking factors used in core power distribution calculations are based on an untilted power distribution.~~

~~If T_q is not restored to within its limits,~~ the reactor continues to operate with an axial power distribution mismatch. Continued operation in this configuration may induce an axial xenon oscillation that causes increased LHRs when the xenon redistributes. ~~If T_q cannot be restored to within its limits within 2 hours, reactor power must be reduced.~~ Reducing THERMAL POWER to ≤ 50% RTP within ~~2~~ hours provides conservative protection from increased peaking due to potential xenon redistribution. ~~The Required Actions are modified by a Note that requires all subsequent actions to be performed once power reduction commences after entering the Condition if T_q is not restored to < 0.10. This procedure ensures corrective action is taken before unrestricted power operation resumes. Following THERMAL POWER reduction to ≤ 50% RTP, T_q must be restored to ≤ [0.03] before THERMAL POWER is increased (Required Action C.3). This Required Action prevents the operator from increasing THERMAL POWER above the conservative limit when the Condition, T_q outside its limits, has existed but allows the unit to continue operation for diagnostic purposes. The Completion Time of Required Action C.3 is modified with a Note to indicate that the cause of the out of limit condition must be corrected prior to increasing THERMAL POWER. This Note also indicates that subsequent power operation above 50% RTP may proceed provided that the measured T_q is verified ≤ [0.03] at least once per hour for 12 hours, or until verified at 95% RTP. This ensures that the power distribution is responding as predicted. The Completion Time of 12 hours is a historical value that allows an acceptable exit from the LCO after the T_q value is verified acceptable for 12 hours or until 95% RTP is reached.~~

BASES

SURVEILLANCE REQUIREMENTS

SR 3.2.~~4~~.1

~~[T_q must be calculated at 12 hour intervals. The 12 hour Frequency prevents significant xenon redistribution between Surveillances.~~

~~OR~~

Tq must be determined at 12 hour intervals when the subchannel deviation alarm is inoperable, and at 12 hour intervals when one excore detector is inoperable and > 75% RTP.

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

B 3.2 POWER DISTRIBUTION LIMITS ~~(Analog)~~

B 3.2.~~4~~ AZIMUTHAL POWER TILT (T_q) ~~(Analog)~~

BASES

BACKGROUND

The purpose of this LCO (AZIMUTHAL POWER TILT (T_q)) is to limit the core power distribution to the initial values assumed in the accident analyses. Operation within the limits imposed by this LCO limits or prevents potential fuel cladding failures that could breach the primary fission product barrier and release fission products to the reactor coolant in the event of a loss of coolant accident (LOCA), loss of flow accident, ejected control element assembly (CEA) accident, or other postulated accident requiring termination by a Reactor Protection System trip function. This LCO limits the amount of damage to the fuel cladding during an accident by ensuring that the plant is operating within acceptable bounding conditions at the onset of a transient.

Methods of controlling the power distribution include:

a. Using CEAs to alter the axial power distribution,

b. Decreasing CEA insertion by boration, thereby improving the radial power distribution, and

c. Correcting off optimum conditions (e.g., a CEA drop or misoperation of the unit) that cause margin degradations.

The core power distribution is controlled so that, in conjunction with other core operating parameters (e.g., CEA insertion and alignment limits), the power distribution does not result in violation of this LCO. The limiting safety system settings and this LCO are based on the accident analyses (Ref~~s~~. 1 ~~and 2~~), so that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences (AOOs), and the limits of acceptable consequences are not exceeded for other postulated accidents.

Limiting power distribution skewing over time also minimizes the xenon distribution skewing, which is a significant factor in controlling the axial power distribution.

Power distribution is a product of multiple parameters, various combinations of which may produce acceptable power distributions. Operation within the design limits of power distribution is accomplished by generating operating limits for linear heat rate (LHR) and departure from nucleate boiling (DNB).

BASES

BACKGROUND (continued)

LINEAR HEAT RATE ( ) AXIAL SHAPE INDEX ( )

The limits on LHR, ~~Total Planar Radial Peaking Factor (F_{XY}^T),~~ Total Integrated Radial Peaking Factor (F_r^T), T_q, and ASI represent limits within which the LHR algorithms are valid. These limits are obtained directly from the core reload analysis.

4
1

Either of the two core power distribution monitoring systems, the Excore Detector Monitoring System or the Incore Detector Monitoring System, provides adequate monitoring of the core power distribution and is capable of verifying that the LCO limits are not exceeded. The Excore Detector Monitoring System performs this function by continuously monitoring ASI with OPERABLE quadrant symmetric excore neutron detectors and by verifying ASI is maintained within the limits specified in the COLR.

In conjunction with the use of the Excore Detector Monitoring System and in establishing the ASI limits, the following assumptions are made:

a. The CEA insertion limits of LCO 3.1.5, "Shutdown CEA Insertion Limits," and LCO 3.1.6, "Regulating CEA Insertion Limits," are satisfied,

b. The T_q restrictions of LCO 3.2.~~4~~ 3 are satisfied, and

4
4

c. ~~F_{xy}^T~~ F_r^T does not exceed the limits of LCO 3.2.2.

The Incore Detector Monitoring System continuously provides a more direct measure of the peaking factors, and the alarms ~~that have been~~ established for the individual incore detector segments ensure that the peak LHRs are maintained within the limits specified in the COLR. The setpoints for these alarms include tolerances~~, set in conservative directions, for:~~ described in Reference 3.

1

3

~~a. A measurement calculational uncertainty factor of 1.062,~~

~~b. An engineering uncertainty factor of 1.03,~~

~~c. An allowance of 1.002 for axial fuel densification and thermal expansion, and~~

~~d. A THERMAL POWER measurement uncertainty factor of 1.02.~~

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition 1) or AOOs (Condition 2) (Ref. ~~3~~, GDC 10). The power distribution and CEA insertion and alignment LCOs preclude core power distributions that violate the following fuel design criteria:

a. During a LOCA, peak cladding temperature must not exceed 2200°F (Ref. ~~4~~),

b. During a loss of flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB condition (Ref. ~~3~~, GDC 10),

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. ~~[~~ ~~]~~), and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. ~~3~~, GDC 26).

The power density at any point in the core must be limited to maintain the fuel design criteria (Ref. ~~4~~). This process is accomplished by maintaining the power distribution and reactor coolant conditions so that the peak LHR and DNB parameters are within operating limits supported by the accident analysis (Ref. 1) with due regard for the correlations between measured quantities, the power distribution, and uncertainties in determining the power distribution.

Fuel cladding failure during a LOCA is limited by restricting the maximum linear heat generation rate ~~(LHGR)~~ so that the peak cladding temperature does not exceed 2200°F (Ref. ~~4~~). High peak cladding temperatures are assumed to cause severe cladding failure by oxidation due to a Zircaloy water reaction.

The LCOs governing LHR, ASI, and the Reactor Coolant System ensure that these criteria are met as long as the core is operated within the ASI~~,~~ F_{xy}^T~~,~~ and F_r^T limits specified in the COLR, and within the T_q limits. The latter are process variables that characterize the three dimensional power distribution of the reactor core. Operation within the limits for these variables ensures that their actual values are within the range used in the accident analyses.

BASES

APPLICABLE SAFETY ANALYSES (continued)

This potential for fuel cladding damage exists because

Fuel cladding damage does not normally occur while the reactor is operating at conditions outside these LCOs during ~~otherwise~~ normal operation. Fuel cladding damage could result, however, if an accident or AOO occurs from initial conditions outside the limits of these LCOs. Changes in the power distribution cause increased power peaking and correspondingly increased local LHRs.

The T_q satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

certain

The power distribution LCO limits are based on correlations between power peaking and ~~the~~ measured variables used as inputs to the LHR and DNB operating limits. The power distribution LCO limits, except T_q, are provided in the COLR. The limits on LHR ensure that in the event of a LOCA, the peak temperature of the fuel cladding does not exceed 2200°F.

APPLICABILITY

In MODE 1 with THERMAL POWER > 50% RTP, T_q must be maintained within the limits assumed in accident analysis to ensure that fuel damage does not result following an AOO. In other MODES, this LCO does not apply because THERMAL POWER is not sufficient to require a limit on T_q.

ACTIONS

A.1 and A.2

≤

within 2 hours

If the measured T_q is > ~~[~~0.03~~]~~ and ~~<~~ 0.10, the calculation of T_q may be nonconservative. T_q must be restored within 2 hours or F^T_{XY} ~~and~~ F^T_r must be determined to be within the limits of LCO 3.2.2 ~~and LCO 3.2.3~~, and determined to be within these limits every 8 hours thereafter, as long as T_q is out of limits. Two hours is sufficient time to allow the operator to reposition CEAs, and significant radial xenon redistribution cannot occur within this time. The 8 hour Completion Time ensures changes in F^T_{XY} ~~and~~ F^T_r can be identified before the limits of LCO 3.2.2 ~~and LCO 3.2.3, respectively,~~ are exceeded.

C

~~B~~.1

conservative protection from increased peaking due to potential xenon redistribution and

or B

If Required Actions and associated Completion Times of Condition A are not met, THERMAL POWER must be reduced to ≤ 50% RTP. This requirement provides reasonable assurance that the core is operating within its thermal limits ~~and places the core in a conservative condition~~. Four hours is a reasonable time to reach 50% RTP in an orderly manner and without challenging plant systems.

BASES

ACTIONS (continued)

~~C~~.1, ~~C.2,~~ and ~~C.3~~

With T_q > 0.10, F^T_{XY} ~~and~~ F^T_r must be within ~~their~~ specified limits to ensure that acceptable flux peaking factors are maintained. Based on operating experience, 1 hour is sufficient time for the operator to evaluate these factors. If F^T_{XY} ~~and~~ F^T_r ~~are~~ within limits, operation may proceed for a total of 2 hours after the Condition is entered while attempts are made to restore T_q to within its limit.

If T_q ≤ 0.10 cannot be achieved, power must be reduced to ≤ 50% RTP within ~~2~~ hours. ~~If the tilt is generated due to a CEA misalignment, operating at ≤ 50% RTP allows for the recovery of the CEA. Except as a result of CEA misalignment, T_q > 0.10 is not expected; if it occurs, continued operation of the reactor may be necessary to discover the cause of the tilt. If this procedure is followed, operation is restricted to only those conditions required to identify the cause of the tilt. It is necessary to account explicitly for power asymmetries because the radial power peaking factors used in core power distribution calculations are based on an untilted power distribution.~~

~~If T_q is not restored to within its limits,~~ the reactor continues to operate with an axial power distribution mismatch. Continued operation in this configuration may induce an axial xenon oscillation that causes increased LHRs when the xenon redistributes. ~~If T_q cannot be restored to within its limits within 2 hours, reactor power must be reduced.~~ Reducing THERMAL POWER to ≤ 50% RTP within ~~2~~ hours provides conservative protection from increased peaking due to potential xenon redistribution. ~~The Required Actions are modified by a Note that requires all subsequent actions to be performed once power reduction commences after entering the Condition if T_q is not restored to < 0.10. This procedure ensures corrective action is taken before unrestricted power operation resumes. Following THERMAL POWER reduction to ≤ 50% RTP, T_q must be restored to ≤ [0.03] before THERMAL POWER is increased (Required Action C.3). This Required Action prevents the operator from increasing THERMAL POWER above the conservative limit when the Condition, T_q outside its limits, has existed but allows the unit to continue operation for diagnostic purposes. The Completion Time of Required Action C.3 is modified with a Note to indicate that the cause of the out of limit condition must be corrected prior to increasing THERMAL POWER. This Note also indicates that subsequent power operation above 50% RTP may proceed provided that the measured T_q is verified ≤ [0.03] at least once per hour for 12 hours, or until verified at 95% RTP. This ensures that the power distribution is responding as predicted. The Completion Time of 12 hours is a historical value that allows an acceptable exit from the LCO after the T_q value is verified acceptable for 12 hours or until 95% RTP is reached.~~

JUSTIFICATION FOR DEVIATIONS
ITS 3.2.3, BASES, AZIMUTHAL POWER TILT (T_q)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The ISTS contains tolerances to be applied to the incore detector alarm setpoints. PSL Unit 1 UFSAR, Section 13.8, Licensee-Controlled Technical Specification Requirements, and PSL Unit 2 UFSAR, Section 13.7, Licensee-Controlled Technical Specification Requirements, each contain these tolerances to be applied to the incore detector alarm setpoints. Additionally, these tolerances will be provided in the Technical Requirements Manual. Therefore, the tolerances to be applied to the incore detector alarm setpoints are deleted.

4. The ISTS includes ISTS 3.2.1, Linear Heat Rate (LHR), ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^T), ISTS 3.2.3, Total Integrated Radial Peaking Factor (F_r^T), ISTS 3.2.4, Azimuthal Power Tilt (T_q), and ISTS 3.2.5, Axial Shape Index (ASI). CTS do not include a Specification for ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^T). The CTS and ISTS are renumbered. CTS 3.2.3, Total Integrated Radial Peaking Factor (F_r^T), CTS 3.2.4, Azimuthal Power Tilt (T_q), and CTS 3.2.5, Axial Shape Index (ASI), are renumbered as ITS 3.2.2, ITS 3.2.3, and ITS 3.2.4, respectively.

5. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

6. ISTS Condition B is renumbered as ITS Condition C, and ISTS Condition C is renumbered as ITS Condition B. ITS Condition C deletes the verbiage “of Condition A” so ITS Condition C and Required Action C.1 apply to both ITS Condition A and ITS Condition B.

7. ISTS Bases Actions C.1, C.2, and C.3 changes support the CTS 3.2.4 and ITS 3.2.3 changes.

DISCUSSION OF CHANGES
ITS 3.2.4, AXIAL SHAPE INDEX (ASI)

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

None

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

None

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* CTS 3.2.5 states that the Applicability is MODE 1 and when the LCO is not met, the actions require restoring the parameter within 2 hours or reducing THERMAL POWER to ≤ 5% of RATED THERMAL POWER (i.e, MODE 2) within the next 4 hours. ITS 3.2.4 states that the Applicability is MODE 1 with THERMAL POWER ≥ 40% RTP and the Required Actions are consistent with CTS except THERMAL is reduced to < 40% RTP, which results placing the unit in a condition where ASI no longer applies. This changes the CTS by relaxing the Applicability to MODE 1 with THERMAL POWER ≥ 40% RTP and corresponding change to only require THERMAL POWER to be reduced < 40% RTP consistent with the revised Applicability.

The purpose of CTS 3.2.5 Applicability and ITS 3.2.4 Applicability is to establish the plant conditions where ASI is assumed in the safety analysis. PSL Unit 1 and Unit 2 safety analysis apply ASI at ≥ 40% RTP. The ASI limits curve specified in the COLR also explicitly state that the limits do not apply below 40% RTP. Therefore, below 40% RTP, the ASI power distribution limit is not applicable. Other limits assumed in the accident analysis ensure fuel damage does not occur below 40% RTP (e.g., linear heat rate (LHR) limit, power dependent rod insertion limits, CEA alignment, sequence, and overlap limits, and reactor coolant conditions; pressure, temperature, flow). The power distribution limits are based on correlations between power peaking and certain measured variables used as

inputs to the LHR and DNB operating limits. The limitation on ASI, along with the limitations of LCO 3.3.1, "Reactor Protection System Instrumentation," represents a conservative envelope of operating conditions consistent with the assumptions that have been analytically demonstrated adequate for maintaining an acceptable minimum DNBR throughout all AOOs.

This change is acceptable because the LCO requirements applied in the ITS Applicability continues to ensure process variables, structures, systems, and components are maintained in the conditions assumed in the safety analyses and licensing basis. In MODE 1 with THERMAL POWER ≥ 40% RTP, ASI must be maintained within the power distribution limits assumed in the accident analyses to ensure that fuel damage does not result following an AOO. In MODE 1 with THERMAL POWER < 40% RTP, THERMAL POWER is not sufficient to require a limit on ASI power distribution.

This change is designated as less restrictive because the LCO requirements will not be applied under plant conditions in which they would be applied under the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.2.4, AXIAL SHAPE INDEX (ASI)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The ISTS includes ISTS 3.2.1, Linear Heat Rate (LHR), ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^{T}), ISTS 3.2.3, Total Integrated Radial Peaking Factor (F_{r}^{T}), ISTS 3.2.4, Azimuthal Power Tilt (T_q), and ISTS 3.2.5, Axial Shape Index (ASI). CTS do not include a Specification for ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^{T}). The CTS and ISTS are renumbered. CTS 3.2.3, Total Integrated Radial Peaking Factor (F_{r}^{T}), CTS 3.2.4, Azimuthal Power Tilt (T_q), and CTS 3.2.5, Axial Shape Index (ASI), are renumbered as ITS 3.2.2, ITS 3.2.3, and ITS 3.2.4, respectively.

4. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

5. ISTS 3.2.5 (renumbered as ITS 3.2.4) Applicability and Required Action B.1 are changed to reflect relaxing the CTS Applicability. ITS 3.2.4 Applicability is MODE 1 with THERMAL POWER ≥ 40% RTP. This changes the CTS by relaxing the Applicability from MODE 1, to MODE 1 with THERMAL POWER ≥ 40% RTP. See DOC L01 for a discussion of changes for relaxing the CTS Applicability.

B 3.2 POWER DISTRIBUTION LIMITS ~~(Analog)~~

5

B 3.2.~~5~~ AXIAL SHAPE INDEX (ASI) ~~(Analog)~~

4

4

BASES

BACKGROUND

The purpose of this LCO (AXIAL SHAPE INDEX (ASI)) is to limit the core power distribution to the initial values assumed in the accident analysis. Operation within the limits imposed by this LCO either limits or prevents potential fuel cladding failures that could breach the primary fission product barrier and release fission products to the reactor coolant in the event of a loss of coolant accident (LOCA), loss of flow accident, ejected control element assembly (CEA) accident, or other postulated accident requiring termination by a Reactor Protection System trip function. This LCO limits the amount of damage to the fuel cladding during an accident by ensuring that the plant is operating within acceptable bounding conditions at the onset of a transient.

Methods of controlling the power distribution include:

a. Using CEAs to alter the axial power distribution,

b. Decreasing CEA insertion by boration, thereby improving the radial power distribution, and

c. Correcting off optimum conditions (e.g., a CEA drop or misoperation of the unit) that cause margin degradations.

The core power distribution is controlled so that, in conjunction with other core operating parameters (e.g., CEA insertion and alignment limits), the power distribution does not result in violation of this LCO. The limiting safety system settings and this LCO are based on the accident analyses (Ref~~s~~. 1 ~~and 2~~), so that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences (AOOs), and the limits of acceptable consequences are not exceeded for other postulated accidents.

1

Limiting power distribution skewing over time also minimizes the xenon distribution skewing, which is a significant factor in controlling the axial power distribution.

Power distribution is a product of multiple parameters, various combinations of which may produce acceptable power distributions. Operation within the design limits of power distribution is accomplished by generating operating limits on linear heat rate (LHR) and departure from nucleate boiling (DNB).

BASES

BACKGROUND (continued)

The limits on LHR, ~~Total Planar Radial Peaking Factor (F_{XY}^T),~~ Total Integrated Radial Peaking Factor (F_r^T), T_q, and ASI represent limits within which the LHR algorithms are valid. These limits are obtained directly from the core reload analysis.

Either of the two core power distribution monitoring systems, the Excore Detector Monitoring System and the Incore Detector Monitoring System, provide adequate monitoring of the core power distribution and ~~are~~ is capable of verifying that the LHR does not exceed its limits. The Excore Detector Monitoring System performs this function by continuously monitoring ~~the~~ ASI with the OPERABLE quadrant symmetric excore neutron flux detectors and verifying that the ASI is maintained within the allowable limits specified in the COLR.

In conjunction with the use of the Excore Detector Monitoring System and in establishing the ASI limits, the following conditions are assumed:

a. The CEA insertion limits of LCO 3.1.5, "Shutdown CEA Insertion Limits," and LCO 3.1.6, "Regulating CEA Insertion Limits," are satisfied,

b. The T_q restrictions of LCO 3.2.~~4~~ are satisfied, and

c. ~~F_{xy}^T~~ F_r^T does not exceed the limits of LCO 3.2.2.

The Incore Detector Monitoring System continuously provides a more direct measure of the peaking factors, and the alarms ~~that have been~~ established for the individual incore detector segments ensure that the peak LHR is maintained within the limits specified in the COLR. The setpoints for these alarms include tolerances~~, set in conservative directions, as follows:~~ described in Reference 3.

~~a. A measurement calculational uncertainty factor of 1.062,~~

~~b. An engineering uncertainty factor of 1.03,~~

~~c. An allowance of 1.002 for axial fuel densification and thermal expansion, and~~

~~d. A THERMAL POWER measurement uncertainty factor of 1.02.~~

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition 1) or AOOs (Condition 2) (Ref. ~~3~~, GDC 10). The power distribution and CEA insertion and alignment LCOs prevent core power distributions ~~from reaching levels~~ that violate the following fuel design criteria:

a. During a LOCA, peak cladding temperature must not exceed 2200°F (Ref. ~~4~~),

b. During a loss of flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB condition (Ref. ~~3~~, GDC 10),

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. ~~[ ]~~), and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. ~~3~~, GDC 26).

The power density at any point in the core must be limited to maintain the fuel design criteria (Ref. ~~4~~). This limitation is accomplished by maintaining the power distribution and reactor coolant conditions so that the peak LHR and DNB parameters are within operating limits supported by the accident analyses (Ref. 1) with due regard for the correlations ~~among~~ between measured quantities, the power distribution, and uncertainties in the determination of power distribution.

Fuel cladding failure during a LOCA is limited by restricting the maximum linear heat generation rate so that the peak cladding temperature does not exceed 2200°F (Ref. ~~4~~). High peak cladding temperatures are assumed to cause severe cladding failure by oxidation due to a Zircaloy water reaction.

The LCOs governing LHR, ASI, and the Reactor Coolant System ensure that these criteria are met as long as the core is operated within the ASI~~,~~ F_{XY}^T, and F_r^T limits specified in the COLR, and within the T_q limits. The latter are process variables that characterize the three dimensional power distribution of the reactor core. Operation within the limits for these variables ensures that their actual values are within the ranges used in the accident analyses.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Fuel cladding damage does not normally occur while the reactor is operating at conditions outside these LCOs during normal operation. Fuel cladding damage results, however, when an accident or AOO occurs from initial conditions outside the limits of these LCOs. This potential for fuel cladding damage exists because changes in the power distribution can cause increased power peaking and correspondingly increased local LHRs.

The ASI satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The power distribution LCO limits are based on correlations between power peaking and certain measured variables used as inputs to the LHR and DNB operating limits. These power distribution LCO limits, except T_q, are provided in the COLR. The limitation on LHR ensures that in the event of a LOCA, the peak temperature of the fuel cladding does not exceed 2200°F.

The limitation on ASI, along with the limitations of LCO 3.3.1, "Reactor Protection System Instrumentation," represents a conservative envelope of operating conditions consistent with the assumptions that have been analytically demonstrated adequate for maintaining an acceptable minimum DNBR throughout all AOOs. Of these, the loss of flow transient is the most limiting. Operation of the core with conditions within the specified limits ensures that an acceptable minimum margin from DNB conditions is maintained in the event of any AOO, including a loss of flow transient.

APPLICABILITY

In MODE 1 with THERMAL POWER ~~>~~ ≥ 40 ~~20~~% RTP, power distribution must be maintained within the limits assumed in the accident analyses to ensure that fuel damage does not result following an AOO. In other MODES, this LCO does not apply because THERMAL POWER is not sufficient to require a limit on the core power distribution. ~~Below 20% RTP the incore detector accuracy is not reliable~~. 6

ACTIONS

A.1

Operating the core within ASI limits specified in the COLR and within the limits of LCO 3.3.1 ensures an acceptable margin for DNB and for maintaining local power density in the event of an AOO. Maintaining ASI within limits also ensures that the limits of 10 CFR 50.46 are not exceeded during accidents. The Required Actions to restore ASI must be completed within 2 hours to limit the duration the plant is operated outside the initial conditions assumed in the accident analyses. In addition, this Completion Time is sufficiently short that the xenon distribution in the core cannot change significantly.

BASES

ACTIONS (continued)

B.1

If the ASI cannot be restored to within its specified limits~~, or ASI cannot be determined because of Excore Detector Monitoring System inoperability,~~ core power must be reduced. Reducing THERMAL POWER to ~~≤~~ 20% RTP provides reasonable assurance that the core is operating farther from thermal limits and places the core in a conservative condition. Four hours is a reasonable amount of time, based on operating experience, to reduce THERMAL POWER to ~~≤ 20~~% RTP in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.~~5~~.1

Verifying that the ASI is within the specified limits provides reasonable assurance that the core is not approaching DNB conditions. ~~[A Frequency of 12 hours is adequate for the operator to identify trends in conditions that result in an approach to the ASI limits, because the mechanisms that affect the ASI, such as xenon redistribution or CEA drive mechanism malfunctions, cause the ASI to change slowly and should be discovered before the limits are exceeded.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

B 3.2.~~5~~ AXIAL SHAPE INDEX (ASI) ~~(Analog)~~

4

BASES

BACKGROUND

The purpose of this LCO (AXIAL SHAPE INDEX (ASI)) is to limit the core power distribution to the initial values assumed in the accident analysis. Operation within the limits imposed by this LCO either limits or prevents potential fuel cladding failures that could breach the primary fission product barrier and release fission products to the reactor coolant in the event of a loss of coolant accident (LOCA), loss of flow accident, ejected control element assembly (CEA) accident, or other postulated accident requiring termination by a Reactor Protection System trip function. This LCO limits the amount of damage to the fuel cladding during an accident by ensuring that the plant is operating within acceptable bounding conditions at the onset of a transient.

Methods of controlling the power distribution include:

a. Using CEAs to alter the axial power distribution,

b. Decreasing CEA insertion by boration, thereby improving the radial power distribution, and

c. Correcting off optimum conditions (e.g., a CEA drop or misoperation of the unit) that cause margin degradations.

The core power distribution is controlled so that, in conjunction with other core operating parameters (e.g., CEA insertion and alignment limits), the power distribution does not result in violation of this LCO. The limiting safety system settings and this LCO are based on the accident analyses (Ref~~s~~. 1 ~~and 2~~), so that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences (AOOs), and the limits of acceptable consequences are not exceeded for other postulated accidents.

Limiting power distribution skewing over time also minimizes the xenon distribution skewing, which is a significant factor in controlling the axial power distribution.

Power distribution is a product of multiple parameter rs, various combinations of which may produce acceptable power distributions. Operation within the design limits of power distribution is accomplished by generating operating limits on linear heat rate (LHR) and departure from nucleate boiling (DNB).

BASES

BACKGROUND (continued)

The limits on LHR, ~~Total Planar Radial Peaking Factor (F_{XY}^T),~~ Total Integrated Radial Peaking Factor (F_r^T), T_q, and ASI represent limits within which the LHR algorithms are valid. These limits are obtained directly from the core reload analysis.

Either of the two core power distribution monitoring systems, the Excore Detector Monitoring System and the Incore Detector Monitoring System, provide adequate monitoring of the core power distribution and ~~are~~ is capable of verifying that the LHR does not exceed its limits. The Excore Detector Monitoring System performs this function by continuously monitoring ~~the~~ ASI with the OPERABLE quadrant symmetric excore neutron flux detectors and verifying that the ASI is maintained within the allowable limits specified in the COLR.

In conjunction with the use of the Excore Detector Monitoring System and in establishing the ASI limits, the following conditions are assumed:

a. The CEA insertion limits of LCO 3.1.5, "Shutdown CEA Insertion Limits," and LCO 3.1.6, "Regulating CEA Insertion Limits," are satisfied,

b. The T_q restrictions of LCO 3.2.~~4~~ 3 are satisfied, and

c. ~~F_{xy}^T~~ F_r^T does not exceed the limits of LCO 3.2.2.

The Incore Detector Monitoring System continuously provides a more direct measure of the peaking factors, and the alarms ~~that have been~~ established for the individual incore detector segments ensure that the peak LHR is maintained within the limits specified in the COLR. The setpoints for these alarms include tolerances~~, set in conservative directions, as follows:~~ described in Reference 3.

~~a. A measurement calculational uncertainty factor of 1.062,~~

~~b. An engineering uncertainty factor of 1.03,~~

~~c. An allowance of 1.002 for axial fuel densification and thermal expansion, and~~

~~A THERMAL POWER measurement uncertainty factor of 1.02.~~

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition 1) or AOOs (Condition 2) (Ref. ~~3~~, GDC 10). The power distribution and CEA insertion and alignment LCOs prevent core power distributions ~~from reaching levels~~ that violate the following fuel design criteria:

a. During a LOCA, peak cladding temperature must not exceed 2200°F (Ref. ~~4~~),

b. During a loss of flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB condition (Ref. ~~3~~, GDC 10),

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 2~~8~~0 cal/gm (Ref. ~~[~~ ~~]~~), and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. ~~3~~, GDC 26).

The power density at any point in the core must be limited to maintain the fuel design criteria (Ref. ~~4~~). This limitation is accomplished by maintaining the power distribution and reactor coolant conditions so that the peak LHR and DNB parameters are within operating limits supported by the accident analyses (Ref. 1) with due regard for the correlations ~~among~~ between measured quantities, the power distribution, and uncertainties in the determination of power distribution.

Fuel cladding failure during a LOCA is limited by restricting the maximum linear heat generation rate so that the peak cladding temperature does not exceed 2200°F (Ref. ~~4~~). High peak cladding temperatures are assumed to cause severe cladding failure by oxidation due to a Zircaloy water reaction.

The LCOs governing LHR, ASI, and the Reactor Coolant System ensure that these criteria are met as long as the core is operated within the ASI~~,~~ F_{XY}^T~~,~~ and F_r^T limits specified in the COLR, and within the T_q limits. The latter are process variables that characterize the three dimensional power distribution of the reactor core. Operation within the limits for these variables ensures that their actual values are within the ranges used in the accident analyses.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Fuel cladding damage does not normally occur while the reactor is operating at conditions outside these LCOs during normal operation. Fuel cladding damage results, however, when an accident or AOO occurs from initial conditions outside the limits of these LCOs. This potential for fuel cladding damage exists because changes in the power distribution can cause increased power peaking and correspondingly increased local LHRs.

The ASI satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO

The power distribution LCO limits are based on correlations between power peaking and certain measured variables used as inputs to the LHR and DNB operating limits. These power distribution LCO limits, except T_q, are provided in the COLR. The limitation on LHR ensures that in the event of a LOCA, the peak temperature of the fuel cladding does not exceed 2200°F.

The limitation on ASI, along with the limitations of LCO 3.3.1, "Reactor Protection System Instrumentation," represents a conservative envelope of operating conditions consistent with the assumptions that have been analytically demonstrated adequate for maintaining an acceptable minimum DNBR throughout all AOOs. Of these, the loss of flow transient is the most limiting. Operation of the core with conditions within the specified limits ensures that an acceptable minimum margin from DNB conditions is maintained in the event of any AOO, including a loss of flow transient.

APPLICABILITY

In MODE 1 with THERMAL POWER ≥ 40 ~~> 20~~% RTP, power distribution must be maintained within the limits assumed in the accident analyses to ensure that fuel damage does not result following an AOO. In other MODES, this LCO does not apply because THERMAL POWER is not sufficient to require a limit on the core power distribution. ~~Below 20% RTP the incore detector accuracy is not reliable~~. 6

ACTIONS

A.1

Operating the core within ASI limits specified in the COLR and within the limits of LCO 3.3.1 ensures an acceptable margin for DNB and for maintaining local power density in the event of an AOO. Maintaining ASI within limits also ensures that the limits of 10 CFR 50.46 are not exceeded during accidents. The Required Actions to restore ASI must be completed within 2 hours to limit the duration the plant is operated outside the initial conditions assumed in the accident analyses. In addition, this Completion Time is sufficiently short that the xenon distribution in the core cannot change significantly.

BASES

ACTIONS (continued)

B.1

If the ASI cannot be restored to within its specified limits~~, or ASI cannot be determined because of Excore Detector Monitoring System inoperability,~~ core power must be reduced. Reducing THERMAL POWER to ~~≤~~ 20% RTP provides reasonable assurance that the core is operating farther from thermal limits and places the core in a conservative condition. Four hours is a reasonable amount of time, based on operating experience, to reduce THERMAL POWER to ~~≤~~ 20% RTP in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.~~5~~.1

Verifying that the ASI is within the specified limits provides reasonable assurance that the core is not approaching DNB conditions. ~~[A Frequency of 12 hours is adequate for the operator to identify trends in conditions that result in an approach to the ASI limits, because the mechanisms that affect the ASI, such as xenon redistribution or CEA drive mechanism malfunctions, cause the ASI to change slowly and should be discovered before the limits are exceeded.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

JUSTIFICATION FOR DEVIATIONS
ITS 3.2.4, BASES, AXIAL SHAPE INDEX (ASI)

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The ISTS contains tolerances to be applied to the incore detector alarm setpoints. PSL Unit 1 UFSAR, Section 13.8, Licensee-Controlled Technical Specification Requirements, and PSL Unit 2 UFSAR, Section 13.7, Licensee-Controlled Technical Specification Requirements, each contain these tolerances to be applied to the incore detector alarm setpoints. Additionally, these tolerances will be provided in the Technical Requirements Manual. Therefore, the tolerances to be applied to the incore detector alarm setpoints are deleted.

4. The ISTS includes ISTS 3.2.1, Linear Heat Rate (LHR), ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^{T}), ISTS 3.2.3, Total Integrated Radial Peaking Factor (F_{r}^{T}), ISTS 3.2.4, Azimuthal Power Tilt (T_q), and ISTS 3.2.5, Axial Shape Index (ASI). CTS do not include a Specification for ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^{T}). The CTS and ISTS are renumbered. CTS 3.2.3, Total Integrated Radial Peaking Factor (F_{r}^{T}), CTS 3.2.4, Azimuthal Power Tilt (T_q), and CTS 3.2.5, Axial Shape Index (ASI), are renumbered as ITS 3.2.2, ITS 3.2.3, and ITS 3.2.4, respectively.

5. The type of plant (Analog) is deleted since it is unnecessary. This information is provided in NUREG-1432, Rev. 5.0, to assist in identifying the appropriate Specification to be used as a model for the plant specific ITS conversion but serves no purpose in a plant specific implementation.

6. ISTS 3.2.5 Bases (renumbered as ITS 3.2.4) Applicability discussion and Action B.1 discussion are changed to reflect relaxing the CTS Applicability. ITS 3.2.4 Applicability is MODE 1 with THERMAL POWER ≥ 40% RTP. This changes the CTS by relaxing the Applicability from MODE 1, to MODE 1 with THERMAL POWER ≥ 40% RTP. See DOC L01 for a discussion of changes for relaxing the CTS Applicability. Additionally, in the Applicability discussion, the statement “below 20% RTP the incore detector accuracy is not reliable” is deleted because the state of the incore detector accuracy at 20% RTP it is not relevant to the condition that below 40% RTP the ASI LCO no longer applies. In the Action B.1 discussion, the statement “or ASI cannot be determined because of Excore Detector Monitoring System inoperability” is deleted because the operability of the Excore Detector Monitoring System is not relevant to the Action B.1 action that when ASI is not restored to within limits within 2 hours, then THERMAL POWER must be reduced to below 40% RTP within 4 hours.

ISTS 3.2.2, TOTAL PLANAR RADIAL PEAKING FACTOR (F_{xy}^{T}) (ANALOG)

1. ISTS 3.2.2, Total Planar Radial Peaking Factor (F_{xy}^{T}) (Analog) Specification is not included in the St. Lucie Plant (PSL) Unit 1 and Unit 2 ITS because the PSL CTS do not include a Specification for Total Planar Radial Peaking Factor (F_{xy}^{T}) (Analog).

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.2 POWER DISTRIBUTION LIMITS (Analog)

B 3.2.2 Total Planar Radial Peaking Factor (F^{T}_{XY}) (Analog)

BASES

BACKGROUND The purpose of this LCO (Total Planar Radial Peaking Factor (F^{T}_{XY})) is to limit the core power distribution to the initial values assumed in the accident analyses. Operation within the limits imposed by this LCO decreases or prevents potential fuel cladding failures that could breach the primary fission product barrier and release fission products to the reactor coolant in the event of a loss of coolant accident (LOCA), loss of flow accident, ejected control element assembly (CEA) accident, or other postulated accident requiring termination by a Reactor Protection System trip function. This LCO limits damage to the fuel cladding during an accident by ensuring that the plant is operating within acceptable bounding conditions at the onset of a transient.

Methods of controlling the power distribution include:

a. Using CEAs to alter the axial power distribution,

b. Decreasing CEA insertion by boration, thereby improving the radial power distribution, and

c. Correcting off optimum conditions (e.g., a CEA drop or misoperation of the unit) that cause margin degradations.

The core power distribution is controlled so that, in conjunction with other core operating parameters (e.g., CEA insertion and alignment limits), the power distribution does not result in violation of this LCO. The limiting safety system settings (LSSS) and this LCO are based on accident analyses (Refs. 1 and 2), so that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences (AOOs) and the limits of acceptable consequences are not exceeded for other postulated accidents.

Limiting power distribution skewing over time also minimizes the xenon distribution skewing, which is a significant factor in controlling the axial power distribution.

Power distribution is a product of multiple parameters, various combinations of which may produce acceptable power distributions. Operation within the design limits of power distribution is accomplished by generating operating limits on the linear heat rate (LHR) and departure from nucleate boiling (DNB).

BASES

BACKGROUND (continued)

The limits on LHR, F^T_{XY}, Total Integrated Radial Peaking Factor (F^T_r), T_q, and ASI represent limits within which the LHR algorithms are valid. These limits are obtained directly from the core reload analysis.

Either of the two core power distribution monitoring systems, the Excore Detector Monitoring System or the Incore Detector Monitoring System, provides adequate monitoring of the core power distribution and is capable of verifying that the LHR does not exceed its limits. The Excore Detector Monitoring System performs this function by continuously monitoring the ASI with the OPERABLE quadrant symmetric excore neutron flux detectors and verifying that the ASI is maintained within the allowable limits specified in the COLR.

In conjunction with the use of the Excore Detector Monitoring System and in establishing the ASI limits, the following assumptions are made:

a. The CEA insertion limits of LCO 3.1.5, "Shutdown CEA Insertion Limits," and LCO 3.1.6, "Regulating CEA Insertion Limits," are satisfied,

b. The T_q restrictions of LCO 3.2.4 are satisfied, and

c. F^T_{XY} does not exceed the limits of this LCO.

The Incore Detector Monitoring System continuously provides a more direct measure of the peaking factors, and the alarms that have been established for the individual incore detector segments ensure that the peak LHRs are maintained within the limits specified in the COLR. The setpoints for these alarms include tolerances, set in conservative directions, for:

a. A measurement calculational uncertainty factor of 1.062,

b. An engineering uncertainty factor of 1.03,

c. An allowance of 1.002 for axial fuel densification and thermal expansion, and

d. A THERMAL POWER measurement uncertainty factor of 1.02.

BASES

APPLICABLE SAFETY ANALYSES

The fuel cladding must not sustain damage as a result of normal operation (Condition 1) or AOOs (Condition 2) (Ref. 3, GDC 10). The Power Distribution and CEA Insertion and Alignment LCOs preclude core power distributions that violate the following fuel design criteria:

a. During a LOCA, peak cladding temperature must not exceed 2200°F (Ref. 4),

b. During a loss of flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a DNB condition (Ref. 3, GDC 10),

c. During an ejected CEA accident, the fission energy input to the fuel must not exceed 280 cal/gm (Ref. [ ]), and

d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck, fully withdrawn (Ref. 3, GDC 26).

The power density at any point in the core must be limited to maintain the fuel design criteria (Ref. 4). This limiting is accomplished by maintaining the power distribution and reactor coolant conditions such that the peak LHR and DNB parameters are within operating limits supported by the accident analyses (Ref. 1) with due regard for the correlations between measured quantities, the power distribution, and the uncertainties in the determination of power distribution.

Fuel cladding failure during a LOCA is limited by restricting the maximum linear heat generation rate so that the peak cladding temperature does not exceed 2200°F (Ref. 4). High peak cladding temperatures are assumed to cause severe cladding failure by oxidation due to a Zircaloy water reaction.

The LCOs governing LHR, ASI, and the Reactor Coolant System ensure that these criteria are met as long as the core is operated within the ASI, F^{T}_{XY}, F^{T}_{r}, and T_q limits specified in the COLR. The latter are process variables that characterize the three dimensional power distribution of the reactor core. Operation within the limits for these variables ensures that their actual values are within the ranges used in the accident analyses.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Fuel cladding damage does not normally occur while at conditions outside the limits of these LCOs during normal operation. Fuel cladding damage could result, however, should an accident or AOO occur from initial conditions outside the limits of these LCOs. This potential for fuel cladding damage exists because changes in the power distribution can cause increased power peaking and correspondingly increased local LHR.

F^{T}_{XY} satisfies Criterion 2 of 10 CFR 50.36(c)(2)(ii).

LCO — The power distribution LCO limits are based on correlations between power peaking and certain measured variables used as inputs to the LHR and DNB ratio operating limits. The power distribution LCO limits, except T_q, are provided in the COLR. The limitation on LHR ensures that in the event of a LOCA the peak temperature of the fuel cladding does not exceed 2200°F.

APPLICABILITY — In MODE 1, power distribution must be maintained within the limits assumed in the accident analyses to ensure that fuel damage does not result following an AOO. In other MODES, this LCO does not apply because there is not sufficient THERMAL POWER to require a limit on the core power distribution.

ACTIONS — A.1 and A.2

A Note modifies Condition A to require Required Actions A.1 and A.2 to be completed if the Condition is entered. This ensures that corrective action is taken prior to unrestricted operation.

The limitations on F^{T}_{XY} provided in the COLR ensure that the assumptions used in the analysis for establishing the LHR, LCO, and LSSS remain valid during operation at the various allowable CEA group insertion limits. If F^{T}_{XY} exceeds its basic limitation, operation may continue under the additional restrictions imposed by these Required Actions (reducing THERMAL POWER and withdrawing CEAs to or beyond the long term steady state insertion limits of LCO 3.1.6), because these additional restrictions adequately ensure that the assumptions used in establishing the LHR, LCO, and LSSS remain valid (Ref. 3). Six hours to return F^{T}_{XY} to within its limit is reasonable and ensures that all CEAs meet the long term steady state insertion limits of LCO 3.1.6.

BASES

ACTIONS (continued)

B.1

If F^{T}_{r} cannot be returned to within its limit, THERMAL POWER must be reduced. A change to MODE 2 provides reasonable assurance that the core is operating within its thermal limits and places the core in a conservative condition. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 2 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.2.1

The periodic Surveillance to determine the calculated F^{T}_{XY} ensures that F^{T}_{XY} remains within the range assumed in the analysis throughout the fuel cycle. Determining the measured F^{T}_{XY} after each fuel loading prior to the reactor exceeding 70% RTP ensures that the core is properly loaded.

[Performance of the Surveillance every 31 days of accumulated operation in MODE 1 provides reasonable assurance that unacceptable changes in the F^{T}_{XY} are promptly detected.

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

---------- REVIEWER'S NOTE ----------
Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.
----------]

The power distribution map can only be obtained after THERMAL POWER exceeds 20% RTP because the incore detectors are not reliable below 20% RTP.

The SR is modified by a Note that requires that SR 3.2.2.2 and SR 3.2.2.3 be completed each time SR 3.2.1.1 is completed. (Values computed by these SRs are required to perform SR 3.2.2.1.) The Note also requires that the incore detectors be used to determine F^{T}_{XY} by using them to obtain a power distribution map with all full length CEAs above the long term steady state insertion limits, as specified in the COLR.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.2.2.2 and SR 3.2.2.3

Measuring the value of F_{XY} and T_q each time a calculated value of F^{I}_{XY} is required ensures that the calculated value of F^{I}_{XY} accurately reflects the condition of the core.

The Frequency for these Surveillances is in accordance with the Frequency requirements of SR 3.2.2.1, because these SRs provide information to complete SR 3.2.2.1.

ACTION STATEMENTS

See ITS 3.3.2

ACTION 1 - With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirement, restore the inoperable channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in HOT STANDBY within the next 6 hours and/or open the protective system trip breakers.

ACTION A

ACTION 2 - ~~With the number of OPERABLE channels one less than the Total Number of Channels, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied:~~

Place affected trip unit

a. ~~The inoperable channel is placed~~ in ~~either the~~ bypass~~ed~~ or trip~~ped condition~~ within 1 hour. ~~For the purposes of testing and maintenance, the inoperable channel may be bypassed for up to 48 hours from time of initial loss of OPERABILITY; however, the inoperable channel shall then be either restored to OPERABLE status or placed in the tripped condition~~.

One or more Functions with one RPS trip unit or associated instrument channel inoperable except for Condition C (excore channel not calibrated with incore detectors).

AND
Restore channel to Operable status within 48 hours.
OR
Place affected unit in trip within 48 hours.

TABLE 3.3-1 (Continued)

ACTION STATEMENTS

~~b. Within one hour, all functional units receiving an input from the inoperable channel are also bypassed or tripped.~~

A07

ACTION A

~~c. The Minimum Channels OPERABLE requirement is met; however, one additional channel may be bypassed for up to 48 hours while performing tests and maintenance on than channel provided the other inoperable channel is placed in the tripped condition.~~

ACTION 3 - With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirement, verify compliance with the SHUTDOWN MARGIN requirements of Specification 3.1.1.1 or 3.1.1.2, as applicable, within 1 hour and at least once per 12 hours thereafter.

See ITS 3.3.11

ACTION 4 - With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirement, be in HOT STANDBY within 6 hours; however, one channel may be bypassed for up to 1 hour for surveillance testing per Specification 4.3.1.1.1.

* With the protective system trip breakers in the closed position, the CEA drive system capable of CEA withdrawal, and fuel in the reactor vessel.

Footnote e

** ~~Mode 1 applicable only when Power Range Neutron Flux power ≤ 15% of RATED THERMAL POWER.~~

Trip not applicable when Thermal Power is > 15% RTP.

A01

Footnote c

(a) Trip may be manually bypassed below 0.5% of RATED THERMAL POWER ~~in conjunction with (d) below~~; bypass shall be automatically removed when Wide Range Logarithmic Neutron Flux power is greater than or equal to 0.5% of RATED THERMAL POWER.

A09

Footnote f

(b) Trip may be manually bypassed below 705 psig; bypass shall be automatically removed at or above 705 psig.

L06

is not applicable and

Footnotes g & h

(c) Trip may be bypassed below 15% of RATED THERMAL POWER; bypass shall be automatically removed when Power Range Neutron Flux power is greater than or equal to 15% of RATED THERMAL POWER.

~~(d) Trip may be bypassed during testing pursuant to Special Test Exception 3.10.3.~~

A09

Footnote d

(e) Trip may be bypassed below 10^{-4}% and above 15% of RATED THERMAL POWER; bypass shall be automatically removed when Wide Range Logarithmic Neutron Flux power is $\geq$ 10^{-4}% and Power Range Neutron Flux power $\leq$ 15% of RATED THERMAL POWER.

(f) Each channel shall be comprised of two trip breakers; actual trip logic shall be one-out-of-two taken twice.

See ITS 3.3.2

~~(g) There shall be at least two decades of overlap between the Wide Range Logarithmic Neutron Flux Monitoring Channels and the Power Range Neutron Flux Monitoring Channels.~~

LA02

h. Trip is only applicable in MODE 1 ≥ 15% RTP.

L06

ACTION STATEMENTS

See ITS 3.3.2

ACTION 1 - With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirement, restore the inoperable channel to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in at least HOT STANDBY within the next 6 hours and/or open the protective system trip breakers.

TABLE 3.3-1 (Continued)

ACTION STATEMENTS

One or more Functions with one RPS trip unit or associated instrument channel inoperable except for Condition C (excore channel not calibrated with incore detectors).

----------NOTE----------
Required Action A.2 must be completed whenever this Condition is entered.

A10

ACTION 2 - a. ~~With the number of channels OPERABLE one less than the Total Number of Channels, STARTUP and/or POWER OPERATION may continue provided the inoperable channel is placed~~ in ~~the~~ bypass~~ed~~ or trip~~ped condition~~ within 1 hour. ~~The channel shall be returned to OPERABLE status no later than during the next COLD SHUTDOWN.~~

ACTION A Required Actions A.1 and A.2

Place affected trip unit

Restore channel to OPERABLE status prior to entering MODE 2 following next MODE 5 entry.

A01

ACTION B Required Action B.1

b. ~~With the number of channels OPERABLE one less than the Minimum Channels OPERABLE, STARTUP and/or POWER OPERATION may continue provided the following conditions are satisfied:~~

One or more Functions with two RPS trip units or associated instrument channels inoperable except for Condition C (excore channel not calibrated with incore detectors).

A01

Place one trip unit in

trip unit

1. ~~Verify that one of the inoperable channels has been~~ bypass~~ed~~ and ~~place~~ the other ~~inoperable channel~~ in ~~the~~ trip~~ped condition~~ within 1 hour.

2. ~~All functional units affected by the bypassed/tripped channel shall also be placed in the bypassed/tripped condition.~~

A07

~~With a channel process measurement circuit that affects multiple functional units inoperable or in test, bypass or trip all associated functional units as listed below:~~

~~Process Measurement Circuit~~	~~Functional Unit Bypassed~~
~~1. Safety Channel – Nuclear Instrumentation~~	
~~Wide Range~~	~~Rate of Change of Power – High (RPS)~~
~~Linear Range~~	~~Variable Power Level – High (RPS)~~ ~~Local Power Density – High (RPS)~~ ~~Thermal Margin/Low Pressure (RPS)~~
~~2. Pressurizer Pressure -~~	~~Pressurizer Pressure – High (RPS)~~ ~~Thermal Margin/Low Pressure (RPS)~~ ~~Pressurizer Pressure – Low (ESF)~~
~~3. Containment Pressure -~~	~~Containment Pressure – High (RPS)~~ ~~Containment Pressure – High (ESF)~~
~~4. Steam Generator Pressure -~~	~~Steam Generator Pressure – Low (RPS)~~ ~~Thermal Margin/Low Pressure (RPS)~~ ~~AFAS-1 and AFAS-2 (AFAS)~~ ~~Steam Generator Pressure – Low (ESF)~~
~~5. Steam Generator Level -~~	~~Steam Generator Level – Low (RPS)~~ ~~If SG-2A, then AFAS-1 (AFAS)~~ ~~If SG-2B, then AFAS-2 (AFAS)~~

ACTION 3 - With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirement, suspend all operations involving positive reactivity changes*. Verify compliance with the SHUTDOWN MARGIN requirements of Specification 3.1.1.1 or 3.1.1.2, as applicable, within 1 hour and at least once per 12 hours thereafter.

See ITS 3.3.11

See ITS 3.3.2

ACTION 4 - With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirements, STARTUP and/or POWER OPERATION may continue provided the reactor trip breakers of the inoperable channel are placed in the tripped condition within 1 hour, otherwise, be in at least HOT STANDBY within 6 hours; however, one channel may be bypassed for up to 1 hour, provided the trip breakers of any inoperable channel are in the tripped condition, for surveillance testing per Specification 4.3.1.1.

ACTION 5 - With the number of OPERABLE channels one less than the Minimum Channels OPERABLE requirement restore the inoperable channel to OPERABLE status within 48 hours or open the reactor trip breakers within the next hour.

See ITS 3.3.11

* Limited plant cooldown or boron dilution is allowed provided the change is accounted for in the calculated SHUTDOWN MARGIN.

SR 3.3.1.6 (1) - Each startup ~~or when required with the reactor trip breakers closed and the CEA drive system capable of rod withdrawal,~~ if not performed in the previous 7 days.

M04

Not required to be performed until 12 hours after THERMAL POWER is ≥ 15% RTP.

SR 3.3.1.2 NOTE 1 (2) - ~~Heat balance only (CHANNEL FUNCTIONAL TEST not included), above 15% of RATED THERMAL POWER; adjust "Nuclear Power Calibrate" potentiometer to null "Nuclear Power – ΔT Power".~~ During PHYSICS TESTS, these daily calibrations may be suspended provided these calibrations are performed upon reaching each major test power plateau and prior to proceeding to the next major test power plateau.

SR 3.3.1.2 NOTE 2

M05

Not required to be performed until 12 hours after THERMAL POWER is ≥ 15% RTP.

SR 3.3.1.3 and NOTE ACTION C.2 (3) - ~~Above 15% of RATED THERMAL POWER,~~ recalibrate the excore detectors ~~which monitor the AXIAL SHAPE INDEX~~ by using the incore detectors or restrict THERMAL POWER ~~during subsequent operations~~ to ≤ 90% of the maximum allowed THERMAL POWER level ~~with the existing reactor coolant pump combination~~.

A05

SR 3.3.1.5 NOTE and SR 3.3.1.8 NOTE (4) - Neutron detectors may be excluded from CHANNEL CALIBRATION.

SR 3.3.1.2 (5) - Adjust "ΔT Pwr Calibrate" potentiometers to make ΔT power signals agree with calorimetric calculation.

See ITS 3.3.2

(6) - In accordance with the Surveillance Frequency Control Program and following maintenance or adjustment of the reactor trip breakers, the CHANNEL FUNCTIONAL TEST shall include verification of the independent OPERABILITY of the undervoltage and shunt trips.

(7) - The fuse circuitry in the matrix fault protection circuitry shall be determined to be OPERABLE by testing with the installed test circuitry.

instrument

Table 3.3.1-1 Footnote a (8) - If the as-found channel setpoint is ~~either~~ outside its predefined as-found acceptance criteria band ~~or is not conservative with respect to the Allowable Value~~, then the channel shall be ~~declared inoperable and shall be~~ evaluated to verify that it is functioning as required before returning the channel to service.

M01

Table 3.3.1-1 Footnote b (9) - ~~The instrument channel setpoint shall be reset to a value that is within the as-left tolerance of the Field Trip Setpoint, otherwise that channel shall not be returned to OPERABLE status. The Field Trip Setpoint and the methodology used to determine the Field Trip Setpoint, the as-found acceptance criteria band, and the as-left acceptance criteria are specified in UFSAR Section 7.2.~~

M02

The instrument channel setpoint shall be reset to a value that is within the as-left acceptance criteria band around the Nominal Trip Setpoint (NTSP) at the completion of the surveillance; otherwise, the channel shall be declared inoperable. Setpoints more conservative than the NTSP are acceptable provided that the as-found and as-left acceptance criteria bands apply to the actual setpoint implemented in the Surveillance procedures to confirm channel performance. The NTSP and the methodologies used to determine the as-found and as-left acceptance criteria bands are specified in the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report, respectively.

SAFETY LIMITS AND LIMITING SAFETY SYSTEM SETTINGS

2.2 LIMITING SAFETY SYSTEM SETTINGS

REACTOR TRIP SETPOINTS

LCO 3.3.1

DISCUSSION OF CHANGES
ITS 3.3.1, REACTOR PROTECTIVE SYSTEM (RPS) INSTRUMENTATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS Table 3.3-1 specifies the "TOTAL NO. OF CHANNELS" and the "MINIMUM CHANNELS OPERABLE" associated with each RPS Functional Unit. For Unit 1 CTS Table 3.3-1 Functional Units 2, 3, 4, 7, 8, 9, 9a, and 11a and for Unit 2 Functional Units 2 through 10, 13a, 14 and 15; the number of channels listed in the "TOTAL NO. OF CHANNELS" column is greater than that listed in the "MINIMUM OPERABLE CHANNELS" column. CTS Table 3.3-1 Action 2 specifies the actions to take with the number of channels OPERABLE one less than required by the "TOTAL NO. OF CHANNELS" column. ITS LCO 3.3.1 requires “Four RPS trip units and associated instrument and bypass removal channels for each Function in Table 3.3.1-1 shall be OPERABLE.” The ITS 3.3.1 ACTIONS require entry when the OPERABLE channels are one less than required by the LCO statement. This changes the CTS by deleting the "MINIMUM CHANNELS OPERABLE" column and utilizing the channel requirements specified in the TOTAL NO. OF CHANNELS column in ITS LCO 3.3.1.

This change is acceptable because the requirements for when actions must be taken remain unchanged. The ITS LCO statement reflects the current requirements in the CTS Actions for when actions are required to be taken. The "MINIMUM CHANNELS OPERABLE" column for CTS Table 3.3-1 has been removed and the "TOTAL NO. OF CHANNELS" column numbers are reflected in ITS LCO 3.3.1. This change is a presentation preference consistent with NUREG-1432, Rev. 5 and PSL CTS Table 3.3-1 Functional Unit Total No. of Channels to Trip column. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 Unit 1 CTS 3.3.1.1 ACTION, Unit 2 CTS 3.3.1 ACTION and CTS Table 3.3-1 provide the compensatory actions to take when RPS instrumentation is inoperable. ITS 3.3.1 ACTIONS provide the compensatory actions for inoperable RPS Instrumentation. The ITS 3.3.1 ACTIONS includes a Note that allows separate Condition entry for each Function. This modifies the CTS by providing a specific allowance to enter the Action for each inoperable RPS instrumentation Function and for certain Functions on a steam generator basis.

The purpose of the CTS Actions is to provide the appropriate compensatory actions for inoperable RPS Functions. This proposed change will allow separate condition entry for each RPS instrumentation Function. This change is acceptable because it clearly states the current requirement. The CTS considers each RPS instrumentation Function to be separate and independent from the

others. In addition, the channels associated with Functions 3 and 6 are allowed separate Condition entry on the specified basis (i.e., per SG) since the channels associated with each steam generator will provide the associated RPS trip based on the logic associated with the channels on the specified basis. This change is designated as administrative because it does not result in technical changes to the CTS.

A04 Unit 1 CTS 4.3.1.1.3 and Unit 2 CTS 4.3.1.3 state, in part, that the RPS RESPONSE TIME test of each reactor trip function "shall include at least one channel per function." ITS SR 3.3.1.9 requires performance of an RPS RESPONSE TIME test but does not explicitly state that the RPS RESPONSE TIME test must include at least one channel per function.

The purpose of the CTS statement in the Surveillance Requirement associated with the RPS RESPONSE TIME test is to ensure required features are tested to verify the RPS instrument Functions are OPERABLE. However, this statement is redundant to the definition of RPS RESPONSE TIME provided in ITS Section 1.1 and therefore is not necessary.

The definition of the RPS RESPONSE TIME states, in part, that the test, "…shall be that time interval from when the monitored parameter exceeds its RPS trip setpoint at the channel sensor until electrical power to the CEAs drive mechanism is interrupted. This encompasses the requirement that at least one channel per Function be included in the RPS RESPONSE TIME. The required testing will continue, per the ITS SR wording and the definition provided in Section 1.1, to include the features necessary to verify the RPS instrument Functions are OPERABLE.

This change is designated as administrative because it does not result in technical changes to the CTS.

A05 CTS Table 4.3-1 footnote 3 states, in part, "with the existing Reactor Coolant Pump combination." ITS SR 3.3.1.3 and Required Action C.2 do not include this specific detail. This changes CTS by removing redundant detail. This change is acceptable because reactor coolant pump (RCP) OPERABILITY and required operation is addressed in other Specifications in CTS and retained in ITS 3.4.1 and 3.4.4. LCO 3.4.1 and LCO 3.4.4 require, in part, a minimum reactor coolant flow and both Reactor Coolant System (RCS) loops to be in operation, respectively (i.e., all four RCPs are in operation) in MODES 1 and 2. The "existing Reactor Coolant Pump combination" is determined by compliance with these LCOs and retention of the information in ITS SR 3.3.1.3 is unnecessary.

This change is acceptable because the requirements for RCP operation remain unchanged and are retained in ITS 3.4.1 and 3.4.4. This change is designated as administrative because it does not result in a technical change to CTS.

A06 CTS Table 2.2-1 Functional Units 2, 3 and 9 (Unit 1) and Functional Units 2 and 4 (Unit 2) specify "Four Reactor Coolant Pumps Operating". The equivalent RPS Functions in ITS Table 3.3.1-1 Functions 1, 3, and 9a do not include this detail. Requirements for reactor coolant pump OPERABILITY and required operation are provided in CTS 3.4.1.1. LCO 3.4.1 and LCO 3.4.4 require, in part, a

minimum reactor coolant flow and both Reactor Coolant System (RCS) loops to be in operation, respectively (i.e., all four RCPs are in operation) in MODES 1 and 2. This changes the CTS by removing the "Four Reactor Coolant Pumps Operating" redundant detail from the RPS specification.

This change is acceptable because the requirements for reactor coolant pump operation remain unchanged. This change is designated as administrative because it does not result in a technical change to CTS.

A07 Unit 1 CTS Table 3.3-1, Action 2.b and Unit 2 CTS Table 3.3-1, Action 2.b.2 state, in part, that all functional units receiving an input from (or affected by) the inoperable channel are (shall be) also bypassed or tripped. ITS 3.3.1 ACTIONS for each Function include a Required Action to place the affected trip unit in trip or bypass within 1 hour. CTS LCO 3.0.2 and ITS LCO 3.0.2 establish that upon discovery of a failure to meet an LCO, the associated ACTIONS shall be met. Therefore, when an instrument channel becomes inoperable, LCO 3.0.2 requires each Function affected by the inoperability shall be declared inoperable and the associated ACTIONS shall be met. Retention of these specific CTS Actions are not necessary and are deleted. This change is designated as administrative because it does not result in a technical change to the CTS.

A08 Unit 1 CTS 3.3.1.1 and Unit 2 CTS 3.3.1 do not contain a default action to perform when the Table 3.3-1 Actions cannot be completed within the required time; therefore, an entry into CTS 3.0.3 would be required. ITS 3.3.1 ACTION F requires reducing THERMAL POWER to < 15% RTP in 6 hours when Required Action and associated Completion Time for Loss of Power Density and Loss of Load Trip Functions are not met. ITS 3.3.1 ACTION G requires the unit to be in MODE 3 in 6 hours when Required Action and associated Completion Time for RPS Functions other than the Loss of Power Density and Loss of Load Trip Functions are not met. (See DOC L06 for discussion of modification to Applicability) This changes the CTS by explicitly stating the required ACTIONS when actions cannot be performed within the required time. R1

The purpose of ITS 3.3.1 ACTIONS F and G is to ensure the plant is brought to a MODE in which the LCO for the RPS Functions does not apply within a reasonable amount of time in a controlled manner because the Technical Specification actions cannot be completed as required. Unit 1 CTS 3.3.1.1 and Unit 2 CTS 3.3.1 are silent on these actions, deferring to CTS 3.0.3 for the actions to accomplish this. With the exception of the Loss of Power Density and Loss of Load Trip Functions, the RPS Functions are required to be OPERABLE in MODES 1 and 2. The Loss of Power Density and Loss of Load Trip Functions are required to be OPERABLE with THERMAL POWER ≥ 15% RTP per ITS Table 3.3.1-1 Footnote (h) (CTS Table 3.3-1 Note (c)). The proposed change is acceptable because the ACTIONS specified in ITS 3.3.1 adopt the ISTS structure for placing the unit outside the MODE of Applicability without changing the time to be below 15% RTP for the Loss of Power Density and Loss of Load Trip Functions and the time specified to enter MODE 3 for the other RPS Functions. Default Conditions eliminate the need to enter LCO 3.0.3 when one or more Required Actions cannot be met within the associated Completion

Times. This change is designated as administrative because it does not result in a technical change to the CTS.

A09 **Unit 2 only:** Current Technical Specifications (CTS) 3/4.10.3 provides an exception to the limitations of CTS 3.4.1 and the requirements of CTS Tables 2.2-1 and 3.3-1. This special test exception permits reactor criticality under reduced flow conditions and is required to perform certain startup and PHYSICS TESTS while at low THERMAL POWER levels. ITS does not contain this special test exception. This changes the CTS by eliminating a special test exception discussion from the footnotes.

This change is acceptable because this type of PHYSICS TEST is no longer performed. As a result, this CTS Special test exception is not needed and the references to the test are removed. This change is designated as administrative because it does not result in a technical change to the CTS and is consistent with the changes addressed in CTS 3/4.10.3.

A10 **Unit 2 only:** CTS 3.3.1 Table 3.3-1 Action 2a provides actions when one channel associated with the RPS Functional Units (except 1, 11, 12, and 13.b) is inoperable. The CTS Action states in part, “The channel shall be returned to OPERABLE status no later than during the next COLD SHUTDOWN.” ITS 3.3.1 ACTION A includes this action to restore the channel to OPERABLE with a Completion Time of, “Prior to entering MODE 2 following the next MODE 5 entry.” This presentation preference is similar to the Completion Time specified in ISTS 3.3.1 (Digital), Required Action A.2. ITS 3.3.1, Condition A is modified by a Note which requires the action to restore the channel to OPERABLE status within the Completion Time to be performed whenever the Condition is entered. This changes the CTS by explicitly stating that the Required Action must be performed within the Completion Time whenever the condition is entered.

This change is necessary to eliminate the conflict with the general CTS 3.0.2 (ITS LCO 3.0.2) requirement that if the LCO is met or is no longer applicable prior to expiration of the specified time interval(s), completion of the ACTIONS is not required, unless otherwise stated. The addition of the Note constitutes an “unless otherwise stated.” The Note will require the action to be completed within the Completion Time even when the LCO is no longer applicable, to ensure the channel is restored to OPERABLE prior to the next reactor startup from MODE 5 conditions. This change is acceptable because it reflects the current understanding and application of the CTS Action requiring the applicable channel to be restored to OPERABLE status whenever the LCO is not met.

This change is designated as administrative as it clarifies the current understanding of the CTS requirement while providing an “unless otherwise stated,” to the requirements of CTS 3.0.2 (ITS LCO 3.0.2).

MORE RESTRICTIVE CHANGES

M01 CTS 2.2.1 ACTION states, in part, that with a RPS instrumentation or interlock setpoint less conservative than the value shown in the Allowable Values column of Table 2.2-1, declare the channel inoperable. ITS Table 3.3.1-1 Footnote (a) states, "If the as-found channel setpoint is outside its predefined as-found

acceptance criteria band, then the channel shall be evaluated to verify that it is functioning as required before returning the channel to service." ITS Bases Section 3.3.1, referring to the Allowable Values, states: "This value is specified in the Technical Specifications in order to define OPERABILITY of the channels and is designated as the Allowable Value." ITS Section 3.3.1 Bases also states, "If the actual setting (as-found setpoint) of the channel is found to be conservative with respect to the Allowable Value but is beyond the as-found acceptance criteria band (e.g., conservative side of the as-found acceptance criteria band), the channel is OPERABLE, but degraded. The degraded condition will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the NTSP (within the allowed acceptance criteria band) and evaluating the channel response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance." CTS Table 4.3-1 Note (8) is similar to the proposed footnote but applies to only the Steam Generator Level – Low RPS Function. This changes the CTS by requiring an evaluation of channel functionality (extent of which is expanded on in the TS Bases) prior to returning it to service in addition to the as-found value being conservative to the Allowable Value and applies to all the RPS Function channels.

The purpose of this Note is to address a concern that the Technical Specification requirements for Limiting Safety System Settings (LSSS) may not be fully in compliance with the intent of 10 CFR 50.36. Specifically, the concern is that the existing Surveillance Requirements may not provide adequate assurance that instruments will actuate safety functions at the point assumed in the applicable safety analysis. 10 CFR 50.36(c)(1)(ii)(A) states, "Limiting safety system settings for nuclear reactors are settings for automatic protective devices related to those variables having significant safety functions. Where a limiting safety system setting is specified for a variable on which a safety limit has been placed, the settings must be so chosen that automatic protective action will correct the abnormal situation before a safety limit is exceeded. If, during operation, it is determined that the automatic safety system does not function as required, the licensee shall take appropriate action, which may include shutting down the reactor." The proposed change clarifies the Technical Specification requirements to ensure that the automatic protective action will correct the abnormal situation before a safety limit is exceeded. Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition. This change is consistent with the ISTS. This change is considered a more restrictive change because additional requirements have been added to Surveillance Requirements.

M02 CTS 2.2.1 ACTION states, in part, to declare the channel inoperable and apply the applicable ACTION statement requirement of Specification 3.3.1.1 (Unit 1) and 3.3.1 (Unit 2) until the channel is restored to OPERABLE status "with its trip

setpoint adjusted consistent with the Trip Setpoint value." ITS Table 3.3.1-1 Footnote (b) states, "The instrument channel setpoint shall be reset to a value that is within the as-left acceptance criteria band around the Nominal Trip Setpoint (NTSP) at the completion of the surveillance; otherwise, the channel shall be declared inoperable. Setpoints more conservative than the NTSP are acceptable provided that the as-found and as-left acceptance criteria bands apply to the actual setpoint implemented in the Surveillance procedures to confirm channel performance. The NTSP and the methodologies used to determine the as-found and as-left acceptance criteria bands are specified in the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report, respectively." CTS Table 4.3-1 Note (9) is similar to the proposed footnote but applies to only the Steam Generator Level – Low RPS Function. This changes the CTS by providing more detailed information describing what "consistent with the Trip Setpoint" means and states a specific location where the NTSPs and the methodology for determining the double-sided NTSP instrument tolerance bands are located. This additional footnote applies to all the RPS Function channels.

The purpose of this Note is to address a concern that the Technical Specification requirements for LSSS may not be fully in compliance with the intent of 10 CFR 50.36. Specifically, the concern is that the existing Surveillance Requirements may not provide adequate assurance that instruments will always actuate safety functions at the point assumed in the applicable safety analysis. 10 CFR 50.36(c)(1)(ii)(A) states, "Limiting safety system settings for nuclear reactors are settings for automatic protective devices related to those variables having significant safety functions. Where a limiting safety system setting is specified for a variable on which a safety limit has been placed, the settings must be so chosen that automatic protective action will correct the abnormal situation before a safety limit is exceeded. If, during operation, it is determined that the automatic safety system does not function as required, the licensee shall take appropriate action, which may include shutting down the reactor." The proposed change clarifies the Technical Specification requirements to ensure that the automatic protective action will correct the abnormal situation before a safety limit is exceeded. This change is consistent with the ISTS. This change is considered a more restrictive change because additional requirements have been added to Surveillance Requirements.

M03 CTS Table 4.3-1 Functional Unit 10 (Unit 1) and Functional Unit 15 (Unit 2) Loss of Load channels and Unit 1 Functional Unit 11 Wide Range Logarithmic Neutron Flux Monitor channels do not require Channel Calibration. ITS SR 3.3.1.8 requires Channel Calibration of each appliable RPS instrument channel including bypass removal functions with a periodic surveillance frequency in accordance with the Surveillance Frequency Control Program (SFCP). A note to the SR excludes neutron flux detectors from the Channel Calibration. This changes the CTS by adding an additional surveillance requirement for the Wide Range Logarithmic Neutron Flux Monitor Power Rate of Change – High (ITS Table 3.3.1-1 Function 2) and the Loss of Load (ITS Table 3.3.1-1 Function 10 (Unit 1) and Function 15 (Unit 2)) RPS Functions.

The proposed change is acceptable because it provides additional assurance that the Wide Range Logarithmic Neutron Flux Monitor Power Rate of Change -

High and Loss of Load RPS Functions are functioning properly. This change is consistent with ISTS.

PSL controls periodic Frequencies for Surveillances in accordance with the SFCP per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, the initial Frequency in accordance with the Surveillance Frequency Control Program will be specified as 18 months consistent with ISTS 3.3.1.8. The periodic Frequency is acceptable based upon the assumption of a 22.5 month calibration interval (18 months plus 25% grace) for the determination of the magnitude of equipment drift and is consistent with the CHANNEL CALIBRATION and CHANNEL FUNCTIONAL TEST Frequencies for the PSL Unit 2 wide range neutron monitoring instrumentation.

The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) "Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program" (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066).

The proposed change is designated more restrictive because it includes additional requirements that are not specified in the CTS.

M04 The CTS channel calibration surveillance assigned to the power range neutron flux high setpoint on Table 4.3-1 consists of adjusting the power range instrument channels to match the calorimetric heat balance calculation. The CTS surveillance is modified by Note (2) that states the surveillance is only required above 15% RTP without specifying a time for first calibration during power escalation. ITS SR 3.3.1.2 is modified by a Note that states the surveillance is not required to be performed until 12 hours after THERMAL POWER is ≥ 15% RTP. The CTS is revised to be consistent with the ISTS. This changes the CTS by adding more specific requirements for the performance of the adjustment of the power range channels to the results of the calorimetric heat balance calculation.

The proposed change provides additional guidance for performing the power range instrumentation surveillance. The ISTS note establishes 12 hours for performing the first adjustment of the power range channels during power escalation. The proposed change is acceptable because it provides additional assurance that the power range instrument adjustments are accomplished in a timely and controlled manner such that the accuracy of the power range instrumentation is maintained within acceptable limits relative to the applicable safety analysis assumptions. As such, the proposed change enhances the assurance provided by the TS that the affected plant equipment is maintained OPERABLE and that the plant continues to be operated in a safe manner. The proposed change is designated more restrictive because it includes a specific additional requirement that is not specified in the CTS.

M05 The CTS channel calibration requirement associated with the power range neutron flux high setpoint on Table 4.3-1 is modified by Note (3). CTS Table 4.3-1 Note (3) specifies that the surveillance recalibrate the excore detectors using the incore detectors above 15% RTP without specifying a first performance time. ITS SR 3.3.1.3 is modified by a Note that states the surveillance is not required to be performed until 12 hours after THERMAL POWER is ≥ 15% RTP. The CTS is revised to conform to the proposed ISTS surveillance requirement. This changes the CTS by placing a new time restriction on the first performance of the surveillance after exceeding the specified power.

The first performance of this surveillance after a shutdown or refueling outage is important to establish the instrument accuracy is within acceptable tolerances. The proposed change is acceptable because it provides assurance that the surveillance is completed in a timely manner and that the instrument accuracy is verified within acceptable limits shortly after a plant startup. As such, the proposed change enhances the assurance provided by the TS that the instrument is maintained operable and that the plant continues to be operated in a safe manner. The proposed change is designated more restrictive because it includes additional requirements that are not specified in the CTS.

M06 **Unit 1 only:** CTS Table 2.2-1 Functional Unit 9 does not include a minimum allowable value for the reactor coolant pressure (RCS). The thermal margin/low pressure trip allowable value is determined based on a RCS minimum pressure or a computed value that is a function of the higher ΔT power or neutron power, reactor inlet temperature, the number of coolant pumps operating and the AXIAL SHAPE INDEX. The proposed ITS 3.3.1 Function 9a adds the minimum pressure value of 1887 psia to the allowable values determined by ITS Figures 3.3.1-1 and 3.3.1-2. This changes the CTS Table 2.2-1 Functional Unit 9 allowable value by adding a minimum pressure value.

The purpose of the thermal margin/low pressure trip is to protect against the occurrence of DNB during steady state operation. This change is acceptable because the RCS pressure (pressurizer pressure) minimum value is an assumption considered in the accident analysis. In addition, the addition of the allowable value is consistent with the PSL Unit 2 thermal margin/low pressure trip allowable value. This changes CTS by adding an allowable value requirement not currently required in CTS. The proposed change is designated more restrictive because it includes additional requirements that are not specified in the CTS.

RELOCATED SPECIFICATIONS

R01 **Unit 2 only:** CTS Tables 2.2-1, 3.3-1, and 4.3-1 provides requirements, in part, for the Loss of Component Cooling Water to Reactor Coolant Pumps – Low reactor trip function. The RPS initiates a reactor trip to protect against violating the core specified acceptable fuel design limits and breaching the reactor coolant pressure boundary (RCPB) during anticipated operational occurrences (AOOs). By tripping the reactor, the RPS also assists the Engineered Safety Features (ESF) systems in mitigating accidents. The protection and monitoring systems have been designed to ensure safe operation of the reactor. This is achieved by

specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the RPS, as well as Limiting Conditions for Operation on other reactor system parameters and equipment performance. Technical Specifications are required by 10 CFR 50.36 to include LSSS for variables that have significant safety functions.

The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function specified in CTS Table 2.2-1, 3.3-1 and 4.3-1 is provided as a plant specific reactor trip as an equipment protective feature required as a stipulation by NRC staff in justifying acceptance of the Reactor Coolant Water Component Cooling Water piping design. This reactor trip is not required for reactor protection and is not assumed in any accident or transient analysis. In addition, this automatic reactor trip feature on a loss of component cooling water (CCW) flow to the reactor coolant pumps (RCPs) is not required to protect against violating the core specified acceptable fuel design limits or breaching the RCPB during AOOs and is not considered an LSSS for a variable that has a significant safety function. As a result, the Loss of Component Cooling Water to Reactor Coolant Pumps – Low reactor trip function will be relocated from the Technical Specifications to the Technical Requirements Manual (TRM).

10 CFR 50.36(c)(2)(ii) Criteria Evaluation:

1. The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function is not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary.

2. The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function is not a process variable, design feature, or operating restriction that is an initial condition of a DBA or transient analysis that either assumes the failure of or challenge to the integrity of a fission product barrier.

3. The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function is not a structure, system, or component that is part of the primary success path or which functions or actuates to mitigate a DBA or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

4. The loss of CCW flow to the RCPs is addressed in the PSL PRA with respect to requiring operator action to recover the CCW flow or remove the RCPs from service. The Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function is not a significant risk contributor to core damage frequency and offsite releases in the PSL PRA. Therefore, the Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function does not represent a structure, system, or component which operating experience

or probabilistic risk assessment has shown to be significant to public health and safety.

Since the selection criteria have not been satisfied for Loss of Component Cooling Water to Reactor Coolant Pumps – Low automatic reactor trip function, the requirements of this reactor trip instrument may be relocated to a licensee controlled document outside the Technical Specifications. Other reactor trip functions that are necessary to protect against violating the core specified acceptable fuel design limits or breaching the RCPB during AOOs are retained in the Technical Specifications (e.g., Reactor Coolant Flow – Low reactor trip and manual reactor trip functions). The Technical Specification requirements for the RPS Loss of Component Cooling Water to Reactor Coolant Pumps – Low Function will be relocated to the TRM. Changes to the TRM will be controlled by the provisions of 10 CFR 50.59. This change is designated as a relocation because the requirements for this instrument do not meet the criteria in 10 CFR 50.36(c)(2)(ii) and have been relocated to the TRM.

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS Table 3.3-1 for RPS instrumentation has three columns stating various requirements for each function. These columns are labeled, "TOTAL NO. OF CHANNELS," "CHANNELS TO TRIP," and "MINIMUM CHANNELS OPERABLE." ITS Table 3.3.1-1 does not retain the "TOTAL NO. OF CHANNELS" or "CHANNELS TO TRIP" columns. This changes the CTS by moving the information of the "TOTAL NO. OF CHANNELS" and "CHANNELS TO TRIP" columns to the ITS Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS 3.3.1 Table 3.3-1 Unit 1 footnote (f) and Unit 2 footnote (g) for Unit 1 CTS Function 2 and Unit 2 CTS Function 13a, respectively, state “There shall be at least two decades of overlap between the Wide Range Logarithmic Neutron Flux Monitoring Channels and the Power Range Neutron Flux Monitoring Channels.” ITS 3.3.1 Functions 1 and 2 do not include this information. The ITS only specifies that channels be OPERABLE. This changes the CTS by moving the design/operational detail to the UFSAR.

The removal of these details, related to system design, from Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The excore instrumentation overlap requirement is a system design detail not related to any RPS reactor trip function. ITS still retains the requirements for Wide Range and Power Range monitoring channels to be OPERABLE. In addition, overlap of the range is checked during power transition to ensure the design requirement for continuous monitoring over the full reactor power range. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. Any changes to the UFSAR are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive change because information relating to system design is being removed from the Technical Specifications.

LA03 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS Table 4.3-1 Functional Unit 2 Note (3) states, in part, "recalibrate the excore detectors which monitor the AXIAL SHAPE INDEX." ITS SR 3.3.1.3 does not contain the system description detail "which monitor the AXIAL SHAPE INDEX." This changes the CTS by moving the system description detail that the excore detectors monitor the AXIAL SHAPE INDEX to the UFSAR.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirements for performance of the surveillance requirement. Also, this change is acceptable because the removed information is adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA04 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements*) CTS 2.2.1 requires the RPS instrumentation setpoints to be set consistent with the Trip Setpoint values shown in Table 2.2-1. However, the CTS 2.2.1 Action is only required to be taken when the setpoint is less conservative than the Allowable Value column of Table 2.2-1. When the setpoint is less conservative than the Allowable Value, the channel is to be declared inoperable and adjusted consistent with the Trip Setpoint value. CTS Table 2.2-1 specifies both the Trip Setpoints and Allowable Values for the RPS Instrumentation Functional Units. ITS 3.3.1 requires the RPS instrumentation for each Function in Table 3.3.1-1 to be OPERABLE. ITS Table 3.3.1-1 specifies only the Allowable Values for the RPS Instrumentation Functions. The Allowable Values represent the OPERABILITY limit of the channels in ITS. This changes the CTS by moving the Trip Setpoints to the Technical Requirements Manual (TRM).

The purpose of the trip setpoint requirements is to ensure required automatic safety systems are actuated to protect against violating core design limits, breaching the Reactor Coolant System pressure boundary, and to mitigate accidents. Pursuant to 10 CFR 50.36(c)(1)(ii)(A), if it is determined that an

automatic protective device for a variable on which a safety limit has been placed (i.e., limiting safety system setting) does not function as required, appropriate action is taken to ensure the abnormal situation is corrected before a safety limit is exceeded, which may include shutting down the reactor. The PSL Instrument Setpoint Methodology calculates nominal trip setpoints (NTSPs) using methods consistent with the guidance provided in NRC Regulatory Guide (RG) 1.105, "Setpoints For Safety-Related Instrumentation," and ANSI/ISA Standard 67.04, "Setpoints for Nuclear Safety-Related Instrumentation." Additionally, pre-defined limits (double-sided Operability limits and as-left limits) are determined for each instrument consistent with the guidance provided in NRC RG 1.105 and ANSI/ISA–RP67.04, "Methodologies for the Determination of Setpoints for Nuclear Safety-Related Instrumentation." The instrument Operability limit band in plant uncertainty calculations is synonymous with the as-found acceptance criteria band specified in ITS and is centered about the nominal equipment setting (clarified in calculations as the field trip setpoint or NTSP). The PSL Instrument Setpoint Methodology, including the method of determining instrument uncertainties, was reviewed by the NRC during the review of Extended Power Uprate (EPU) as documented in the EPU safety evaluations for License Amendments 213 (Unit 1) and 163 (Unit 2), dated July 9, 2012 and September 24, 2012, respectively (NRC ADAMS Accession Nos. ML12181A019 and ML12235A463). The NRC staff determined that the PSL Instrument Setpoint Methodology described in the EPU license request meets the requirements of 10 CFR 50, Appendix A, General Design Criterion 13 and the regulatory guidance in RG 1.105 (EPU SE pg. 92 (Unit 1) and 95 (Unit 2)). The NRC staff also determined that the application of the clarifications of RG 1.105 in Regulatory Issue Summary 2006-17 "NRC Staff Position on the Requirements of 10 CFR 50.36, 'Technical Specifications,' Regarding Limiting Safety System Settings During Periodic Testing and Calibration of Instrument Channels," is acceptable (EPU SE pg. 94 (Unit 1) and 97 (Unit 2)). | R1

The removal of these details for meeting Technical Specification requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the Allowable Values associated with the RPS Instrumentation, which are designated as the Operability limits for the required instrument Functions. Footnotes (a) and (b) in Table 3.3.1-1 are included to ensure channel performance continues to verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology consistent with the NRC guidance specified in RIS 2006-17. Also, this change is acceptable because these types of procedural details will be adequately controlled in the TRM. Any changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA05 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS Table 2.2-1 Functional Unit 3 provides an Allowable Value of "≥ 95% of minimum reactor coolant flow with 4 pumps operating.*" Footnote * refers to CTS LCO 3.2.5 for the minimum reactor coolant flow for 4 pumps

operating. ITS Table 3.3.1-1 Function 3 provides an Allowable Value for Reactor Coolant Flow – Low in terms of percent but does not include the detail of associated reactor coolant flow. This changes the CTS by moving the detail of what the setting in % is based on to the UFSAR.

The removal of this detail, related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the value for each of the Allowable Values. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. Any changes to the UFSAR are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA06 **Unit 2 only:** *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements*) CTS Table 3.3-1, Action 2 states, in part, that all functional units affected by the bypassed/tripped channel shall be placed in the bypassed/tripped condition. CTS Table 3.3-1, Action 2 provides a process instrument and Function bypass list that identifies the associated Functions that must be bypassed if the instrument becomes inoperable. ITS 3.3.1 ACTION A includes a Required Action to place the affected trip unit in trip or bypass within 1 hour. CTS LCO 3.0.2 and ITS LCO 3.0.2 establish that upon discovery of a failure to meet an LCO, the associated ACTIONS shall be met. Therefore, when an instrument channel becomes inoperable, LCO 3.0.2 requires each Function affected by the inoperability shall be declared inoperable and the associated ACTIONS shall be met. The CTS process instrument and Function bypass list is not necessary in the Specifications. This information is removed from the Technical Specifications and moved to the UFSAR.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement that all functional units receiving an input from an inoperable channel are bypassed or tripped. ITS 3.3.1 ACTIONS for each Function include a Required Action to place the affected trip unit in trip or bypass within 1 hour. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA07 **Unit 2 only:** *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* Table 2.2-1 Functional Unit 8, Allowable Values column, includes Note (3), that states, “% of the narrow range steam generator level indication.” ITS Table 3.3.1-1 Steam Generator Level – Low Function (Functions 7.a and 7.b) do not include this design detail. This changes the CTS by moving the detail of what the setting in % is based on to the UFSAR.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the Allowable Value requirement for the Steam Generator Level – Low RPS Function. Also, this change is acceptable because the removed information is currently provided in the UFSAR Section 7.2 where it is adequately controlled. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 **Unit 1 only:** (*Category 2 – Relaxation of Applicability*) CTS Table 3.3-1 Functional Unit 11a Applicability requires OPERABILITY of the Wide Range Logarithmic Neutron Flux Monitor – Rate of Change of Power – High trip function in MODES 1, 2 and *. Footnote * states "with the protective system trip breakers in the closed position and the CEA drive system capable of CEA withdrawal." CTS Table 4.3-1 surveillance requirement applicability for Functional Unit 11 also includes a footnote * which states, "with reactor trip breaker closed." ITS 3.3.1 Function 2 requires the equivalent trip function to be OPERABLE in MODES 1 and 2. This changes the CTS by deleting the requirement for Rate of Change of Power – High trip function to be OPERABLE in MODES other than MODES 1 and 2 with the reactor trip circuit breakers (RTCBs) closed and the CEA drive system capable of CEA withdrawal.

The purpose of the requirement for the Rate of Change of Power – High trip function to be OPERABLE MODES other than MODES 1 and 2 with the RTCBs closed and the CEA drive system capable of CEA withdrawal is to ensure that a withdrawn CEA can be inserted in the event of an uncontrolled reactivity event during shutdown (i.e., MODES 3, 4, and 5). However, the Rate of Change of Power – High trip function is not assumed in any shutdown event (e.g., boron dilution event). The proposed change is consistent with the PSL Unit 2 CTS for the same function.

This change is acceptable because the uncontrolled CEA withdrawal event analysis is initiated from a MODE 2 startup condition at zero power with termination on a high-power trip signal. The high-power trip was used in the event analysis to determine the required initial overpower margin for DNBR and FCM (UFSAR Section 15.2.1). The rate of change of power trip is not credited in any accident analysis as providing primary protection for any limiting case accident, including any shutdown event. Appropriate reactor protection is provided in MODES 3, 4, and 5 when the RTCBs closed and any CEA is capable of being withdrawn by ITS LCO 3.3.2, which requires four Manual Trip channels and associated trip logic to be OPERABLE. Also, ITS LCO 3.3.11 requires two logarithmic neutron flux monitoring channels to be OPERABLE in MODES 3, 4 and 5 to monitor neutron flux power so a loss of SHUTDOWN MARGIN caused by boron dilution can be detected as an increase in flux. This change is

designated as less restrictive because the LCO requirements are applicable in fewer plant conditions than in the CTS.

L02 **Unit 1 only:** (*Category 4 – Relaxation of Required Action*) CTS Table 3.3-1 Action 2.a requires, with the number of OPERABLE channels one less than the Total Number of Channels, to place the inoperable channel in the bypassed or tripped condition but do not provide an action for more than one RPS channel inoperable. Thus, CTS 3.0.3 would be required if two or more RPS Function channels are inoperable. ITS 3.3.1 ACTION B provides an allowance for one or more Functions with two RPS trip units or associated instrument channels inoperable except for the condition when the excore channels are not calibrated with the incore detectors. ITS 3.3.1 ACTION C provides an allowance for one or more Functions with one or more power range excore channels not calibrated within the incore detectors. ITS 3.3.1 ACTION B requires one trip unit to be placed in bypass and the other trip unit must be placed in trip within 1 hour and one trip unit must be restored to OPERABLE status within 48 hours. ITS 3.3.1 ACTION C requires performing SR 3.3.1.3 (Calibrate the power range excore channels with the incore detectors) in 24 hours or restrict THERMAL POWER to ≤ 90% RTP. This changes the CTS by providing actions for the condition of two RPS Function trip units or associated instrument channels inoperable and allowing one or more excore channels not calibrated to within the incore detectors.

The RPS Function channels are configured in a two-out-of-four coincidence. The two-out-of-four RPS logic is changed to a two-out-of-three logic for a given input parameter in one channel at a time by bypassing one channel input to the logic. With one channel of protective instrumentation bypassed, the RPS Function is in two-out-of-three logic, but with another channel failed the RPS may be operating with a two-out-of-two logic. This is outside the assumptions made in the analyses and should be corrected. To correct the problem, the second channel is placed in trip. This places the RPS in a one-out-of-two logic. If any of the other OPERABLE channels receives a trip signal, RPS actuation will occur. Therefore, it is also acceptable to allow an additional channel to be inoperable. When one or more power range excore channels are discovered not calibrated with the incore detectors, time is allowed to calibrate the power range instruments instead of placing the plant in a transient with the excore power range channels not calibrated. Alternatively, THERMAL POWER may be restricted to ≤ 90% RTP to provide additional margin to the fuel thermal limits. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the remaining RPS instrument channels, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the repair period. This change also provides appropriate remedial actions in lieu of requiring initiation of an unnecessary plant transient per ITS LCO 3.0.3 (CTS 3.0.3). The 48-hour Completion Time of proposed Required Action B.2 is based upon operating experience, which has demonstrated that a random failure of another channel occurring during the 48 hour period is a low probability event. The 24-hour Completion Time of proposed Required Actions C.1 and C.2 is adequate to

calibrate the power range excore channels while minimizing the risk of operating in an unsafe condition. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 (*Category 4 – Relaxation of Required Action*) Unit 1 CTS 3.3.1.1 and Unit 2 CTS 3.3.1 do not explicitly provide requirements associated with the bypass removal feature associated with the following CTS Table 3.3-1 RPS Functional Units; Power Rate of Change – High (11.a), Reactor Coolant Flow – Low (3), Steam Generator Pressure – Low (6), Local Power Density – High (8), Thermal Margin/Low Pressure (9), and Loss of Load (10). However, CTS 4.3.1.1.2 and Unit 2 CTS 4.3.1.2 require channel functional and calibration testing of the channel bypass logic, which includes the bypass removal feature. Therefore, per the requirements of CTS 4.0.1 (ITS SR 3.0.1), CTS 3.3.1.1 (Unit 1) and CTS 3.3.1 (Unit 2) encompass the RPS channel bypass removal feature. If an RPS bypass removal channel is inoperable, CTS 3.0.3 is entered since there are no Conditions and Actions specified in the CTS. ITS 3.3.1 also includes Surveillances for the channel bypass removal feature. In addition, ITS 3.3.1 ACTIONS D and E are added to provide remedial measures when the bypass removal capability is inoperable to a required RPS Function channel. ITS Required Actions D.1 and E.1 require disabling the inoperable bypass channel within 1 hour when one or two bypass removal channels is inoperable. When one bypass removal channel is inoperable, ITS 3.3.1 ACTION D alternately allows placing the affected channel in bypass or trip within 1 hour and restoring the channel to OPERABLE status within 48 hours. When two bypass removal channels are inoperable, ITS 3.3.1 ACTION E alternately allows placing one channel in trip and the other channel in bypass and restoring one channel to OPERABLE status within 48 hours. This changes the CTS by adding specific Technical Specification actions when one or two bypass removal channels are inoperable to the applicable Functions.

The purpose of the proposed actions is to provide appropriate remedial actions in the event the automatic bypass removal feature is inoperable. With one or two bypass removal channels inoperable, it is permissible to continue operation with the bypass permissive removal channels failed, providing the bypass is disabled. The Completion Times are consistent with the completion times for the conditions of one or two inoperable RPS channels. This change is also consistent with the ISTS.

This change is considered acceptable because the proposed remedial actions will ensure the related RPS Functions can continue to perform their related safety function when required by the plant design basis and safety analysis by requiring the bypass removal channel to be disabled or take action consistent with the current actions for an inoperable RPS channel. This change also provides appropriate remedial actions in lieu of requiring initiation of an unnecessary plant transient per ITS LCO 3.0.3 (CTS 3.0.3). This change is designated as less restrictive because the ITS ACTIONS provide remedial actions that are less restrictive than the CTS Action requiring a plant shutdown.

L04 **Unit 2 only:** (*Category 4 – Relaxation of Required Action*) CTS Table 3.3-1 Actions 2.a and 2.b provide actions for conditions with the number of OPERABLE

channels one less than the Total Number of Channels and the condition with the number of channels OPERABLE one less than the Minimum Channels OPERABLE. ITS 3.3.1 Conditions A and B also provide Required Actions for these conditions except for the condition when the excore channels are not calibrated with the incore detectors. ITS 3.3.1 ACTION C provides an allowance for one or more Functions with one or more power range excore channels not calibrated within the incore detectors. ITS 3.3.1 ACTION C requires performing SR 3.3.1.3 (Calibrate the power range excore channels with the incore detectors) in 24 hours or restrict THERMAL POWER to ≤ 90% RTP. This changes the CTS by providing actions for the condition of one or more excore channels not calibrated to within the incore detectors.

When one or more power range excore channels is discovered not calibrated with the incore detectors, time is allowed to calibrate the power range instruments instead of placing the plant in a transient with the excore power range channels not calibrated. Alternatively, THERMAL POWER may be restricted to ≤ 90% RTP to provide additional margin to the fuel thermal limits. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the remaining RPS instrument channels, a reasonable time for recalibration, and the low probability of a DBA occurring during the calibration period. The 24-hour Completion Time of proposed Required Actions C.1 and C.2 is adequate to calibrate the power range excore channels while minimizing the risk of operating in an unsafe condition. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L05 **Unit 2 only:** (*Category 6 - Relaxation of Surveillance Requirement Acceptance Criteria*) CTS 4.3.1.1 and Table 4.3-1, Functional Unit 13 (Wide Range Logarithmic Neutron Flux Monitor) require, in part, a CHANNEL CALIBRATION on a Frequency in accordance with the Surveillance Frequency Control Program (SFCP). ITS SR 3.3.1.8 also requires a CHANNEL CALIBRATION but is modified by a Note stating, "Neutron detectors are excluded from CHANNEL CALIBRATION." This changes the CTS by excluding neutron detectors from the CHANNEL CALIBRATION requirement for the Logarithmic Neutron Flux Monitoring channels.

The purpose of a CHANNEL CALIBRATION is to ensure that the channel responds within the necessary range and accuracy to known values of the parameter that the channel monitors. Thus, to perform a channel calibration of a neutron flux channel would require including the neutron flux detector in the calibration. Inclusion of neutron flux detectors in the CHANNEL CALIBRATION process is impractical in power reactor applications because to do so would require subjecting the detectors to known neutron fluxes. Because of the hazards associated with exposing the neutron detectors, CTS Table 4.3-1 Note (4) excludes the detectors of Functional Unit 2 (Variable Power Level High) from CHANNEL CALIBRATION. The logarithmic neutron flux monitoring channels also use neutron detectors, which are subject to the same hazards as the detectors of

the RPS Variable Power Level - High function. The Note excluding the neutron detectors from the calibration is acceptable because they are passive devices with minimal drift and because of the difficulty of simulating a meaningful signal. This proposed change is consistent with historical and current NRC staff requirements as reflected in ISTS. This change is designated as less restrictive because less stringent Surveillance Requirements are being applied in the ITS than were applied in the CTS.

L06 (*Category 2 – Relaxation of Applicability*) CTS Table 3.3-1 requires the OPERABILITY of Loss of Load (Turbine Hydraulic Fluid Pressure – Low) (Unit 1 Functional Unit 10 and Unit 2 Functional Unit 15) and Low Power Density – High (Unit 1 Functional Unit 8 and Unit 2 Functional Unit 9) trip functions in MODE 1. Table 3.3-1 Notation (c) to the function(s) states, "Trip may be bypassed below 15% of RATED THERMAL POWER; bypass shall be automatically removed when Power Range Neutron Flux power is > 15% of RATED THERMAL POWER." In addition, Unit 1 Table 2.2-1 Notation (3) and Unit 2 Notation (5) state, "Trip may be bypassed below 15% of RATED THERMAL POWER; bypass shall be automatically removed when Power Range Neutron Flux power is greater than or equal to 15% of RATED THERMAL POWER." Footnote (g) to ITS Table 3.3.1-1 Functions 8 and 10 provide(s) the same allowance for bypassing and automatically removing the bypass for the Loss of Load and Local Power Density functions. In addition, ITS Footnote (g) provides similar allowances and Footnote (h) is added to clarify the Loss of Load and Local Power Density trip functions are not applicable and may be bypassed when THERMAL POWER is < 15% RTP and the functions are applicable in MODE 1 ≥ 15% RTP. This changes the CTS by relaxing the MODE 1 applicability requirement of the Loss of Load (turbine hydraulic fluid pressure – low) and Local Power Density RPS Functions to MODE 1 ≥ 15% RTP. R1

The purpose of the requirement for the Loss of Load (Turbine Hydraulic Fluid Pressure – Low) RPS Function to be OPERABLE in MODE 1 is to ensure the RPS trip function is OPERABLE in anticipation of a high pressurizer pressure RPS trip following a trip of the main turbine generator. The Loss of Load RPS trip is anticipatory for the loss of heat removal capabilities of the secondary system following a turbine trip. Thus, the trip minimizes the pressure and temperature transients on the reactor by initiating a trip before reaching the Pressurizer Pressure - High trip. The Loss of Load trip also prevents lifting the pressurizer safety valves, power operated relief valves (PORVs), and main steam safety valves (MSSVs) in the event of a main turbine generator trip. The proposed change to the Applicability is consistent with the ISTS.

The purpose of the requirement for the Local Power Density – High RPS Function to be OPERABLE in MODE 1 is to ensure excessive axial peaking will not cause fuel damage. It ensures that neither a DNBR less than the SAFETY LIMIT nor a peak linear heat rate corresponding to the temperature for fuel centerline melting will occur.

These changes are acceptable because the Loss of Load and Local Power Density RPS trips are not required to support any accident or transient event < 15% RTP. The Loss of Load and Local Power Density trips are currently allowed to be bypassed when THERMAL POWER falls below 15%. In addition, the Loss

of Load RPS and Local Power Density trips are not credited in any accident analysis as providing primary protection for any limiting case accident. Appropriate reactor protection continues to be provided below 15% RTP by other reactor trips. This change is designated as less restrictive because the Loss of Load (turbine hydraulic fluid pressure – low) and Local Power Density RPS Functions are applicable in fewer plant conditions than in the CTS.

L07 **Unit 2 only:** (*Category 7- Relaxation of Surveillance Frequency*) CTS 4.3.1.1 and Table 4.3-1, Functional Unit 15 Loss of Load (Turbine Hydraulic Fluid Pressure – Low) requires, in part, a CHANNEL FUNCTIONAL TEST on a Frequency in accordance with the Surveillance Frequency Control Program (SFCP). The Frequency specified in the SFCP is 31 days. ITS SR 3.3.1.6 requires a CHANNEL FUNCTIONAL TEST to be performed for the Loss of Load RPS Function at a Frequency of "Once within 7 days prior to each reactor startup." This changes the CTS by requiring the CHANNEL FUNCTIONAL TEST for the Loss of Load RPS Function to be performed only during a reactor startup instead of on a periodicity. R1

The purpose of a CHANNEL FUNCTIONAL TEST is to verify successful operation of the required contact(s) of a channel relay in between CHANNEL CALIBRATIONS by the verification of the change of state of the relay contacts. The Loss of Load (Turbine Hydraulic Fluid Pressure – Low) trip is anticipatory for events resulting in loss of heat removal capabilities of the secondary system following a turbine trip. The loss of load analysis provided in UFSAR Chapter 15 demonstrates that the high pressurizer pressure RPS trip Function is the primary RPS trip Function for these events. Performing a CHANNEL FUNCTIONAL TEST on a 31 day periodicity in accordance with the SFCP requires the Surveillance to be performed during reactor operation. Performing this test during reactor operation could have the adverse effect of causing a pressure perturbation in the emergency trip fluid header common to all four channels resulting in a main turbine trip and reactor trip. Therefore, it is proposed to revise the frequency to perform this test within 7 days prior to each reactor startup consistent with the Frequency specified for the same surveillance test for the Loss of Load RPS Function in Unit 1 CTS and the ISTS.

This change is considered acceptable because the CHANNEL FUNCTIONAL TEST for the Loss of Load RPS Function will still be performed at a frequency that assures the necessary quality of systems and components is maintained. A review of historical surveillance data has shown that this test consistently passes the Surveillance at the current Frequency and demonstrates that there are no failures that would invalidate an extended surveillance test interval from 31 days in accordance with the SFCP to prior to each reactor startup. Relaxation of this surveillance test interval from the current periodic frequency is offset by eliminating the need to perform the Surveillance during reactor operation, which could result in an unnecessary plant transient. Also, the proposed event based frequency will be retained in the Technical Specifications instead of maintaining a periodic frequency under licensee control. This change is designated as less restrictive because the Surveillance will be performed less frequently under the ITS than currently under the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.1, REACTOR PROTECTIVE SYSTEM (RPS) INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The heading for ISTS 3.3.1 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

4. PSL does not use the terms “as-found tolerance” and “Limiting Trip Setpoint (LTSP)” in plant specific instrument calculations or the Updated Final Safety Analysis Report. Therefore, the use of these terms in Footnotes (a) and (b) in ISTS Table 3.3.1-1 are revised in the ITS to include the plant specific terminology. To comply with the guidance provided in NRC Regulatory Issue Summary 2006-17, “NRC Staff Position on the Requirements of 10 CFR 50.36, ‘Technical Specifications,’ Regarding Limiting Safety System Settings During Periodic Testing and Calibration of Instrument Channels,” the PSL setpoint calculations have been structured to include a Nominal Trip Setpoint (NTSP), also known as the field trip setpoint, and determination of an OPERABILITY limit range, referred to in CTS as acceptance criteria band. For PSL, the Nominal Trip Setpoint (NTSP) is synonymous with the Limiting Trip Setpoint (LTSP) and the as-found acceptance criteria band (i.e., OPERABILITY limit range) is synonymous with the as-found tolerance.

5. This Reactor Coolant System Loops - Test Exceptions Specification is not included in the PSL Unit 1 and Unit 2 ITS because the exception is not needed to perform any required startup or PHYSICS TESTS.

6. The addition of Footnote (e) to Function 2 (Wide Range Logarithmic Neutron Flux Monitor Power Rate of Change – High) in ITS Table 3.3.1-1, reflects current licensing basis as approved in License Amendment 243 (Unit 1) and Amendment 194 (Unit 2), dated October 31, 2017 (NRC ADAMS Accession Number ML17257A015). In addition to allowing the Wide Range Logarithmic Neutron Flux Monitor Power Rate of Change – High RPS Function channels to be bypassed when THERMAL is > 15% RPT, this change allowed the RPS Function to not apply when THERMAL POWER is > 15% RTP. As stated in the NRC Safety Evaluation accompanying the license amendments, the NRC staff determined that the change to limit MODE 1 applicability for the Wide Range Logarithmic Neutron Flux Monitor Power Rate of Change – High RPS Function to ≤15% RTP neither physically changes any plant systems, structures, or components, nor modifies any plant procedure or methodology for this phase of plant operation, and therefore, is acceptable.

7. **Unit 2 only:** ISTS 3.3.1, Required Action A.2.2 is deleted and the Completion Time of Required Action A.2.1 (ITS 3.3.1, Required Action A.2) is modified in the Unit 2 ITS consistent with the PSL current licensing basis to allow the inoperable channel to be in trip or bypass until the next plant startup following entry into MODE 5. In

addition, ISTS Required Action B.2 is unnecessary since ACTION A requires restoration of the channel to OPERABLE status with no option to place the trip unit in the trip condition indefinitely. These changes to the ISTS 3.3.1 ACTIONS A and B are similar to ISTS 3.3.1 (Digital) ACTIONS A and B. The Unit 2 RPS design includes independence of the four protection channels to ensure no single failure (e.g., circuit fault) can adversely affect more than one channel. As discussed in Section 7.2.4 of NUREG-0843, "Safety Evaluation Report - St. Lucie Unit 2," the NRC concluded that the RPS design enhancements were sufficient to ensure the independence of the four protection channels. Thus, the Unit 2 Technical Specifications allow a failed channel to be placed in long term trip or bypass condition provided the channel is restored no later than the next cold shutdown following the channel malfunction. A Note is added to ITS 3.3.1 Condition A stating that Required Action A.2 shall be completed when Condition A is entered. This Note constitutes an "unless otherwise stated" exception to LCO 3.0.2 to require the action to be completed within the associated Completion Time even when the LCO is no longer applicable. The added Note is similar to other Notes in the ISTS (e.g., Note to Condition A of ISTS 3.2.3 and the Note to Conditions A and C of ISTS 3.4.3.).

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.1 Reactor Protective System (RPS) Instrumentation ~~– Operating (Analog)~~ 2

BASES

BACKGROUND

The Reactor Protective System (RPS) initiates a reactor trip to protect against violating the core specified acceptable fuel design limits and breaching the reactor coolant pressure boundary (RCPB) during anticipated operational occurrences (AOOs). By tripping the reactor, the RPS also assists the Engineered Safety Features (ESF) systems in mitigating accidents.

The protection and monitoring systems have been designed to ensure safe operation of the reactor. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the RPS, as well as LCOs on other reactor system parameters and equipment performance.

Technical Specifications are required by 10 CFR 50.36 to include LSSS for variables that have significant safety functions. LSSS are defined by the regulation as "Where a LSSS is specified for a variable on which a safety limit has been placed, the setting must be chosen so that automatic protective actions will correct the abnormal situation before a Safety Limit (SL) is exceeded." The Analytical Limit is the limit of the process variable at which a safety action is initiated, as established by the safety analysis, to ensure that a SL is not exceeded. Any automatic protection action that occurs on reaching the Analytical Limit therefore ensures that the SL is not exceeded. However, in practice, the actual settings for automatic protection channels must be chosen to be more conservative than the Analytical Limit to account for channel uncertainties related to the setting at which the automatic protective action would actually occur.

~~---------- REVIEWER'S NOTE ----------~~

~~The term "Limiting Trip Setpoint" [LTSP] is generic terminology for the calculated trip setting (setpoint) value calculated by means of the plant specific setpoint methodology documented in a document controlled under 10 CFR 50.59. The term [LTSP] indicates that no additional margin has been added between the Analytical Limit and the calculated trip setting.~~

~~"Nominal Trip Setpoint [NTSP]" is the suggested terminology for the actual setpoint implemented in the plant surveillance procedures where margin has been added to the calculated [LTSP]. The as-found and as-left tolerances will apply to the [NTSP] implemented in the Surveillance procedures to confirm channel performance.~~ 4

BASES

BACKGROUND (continued)

~~Licensees are to insert the name of the document(s) controlled under 10 CFR 50.59 that contain the methodology for calculating the as-left and as-found tolerances in Note b of Table 3.3.1-1 for the phrase "[insert the name of a document controlled under 10 CFR 50.59 such as the Technical Requirements Manual or any document incorporated into the facility FSAR]" throughout these Bases.~~ 4

~~Where the [LTSP] is not included in Table 3.3.1-1, the plant specific location for the [LTSP] or [NTSP] must be cited in Note b of Table 3.3.1-1. The brackets indicate plant specific terms may apply, as reviewed and approved by the NRC.~~

Nominal NTSP Reference 1

The ~~[Limiting~~ Trip Setpoint (~~LTSP~~)~~]~~ specified in ~~Table 3.3.1-1~~ is a predetermined setting for a protection channel chosen to ensure automatic actuation prior to the process variable reaching the Analytical Limit and thus ensuring that the SL would not be exceeded. As such, the ~~[LTSP]~~ accounts for uncertainties in setting the channel (e.g., calibration), uncertainties in how the channel might actually perform (e.g., repeatability), changes in the point of action of the channel over time (e.g., drift during surveillance intervals), and any other factors which may influence its actual performance (e.g., harsh accident environments). In this manner, the ~~[LTSP]~~ ensures that SLs are not exceeded. Therefore, the ~~[LTSP]~~ meets the definition of an LSSS (Ref. ~~1~~). 1 3 5 1

NTSP 2

Technical Specifications contain values related to the OPERABILITY of equipment required for safe operation of the facility. OPERABLE is defined in Technical Specifications as "...being capable of performing its safety function(s)." Relying solely on the ~~[LTSP]~~ to define OPERABILITY in Technical Specifications would be an overly restrictive requirement if it were applied as an OPERABILITY limit for the "as-found" value of a protection channel setting during a Surveillance. This would result in Technical Specification compliance problems, as well as reports and corrective actions required by the rule which are not necessary to ensure safety. For example, an automatic protection channel with a setting that has been found to be different from the ~~[LTSP]~~ due to some drift of the setting may still be OPERABLE because drift is to be expected. This expected drift would have been specifically accounted for in the setpoint methodology for calculating the ~~[LTSP]~~ and thus the automatic protective action would still have ensured that the SL would not be exceeded with the "as-found" setting of the protection channel. Therefore, the channel would still be OPERABLE because it would have performed its safety function and the only corrective action required would be to reset the channel within the established as-left ~~tolerance~~ around the ~~[LTSP]~~ to account for further drift during the next surveillance interval. Note that, 3

NTSP

acceptance criteria band NTSP 5

BASES

BACKGROUND (continued)

acceptance criteria band

although the channel is OPERABLE under these circumstances, the trip setpoint must be left adjusted to a value within the as-left ~~tolerance~~ in accordance with uncertainty assumptions stated in the referenced setpoint methodology (as-left criteria), and confirmed to be operating within the statistical allowances of the uncertainty terms assigned (as-found criteria). 5

However, there is also some point beyond which the channel may not be able to perform its function due to, for example, greater than expected drift. This value needs to be specified in the Technical Specifications in order to define OPERABILITY of the channels and is designated as the Allowable Value.

acceptance criteria band (e.g., conservative side of the as-found acceptance criteria band)

If the actual setting (as-found setpoint) of the channel is found to be conservative with respect to the Allowable Value but is beyond the as-found ~~tolerance band~~, the channel is OPERABLE, but degraded. The degraded condition will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the ~~[Nominal Trip Setpoint (~~NTSP~~)]~~ (within the allowed ~~tolerance~~), and evaluating the channel response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation. 5 3

acceptance criteria band

During AOOs, which are those events expected to occur one or more times during the plant life, the acceptable limits are:

- The departure from nucleate boiling ratio (DNBR) shall be maintained above the SL value to prevent departure from nucleate boiling,
- Fuel centerline melting shall not occur, and
- The Reactor Coolant System (RCS) pressure SL of ~~[~~2750~~]~~ psia shall not be exceeded. 3

Maintaining the parameters within the above values ensures that the offsite dose will be within the ~~10 CFR 50 (Ref. 2) and~~ 10 CFR ~~100~~ (Ref. ~~3~~) criteria during AOOs. 1

4

50.67

BASES

BACKGROUND (continued)

Accidents are events that are analyzed even though they are not expected to occur during the plant life. The acceptable limit during accidents is that the offsite dose shall be maintained within an acceptable fraction of 10 CFR ~~100~~ (Ref. ~~3~~) limits. Different accident categories allow a different fraction of these limits based on probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event. 1

50.67 4

The RPS is segmented into four interconnected modules. These modules are:

- Measurement channels,
- Bistable trip units,
- RPS Logic, and
- Reactor trip circuit breakers (RTCBs).

This LCO addresses measurement channels and bistable trip units. It also addresses the automatic bypass removal feature for those trips with operating bypasses. The RPS Logic and RTCBs are addressed in LCO 3.3.~~3~~, "Reactor Protective System (RPS) Logic and Trip Initiation." 1

2

The role of each of these modules in the RPS, including those associated with the logic and RTCBs, is discussed below.

Measurement Channels

Measurement channels, consisting of field transmitters or process sensors and associated instrumentation, provide a measurable electronic signal based upon the physical characteristics of the parameter being measured.

The excore nuclear instrumentation and the analog core protection calculators (CPCs) are considered components in the measurement channels. The wide range nuclear instruments (NIs) provide a Power Rate of Change - High Trip. Three RPS trips use a power level designated as Q power as an input. Q power is the higher of NI power and primary calorimetric power (ΔT power) based on RCS hot leg and cold leg temperatures. Trips using Q power as an input include the Variable ~~High~~ Power Trip (VHPT) - High, Thermal Margin/Low Pressure (TM/LP), and the ~~Axial~~ Power ~~Distribution (APD)~~ - High trips. 1

Level Local Density

BASES

BACKGROUND (continued)

Local Power Density

The analog CPCs provide the complex signal processing necessary to calculate the TM/LP trip setpoint, ~~APD~~ trip setpoint, VHPT trip setpoint, and Q power calculation. 1

linear

Local Power Density

The excore NIs (wide range and ~~power~~ range) and the analog CPCs (TM/LP and ~~APD~~ calculators) are mounted in the RPS cabinet, with one channel of each in each of the four RPS bays. 1

Four identical measurement channels, designated channels A through D, with electrical and physical separation are provided for each parameter used in the direct generation of trip signals. Measurement channels provide input to one or more RPS bistables within the same RPS channel. In addition, some measurement channels may also be used as inputs to Engineered Safety Features Actuation System (ESFAS) bistables, and most provide indication in the control room. Measurement channels used as an input to the RPS are never used for control functions.

When a channel monitoring a parameter exceeds a predetermined setpoint, indicating an unsafe condition, the bistable monitoring the parameter in that channel will trip. Tripping two or more channels of

the

bistables monitoring the same parameter de-energizes Matrix Logic, 7
which in turn de-energizes the Initiation Logic. This causes all eight RTCBs to open, interrupting power to the control element assemblies (CEAs), allowing them to fall into the core.

Three of the four measurement and bistable channels are necessary to meet the redundancy and testability of GDC 21 in 10 CFR 50, Appendix A (Ref. ~~2~~ 3). The fourth channel provides additional flexibility by allowing one 1
channel to be removed from service (trip channel bypass) for maintenance or testing while still maintaining a minimum two-out-of-three logic. Thus, even with a channel inoperable, no single additional failure in the RPS can either cause an inadvertent trip or prevent a required trip from occurring.

Since no single failure will either cause or prevent a protective system actuation, and no protective channel feeds a control channel, this arrangement meets the requirements of IEEE Standard 279-1971 (Ref. ~~4~~ 5). 1

NTSP

Many of the RPS trips are generated by comparing a single measurement to a fixed bistable ~~[LTSP]~~. Certain Functions, however, make use of more 3
than one measurement to provide a trip. The following trips use multiple measurement channel inputs:

BASES

BACKGROUND (continued)

- Steam Generator Level - Low

  This trip uses the lower of the two steam generator levels as an input to a common bistable.

- Steam Generator Pressure - Low

  This trip uses the lower of the two steam generator pressures as an input to a common bistable.

- Variable ~~High~~ Power Trip (VHPT) - High (Level) (1)

  The VHPT uses Q power as its only input. Q power is the higher of NI power and ΔT power. It has a trip setpoint that tracks power levels downward so that it is always within a fixed increment above current power, subject to a minimum value.

  On power increases, the trip setpoint remains fixed unless manually reset, at which point it increases to the new setpoint, a fixed increment above Q power at the time of reset, subject to a maximum value. Thus, during power escalation, the trip setpoint must be repeatedly reset to avoid a reactor trip.

- Thermal Margin/Low Pressure (TM/LP) and Steam Generator Pressure Difference

  Q power is only one of several inputs to the TM/LP trip. Other inputs include internal ASI and cold leg temperature based on the higher of two cold leg resistance temperature detectors. The TM/LP trip setpoint is a complex function of these inputs and represents a minimum acceptable RCS pressure to be compared to actual RCS pressure in the TM/LP trip unit.

  Steam generator pressure is also an indirect input to the TM/LP trip via the Steam Generator Pressure Difference. This Function provides a reactor trip when the secondary pressure in either steam generator exceeds that of the other generator by greater than a fixed amount. The trip is implemented by biasing the TM/LP trip setpoint upward so as to ensure TM/LP trip if an asymmetric steam generator transient is detected.

- ~~Axial Power Distribution (APD)~~ – High

  Q Power and ASI are inputs to the ~~APD~~ trip. The ~~APD~~ trip setpoint is a function of Q power, being more restrictive at higher power levels. It provides a reactor trip if actual ASI exceeds the ~~APD~~ trip setpoint. (Local Power Density) (Local Power Density) (1)

BASES

BACKGROUND (continued)

Bistable Trip Units

Bistable trip units, mounted in the RPS cabinet, receive an analog input from the measurement channels, compare the analog input to trip setpoints, and provide contact output to the Matrix Logic. They also provide local trip indication and remote annunciation.

There are four channels of bistable trip units, designated A through D, for each RPS Function, one for each measurement channel. Bistable output relays de-energize when a trip occurs.

The contacts from these bistable relays are arranged into six coincidence matrices, comprising the Matrix Logic. If bistables monitoring the same parameter in at least two channels trip, the Matrix Logic will generate a reactor trip (two-out-of-four logic).

Some of the RPS measurement channels provide contact outputs to the RPS, so the comparison of an analog input to a trip setpoint is not necessary. In these cases, the bistable trip unit is replaced with an auxiliary trip unit. The auxiliary trip units provide contact multiplication so the single input contact opening can provide multiple contact outputs to the coincidence logic as well as trip indication and annunciation.

Local Power Density

turbine generator control system hydraulic

Local Power Density

Trips employing auxiliary trip units include the Loss of Load trip and the ~~APD~~ - High trip. The Loss of Load trip is a contact input from the ~~Electro Hydraulic Control System~~ control oil pressure ~~on each of the~~ four high pressure ~~stop valves~~.

switches mounted on the emergency trip fluid line common header.

sensed by

1

R1

The ~~APD~~ trip, described above, is a complex function in which the actual trip comparison is performed within the CPC. Therefore the ~~APD~~ - High trip unit employs a contact input from the CPC.

1

Local Power Density

All RPS trips, with the exception of the Loss of Load trip, generate a pretrip alarm as the trip setpoint is approached.

6

The trip setpoints used in the bistable trip units are based on the analytical limits stated in Reference ~~5~~. The calculation of the ~~[LTSP]~~ specified in Table 3.3.1-1 is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration ~~tolerances~~, instrumentation uncertainties, instrument drift, and severe environment errors - for those RPS channels that must function in harsh environments, as defined by 10 CFR 50.49 (Ref. ~~6~~) - Allowable Values specified in Table 3.3.1-1, in the accompanying LCO,

NTSP

3

acceptance criteria bands

5

7

1

BASES

BACKGROUND (continued)

are conservatively adjusted with respect to the analytical limits. A detailed description of the methodology used to calculate the trip setpoints, including their explicit uncertainties, is provided in ~~the "Plant Protection System Selection of Trip Setpoint Values"~~ (Ref. ~~7~~). The trip setpoint entered into the bistable is normally still more conservative than that specified by the Allowable Value, to account for changes in random measurement errors detectable by a CHANNEL FUNCTIONAL TEST. One example of such a change in measurement error is drift during the interval between surveillances.

IC-3.17, "Instrument Setpoint Methodology for Nuclear Power Plants" 8 1

The ~~[~~LTSP~~]~~ is the value at which the bistable is set and is the expected value to be achieved during calibration. The ~~[~~LTSP~~]~~ value is the LSSS and ensures the safety analysis limits are met for the surveillance interval selected when a channel is adjusted based on stated channel uncertainties.

NTSP 3

~~[~~LTSPs~~]~~, in conjunction with the use of as-found and as-left ~~tolerances~~, consistent with the requirements of the Allowable Value will ensure that SLs of Chapter 2.0 are not violated during AOOs and the consequences of DBAs will be acceptable, providing the plant is operated from within the LCOs at the onset of the AOO or DBA and the equipment functions as designed.

acceptance criteria bands 3 5

Note that in the accompanying LCO 3.3.1, the Allowable Values of Table 3.3.1-1 are the least conservative value of the as-found setpoint that a channel can have during a periodic CHANNEL CALIBRATION or CHANNEL FUNCTIONAL TEST.

RPS Logic

The RPS Logic, addressed in LCO 3.3.~~3~~, consists of both Matrix and Initiation Logic and employs a scheme that provides a reactor trip when bistables in any two out of the four channels sense the same input parameter trip. This is called a two-out-of-four trip logic. ~~This logic and the RTCB configuration are shown in Figure B 3.3.1-1.~~

2 1 6

Bistable relay contact outputs from the four channels are configured into six logic matrices. Each logic matrix checks for a coincident trip in the same parameter in two bistable channels. The matrices are designated the AB, AC, AD, BC, BD, and CD matrices to reflect the bistable channels being monitored. Each logic matrix contains four normally energized matrix relays. When a coincidence is detected, consisting of a trip in the same Function in the two channels being monitored by the logic matrix, all four matrix relays de-energize.

BASES

BACKGROUND (continued)

The matrix relay contacts are arranged into trip paths, with one of the four matrix relays in each matrix opening contacts in one of the four trip paths. Each trip path provides power to one of the four normally energized RTCB control relays (K1, K2, K3, and K4). The trip paths thus each have six contacts in series, one from each matrix, and perform a logical OR function, opening the RTCBs if any one or more of the six logic matrices indicate a coincidence condition.

Each trip path is responsible for opening one set of two of the eight RTCBs. The RTCB control relays (K-relays), when de-energized, interrupt power to the breaker undervoltage trip attachments and simultaneously apply power to the shunt trip attachments on each of the two breakers. Actuation of either the undervoltage or shunt trip attachment is sufficient to open the RTCB and interrupt power from the motor generator (MG) sets to the control element drive mechanisms (CEDMs).

When a coincidence occurs in two RPS channels, all four matrix relays in the affected matrix de-energize. This in turn de-energizes all four RTCB control relays, which simultaneously de-energize the undervoltage and energize the shunt trip attachments in all eight RTCBs, tripping them open.

Matrix Logic refers to the matrix power supplies, trip channel bypass contacts, and interconnecting matrix wiring between bistable and auxiliary trip units, up to but not including the matrix relays. Contacts in the bistable and auxiliary trip units are excluded from the Matrix Logic definition, since they are addressed as part of the measurement channel.

The Initiation Logic consists of the trip path power source, matrix relays and their associated contacts, all interconnecting wiring, and solid state (auxiliary) relays through the K-relay contacts in the RTCB control circuitry.

It is possible to change the two-out-of-four RPS Logic to a two-out-of-three logic for a given input parameter in one channel at a time by trip channel bypassing select portions of the Matrix Logic. Trip channel bypassing a bistable effectively shorts the bistable relay contacts in the three matrices associated with that channel. Thus, the bistables will function normally, producing normal trip indication and annunciation, but a reactor trip will not occur unless two additional channels indicate a trip condition. Trip channel bypassing can be simultaneously performed on

BASES

BACKGROUND (continued)

A mechanical interlock (key capture) in conjunction with administrative control

any number of parameters in any number of channels, providing each parameter is bypassed in only one channel at a time. ~~An interlock~~ prevents simultaneous trip channel bypassing of the same parameter in more than one channel. Trip channel bypassing is normally employed during maintenance or testing. 1

For those plants that have demonstrated sufficient channel to channel independence, two-out-of-three logic is the minimum that is required to provide adequate plant protection, since a failure of one channel still ensures a reactor trip would be generated by the two remaining OPERABLE channels. Two-out-of-three logic also prevents inadvertent trips caused by any single channel failure in a trip condition.

Zero Power Mode trips (Reactor Coolant Flow – Low and Thermal Margin/Low Pressure), Local Power Density - High, Loss of Load -High,

Local Power Density

In addition to the trip channel bypasses, there are also operating bypasses on select RPS trips. Some of these bypasses are enabled manually, others automatically, in all four RPS channels when plant conditions do not warrant the specific trip protection. All operating bypasses are automatically removed when enabling bypass conditions are no longer satisfied. Trips with operating bypasses include Power Rate of Change - High, ~~Reactor Coolant Flow - Low,~~ Steam Generator Pressure - Low, ~~APD - High, TM/LP,~~ and Steam Generator Pressure Difference. ~~[~~The Loss of Load trip, Power Rate of Change - High, and ~~APD~~ - High operating bypasses are automatically enabled and disabled.~~]~~ 1 3 R1

The Variable Power Level Trip – High bypass is manual enable but automatically

Reactor Trip Circuit Breakers (RTCBs)

2

The reactor trip switchgear, addressed in LCO 3.3.~~3 and shown in Figure B 3.3.1-1~~, consists of eight RTCBs, which are operated in four sets of two breakers (four channels). Power input to the reactor trip switchgear comes from two full capacity MG sets operated in parallel such that the loss of either MG set does not de-energize the CEDMs. There are two separate CEDM power supply buses, each bus powering half of the CEDMs. Power is supplied from the MG sets to each bus via two redundant paths (trip legs). Trip legs 1A and 1B supply power to CEDM bus 1. Trip legs 2A and 2B supply power to CEDM bus 2. This ensures that a fault or the opening of a breaker in one trip leg (i.e., for testing purposes) will not interrupt power to the CEDM buses. 6

Each of the four trip legs consists of two RTCBs in series. The two RTCBs within a trip leg are actuated by separate initiation circuits.

BASES

BACKGROUND (continued)

The eight RTCBs are operated as four sets of two breakers (four channels). For example, if a breaker receives an open signal in trip leg A (for CEDM bus 1), an identical breaker in trip leg B (for CEDM bus 2) will also receive an open signal. This arrangement ensures that power is interrupted to both CEDM buses, thus preventing trip of only half of the CEAs (a half trip). Any one inoperable breaker in a channel will make the entire channel inoperable.

Each set of RTCBs is operated by either a Manual Trip push button or an RPS actuated K-relay. There are four Manual Trip push buttons, arranged in two sets of two~~, as shown in Figure B 3.3.1-1~~. Depressing both push buttons in either set will result in a reactor trip. 6

When a Manual Trip is initiated using the control room push buttons, the RPS trip paths and K-relays are bypassed, and the RTCB undervoltage and shunt trip attachments are actuated independent of the RPS.

Manual Trip circuitry includes the push button and interconnecting wiring to both RTCBs necessary to actuate both the undervoltage and shunt trip attachments but excludes the K-relay contacts and their interconnecting wiring to the RTCBs, which are considered part of the Initiation Logic.

Functional testing of the entire RPS, from bistable input through the opening of individual sets of RTCBs, can be performed either at power or shutdown and is ~~normally~~ performed ~~on a quarterly basis~~. per the Surveillance Frequency Control Program 1 3
FSAR, Section ~~[~~7.2~~]~~ (Ref. ~~3~~), explains RPS testing in more detail. U 9

APPLICABLE SAFETY ANALYSES

Each of the analyzed accidents and transients can be detected by one or more RPS Functions. The accident analysis contained in Reference ~~5~~ takes credit for most RPS trip Functions. Functions not specifically credited in the accident analysis are part of the NRC approved licensing basis for the plant. These Functions may provide protection for conditions that do not require dynamic transient analysis to demonstrate Function performance. Other Functions, such as the Loss of Load trip, are purely equipment protective, and their use minimizes the potential for equipment damage. 6 1

Permissive and interlock setpoints allow the blocking of trips during plant startups, and restoration of trips when the permissive conditions are not satisfied, but they are not explicitly modeled in the Safety Analyses. These permissives and interlocks ensure that the starting conditions are consistent with the safety analysis, before preventive or mitigating actions occur. Because these permissives or interlocks are only one of multiple conservative starting assumptions for the accident analysis, they are generally considered as nominal values without regard to measurement accuracy.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The specific safety analyses applicable to each protective Function are identified below:

1. Variable ~~High~~ Power Trip (VHPT) - High

Level

The VHPT provides reactor core protection against positive reactivity excursions that are too rapid for a Pressurizer Pressure - High or TM/LP trip to protect against. The following events require VHPT protection:

- Uncontrolled CEA withdrawal event,
- Excess load,
- ~~Excess feedwater heat removal event,~~
- CEA ejection event, and
-
- Main steam line break (MSLB) ~~(outside containment)~~.

1

R1

two

third and fourth

The first t~~hree~~ events are AOOs, and fuel integrity is maintained. The ~~fourth and fifth~~ are accidents, and limited fuel damage may occur.

2. Power Rate of Change - High

The Power Rate of Change - High trip is used to trip the reactor when excore ~~[~~logarithmic~~]~~ power indicates an excessive rate of change. The Power Rate of Change - High Function ~~minimizes transients for events such as a continuous CEA withdrawal or a boron dilution event from low power levels~~. The trip may be bypassed when THERMAL POWER is < 1E-4% RTP, when poor counting statistics may lead to erroneous indication. ~~It is also~~ bypassed at > 15% RTP, where moderator temperature coefficient and fuel temperature coefficient make high rate of change of power unlikely. With the RTCBs open, the Power Rate of Change - High trip is not required to be OPERABLE; however, the indication ~~and alarm~~ Function~~s~~ of at least two channels ~~are~~ required by LCO 3.3.1~~3~~, "~~[~~Logarithmic~~]~~ ~~Power~~ Monitoring ~~Channels~~," to be OPERABLE. LCO 3.3.1~~3~~ ensures the ~~[~~logarithmic~~]~~ channels are available to detect ~~and alert the operator to~~ a boron dilution event.

is not credited in the accident analysis as providing primary protection for any limiting case AOO or accident.

3
1

In addition, the trip is not required to be OPERABLE and is

Neutron Flux

is

3
1
1
3

3
1

BASES

APPLICABLE SAFETY ANALYSES (continued)

3. Reactor Coolant Flow - Low

The Reactor Coolant Flow - Low trip provides protection during the following events:

- Loss of RCS flow,
- Loss of ~~nonemergency~~ AC power, and
- Reactor coolant pump (RCP) seized /sheared shaft~~,~~
- ~~RCP sheared shaft, and~~
- ~~Certain MSLB events~~.

The loss of RCS flow and ~~of nonemergency~~ AC power events are AOOs where fuel integrity is maintained. The RCP seized shaft~~,~~ and sheared shaft~~, and MSLBs~~ are accidents where fuel damage may result.

4. Pressurizer Pressure - High

The Pressurizer Pressure - High trip, in conjunction with pressurizer safety valves and main steam safety valves (MSSVs), provides protection against overpressure conditions in the RCS during the following events:

- Loss of condenser vacuum with a concurrent loss of offsite power,
- Loss of condenser vacuum with a concurrent loss of one 6.9 kV bus,
- ~~Isolation of turbine at 102% power~~, Loss of External Load/Turbine trip
- ~~Feedwater System pipe breaks between the steam generator and check valve~~,
- CEA withdrawal, and
- Loss of feedwater flow.

1

R1

BASES

APPLICABLE SAFETY ANALYSES (continued)

5. Containment Pressure - High

The Containment Pressure - High trip prevents exceeding the containment design pressure during certain loss of coolant accidents (LOCAs) or feedwater line break accidents. It ensures a reactor trip prior to, or concurrent with, a LOCA, thus assisting the ESFAS in the event of a LOCA or MSLB. Since these are accidents, SLs may be violated. However, the consequences of the accident will be acceptable.

6. Steam Generator Pressure - Low

The Steam Generator Pressure - Low trip provides protection against an excessive rate of heat extraction from the steam generators, which would result in a rapid uncontrolled cooldown of the RCS. This trip is needed to shut down the reactor and assist the ESFAS in the event of an MSLB. Since these are accidents, SLs may be violated. However, the consequences of the accident will be acceptable.

7.a, 7.b. Steam Generator A and B Level - Low

The Steam Generator A Level - Low and Steam Generator B Level - Low trips are required for the following events:

- ~~Steam System piping failures,~~
- Feedwater System pipe breaks,
- ~~Inadvertent opening of a steam generator atmospheric dump valve (ADV),~~
- Loss of normal feedwater, and
- Asymmetric loss of feedwater.

Excess Load

1
R1

The Steam Generator Level - Low trip ensures that low DNBR, high local power density, and the RCS pressure SLs are maintained during normal operation and AOOs, and, in conjunction with the ESFAS, the consequences of the Feedwater System pipe break accident will be acceptable.

BASES

APPLICABLE SAFETY ANALYSES (continued)

8. ~~Axial Power Distribution (APD)~~ - High

Local Power Density

The ~~APD~~ - High trip ensures that excessive axial peaking, such as that due to axial xenon oscillations, will not cause fuel damage. It ensures that neither a DNBR less than the SL nor a peak linear heat rate that corresponds to the temperature for fuel centerline melting will occur. This trip is the primary protection against fuel centerline melting. 1

9. Thermal Margin

a. Thermal Margin/Low Pressure (TM/LP)

The TM/LP trip prevents exceeding the DNBR SL during AOOs and aids the ESFAS during certain accidents. The following events require TM/LP protection:

- Excess load ~~(inadvertent opening of a steam generator ADV)~~, R1
- RCS depressurization (inadvertent safety or power operated relief valves (PORVs) opening), R1
- Steam generator tube rupture, and
- LOCA accident.

The first two events are AOOs, and fuel integrity is maintained. The third and fourth are accidents, and limited fuel damage may occur although only the LOCA is expected to result in fuel damage. The trip is initiated whenever the RCS pressure signal drops below a minimum value (P_{min}) or a computed value (P_{var}) as described below, whichever is higher. The computed value is a Function Q power, ASI, as determined from the axially split excore detectors~~,~~ and reactor inlet (cold leg) temperature~~, and the number of RCPs operating~~. 1

and

The minimum value of reactor coolant flow rate, the maximum ~~T~~$_Q$, and the maximum CEA deviation permitted for continuous operation are assumed in the generation of this trip Function. In addition, CEA group sequencing in accordance with LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits," is assumed. Finally, the maximum insertion of CEA banks that can occur during any AOO prior to a VHPT is assumed. 1

azimuthal tilt

BASES

APPLICABLE SAFETY ANALYSES (continued)

b. Steam Generator Pressure Difference

The Steam Generator Pressure Difference provides protection for those AOOs associated with secondary system malfunctions that result in asymmetric primary coolant temperatures. The most limiting event is closure of a single main steam isolation valve. Steam Generator Pressure Difference is provided by comparing the secondary pressure in both steam generators in the TM/LP calculator. If the pressure in either exceeds that in the other by the trip setpoint, a TM/LP trip will result.

10. Loss of Load

The Loss of Load ~~(~~turbine ~~stop valve (TSV) control oil pressure~~) trip is anticipatory for the loss of heat removal capabilities of the secondary system following a turbine trip. The Loss of Load trip prevents lifting the pressurizer safety valves, PORVs, and MSSVs in the event of a turbine generator trip. Thus, the trip minimizes the pressure and temperature transients on the reactor by initiating a trip well before reaching the Pressurizer Pressure - High trip and pressurizer safety valve setpoints. The four RPS Loss of Load reactor trip channels receive their input from ~~sensors mounted on the high pressure TSV actuators. Since there are four high pressure TSVs, one actuator per valve and one sensor per actuator, each sensor sends its signal to a different RPS channel. When the turbine trips, control oil is dumped from the high pressure TSVs. When the control oil pressure drops to the appropriate setpoint, a reactor trip signal is generated.~~

Hydraulic Fluid Pressure - Low

four redundant pressure switches mounted on the emergency trip fluid line common header, to serve as the loss of load, turbine trip input to the Reactor Protective System logic matrices. Actuation of any two of the pressure switches on low hydraulic oil pressure causes a reactor trip.

R1 1

1

Interlocks/Bypasses

The bypasses and their Allowable Values are addressed in footnotes to Table 3.3.1-1. They are not otherwise addressed as specific Table entries.

The automatic bypass removal features must function as a backup to manual actions for all safety related trips to ensure the trip Functions are not operationally bypassed when the safety analysis assumes the Functions are not bypassed. The RPS operating bypasses are:

Zero power mode bypass (ZPMB) removal on the TM/LP, Steam Generator Pressure Difference, and reactor coolant low flow trips when THERMAL POWER is < 1~~E-4~~% RTP. This bypass is manually enabled below the specified setpoint to permit low power testing. The wide range NI Level 1 bistable in the wide range drawer permits manual bypassing below the setpoint and removes the bypass above the setpoint.

APPLICABLE SAFETY ANALYSES (continued)

Power rate of change bypass removal. The Power Rate of Change - High trip is automatically bypassed at < 1E-4% RTP, as sensed by the wide range NI Level 2 bistable, and at > ~~12~~% RTP by the power range NI Level 1 bistable, mounted in their respective NI drawers. Automatic bypass removal is also effected by these bistables when conditions are no longer satisfied.

Local Power Density

Loss of Load and ~~APD~~ - High bypass removal. The Loss of Load and ~~APD~~ - High trips are automatically bypassed when at < 15% RTP as sensed by the power range NI Level 1 bistable. The bypass is automatically removed by this bistable above the setpoint. This same bistable is used to bypass the Power Rate of Change - High trip.

Steam Generator Pressure - Low bypass removal. The Steam Generator Pressure - Low trip is manually enabled below the pretrip setpoint. The permissive is removed, and the bypass automatically removed, when the Steam Generator Pressure - Low pretrip clears.

The RPS instrumentation satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires all instrumentation performing an RPS Function to be OPERABLE. Failure of any required portion of the instrument channel renders the affected channel(s) inoperable and reduces the reliability of the affected Functions. The specific criteria for determining channel OPERABILITY differ slightly between Functions. These criteria are discussed on a Function by Function basis below.

Actions allow maintenance (trip channel) bypass of individual channels, but ~~the bypass activates interlocks that prevent~~ operation with a second channel in the same Function bypassed. Plants are restricted to 48 hours in a trip channel bypass condition before either restoring the Function to four channel operation (two-out-of-four logic) or placing the channel in trip (one-out-of-three logic). ~~At plants where adequate channel to channel independence has been demonstrated, specific exceptions may be approved by the NRC staff to permit one of the two-out-of-four channels to be bypassed for an extended period of time.~~

is prevented by mechanical interlock (key capture)

the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report, respectively

Allowable Values for RPS Instrumentation Functions are specified in Table 3.3.1-1. ~~[~~LTSPs~~]~~ and the methodologies for calculation of the as-left and as-found ~~tolerances~~ are described in ~~[insert the name of a document controlled under 10 CFR 50.59 such as the Technical Requirements Manual or any document incorporated into the facility FSAR]~~. The ~~[~~LTSPs~~]~~ are selected to ensure that the actual setpoints remain conservative with respect to the as-found ~~tolerance~~ band between successive CHANNEL CALIBRATIONS. After each calibration the trip setpoint shall be left within the as-left band around the ~~[~~LTSP~~]~~.

NTSPs

NTSPs

acceptance criteria

NTSP

BASES

LCO (continued)

The following Bases for each trip Function identify the above RPS trip Function criteria items that are applicable to establish the trip Function OPERABILITY.

Level

1. Variable ~~High~~ Power Trip (VHPT) - High 1

This LCO requires all four channels of the VHPT to be OPERABLE in MODES 1 and 2.

The Allowable Value is high enough to provide an operating envelope that prevents unnecessary Linear Power Level - High reactor VHPT - High trips during normal plant operations. The Allowable Value is low enough for the system to maintain a margin to unacceptable fuel cladding damage should a CEA ejection accident occur.

The VHPT setpoint is operator adjustable and can be set at a fixed increment above the indicated THERMAL POWER level. Operator action is required to increase the trip setpoint as THERMAL POWER is increased. The trip setpoint is automatically decreased as THERMAL POWER decreases. The ~~[LTSP]~~ has a maximum and a minimum setpoint. 3

NTSP

NTSP

Adding to this maximum value the possible variation in ~~[LTSP]~~ due to calibration and instrument errors, the maximum actual steady state THERMAL POWER level at which a trip would be actuated is ~~112~~% RTP, which is the value used in the safety analyses. 3

107

R1

conservative with respect to

of 112% RTP

1

Calibration and instrument errors are considered within the setpoint calculations. The stated minimum and maximum Allowable Values and step values are the assumed safety analysis values.

~~To account for these errors, the safety analysis minimum value is 40% RTP. The 10% step is a maximum value assumed in the safety analysis. There is no uncertainty applied to the step.~~

R1

2. Power Rate of Change - High

MODE 1 with THERMAL POWER ≤ 15% RTP and MODE 2

This LCO requires four channels of Power Rate of Change - High to be OPERABLE in ~~MODES 1 and 2, as well as in MODES 3, 4, and 5 when the RTCBs are closed and the CEA Drive System is capable of CEA withdrawal~~. 1

The high power rate of change trip serves as a backup to the administratively enforced startup rate limit. The Function is not credited in the accident analyses; therefore, the Allowable Value for the trip or bypass Functions is not derived from analytical limits.

BASES

LCO (continued)

3. Reactor Coolant Flow - Low

This LCO requires four channels of Reactor Coolant Flow - Low to be OPERABLE in MODES 1 and 2.

1 The trip may be manually bypassed when THERMAL POWER falls below ~~1E-4~~% RTP. This bypass is part of the ZPMB circuitry, which also bypasses the TM/LP trip and provides a ΔT power block signal to the Q power select logic. This ZPMB allows low power physics testing at reduced RCS temperatures and pressures. It also allows heatup and cooldown with shutdown CEAs withdrawn.

This trip is set high enough to maintain fuel integrity during a loss of flow condition. The setting is low enough to allow for normal operating fluctuations from offsite power. ~~To account for analysis uncertainty, the value in the safety analysis is 93% RTP.~~

4. Pressurizer Pressure - High

This LCO requires four channels of Pressurizer Pressure - High to be OPERABLE in MODES 1 and 2.

The Allowable Value is set high enough to allow for pressure increases in the RCS during normal operation (i.e., plant transients) not indicative of an abnormal condition. The setting is below the lift setpoint of the pressurizer safety valves and low enough to initiate a reactor trip when an abnormal condition is indicated. ~~The difference between the Allowable Value and the analysis setpoint of 2470 psia includes allowance for harsh environment.~~

The Pressurizer Pressure - High trip concurrent with PORV operation avoids unnecessary operation of the pressurizer safety valves.

5. Containment Pressure - High

This LCO requires four channels of Containment Pressure - High to be OPERABLE in MODES 1 and 2.

The Allowable Value is high enough to allow for small pressure increases in containment expected during normal operation (i.e., plant heatup) that are not indicative of an abnormal condition. The setting is low enough to initiate a reactor trip to prevent containment pressure from exceeding design pressure following a DBA.

BASES

LCO (continued)

6. Steam Generator Pressure - Low

This LCO requires four channels of Steam Generator Pressure - Low per steam generator to be OPERABLE in MODES 1 and 2.

The Allowable Value is sufficiently below the full load operating value for steam pressure so as not to interfere with normal plant operation, but still high enough to provide the required protection in the event of excessive steam demand. Since excessive steam demand causes the RCS to cool down, resulting in positive reactivity addition to the core, a reactor trip is required to offset that effect.

~~The difference between the Allowable Value and the safety analysis value of 600 psia includes harsh environment uncertainties.~~ 1

The Function may be manually bypassed as steam generator pressure is reduced during controlled plant shutdowns. This bypass is permitted at a preset steam generator pressure. The bypass, in conjunction with the ZPMB, allows testing at low temperatures and pressures, and heatup and cooldown with the shutdown CEAs withdrawn. From a bypass condition the trip will be reinstated automatically as steam generator pressure increases above the preset pressure.

7.a, 7.b. Steam Generator Level – Low

This LCO requires four channels of Steam Generator Level - Low per steam generator to be OPERABLE in MODES 1 and 2.

The Allowable Value is sufficiently below the normal operating level for the steam generators so as not to cause a reactor trip during normal plant operations. The trip setpoint is high enough to ensure a reactor trip signal is generated before water level drops below the top of the feed ring~~. The difference between the Allowable Value and the measurement value includes 10 inches of measurement uncertainty. The specified setpoint ensures there will be sufficient water inventory to provide a 10 minute margin before auxiliary feedwater is required for the removal of decay heat.~~ 1

BASES

LCO (continued)

8. ~~Axial Power Distribution (APD)~~ - High

Local Power Density

This LCO requires four channels of ~~APD~~ - High to be OPERABLE in MODE 1 ≥ 15% RTP.

The Allowable Value curve was derived from an analysis of many axial power shapes with allowances for instrumentation inaccuracies and the uncertainty associated with the excore to incore ASI relationship. 1

Local Power Density

The ~~APD~~ trip is automatically bypassed at < 15% RTP, where it is not required for reactor protection.

9. Thermal Margin

a. Thermal Margin/Low Pressure (TM/LP)

This LCO requires four channels of TM/LP to be OPERABLE in MODES 1 and 2.

The Allowable Value includes allowances for equipment response time, measurement uncertainties, processing error, and a further allowance to compensate for the time delay associated with providing effective termination of the occurrence that exhibits the most rapid decrease in margin to the SL.

1

This trip may be manually bypassed when THERMAL POWER falls below ~~1E-4~~% RTP. This bypass is part of the ZPMB circuitry, which also bypasses the Reactor Coolant Flow - Low trip and provides a ΔT power block signal to the Q power select logic. This ZPMB allows low power physics testing at reduced RCS temperatures and pressures. It also allows heatup and cooldown with shutdown CEAs withdrawn. 1

b. Steam Generator Pressure Difference

This LCO requires four channels of Steam Generator Pressure Difference to be OPERABLE in MODES 1 and 2.

The Allowable Value is high enough to avoid trips caused by normal operation and minor transients, but ensures DNBR protection in the event of Design Basis Events. ~~The difference between the Allowable Value and the 175 psia analysis setpoint allows for 40 psia of measurement uncertainty.~~ 1

BASES

LCO (continued)

1 The trip may be bypassed when THERMAL POWER falls below ~~1E-4~~% RTP. The Steam Generator Pressure Difference is subject to the ZPMB, since it is an input to the TM/LP trip and is not required for protection at low power levels. 1

10. Loss of Load

The LCO requires four Loss of Load trip channels to be OPERABLE in MODE 1 ≥ 15% RTP.

The Loss of Load trip may be bypassed when THERMAL POWER falls below 15%, since it is no longer needed to prevent lifting of the pressurizer safety valves, steam generator safety valves, or PORVs in the event of a Loss of Load. The Nuclear Steam Supply System and the Steam Dump System are capable of accommodating the Loss of Load without requiring the use of the above equipment.

Interlocks/Bypasses

The LCO on bypass permissive removal channels requires that the automatic bypass removal feature of all four operating bypass channels be OPERABLE for each RPS Function with an operating bypass in the MODES addressed in the specific LCO for each Function. All four bypass removal channels must be OPERABLE to ensure that none of the four RPS channels are inadvertently bypassed.

The LCO applies to the bypass removal feature only. If the bypass enable Function is failed so as to prevent entering a bypass condition, operation may continue.

The interlock Allowable Values are based on analysis requirements for the bypassed functions. These are discussed above as part of the LCO discussion for the affected Functions.

APPLICABILITY This LCO is applicable in accordance with Table 3.3.1-1. Most RPS trips are required to be OPERABLE in MODES 1 and 2 because the reactor is critical in these MODES. The trips are designed to take the reactor subcritical, maintaining the SLs during AOOs and assisting the ESFAS in providing acceptable consequences during accidents. Exceptions are addressed in footnotes to the table. Exceptions to this APPLICABILITY are:

Local Power Density

- The ~~APD~~ - High Trip and Loss of Load are only applicable in MODE 1 ≥ 15% RTP because they may be automatically bypassed at < 15% RTP, where they are no longer needed. 1

BASES

APPLICABILITY (continued)

- ~~The Power Rate of Change - High trip, RPS Logic, RTCBs, and Manual Trip are also required in MODES 3, 4, and 5, with the RTCBs closed, to provide protection for boron dilution and CEA withdrawal events. The Power Rate of Change - High trip in these lower MODES is addressed in LCO 3.3.2, "Reactor Protective System (RPS) Instrumentation - Shutdown." The RPS Logic in MODES 1, 2, 3, 4, and 5 is addressed in LCO 3.3.3.~~

1

The RPS

~~Most~~ trips are not required to be OPERABLE in MODES 3, 4, and 5. In MODES 3, 4, and 5, the emphasis is placed on return to power events. The reactor is protected in these MODES by ensuring adequate SDM.

ACTIONS

acceptance criteria band

The most common causes of channel inoperability are outright failure or drift of the bistable or process module sufficient to exceed the ~~tolerance~~ allowed by the plant specific setpoint analysis. Typically, the drift is found to be small and results in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the process instrument is set up for adjustment to bring it to within specification. If the trip setpoint is nonconservative with respect to the Allowable Value in Table 3.3.1-1, the channel is declared inoperable immediately, and the appropriate Condition(s) must be entered immediately.

5

In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value, or the channel is not functioning as required, or the transmitter, instrument loop, signal processing electronics, or RPS bistable trip unit is found inoperable, then all affected Functions provided by that channel must be declared inoperable, and the plant must enter the Condition for the particular protection Function affected.

When the number of inoperable channels in a trip Function exceeds that specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 is immediately entered if applicable in the current MODE of operation.

A Note has been added to the ACTIONS to clarify the application of the Completion Time rules. The Conditions of this Specification may be entered independently for each Function. The Completion Times of each inoperable Function will be tracked separately for each Function, starting from the time the Condition was entered.

BASES

ACTIONS (continued)

A.1, A.2.1, and A.2.2

Condition A applies to the failure of a single channel in any RPS automatic trip Function. RPS coincidence logic is normally two-out-of-four.

If one RPS bistable trip unit or associated instrument channel is inoperable, startup or power operation is allowed to continue, providing the inoperable trip unit is placed in bypass or trip within 1 hour (Required Action A.1). With one channel in bypass, no additional random failure of a single channel could spuriously trip the reactor and a valid trip signal can still trip the reactor. With one channel in trip, an additional random failure of a single channel could spuriously trip the reactor. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to restore, bypass, or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel while ensuring that the risk involved in operating with the failed channel is acceptable.

The failed channel is restored to OPERABLE status or is placed in trip within ~~[~~48~~]~~ hours ~~[or in accordance with the Risk Informed Completion Time Program]~~ (Required Action A.2.1 or Required Action A.2.2). Required Action A.2.1 restores the full capability of the Function.

~~[~~Required Action A.2.2 places the Function in a one-out-of-three configuration. In this configuration, common cause failure of dependent channels cannot prevent trip.~~]~~

The Completion Time of ~~[~~48~~]~~ hours is based on operating experience, which has demonstrated that a random failure of a second channel occurring during the ~~[~~48~~]~~ hour period is a low probability event. 3

B.1 and B.2

Condition B applies to the failure of two channels in any RPS automatic trip Function.

Required Action B.1 provides for placing one inoperable channel in bypass and the other channel in trip within the Completion Time of 1 hour. This Completion Time is sufficient to allow the operator to take all appropriate actions for the failed channels while ensuring that the risk involved in operating with the failed channels is acceptable. With one channel of protective instrumentation bypassed, the RPS is in a two-out-of-three logic; but with another channel failed, the RPS may be operating

BASES

ACTIONS (continued)

in a two-out-of-two logic. This is outside the assumptions made in the analyses and should be corrected. To correct the problem, the second channel is placed in trip. This places the RPS in a one-out-of-two logic. If any of the other OPERABLE channels receives a trip signal, the reactor will trip.

One channel should be restored to OPERABLE status within ~~[~~48~~]~~ hours ~~[or in accordance with the Risk Informed Completion Time Program]~~ for reasons similar to those stated under Condition A. After one channel is restored to OPERABLE status, the provisions of Condition A still apply to the remaining inoperable channel. Therefore, the channel that is still inoperable after completion of Required Action B.2 must be placed in trip if more than ~~[~~48~~]~~ hours have elapsed since the initial channel failure. 3

C.1 and C.2

Local Power Density

The excore detectors are used to generate the internal ASI used as an input to the TM/LP and ~~APD~~ - High trips. Incore detectors provide a more accurate measurement of ASI. If one or more excore detectors cannot be calibrated to match incore detectors, power is restricted or reduced during subsequent operations because of increased uncertainty associated with using uncalibrated excore detectors. 3

The Completion Time of 24 hours is adequate to perform the SR while minimizing the risk of operating in an unsafe condition.

D.1, D.2.1, D.2.2.1, and D.2.2.2

Condition D applies to one automatic bypass removal channel inoperable. If the bypass removal channel for any operating bypass cannot be restored to OPERABLE status, the associated RPS channel may be considered OPERABLE only if the bypass is not in effect. Otherwise, the affected RPS channel must be declared inoperable, as in Condition A, and the bypass either removed or the bypass removal channel repaired. The Bases for Required Actions and Completion Times are the same as discussed for Condition A.

E.1, E.2.1, and E.2.2

Condition E applies to two inoperable automatic bypass removal channels. If the bypass removal channels cannot be restored to OPERABLE status, the associated RPS channel may be considered OPERABLE only if the bypass is not in effect. Otherwise, the affected

BASES

ACTIONS (continued)

RPS channels must be declared inoperable, as in Condition B, and the bypass either removed or the bypass removal channel repaired. Also, Required Action E.2.2 provides for the restoration of the one affected automatic trip channel to OPERABLE status within the rules of Completion Time specified under Condition B. Completion Times are consistent with Condition B.

F.1

Condition F is entered when the Required Action and associated Completion Time of Conditions A, B, C, D, or E are not met for the ~~Axial Power Distribution~~ Local Power Density and Loss of Load Trip Functions. 1

If the Required Actions associated with these Conditions cannot be completed within the required Completion Times, the reactor must be brought to a MODE in which the Required Actions do not apply. The allowed Completion Time of 6 hours to reduce THERMAL POWER to < 15% RTP is reasonable, based on operating experience, to decrease power to < 15% RTP from full power conditions in an orderly manner and without challenging plant systems.

G.1

Condition G is entered when the Required Action and associated Completion Time of Conditions A, B, C, D, E, or F are not met.

If the Required Actions associated with these Conditions cannot be completed within the required Completion Times, the reactor must be brought to a MODE in which the Required Actions do not apply. The allowed Completion Time of 6 hours to be in MODE 3 is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

The SRs for any particular RPS Function are found in the SR column of Table 3.3.1-1 for that Function. Most Functions are subject to CHANNEL CHECK, CHANNEL FUNCTIONAL TEST, CHANNEL CALIBRATION, and response time testing.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~In order for a plant to take credit for topical reports as the basis for justifying Frequencies, topical reports must be supported by an NRC staff SER that establishes the acceptability of each topical report for that plant (Ref. 9).~~
~~---~~

~~----------REVIEWER'S NOTE----------~~
~~Notes a and b are applied to the setpoint verification Surveillances for each RPS Instrumentation – Operating (Analog) Function in Table 3.3.1-1 unless one or more of the following exclusions apply:~~

~~1. Manual actuation circuits, automatic actuation logic circuits or instrument functions that derive input from contacts which have no associated sensor or adjustable device, e.g., limit switches, breaker position switches, manual actuation switches, float switches, proximity detectors, etc. are excluded. In addition, those permissives and interlocks that derive input from a sensor or adjustable device that is tested as part of another TS function are excluded.~~

~~2. Settings associated with safety relief valves are excluded. The performance of these components is already controlled (i.e., trended with as-left and as-found limits) under the ASME Code for Operation and Maintenance of Nuclear Power Plants testing program.~~

~~3. Functions and Surveillance Requirements which test only digital components are normally excluded. There is no expected change in result between SR performances for these components. Where separate as-left and as-found tolerance is established for digital component SRs, the requirements would apply.~~
~~---~~ 3

SR 3.3.1.1

Performance of the CHANNEL CHECK ensures that gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

BASES

SURVEILLANCE REQUIREMENTS (continued)

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the transmitter or the signal processing equipment has drifted outside its limits.

~~[The Frequency, about once every shift, is based on operating experience that demonstrates the rarity of channel failure. Since the probability of two random failures in redundant channels in any 12 hour period is extremely low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of the displays associated with the LCO required channels.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4 3

SR 3.3.1.2

15 A daily calibration (heat balance) is performed when THERMAL POWER is ≥ ~~20~~%. The daily calibration shall consist of adjusting the "nuclear power calibrate" potentiometers to agree with the calorimetric calculation ~~if the absolute difference is > 1.5%~~. The "ΔT power calibrate" potentiometers are then used to null the "nuclear power - ΔT power" indicators on the RPS Reactor Power Calibration and Indication panel. Performance of the daily calibration ensures that the two inputs to the Q power measurement are indicating accurately with respect to the much more accurate secondary calorimetric calculation. 1 1

~~[The Frequency of 24 hours is based on plant operating experience and takes into account indications and alarms located in the control room to detect deviations in channel outputs.~~ 3

~~OR~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4 3

15 The Frequency is modified by a Note indicating this Surveillance must be performed within 12 hours after THERMAL POWER is ≥ ~~20~~% RTP. The secondary calorimetric is inaccurate at lower power levels. The 12 hours allows time requirements for plant stabilization, data taking, and instrument calibration. 1

A second Note indicates the ~~daily~~ calibration may be suspended during PHYSICS TESTS. This ensures that calibration is proper preceding and following physics testing at each plateau, recognizing that during testing, changes in power distribution and RCS temperature may render the calorimetric inaccurate. 1 R1

SR 3.3.1.3

It is necessary to calibrate the excore power range channel upper and lower subchannel amplifiers such that the internal ASI used in the TM/LP and ~~APD~~ - High trips reflects the true core power distribution as determined by the incore detectors. A Note to the Frequency indicates the Surveillance is required within 12 hours after THERMAL POWER is ≥ ~~[20]~~% RTP. Uncertainties in the excore and incore measurement process make it impractical to calibrate when THERMAL POWER is < ~~[20]~~% RTP. The Completion Time of 12 hours allows time for plant stabilization, data taking, and instrument calibration. If the excore detectors are not properly calibrated to agree with the incore detectors, power is restricted during subsequent operations because of increased uncertainty associated with using uncalibrated excore detectors. ~~[The 31 day Frequency is adequate, based on operating experience of the excore linear amplifiers and the slow burnup of the detectors. The excore readings are a strong function of the power produced in the peripheral fuel bundles and do not represent an integrated reading across the core. Slow changes in neutron flux during the fuel cycle can also be detected at this Frequency.~~

~~----------]~~ 4 3

SR 3.3.1.4

A CHANNEL FUNCTIONAL TEST is performed on each RPS instrument channel, except Loss of Load and Power Rate of Change to ensure the entire channel will perform its intended function when needed. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

In addition to power supply tests, The RPS CHANNEL FUNCTIONAL TEST consists of three overlapping tests as described in Reference ~~8~~ 9. These tests verify that the RPS is capable of performing its intended function, from bistable input through the RTCBs. They include:

Bistable Tests

The bistable setpoint must be found to trip conservative with respect to the Allowable Values specified in the LCO and left set consistent with the assumptions of the plant specific setpoint analysis (Ref. ~~7~~). As-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the frequency extension analysis. The requirements for this review are outlined in Reference 10. 8 1

acceptance criteria A test signal is superimposed on the input in one channel at a time to verify that the bistable trips within the specified ~~tolerance~~ around the setpoint. This is done with the affected RPS channel trip channel bypassed. Any setpoint adjustment shall be consistent with the assumptions of the current plant specific setpoint analysis. 1

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.3.1.4 is modified by two Notes as identified in Table 3.3.1-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value. 5
Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition.
The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[LTSP]~~. Where a setpoint more conservative than the ~~[LTSP]~~ is used in the plant surveillance procedures ~~[NTSP]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and ~~/or~~ Analytical Limit is maintained. If the as-left channel setting cannot be returned to a setting within the as-left ~~tolerance~~ of the ~~[LTSP]~~, then the channel shall be declared inoperable. 5 3 5 1 3 5

The second Note also requires that ~~[LTSP]~~ and the methodologies for calculating the as-left and the as-found ~~tolerances~~ be in ~~[insert the facility FSAR reference or the name of any document incorporated into the facility FSAR by reference]~~. 3 5

Matrix Logic Tests

Matrix Logic tests are addressed in LCO 3.3.~~3~~2. This test is performed one matrix at a time. It verifies that a coincidence in the two input channels for each Function removes power from the matrix relays. During testing, power is applied to the matrix relay test coils and prevents the matrix relay contacts from assuming their de-energized state. This test will detect any short circuits around the bistable contacts in the coincidence logic, such as may be caused by faulty bistable relay or trip channel bypass contacts. 1

BASES

SURVEILLANCE REQUIREMENTS (continued)

Trip Path Tests

Trip Path (Initiation Logic) tests are addressed in LCO 3.3.~~3~~. These tests are similar to the Matrix Logic tests, except that test power is withheld from one matrix relay at a time, allowing the initiation circuit to de-energize, opening the affected set of RTCBs. The RTCBs must then be closed prior to testing the other three initiation circuits, or a reactor trip may result.

~~[The Frequency of [92] days is based on the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 10).~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

SR 3.3.1.5

A CHANNEL CALIBRATION of the excore power range channels ensures that the channels are reading accurately and within ~~tolerance~~. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

~~The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the frequency extension analysis. The requirements for this review are outlined in Reference [10].~~

A Note is added stating that the neutron detectors are excluded from CHANNEL CALIBRATION because they are passive devices with minimal drift and because of the difficulty of simulating a meaningful signal. Slow changes in detector sensitivity are compensated for by

BASES

SURVEILLANCE REQUIREMENTS (continued)

performing the ~~daily~~ calorimetric calibration (SR 3.3.1.2) and the ~~monthly~~ linear subchannel gain check (SR 3.3.1.3). In addition, associated control room indications are continuously monitored by the operators. 1

~~[The Frequency of 92 days is acceptable, based on plant operating experience, and takes into account indications and alarms available to the operator in the control room.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 4 3

SR 3.3.1.5 is modified by two Notes as identified in Table 3.3.1-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value. 5
Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition.
The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[LTSP]~~. Where a setpoint more conservative than the ~~[LTSP]~~ is used in the plant surveillance procedures ~~[NTSP]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and/or Analytical Limit is maintained. If the as-left channel setting cannot be returned to a setting within the as-left ~~tolerance~~ of the ~~[LTSP]~~, then the channel shall be declared inoperable. 5 5 3 5

SR 3.3.1.6

A CHANNEL FUNCTIONAL TEST on the Loss of Load and Power Rate of Change channels is performed prior to a reactor startup to ensure the entire channel will perform its intended function if required. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. ~~The Loss of Load pressure sensor cannot be tested during reactor operation without closing the high pressure TSV, which would result in a turbine trip or reactor trip.~~ The Power Rate of Change - High trip Function is required during startup operation and is bypassed when shut down or > 15% RTP.

The Loss of Load trip Function is not tested during reactor operation because performing this test during operation could cause a pressure perturbation in the emergency trip fluid header common to all four channels resulting in a turbine trip and reactor trip.

1 R1

SR 3.3.1.6 is modified by two Notes as identified in Table 3.3.1-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value. Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition.

SR 3.3.1.7

SR 3.3.1.7 is a CHANNEL FUNCTIONAL TEST similar to SR 3.3.1.4, except SR 3.3.1.7 is applicable only to bypass Functions ~~and is performed once within 92 days prior to each startup~~. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. Proper operation of bypass permissives is critical during plant startup because the bypasses must be in place to allow startup operation and must be removed at the appropriate points during power ascent to enable certain reactor trips. ~~Consequently, the appropriate time to verify bypass removal function OPERABILITY is just prior to startup. The allowance to conduct this test within 92 days of startup is based on the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 10).~~ Once the operating bypasses are removed, the bypasses must not fail in such a way that the associated trip Function gets inadvertently bypassed. This feature is verified by the trip Function CHANNEL FUNCTIONAL TEST, SR 3.3.1.4. ~~Therefore, further testing of the bypass function after startup is unnecessary.~~

1 R1

1 R1

1 R1

SR 3.3.1.8

SR 3.3.1.8 is the performance of a CHANNEL CALIBRATION.

CHANNEL CALIBRATION is a complete check of the instrument channel including the sensor. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the frequency extension analysis. The requirements for this review are outlined in Reference ~~[~~10~~]~~. 3

SR 3.3.1.8 is modified by two Notes as identified in Table 3.3.1-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value 5 (e.g., outside the conservative side of the as-found acceptance criteria band). Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition.

The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[LTSP]~~. Where a setpoint more conservative than the ~~[LTSP]~~ is used in the plant surveillance procedures ~~[NTSP]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and/or Analytical Limit is maintained. If the as-left channel setting cannot be returned to a setting within the as-left ~~tolerance~~ of the ~~[LTSP]~~, then the channel shall be declared inoperable. 5 5 3 5

The second Note also requires that ~~[LTSP]~~ and the methodologies for calculating the as-left and the as-found ~~tolerances~~ be in ~~[insert the facility FSAR reference or the name of any document incorporated into the facility FSAR by reference]~~ . the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report, respectively 5 3

~~[The Frequency is based upon the assumption of an 18 month calibration interval for the determination of the magnitude of equipment drift.~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

Testing may be performed in one measurement or in overlapping segments, with verification that all components are tested.

~~----------REVIEWER'S NOTE----------~~
~~Applicable portions of the following TS Bases are applicable to plants adopting CEOG Topical Report CE NPSD-1167-1, "Elimination of Pressure Sensor Response Time Testing Requirements," and the methodology contained in Attachment 1 to TSTF-569.~~
~~----------~~ 4

Response time may be verified by any series of sequential, overlapping or total channel measurements, including allocated sensor response time, such that the response time is verified. Allocations for sensor response times may be obtained from records of test results, vendor test data, or vendor engineering specifications. Topical Report CE NPSD-1167-A, "Elimination of Pressure Sensor Response Time Testing Requirements," (Ref. ~~1~~1) provides the basis and methodology for using allocated sensor response times in the overall verification of the channel response time for specific sensors identified in the Topical Report. The response time may be verified for components that replace the components that were previously evaluated in Ref. ~~1~~1 provided that the components have been evaluated in accordance with the NRC approved methodology as discussed in Attachment 1 to TSTF-569, "Methodology to Eliminate Pressure Sensor and Protection Channel (for Westinghouse Plants only) Response Time Testing," (Ref. ~~1~~2). Response time verification for other sensor types must be demonstrated by test. The allocation of sensor response times must be verified prior to placing a new component in operation and reverified after maintenance that may adversely affect the sensor response time.

10 10 11 1 R1 R1 R1

A Note is added to indicate that the neutron detectors are excluded from RPS RESPONSE TIME testing because they are passive devices with minimal drift and because of the difficulty of simulating a meaningful signal. Slow changes in detector sensitivity are compensated for by performing the ~~daily~~ calorimetric calibration (SR 3.3.1.2).

Figure B 3.3.1-1 (page 1 of 1)
Functional Diagram of the Two-Out-of-Four Logic and RTCB Configuration

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.1 Reactor Protective System (RPS) Instrumentation ~~– Operating (Analog)~~ 2

BASES

BACKGROUND

The Reactor Protective System (RPS) initiates a reactor trip to protect against violating the core specified acceptable fuel design limits and breaching the reactor coolant pressure boundary (RCPB) during anticipated operational occurrences (AOOs). By tripping the reactor, the RPS also assists the Engineered Safety Features (ESF) systems in mitigating accidents.

The protection and monitoring systems have been designed to ensure safe operation of the reactor. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the RPS, as well as LCOs on other reactor system parameters and equipment performance.

Technical Specifications are required by 10 CFR 50.36 to include LSSS for variables that have significant safety functions. LSSS are defined by the regulation as "Where a LSSS is specified for a variable on which a safety limit has been placed, the setting must be chosen so that automatic protective actions will correct the abnormal situation before a Safety Limit (SL) is exceeded." The Analytical Limit is the limit of the process variable at which a safety action is initiated, as established by the safety analysis, to ensure that a SL is not exceeded. Any automatic protection action that occurs on reaching the Analytical Limit therefore ensures that the SL is not exceeded. However, in practice, the actual settings for automatic protection channels must be chosen to be more conservative than the Analytical Limit to account for channel uncertainties related to the setting at which the automatic protective action would actually occur.

~~---------- REVIEWER'S NOTE ----------~~

~~The term "Limiting Trip Setpoint" [LTSP] is generic terminology for the calculated trip setting (setpoint) value calculated by means of the plant specific setpoint methodology documented in a document controlled under 10 CFR 50.59. The term [LTSP] indicates that no additional margin has been added between the Analytical Limit and the calculated trip setting.~~

~~"Nominal Trip Setpoint [NTSP]" is the suggested terminology for the actual setpoint implemented in the plant surveillance procedures where margin has been added to the calculated [LTSP]. The as-found and as-left tolerances will apply to the [NTSP] implemented in the Surveillance procedures to confirm channel performance.~~ 4

BASES

BACKGROUND (continued)

~~Licensees are to insert the name of the document(s) controlled under 10 CFR 50.59 that contain the methodology for calculating the as-left and as-found tolerances in Note b of Table 3.3.1-1 for the phrase "[insert the name of a document controlled under 10 CFR 50.59 such as the Technical Requirements Manual or any document incorporated into the facility FSAR]" throughout these Bases.~~

~~Where the [LTSP] is not included in Table 3.3.1-1, the plant specific location for the [LTSP] or [NTSP] must be cited in Note b of Table 3.3.1-1. The brackets indicate plant specific terms may apply, as reviewed and approved by the NRC.~~

4

Nominal NTSP Reference 1

The ~~[Limiting~~ Trip Setpoint (~~LTSP~~)~~]~~ specified in ~~Table 3.3.1-1~~ is a predetermined setting for a protection channel chosen to ensure automatic actuation prior to the process variable reaching the Analytical Limit and thus ensuring that the SL would not be exceeded. As such, the ~~[LTSP]~~ accounts for uncertainties in setting the channel (e.g., calibration), uncertainties in how the channel might actually perform (e.g., repeatability), changes in the point of action of the channel over time (e.g., drift during surveillance intervals), and any other factors which may influence its actual performance (e.g., harsh accident environments). In this manner, the ~~[LTSP]~~ ensures that SLs are not exceeded. Therefore, the ~~[LTSP]~~ meets the definition of an LSSS (Ref. ~~1~~).

1 3 1

NTSP 2

Technical Specifications contain values related to the OPERABILITY of equipment required for safe operation of the facility. OPERABLE is defined in Technical Specifications as "...being capable of performing its safety function(s)." Relying solely on the ~~[LTSP]~~ to define OPERABILITY in Technical Specifications would be an overly restrictive requirement if it were applied as an OPERABILITY limit for the "as-found" value of a protection channel setting during a Surveillance. This would result in Technical Specification compliance problems, as well as reports and corrective actions required by the rule which are not necessary to ensure safety. For example, an automatic protection channel with a setting that has been found to be different from the ~~[LTSP]~~ due to some drift of the setting may still be OPERABLE because drift is to be expected. This expected drift would have been specifically accounted for in the setpoint methodology for calculating the ~~[LTSP]~~ and thus the automatic protective action would still have ensured that the SL would not be exceeded with the "as-found" setting of the protection channel. Therefore, the channel would still be OPERABLE because it would have performed its safety function and the only corrective action required would be to reset the channel within the established as-left ~~tolerance~~ around the ~~[LTSP]~~ to account for further drift during the next surveillance interval. Note that,

NTSP

3

acceptance criteria band NTSP 5

BASES

BACKGROUND (continued)

acceptance criteria band

although the channel is OPERABLE under these circumstances, the trip setpoint must be left adjusted to a value within the as-left ~~tolerance~~ in accordance with uncertainty assumptions stated in the referenced setpoint methodology (as-left criteria), and confirmed to be operating within the statistical allowances of the uncertainty terms assigned (as-found criteria). 5

However, there is also some point beyond which the channel may not be able to perform its function due to, for example, greater than expected drift. This value needs to be specified in the Technical Specifications in order to define OPERABILITY of the channels and is designated as the Allowable Value.

acceptance criteria band (e.g., conservative side of the as-found acceptance criteria band)

If the actual setting (as-found setpoint) of the channel is found to be conservative with respect to the Allowable Value but is beyond the as-found ~~tolerance band~~, the channel is OPERABLE, but degraded. The degraded condition will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the ~~[Nominal Trip Setpoint (~~NTSP~~)]~~ (within the allowed ~~tolerance~~), and evaluating the channel response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation. 5 3

acceptance criteria band

During AOOs, which are those events expected to occur one or more times during the plant life, the acceptable limits are:

- The departure from nucleate boiling ratio (DNBR) shall be maintained above the SL value to prevent departure from nucleate boiling,
- Fuel centerline melting shall not occur, and
- The Reactor Coolant System (RCS) pressure SL of ~~[~~2750~~]~~ psia shall not be exceeded. 3

Maintaining the parameters within the above values ensures that the offsite dose will be within the ~~10 CFR 50 (Ref. 2) and~~ 10 CFR ~~100~~ (Ref. ~~3~~) criteria during AOOs. 1

4

50.67

BASES

BACKGROUND (continued)

Accidents are events that are analyzed even though they are not expected to occur during the plant life. The acceptable limit during accidents is that the offsite dose shall be maintained within an acceptable fraction of 10 CFR ~~100~~ (Ref. ~~3~~) limits. Different accident categories allow a different fraction of these limits based on probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event. 1

50.67

4

The RPS is segmented into four interconnected modules. These modules are:

- Measurement channels,
- Bistable trip units,
- RPS Logic, and
- Reactor trip circuit breakers (RTCBs).

This LCO addresses measurement channels and bistable trip units. It also addresses the automatic bypass removal feature for those trips with operating bypasses. The RPS Logic and RTCBs are addressed in LCO 3.3.~~3~~, "Reactor Protective System (RPS) Logic and Trip Initiation." 1

2

The role of each of these modules in the RPS, including those associated with the logic and RTCBs, is discussed below.

Measurement Channels

Measurement channels, consisting of field transmitters or process sensors and associated instrumentation, provide a measurable electronic signal based upon the physical characteristics of the parameter being measured.

The excore nuclear instrumentation and the analog core protection calculators (CPCs) are considered components in the measurement channels. The wide range nuclear instruments (NIs) provide a Power Rate of Change - High Trip. Three RPS trips use a power level designated as Q power as an input. Q power is the higher of NI power and primary calorimetric power (ΔT power) based on RCS hot leg and cold leg temperatures. Trips using Q power as an input include the Variable ~~High~~ Power Trip (VHPT) - High, Thermal Margin/Low Pressure (TM/LP), and the ~~Axial~~ Power ~~Distribution (APD)~~ - High trips. 1

Level

Local

Density

BASES

BACKGROUND (continued)

Local Power Density

The analog CPCs provide the complex signal processing necessary to calculate the TM/LP trip setpoint, ~~APD~~ trip setpoint, VHPT trip setpoint, and Q power calculation. 1

linear

Local Power Density

The excore NIs (wide range and ~~power~~ range) and the analog CPCs (TM/LP and ~~APD~~ calculators) are mounted in the RPS cabinet, with one channel of each in each of the four RPS bays. 1

Four identical measurement channels, designated channels A through D, with electrical and physical separation are provided for each parameter used in the direct generation of trip signals. Measurement channels provide input to one or more RPS bistables within the same RPS channel. In addition, some measurement channels may also be used as inputs to Engineered Safety Features Actuation System (ESFAS) bistables, and most provide indication in the control room. Measurement channels used as an input to the RPS are never used for control functions.

When a channel monitoring a parameter exceeds a predetermined setpoint, indicating an unsafe condition, the bistable monitoring the parameter in that channel will trip. Tripping two or more channels of

the

bistables monitoring the same parameter de-energizes Matrix Logic, which in turn de-energizes the Initiation Logic. This causes all eight RTCBs to open, interrupting power to the control element assemblies (CEAs), allowing them to fall into the core. 7

Three of the four measurement and bistable channels are necessary to meet the redundancy and testability of GDC 21 in 10 CFR 50, Appendix A (Ref. ~~2~~). The fourth channel provides additional flexibility by allowing one channel to be removed from service (trip channel bypass) for maintenance or testing while still maintaining a minimum two-out-of-three logic. Thus, even with a channel inoperable, no single additional failure in the RPS can either cause an inadvertent trip or prevent a required trip from occurring. 1

3

Since no single failure will either cause or prevent a protective system actuation, and no protective channel feeds a control channel, this arrangement meets the requirements of IEEE Standard 279-1971 (Ref. 4). 1

5

NTSP

Many of the RPS trips are generated by comparing a single measurement to a fixed bistable ~~[LTSP]~~. Certain Functions, however, make use of more than one measurement to provide a trip. The following trips use multiple measurement channel inputs: 3

BASES

BACKGROUND (continued)

- Steam Generator Level - Low

  This trip uses the lower of the two steam generator levels as an input to a common bistable.

- Steam Generator Pressure - Low

  This trip uses the lower of the two steam generator pressures as an input to a common bistable.

- Variable ~~High~~ Power Trip (VHPT) - High (Level) 1

  The VHPT uses Q power as its only input. Q power is the higher of NI power and ΔT power. It has a trip setpoint that tracks power levels downward so that it is always within a fixed increment above current power, subject to a minimum value.

  On power increases, the trip setpoint remains fixed unless manually reset, at which point it increases to the new setpoint, a fixed increment above Q power at the time of reset, subject to a maximum value. Thus, during power escalation, the trip setpoint must be repeatedly reset to avoid a reactor trip.

- Thermal Margin/Low Pressure (TM/LP) and Steam Generator Pressure Difference

  Q power is only one of several inputs to the TM/LP trip. Other inputs include internal ASI and cold leg temperature based on the higher of two cold leg resistance temperature detectors. The TM/LP trip setpoint is a complex function of these inputs and represents a minimum acceptable RCS pressure to be compared to actual RCS pressure in the TM/LP trip unit.

  Steam generator pressure is also an indirect input to the TM/LP trip via the Steam Generator Pressure Difference. This Function provides a reactor trip when the secondary pressure in either steam generator exceeds that of the other generator by greater than a fixed amount. The trip is implemented by biasing the TM/LP trip setpoint upward so as to ensure TM/LP trip if an asymmetric steam generator transient is detected.

- ~~Axial Power Distribution (APD)~~ – High

  Q Power and ASI are inputs to the ~~APD~~ trip. The ~~APD~~ trip setpoint is a function of Q power, being more restrictive at higher power levels. It provides a reactor trip if actual ASI exceeds the ~~APD~~ trip setpoint. (Local Power Density) (Local Power Density) 1

BASES

BACKGROUND (continued)

Bistable Trip Units

Bistable trip units, mounted in the RPS cabinet, receive an analog input from the measurement channels, compare the analog input to trip setpoints, and provide contact output to the Matrix Logic. They also provide local trip indication and remote annunciation.

There are four channels of bistable trip units, designated A through D, for each RPS Function, one for each measurement channel. Bistable output relays de-energize when a trip occurs.

The contacts from these bistable relays are arranged into six coincidence matrices, comprising the Matrix Logic. If bistables monitoring the same parameter in at least two channels trip, the Matrix Logic will generate a reactor trip (two-out-of-four logic).

Some of the RPS measurement channels provide contact outputs to the RPS, so the comparison of an analog input to a trip setpoint is not necessary. In these cases, the bistable trip unit is replaced with an auxiliary trip unit. The auxiliary trip units provide contact multiplication so the single input contact opening can provide multiple contact outputs to the coincidence logic as well as trip indication and annunciation.

Local Power Density

turbine generator control system hydraulic

Local Power Density

Trips employing auxiliary trip units include the Loss of Load trip and the ~~APD~~ - High trip. The Loss of Load trip is a contact input from the ~~Electro Hydraulic Control System~~ control oil pressure ~~on each of the~~ four high pressure ~~stop valves~~.

switches mounted on the emergency trip fluid line common header

sensed by

1

R1

The ~~APD~~ trip, described above, is a complex function in which the actual trip comparison is performed within the CPC. Therefore the ~~APD~~ - High trip unit employs a contact input from the CPC.

1

Local Power Density

All RPS trips, with the exception of the Loss of Load trip, generate a pretrip alarm as the trip setpoint is approached.

6

The trip setpoints used in the bistable trip units are based on the analytical limits stated in Reference ~~5~~. The calculation of the ~~[LTSP]~~ specified in Table 3.3.1-1 is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration ~~tolerances~~, instrumentation uncertainties, instrument drift, and severe environment errors - for those RPS channels that must function in harsh environments, as defined by 10 CFR 50.49 (Ref. ~~6~~) - Allowable Values specified in Table 3.3.1-1, in the accompanying LCO,

NTSP

3

acceptance criteria bands

1

5

7

BASES

BACKGROUND (continued)

are conservatively adjusted with respect to the analytical limits. A detailed description of the methodology used to calculate the trip setpoints, including their explicit uncertainties, is provided in ~~the "Plant Protection System Selection of Trip Setpoint Values"~~ (Ref. ~~7~~). The trip setpoint entered into the bistable is normally still more conservative than that specified by the Allowable Value, to account for changes in random measurement errors detectable by a CHANNEL FUNCTIONAL TEST. One example of such a change in measurement error is drift during the interval between surveillances.

IC-3.17, "Instrument Setpoint Methodology for Nuclear Power Plants" 8 1

The ~~[~~LTSP~~]~~ is the value at which the bistable is set and is the expected value to be achieved during calibration. The ~~[~~LTSP~~]~~ value is the LSSS and ensures the safety analysis limits are met for the surveillance interval selected when a channel is adjusted based on stated channel uncertainties.

NTSP 3

~~[~~LTSPs~~]~~, in conjunction with the use of as-found and as-left ~~tolerances~~, consistent with the requirements of the Allowable Value will ensure that SLs of Chapter 2.0 are not violated during AOOs and the consequences of DBAs will be acceptable, providing the plant is operated from within the LCOs at the onset of the AOO or DBA and the equipment functions as designed.

acceptance criteria bands 3 5

Note that in the accompanying LCO 3.3.1, the Allowable Values of Table 3.3.1-1 are the least conservative value of the as-found setpoint that a channel can have during a periodic CHANNEL CALIBRATION or CHANNEL FUNCTIONAL TEST.

RPS Logic

The RPS Logic, addressed in LCO 3.3.~~3~~, consists of both Matrix and Initiation Logic and employs a scheme that provides a reactor trip when bistables in any two out of the four channels sense the same input parameter trip. This is called a two-out-of-four trip logic. ~~This logic and the RTCB configuration are shown in Figure B 3.3.1-1.~~

2 1 6

Bistable relay contact outputs from the four channels are configured into six logic matrices. Each logic matrix checks for a coincident trip in the same parameter in two bistable channels. The matrices are designated the AB, AC, AD, BC, BD, and CD matrices to reflect the bistable channels being monitored. Each logic matrix contains four normally energized matrix relays. When a coincidence is detected, consisting of a trip in the same Function in the two channels being monitored by the logic matrix, all four matrix relays de-energize.

BASES

BACKGROUND (continued)

The matrix relay contacts are arranged into trip paths, with one of the four matrix relays in each matrix opening contacts in one of the four trip paths. Each trip path provides power to one of the four normally energized RTCB control relays (K1, K2, K3, and K4). The trip paths thus each have six contacts in series, one from each matrix, and perform a logical OR function, opening the RTCBs if any one or more of the six logic matrices indicate a coincidence condition.

Each trip path is responsible for opening one set of two of the eight RTCBs. The RTCB control relays (K-relays), when de-energized, interrupt power to the breaker undervoltage trip attachments and simultaneously apply power to the shunt trip attachments on each of the two breakers. Actuation of either the undervoltage or shunt trip attachment is sufficient to open the RTCB and interrupt power from the motor generator (MG) sets to the control element drive mechanisms (CEDMs).

When a coincidence occurs in two RPS channels, all four matrix relays in the affected matrix de-energize. This in turn de-energizes all four RTCB control relays, which simultaneously de-energize the undervoltage and energize the shunt trip attachments in all eight RTCBs, tripping them open.

Matrix Logic refers to the matrix power supplies, trip channel bypass contacts, and interconnecting matrix wiring between bistable and auxiliary trip units, up to but not including the matrix relays. Contacts in the bistable and auxiliary trip units are excluded from the Matrix Logic definition, since they are addressed as part of the measurement channel.

The Initiation Logic consists of the trip path power source, matrix relays and their associated contacts, all interconnecting wiring, and solid state (auxiliary) relays through the K-relay contacts in the RTCB control circuitry.

It is possible to change the two-out-of-four RPS Logic to a two-out-of-three logic for a given input parameter in one channel at a time by trip channel bypassing select portions of the Matrix Logic. Trip channel bypassing a bistable effectively shorts the bistable relay contacts in the three matrices associated with that channel. Thus, the bistables will function normally, producing normal trip indication and annunciation, but a reactor trip will not occur unless two additional channels indicate a trip condition. Trip channel bypassing can be simultaneously performed on

BASES

BACKGROUND (continued)

A mechanical interlock (key capture) in conjunction with administrative control

any number of parameters in any number of channels, providing each parameter is bypassed in only one channel at a time. ~~An interlock~~ prevents simultaneous trip channel bypassing of the same parameter in more than one channel. Trip channel bypassing is normally employed during maintenance or testing. 1

For those plants that have demonstrated sufficient channel to channel independence, two-out-of-three logic is the minimum that is required to provide adequate plant protection, since a failure of one channel still ensures a reactor trip would be generated by the two remaining OPERABLE channels. Two-out-of-three logic also prevents inadvertent trips caused by any single channel failure in a trip condition.

Zero Power Mode trips (Reactor Coolant Flow – Low and Thermal Margin/Low Pressure), Local Power Density - High, Loss of Load -High,

Local Power Density

In addition to the trip channel bypasses, there are also operating bypasses on select RPS trips. Some of these bypasses are enabled manually, others automatically, in all four RPS channels when plant conditions do not warrant the specific trip protection. All operating bypasses are automatically removed when enabling bypass conditions are no longer satisfied. Trips with operating bypasses include Power Rate of Change - High, ~~Reactor Coolant Flow - Low,~~ Steam Generator Pressure - Low, ~~APD - High, TM/LP,~~ and Steam Generator Pressure Difference. ~~[~~The Loss of Load trip, Power Rate of Change - High, and ~~APD~~ - High operating bypasses are automatically enabled and disabled.~~]~~ 1 3 R1

The Variable Power Level Trip – High bypass is manual enable but automatically

Reactor Trip Circuit Breakers (RTCBs)

2

The reactor trip switchgear, addressed in LCO 3.3.~~3 and shown in Figure B 3.3.1-1~~, consists of eight RTCBs, which are operated in four sets of two breakers (four channels). Power input to the reactor trip switchgear comes from two full capacity MG sets operated in parallel such that the loss of either MG set does not de-energize the CEDMs. There are two separate CEDM power supply buses, each bus powering half of the CEDMs. Power is supplied from the MG sets to each bus via two redundant paths (trip legs). Trip legs 1A and 1B supply power to CEDM bus 1. Trip legs 2A and 2B supply power to CEDM bus 2. This ensures that a fault or the opening of a breaker in one trip leg (i.e., for testing purposes) will not interrupt power to the CEDM buses. 6

Each of the four trip legs consists of two RTCBs in series. The two RTCBs within a trip leg are actuated by separate initiation circuits.

BASES

BACKGROUND (continued)

The eight RTCBs are operated as four sets of two breakers (four channels). For example, if a breaker receives an open signal in trip leg A (for CEDM bus 1), an identical breaker in trip leg B (for CEDM bus 2) will also receive an open signal. This arrangement ensures that power is interrupted to both CEDM buses, thus preventing trip of only half of the CEAs (a half trip). Any one inoperable breaker in a channel will make the entire channel inoperable.

Each set of RTCBs is operated by either a Manual Trip push button or an RPS actuated K-relay. There are four Manual Trip push buttons~~,~~ arranged in two sets of two~~, as shown in Figure B 3.3.1-1~~. Depressing both push buttons in either set will result in a reactor trip. 6

When a Manual Trip is initiated using the control room push buttons, the RPS trip paths and K-relays are bypassed, and the RTCB undervoltage and shunt trip attachments are actuated independent of the RPS.

Manual Trip circuitry includes the push button and interconnecting wiring to both RTCBs necessary to actuate both the undervoltage and shunt trip attachments but excludes the K-relay contacts and their interconnecting wiring to the RTCBs, which are considered part of the Initiation Logic.

Functional testing of the entire RPS, from bistable input through the opening of individual sets of RTCBs, can be performed either at power or shutdown and is ~~normally~~ performed ~~on a quarterly basis~~. per the Surveillance Frequency Control Program 9 1 3
FSAR, Section ~~[~~7.2~~]~~ (Ref. ~~3~~), explains RPS testing in more detail. U

APPLICABLE SAFETY ANALYSES

Each of the analyzed accidents and transients can be detected by one or more RPS Functions. The accident analysis contained in Reference ~~5~~ takes credit for most RPS trip Functions. Functions not specifically credited in the accident analysis are part of the NRC approved licensing basis for the plant. These Functions may provide protection for conditions that do not require dynamic transient analysis to demonstrate Function performance. Other Functions, such as the Loss of Load trip, are purely equipment protective, and their use minimizes the potential for equipment damage. 6 1

Permissive and interlock setpoints allow the blocking of trips during plant startups, and restoration of trips when the permissive conditions are not satisfied, but they are not explicitly modeled in the Safety Analyses. These permissives and interlocks ensure that the starting conditions are consistent with the safety analysis, before preventive or mitigating actions occur. Because these permissives or interlocks are only one of multiple conservative starting assumptions for the accident analysis, they are generally considered as nominal values without regard to measurement accuracy.

BASES

APPLICABLE SAFETY ANALYSES (continued)

The specific safety analyses applicable to each protective Function are identified below:

1. Variable ~~High~~ Power Level Trip (VHPT) - High 1

The VHPT provides reactor core protection against positive reactivity excursions that are too rapid for a Pressurizer Pressure - High or TM/LP trip to protect against. The following events require VHPT protection:

- Uncontrolled CEA withdrawal event,
- Excess load, R1
- Excess feedwater heat removal event,
- CEA ejection event, and
-
- Main steam line break (MSLB) ~~(outside containment)~~. R1

The first three events are AOOs, and fuel integrity is maintained. The fourth and fifth are accidents, and limited fuel damage may occur.

2. Power Rate of Change - High

The Power Rate of Change - High trip is used to trip the reactor when excore ~~[~~logarithmic~~]~~ power indicates an excessive rate of change. The Power Rate of Change - High Function ~~minimizes transients for events such as a continuous CEA withdrawal or a boron dilution event from low power levels~~. The trip may be bypassed when THERMAL POWER is < 1E-4% RTP, when poor counting statistics may lead to erroneous indication. ~~It is also~~ bypassed at > 15% RTP, where moderator temperature coefficient and fuel temperature coefficient make high rate of change of power unlikely. With the RTCBs open, the Power Rate of Change - High trip is not required to be OPERABLE; however, the indication ~~and alarm~~ Function~~s~~ of at least two channels ~~are~~ is required by LCO 3.3.1~~3~~, "~~[~~Logarithmic~~]~~ ~~Power~~ Monitoring ~~Channels~~," to be OPERABLE. LCO 3.3.1~~3~~ ensures the ~~[~~logarithmic~~]~~ channels are available to detect ~~and alert the operator to~~ a boron dilution event.

is not credited in the accident analysis as providing primary protection for any limiting case AOO or accident.

In addition, the trip is not required to be OPERABLE and is

Neutron Flux

3 1 1 3 1 1 3 1

BASES

APPLICABLE SAFETY ANALYSES (continued)

3. Reactor Coolant Flow - Low

The Reactor Coolant Flow - Low trip provides protection during the following events:

- Loss of RCS flow,
- Loss of ~~nonemergency~~ AC power,
- Reactor coolant pump (RCP) seized shaft, and
- RCP sheared shaft~~, and~~
- ~~Certain MSLB events~~.

R1

The loss of RCS flow and ~~of nonemergency~~ AC power events are AOOs where fuel integrity is maintained. The RCP seized shaft, and sheared shaft~~, and MSLBs~~ are accidents where fuel damage may result.

4. Pressurizer Pressure - High

The Pressurizer Pressure - High trip, in conjunction with pressurizer safety valves and main steam safety valves (MSSVs), provides protection against overpressure conditions in the RCS during the following events:

1

- Loss of condenser vacuum with a concurrent loss of offsite power,
- Loss of condenser vacuum with a concurrent loss of one 6.9 kV bus,
- ~~Isolation of turbine at 102% power~~ Turbine trip,
- Feedwater ~~System pipe breaks between the steam generator and check valve~~ line break (small),
- CEA withdrawal, and
- Loss of feedwater flow.

R1

BASES

APPLICABLE SAFETY ANALYSES (continued)

5. Containment Pressure - High

The Containment Pressure - High trip prevents exceeding the containment design pressure during certain loss of coolant accidents (LOCAs) or feedwater line break accidents. It ensures a reactor trip prior to, or concurrent with, a LOCA, thus assisting the ESFAS in the event of a LOCA or MSLB. Since these are accidents, SLs may be violated. However, the consequences of the accident will be acceptable.

6. Steam Generator Pressure - Low

The Steam Generator Pressure - Low trip provides protection against an excessive rate of heat extraction from the steam generators, which would result in a rapid uncontrolled cooldown of the RCS. This trip is needed to shut down the reactor and assist the ESFAS in the event of an MSLB. Since these are accidents, SLs may be violated. However, the consequences of the accident will be acceptable.

7.a, 7.b. Steam Generator A and B Level - Low

The Steam Generator A Level - Low and Steam Generator B Level - Low trips are required for the following events:

- Steam System piping failures,
- Feedwater System pipe breaks,
- ~~Inadvertent opening of a steam generator atmospheric dump valve (ADV),~~ Excess Load and
- Loss of normal feedwater~~, and~~
- ~~Asymmetric loss of feedwater~~.

R1 1

The Steam Generator Level - Low trip ensures that low DNBR, high local power density, and the RCS pressure SLs are maintained during normal operation and AOOs, and, in conjunction with the ESFAS, the consequences of the Feedwater System pipe break accident will be acceptable.

BASES

APPLICABLE SAFETY ANALYSES (continued)

8. ~~Axial Power Distribution (APD)~~ - High

Local Power Density

1

The ~~APD~~ - High trip ensures that excessive axial peaking, such as that due to axial xenon oscillations, will not cause fuel damage. It ensures that neither a DNBR less than the SL nor a peak linear heat rate that corresponds to the temperature for fuel centerline melting will occur. This trip is the primary protection against fuel centerline melting.

9. Thermal Margin

a. Thermal Margin/Low Pressure (TM/LP)

The TM/LP trip prevents exceeding the DNBR SL during AOOs and aids the ESFAS during certain accidents. The following events require TM/LP protection:

- Excess load ~~(inadvertent opening of a steam generator ADV)~~, R1
- RCS depressurization (inadvertent safety or power operated relief valves (PORVs) opening), R1
- Steam generator tube rupture, and
- LOCA accident.

The first two events are AOOs, and fuel integrity is maintained. The third and fourth are accidents, and limited fuel damage may occur although only the LOCA is expected to result in fuel damage. The trip is initiated whenever the RCS pressure signal drops below a minimum value (P_{min}) or a computed value (P_{var}) as described below, whichever is higher. The computed value is a Function Q power, ASI, as determined from the axially split excore detectors~~,~~ and reactor inlet (cold leg) temperature~~, and the number of RCPs operating~~.

and

1

The minimum value of reactor coolant flow rate, the maximum ~~T~~$_Q$, and the maximum CEA deviation permitted for continuous operation are assumed in the generation of this trip Function. In addition, CEA group sequencing in accordance with LCO 3.1.6, "Regulating Control Element Assembly (CEA) Insertion Limits," is assumed. Finally, the maximum insertion of CEA banks that can occur during any AOO prior to a VHPT is assumed.

azimuthal tilt

1

BASES

APPLICABLE SAFETY ANALYSES (continued)

b. Steam Generator Pressure Difference

The Steam Generator Pressure Difference provides protection for those AOOs associated with secondary system malfunctions that result in asymmetric primary coolant temperatures. The most limiting event is closure of a single main steam isolation valve. Steam Generator Pressure Difference is provided by comparing the secondary pressure in both steam generators in the TM/LP calculator. If the pressure in either exceeds that in the other by the trip setpoint, a TM/LP trip will result.

10. Loss of Load

Hydraulic Fluid Pressure - Low

R1

1

The Loss of Load (turbine ~~stop valve (TSV)~~ control oil pressure) trip is anticipatory for the loss of heat removal capabilities of the secondary system following a turbine trip. The Loss of Load trip prevents lifting the pressurizer safety valves, PORVs, and MSSVs in the event of a turbine generator trip. Thus, the trip minimizes the pressure and temperature transients on the reactor by initiating a trip well before reaching the Pressurizer Pressure - High trip and pressurizer safety valve setpoints. The four RPS Loss of Load reactor trip channels receive their input from ~~sensors mounted on the high pressure TSV actuators. Since there are four high pressure TSVs, one actuator per valve and one sensor per actuator, each sensor sends its signal to a different RPS channel. When the turbine trips, control oil is dumped from the high pressure TSVs. When the control oil pressure drops to the appropriate setpoint, a reactor trip signal is generated.~~

four redundant pressure switches mounted on the emergency trip fluid line common header, to serve as the loss of load, turbine trip input to the Reactor Protective System logic matrices. Actuation of any two of the pressure switches on low hydraulic oil pressure causes a reactor trip.

1

Interlocks/Bypasses

The bypasses and their Allowable Values are addressed in footnotes to Table 3.3.1-1. They are not otherwise addressed as specific Table entries.

The automatic bypass removal features must function as a backup to manual actions for all safety related trips to ensure the trip Functions are not operationally bypassed when the safety analysis assumes the Functions are not bypassed. The RPS operating bypasses are:

Zero power mode bypass (ZPMB) removal on the TM/LP, Steam Generator Pressure Difference, and reactor coolant low flow trips when THERMAL POWER is < ~~1E-4~~ 0.5% RTP. This bypass is manually enabled below the specified setpoint to permit low power testing. The wide range NI Level 1 bistable in the wide range drawer permits manual bypassing below the setpoint and removes the bypass above the setpoint.

1

BASES

APPLICABLE SAFETY ANALYSES (continued)

Power rate of change bypass removal. The Power Rate of Change - High trip is automatically bypassed at < 1E-4% RTP, as sensed by the wide range NI Level 2 bistable, and at > ~~12~~15% RTP by the power range NI Level 1 bistable, mounted in their respective NI drawers. Automatic bypass removal is also effected by these bistables when conditions are no longer satisfied. 1

Local Power Density

Loss of Load and ~~APD~~ - High bypass removal. The Loss of Load and ~~APD~~ - High trips are automatically bypassed when at < 15% RTP as sensed by the power range NI Level 1 bistable. The bypass is automatically removed by this bistable above the setpoint. This same bistable is used to bypass the Power Rate of Change - High trip. 1

Steam Generator Pressure - Low bypass removal. The Steam Generator Pressure - Low trip is manually enabled below the pretrip setpoint. The permissive is removed, and the bypass automatically removed, when the Steam Generator Pressure - Low pretrip clears.

The RPS instrumentation satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires all instrumentation performing an RPS Function to be OPERABLE. Failure of any required portion of the instrument channel renders the affected channel(s) inoperable and reduces the reliability of the affected Functions. The specific criteria for determining channel OPERABILITY differ slightly between Functions. These criteria are discussed on a Function by Function basis below.

Actions allow maintenance (trip channel) bypass of individual channels, but ~~the bypass activates interlocks that prevent~~ operation with a second channel in the same Function bypassed~~.~~. ~~Plants are restricted to 48 hours in a trip channel bypass condition before either restoring the Function to four channel operation (two-out-of-four logic) or placing the channel in trip (one-out-of-three logic). At plants where adequate channel to channel independence has been demonstrated, specific exceptions may be approved by the NRC staff to permit one of the two-out-of-four channels to be bypassed for an extended period of time.~~ R1 1

is prevented by mechanical interlock (key capture)

the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report, respectively

NTSPs

Allowable Values for RPS Instrumentation Functions are specified in Table 3.3.1-1. ~~[~~LTSPs~~]~~ and the methodologies for calculation of the as-left and as-found ~~tolerances~~ are described in ~~[insert the name of a document controlled under 10 CFR 50.59 such as the Technical Requirements Manual or any document incorporated into the facility FSAR]~~. The ~~[~~LTSPs~~]~~ are selected to ensure that the actual setpoints remain conservative with respect to the as-found ~~tolerance~~ band between successive CHANNEL CALIBRATIONS. After each calibration the trip setpoint shall be left within the as-left band around the ~~[~~LTSP~~]~~. 5 3 5

NTSPs

acceptance criteria

NTSP

BASES

LCO (continued)

The following Bases for each trip Function identify the above RPS trip Function criteria items that are applicable to establish the trip Function OPERABILITY.

Level

1. Variable ~~High~~ Power Trip (VHPT) - High 1

This LCO requires all four channels of the VHPT to be OPERABLE in MODES 1 and 2.

The Allowable Value is high enough to provide an operating envelope that prevents unnecessary Linear Power Level - High reactor VHPT - High trips during normal plant operations. The Allowable Value is low enough for the system to maintain a margin to unacceptable fuel cladding damage should a CEA ejection accident occur.

The VHPT setpoint is operator adjustable and can be set at a fixed increment above the indicated THERMAL POWER level. Operator action is required to increase the trip setpoint as THERMAL POWER is increased. The trip setpoint is automatically decreased as THERMAL POWER decreases. The ~~[LTSP]~~ has a maximum and a minimum setpoint. 3

NTSP

NTSP

Adding to this maximum value the possible variation in ~~[LTSP]~~ due to calibration and instrument errors, the maximum actual steady state THERMAL POWER level at which a trip would be actuated is ~~112~~% RTP, which is the value used in the safety analyses. 3 R1

107

conservative with respect to

of 112% RTP

1

Calibration and instrument errors are considered within the setpoint calculations. The stated minimum and maximum Allowable Values and step values are the assumed safety analysis values.

~~To account for these errors, the safety analysis minimum value is 40% RTP. The 10% step is a maximum value assumed in the safety analysis. There is no uncertainty applied to the step.~~ R1

2. Power Rate of Change - High

MODE 1 with THERMAL POWER ≤ 15% RTP and MODE 2

This LCO requires four channels of Power Rate of Change - High to be OPERABLE in ~~MODES 1 and 2, as well as in MODES 3, 4, and 5 when the RTCBs are closed and the CEA Drive System is capable of CEA withdrawal~~. 1

The high power rate of change trip serves as a backup to the administratively enforced startup rate limit. The Function is not credited in the accident analyses; therefore, the Allowable Value for the trip or bypass Functions is not derived from analytical limits.

BASES

LCO (continued)

3. Reactor Coolant Flow - Low

This LCO requires four channels of Reactor Coolant Flow - Low to be OPERABLE in MODES 1 and 2.

0.5 The trip may be manually bypassed when THERMAL POWER falls below ~~1E-4~~% RTP. This bypass is part of the ZPMB circuitry, which also bypasses the TM/LP trip and provides a ΔT power block signal to the Q power select logic. This ZPMB allows low power physics testing at reduced RCS temperatures and pressures. It also allows heatup and cooldown with shutdown CEAs withdrawn.

This trip is set high enough to maintain fuel integrity during a loss of flow condition. The setting is low enough to allow for normal operating fluctuations from offsite power. ~~To account for analysis uncertainty, the value in the safety analysis is 93% RTP.~~

4. Pressurizer Pressure - High

This LCO requires four channels of Pressurizer Pressure - High to be OPERABLE in MODES 1 and 2.

The Allowable Value is set high enough to allow for pressure increases in the RCS during normal operation (i.e., plant transients) not indicative of an abnormal condition. The setting is below the lift setpoint of the pressurizer safety valves and low enough to initiate a reactor trip when an abnormal condition is indicated. ~~The difference between the Allowable Value and the analysis setpoint of 2470 psia includes allowance for harsh environment.~~

1

The Pressurizer Pressure - High trip concurrent with PORV operation avoids unnecessary operation of the pressurizer safety valves.

5. Containment Pressure - High

This LCO requires four channels of Containment Pressure - High to be OPERABLE in MODES 1 and 2.

The Allowable Value is high enough to allow for small pressure increases in containment expected during normal operation (i.e., plant heatup) that are not indicative of an abnormal condition. The setting is low enough to initiate a reactor trip to prevent containment pressure from exceeding design pressure following a DBA.

BASES

LCO (continued)

6. Steam Generator Pressure - Low

This LCO requires four channels of Steam Generator Pressure - Low per steam generator to be OPERABLE in MODES 1 and 2.

The Allowable Value is sufficiently below the full load operating value for steam pressure so as not to interfere with normal plant operation, but still high enough to provide the required protection in the event of excessive steam demand. Since excessive steam demand causes the RCS to cool down, resulting in positive reactivity addition to the core, a reactor trip is required to offset that effect.

~~The difference between the Allowable Value and the safety analysis value of 600 psia includes harsh environment uncertainties.~~ 1

The Function may be manually bypassed as steam generator pressure is reduced during controlled plant shutdowns. This bypass is permitted at a preset steam generator pressure. The bypass, in conjunction with the ZPMB, allows testing at low temperatures and pressures, and heatup and cooldown with the shutdown CEAs withdrawn. From a bypass condition the trip will be reinstated automatically as steam generator pressure increases above the preset pressure.

7.a, 7.b. Steam Generator Level – Low

This LCO requires four channels of Steam Generator Level - Low per steam generator to be OPERABLE in MODES 1 and 2.

The Allowable Value is sufficiently below the normal operating level for the steam generators so as not to cause a reactor trip during normal plant operations. The trip setpoint is high enough to ensure a reactor trip signal is generated before water level drops below the top of the feed ring. ~~The difference between the Allowable Value and the measurement value includes 10 inches of measurement uncertainty. The specified setpoint ensures there will be sufficient water inventory to provide a 10 minute margin before auxiliary feedwater is required for the removal of decay heat.~~ 1

BASES

LCO (continued)

8. ~~Axial Power Distribution (APD)~~ - High

Local Power Density

This LCO requires four channels of ~~APD~~ - High to be OPERABLE in MODE 1 ≥ 15% RTP.

The Allowable Value curve was derived from an analysis of many axial power shapes with allowances for instrumentation inaccuracies and the uncertainty associated with the excore to incore ASI relationship. 1

Local Power Density

The ~~APD~~ trip is automatically bypassed at < 15% RTP, where it is not required for reactor protection.

9. Thermal Margin

a. Thermal Margin/Low Pressure (TM/LP)

This LCO requires four channels of TM/LP to be OPERABLE in MODES 1 and 2.

The Allowable Value includes allowances for equipment response time, measurement uncertainties, processing error, and a further allowance to compensate for the time delay associated with providing effective termination of the occurrence that exhibits the most rapid decrease in margin to the SL.

0.5

This trip may be manually bypassed when THERMAL POWER falls below ~~1E-4~~% RTP. This bypass is part of the ZPMB circuitry, which also bypasses the Reactor Coolant Flow - Low trip and provides a ΔT power block signal to the Q power select logic. This ZPMB allows low power physics testing at reduced RCS temperatures and pressures. It also allows heatup and cooldown with shutdown CEAs withdrawn. 1

b. Steam Generator Pressure Difference

This LCO requires four channels of Steam Generator Pressure Difference to be OPERABLE in MODES 1 and 2.

The Allowable Value is high enough to avoid trips caused by normal operation and minor transients, but ensures DNBR protection in the event of Design Basis Events. ~~The difference between the Allowable Value and the 175 psia analysis setpoint allows for 40 psia of measurement uncertainty.~~ 1

BASES

LCO (continued)

0.5 The trip may be bypassed when THERMAL POWER falls below ~~1E-4~~% RTP. The Steam Generator Pressure Difference is subject to the ZPMB, since it is an input to the TM/LP trip and is not required for protection at low power levels. 1

10. Loss of Load

The LCO requires four Loss of Load trip channels to be OPERABLE in MODE 1 ≥ 15% RTP.

The Loss of Load trip may be bypassed when THERMAL POWER falls below 15%, since it is no longer needed to prevent lifting of the pressurizer safety valves, steam generator safety valves, or PORVs in the event of a Loss of Load. The Nuclear Steam Supply System and the Steam Dump System are capable of accommodating the Loss of Load without requiring the use of the above equipment.

Interlocks/Bypasses

The LCO on bypass permissive removal channels requires that the automatic bypass removal feature of all four operating bypass channels be OPERABLE for each RPS Function with an operating bypass in the MODES addressed in the specific LCO for each Function. All four bypass removal channels must be OPERABLE to ensure that none of the four RPS channels are inadvertently bypassed.

The LCO applies to the bypass removal feature only. If the bypass enable Function is failed so as to prevent entering a bypass condition, operation may continue.

The interlock Allowable Values are based on analysis requirements for the bypassed functions. These are discussed above as part of the LCO discussion for the affected Functions.

APPLICABILITY This LCO is applicable in accordance with Table 3.3.1-1. Most RPS trips are required to be OPERABLE in MODES 1 and 2 because the reactor is critical in these MODES. The trips are designed to take the reactor subcritical, maintaining the SLs during AOOs and assisting the ESFAS in providing acceptable consequences during accidents. Exceptions are addressed in footnotes to the table. Exceptions to this APPLICABILITY are:

Local Power Density

- The ~~APD~~ - High Trip and Loss of Load are only applicable in MODE 1 ≥ 15% RTP because they may be automatically bypassed at < 15% RTP, where they are no longer needed. 1

BASES

APPLICABILITY (continued)

- ~~The Power Rate of Change - High trip, RPS Logic, RTCBs, and Manual Trip are also required in MODES 3, 4, and 5, with the RTCBs closed, to provide protection for boron dilution and CEA withdrawal events. The Power Rate of Change - High trip in these lower MODES is addressed in LCO 3.3.2, "Reactor Protective System (RPS) Instrumentation - Shutdown." The RPS Logic in MODES 1, 2, 3, 4, and 5 is addressed in LCO 3.3.3.~~

1

The RPS

~~Most~~ trips are not required to be OPERABLE in MODES 3, 4, and 5. In MODES 3, 4, and 5, the emphasis is placed on return to power events. The reactor is protected in these MODES by ensuring adequate SDM.

ACTIONS

acceptance criteria band

The most common causes of channel inoperability are outright failure or drift of the bistable or process module sufficient to exceed the ~~tolerance~~ allowed by the plant specific setpoint analysis. Typically, the drift is found to be small and results in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the process instrument is set up for adjustment to bring it to within specification. If the trip setpoint is nonconservative with respect to the Allowable Value in Table 3.3.1-1, the channel is declared inoperable immediately, and the appropriate Condition(s) must be entered immediately.

5

In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value, or the channel is not functioning as required, or the transmitter, instrument loop, signal processing electronics, or RPS bistable trip unit is found inoperable, then all affected Functions provided by that channel must be declared inoperable, and the plant must enter the Condition for the particular protection Function affected.

When the number of inoperable channels in a trip Function exceeds that specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 is immediately entered if applicable in the current MODE of operation.

A Note has been added to the ACTIONS to clarify the application of the Completion Time rules. The Conditions of this Specification may be entered independently for each Function. The Completion Times of each inoperable Function will be tracked separately for each Function, starting from the time the Condition was entered.

BASES

ACTIONS (continued)

A.1~~, A.2.1,~~ and A.2~~.2~~ 9

Condition A applies to the failure of a single channel in any RPS automatic trip Function. RPS coincidence logic is normally two-out-of-four.

If one RPS bistable trip unit or associated instrument channel is inoperable, startup or power operation is allowed to continue, providing the inoperable trip unit is placed in bypass or trip within 1 hour (Required Action A.1). With one channel in bypass, no additional random failure of a single channel could spuriously trip the reactor and a valid trip signal can still trip the reactor. With one channel in trip, an additional random failure of a single channel could spuriously trip the reactor. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to restore, bypass, or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel while ensuring that the risk involved in operating with the failed channel is acceptable.

Insert 1

~~The failed channel is restored to OPERABLE status or is placed in trip within [48] hours [or in accordance with the Risk Informed Completion Time Program] (Required Action A.2.1 or Required Action A.2.2). Required Action A.2.1 restores the full capability of the Function.~~

~~[Required Action A.2.2 places the Function in a one-out-of-three configuration. In this configuration, common cause failure of dependent channels cannot prevent trip.]~~

~~The Completion Time of [48] hours is based on operating experience, which has demonstrated that a random failure of a second channel occurring during the [48] hour period is a low probability event.~~ 9

B.1 ~~and B.2~~ 9

Condition B applies to the failure of two channels in any RPS automatic trip Function.

Required Action B.1 provides for placing one inoperable channel in bypass and the other channel in trip within the Completion Time of 1 hour. This Completion Time is sufficient to allow the operator to take all appropriate actions for the failed channels while ensuring that the risk involved in operating with the failed channels is acceptable. With one channel of protective instrumentation bypassed, the RPS is in a two-out-of-three logic; but with another channel failed, the RPS may be operating

9 1

INSERT 1

Additionally, the failed channel must be restored to OPERABLE status prior to entering MODE 2 following the next MODE 5 entry. The Completion Time of Required Action A.2 is based on adequate channel to channel independence, which allows a two-out-of-three channel operation since no single failure will cause or prevent a reactor trip. However, it is expected that the inoperable channel will be restored to OPERABLE status at the first reasonable opportunity. The determination of the first reasonable opportunity should include consideration of the impact on plant risk (from delaying restoration of the channel as well as any plant configuration changes required or shutting the plant down to repair the channel) and impact on any analysis assumptions, in addition to unit conditions, planning, availability of personnel, and the time required to repair the channel. This risk impact should be managed through the program in place to implement 10 CFR 50.65(a)(4) and NRC Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants."

Condition A is modified by a Note requiring Required Action A.2 to be completed whenever the Condition is entered even when the LCO is no longer applicable to ensure the channel is restored to OPERABLE prior to the next reactor startup from MODE 5 conditions.

BASES

ACTIONS (continued)

in a two-out-of-two logic. This is outside the assumptions made in the analyses and should be corrected. To correct the problem, the second channel is placed in trip. This places the RPS in a one-out-of-two logic. If any of the other OPERABLE channels receives a trip signal, the reactor will trip.

Insert 2

~~One channel should be restored to OPERABLE status within [48] hours [or in accordance with the Risk Informed Completion Time Program] for reasons similar to those stated under Condition A. After one channel is restored to OPERABLE status, the provisions of Condition A still apply to the remaining inoperable channel. Therefore, the channel that is still inoperable after completion of Required Action B.2 must be placed in trip if more than [48] hours have elapsed since the initial channel failure.~~ 9

C.1 and C.2

Local Power Density

The excore detectors are used to generate the internal ASI used as an input to the TM/LP and ~~APD~~ - High trips. Incore detectors provide a more accurate measurement of ASI. If one or more excore detectors cannot be calibrated to match incore detectors, power is restricted or reduced during subsequent operations because of increased uncertainty associated with using uncalibrated excore detectors. 3

The Completion Time of 24 hours is adequate to perform the SR while minimizing the risk of operating in an unsafe condition.

D.1, D.2.1, D.2.2.1, and D.2.2.2

Condition D applies to one automatic bypass removal channel inoperable. If the bypass removal channel for any operating bypass cannot be restored to OPERABLE status, the associated RPS channel may be considered OPERABLE only if the bypass is not in effect. Otherwise, the affected RPS channel must be declared inoperable, as in Condition A, and the bypass either removed or the bypass removal channel repaired. The Bases for Required Actions and Completion Times are the same as discussed for Condition A.

E.1, E.2.1, and E.2.2

Condition E applies to two inoperable automatic bypass removal channels. If the bypass removal channels cannot be restored to OPERABLE status, the associated RPS channel may be considered OPERABLE only if the bypass is not in effect. Otherwise, the affected

9 **INSERT 2** 1

One of the two inoperable channels will need to be restored to OPERABLE status prior to the next required CHANNEL FUNCTIONAL TEST, because channel surveillance testing on an OPERABLE channel requires that the OPERABLE channel be placed in bypass. However, it is not possible to bypass more than one RPS channel and placing a second channel in trip will result in a reactor trip. Therefore, if one RPS channel is in trip and a second channel is in bypass, a third inoperable channel would place the unit in LCO 3.0.3.

BASES

ACTIONS (continued)

RPS channels must be declared inoperable, as in Condition B, and the bypass either removed or the bypass removal channel repaired. Also, Required Action E.2.2 provides for the restoration of the one affected automatic trip channel to OPERABLE status within the rules of Completion Time specified under Condition B. Completion Times are consistent with Condition B.

F.1

Condition F is entered when the Required Action and associated Completion Time of Conditions A, B, C, D, or E are not met for the ~~Axial Power Distribution~~ Local Power Density and Loss of Load Trip Functions. 1

If the Required Actions associated with these Conditions cannot be completed within the required Completion Times, the reactor must be brought to a MODE in which the Required Actions do not apply. The allowed Completion Time of 6 hours to reduce THERMAL POWER to < 15% RTP is reasonable, based on operating experience, to decrease power to < 15% RTP from full power conditions in an orderly manner and without challenging plant systems.

G.1

Condition G is entered when the Required Action and associated Completion Time of Conditions A, B, C, D, E, or F are not met.

If the Required Actions associated with these Conditions cannot be completed within the required Completion Times, the reactor must be brought to a MODE in which the Required Actions do not apply. The allowed Completion Time of 6 hours to be in MODE 3 is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

The SRs for any particular RPS Function are found in the SR column of Table 3.3.1-1 for that Function. Most Functions are subject to CHANNEL CHECK, CHANNEL FUNCTIONAL TEST, CHANNEL CALIBRATION, and response time testing.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~In order for a plant to take credit for topical reports as the basis for justifying Frequencies, topical reports must be supported by an NRC staff SER that establishes the acceptability of each topical report for that plant (Ref. 9).~~
~~---~~

~~----------REVIEWER'S NOTE----------~~
~~Notes a and b are applied to the setpoint verification Surveillances for each RPS Instrumentation – Operating (Analog) Function in Table 3.3.1-1 unless one or more of the following exclusions apply:~~

~~1. Manual actuation circuits, automatic actuation logic circuits or instrument functions that derive input from contacts which have no associated sensor or adjustable device, e.g., limit switches, breaker position switches, manual actuation switches, float switches, proximity detectors, etc. are excluded. In addition, those permissives and interlocks that derive input from a sensor or adjustable device that is tested as part of another TS function are excluded.~~

~~2. Settings associated with safety relief valves are excluded. The performance of these components is already controlled (i.e., trended with as-left and as-found limits) under the ASME Code for Operation and Maintenance of Nuclear Power Plants testing program.~~

~~3. Functions and Surveillance Requirements which test only digital components are normally excluded. There is no expected change in result between SR performances for these components. Where separate as-left and as-found tolerance is established for digital component SRs, the requirements would apply.~~
~~---~~ 3

SR 3.3.1.1

Performance of the CHANNEL CHECK ensures that gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

BASES

SURVEILLANCE REQUIREMENTS (continued)

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the transmitter or the signal processing equipment has drifted outside its limits.

~~[The Frequency, about once every shift, is based on operating experience that demonstrates the rarity of channel failure. Since the probability of two random failures in redundant channels in any 12 hour period is extremely low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The CHANNEL CHECK supplements less formal, but more frequent, checks of channel OPERABILITY during normal operational use of the displays associated with the LCO required channels.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4 3

SR 3.3.1.2

15 A daily calibration (heat balance) is performed when THERMAL POWER is ≥ ~~20~~%. The daily calibration shall consist of adjusting the "nuclear power calibrate" potentiometers to agree with the calorimetric calculation ~~if the absolute difference is > 1.5%~~. The "ΔT power calibrate" potentiometers are then used to null the "nuclear power - ΔT power" indicators on the RPS Reactor Power Calibration and Indication panel. Performance of the daily calibration ensures that the two inputs to the Q power measurement are indicating accurately with respect to the much more accurate secondary calorimetric calculation. 1 1

~~[The Frequency of 24 hours is based on plant operating experience and takes into account indications and alarms located in the control room to detect deviations in channel outputs.~~ 3

~~OR~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~[REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 4 3

15 The Frequency is modified by a Note indicating this Surveillance must be performed within 12 hours after THERMAL POWER is ≥ ~~20~~% RTP. The secondary calorimetric is inaccurate at lower power levels. The 12 hours allows time requirements for plant stabilization, data taking, and instrument calibration. 1

A second Note indicates the ~~daily~~ calibration may be suspended during PHYSICS TESTS. This ensures that calibration is proper preceding and following physics testing at each plateau, recognizing that during testing, changes in power distribution and RCS temperature may render the calorimetric inaccurate. | R1

SR 3.3.1.3

Local Power Density It is necessary to calibrate the excore power range channel upper and lower subchannel amplifiers such that the internal ASI used in the TM/LP and ~~APD~~ - High trips reflects the true core power distribution as determined by the incore detectors. A Note to the Frequency indicates the Surveillance is required within 12 hours after THERMAL POWER is ≥ ~~[20]~~% RTP. Uncertainties in the excore and incore measurement process make it impractical to calibrate when THERMAL POWER is < ~~[20]~~% RTP. The Completion Time of 12 hours allows time for plant stabilization, data taking, and instrument calibration. If the excore detectors are not properly calibrated to agree with the incore detectors, power is restricted during subsequent operations because of increased uncertainty associated with using uncalibrated excore detectors. ~~[The 31 day Frequency is adequate, based on operating experience of the excore linear amplifiers and the slow burnup of the detectors. The excore readings are a strong function of the power produced in the peripheral fuel bundles and do not represent an integrated reading across the core. Slow changes in neutron flux during the fuel cycle can also be detected at this Frequency.~~ 1 15 15 3

~~----------]~~

SR 3.3.1.4

A CHANNEL FUNCTIONAL TEST is performed on each RPS instrument channel, except Loss of Load and Power Rate of Change to ensure the entire channel will perform its intended function when needed. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

In addition to power supply tests, The RPS CHANNEL FUNCTIONAL TEST consists of three overlapping tests as described in Reference ~~8~~ 9. These tests verify that the RPS is capable of performing its intended function, from bistable input through the RTCBs. They include:

Bistable Tests

The bistable setpoint must be found to trip conservative with respect to the Allowable Values specified in the LCO and left set consistent with the assumptions of the plant specific setpoint analysis (Ref. ~~7~~). As-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the frequency extension analysis. The requirements for this review are outlined in Reference 10.

acceptance criteria

A test signal is superimposed on the input in one channel at a time to verify that the bistable trips within the specified ~~tolerance~~ around the setpoint. This is done with the affected RPS channel trip channel bypassed. Any setpoint adjustment shall be consistent with the assumptions of the current plant specific setpoint analysis.

BASES

SURVEILLANCE REQUIREMENTS (continued)

SR 3.3.1.4 is modified by two Notes as identified in Table 3.3.1-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value (e.g., outside the conservative side of the as-found acceptance criteria band). 5 Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition. The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[LTSP]~~. Where a setpoint more conservative than the ~~[LTSP]~~ is used in the plant surveillance procedures ~~[NTSP]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and ~~/or~~ Analytical Limit is maintained. If the as-left channel setting cannot be returned to a setting within the as-left ~~tolerance~~ of the ~~[LTSP]~~, then the channel shall be declared inoperable.

5 3 5 1 3 5

The second Note also requires that ~~[LTSP]~~ and the methodologies for calculating the as-left and the as-found ~~tolerances~~ be in ~~[insert the facility FSAR reference or the name of any document incorporated into the facility FSAR by reference]~~. the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report, respectively

3 5

Matrix Logic Tests

Matrix Logic tests are addressed in LCO 3.3.~~3~~ 2. This test is performed one matrix at a time. It verifies that a coincidence in the two input channels for each Function removes power from the matrix relays. During testing, power is applied to the matrix relay test coils and prevents the matrix relay contacts from assuming their de-energized state. This test will detect any short circuits around the bistable contacts in the coincidence logic, such as may be caused by faulty bistable relay or trip channel bypass contacts. 1

BASES

SURVEILLANCE REQUIREMENTS (continued)

Trip Path Tests

Trip Path (Initiation Logic) tests are addressed in LCO 3.3.~~3~~. These tests are similar to the Matrix Logic tests, except that test power is withheld from one matrix relay at a time, allowing the initiation circuit to de-energize, opening the affected set of RTCBs. The RTCBs must then be closed prior to testing the other three initiation circuits, or a reactor trip may result.

~~[The Frequency of [92] days is based on the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 10).~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~

SR 3.3.1.5

A CHANNEL CALIBRATION of the excore power range channels ensures that the channels are reading accurately and within ~~tolerance~~. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the frequency extension analysis. The requirements for this review are outlined in Reference ~~[~~10~~]~~.

A Note is added stating that the neutron detectors are excluded from CHANNEL CALIBRATION because they are passive devices with minimal drift and because of the difficulty of simulating a meaningful signal. Slow changes in detector sensitivity are compensated for by

BASES

SURVEILLANCE REQUIREMENTS (continued)

performing the ~~daily~~ calorimetric calibration (SR 3.3.1.2) and the ~~monthly~~ linear subchannel gain check (SR 3.3.1.3). In addition, associated control room indications are continuously monitored by the operators. 1

~~[The Frequency of 92 days is acceptable, based on plant operating experience, and takes into account indications and alarms available to the operator in the control room.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~]~~ 4 3

SR 3.3.1.5 is modified by two Notes as identified in Table 3.3.1-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value. 5
Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition.
The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[LTSP]~~. Where a setpoint more conservative than the ~~[LTSP]~~ is used in the plant surveillance procedures ~~[NTSP]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and/or Analytical Limit is maintained. the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report, respectively

SR 3.3.1.6

A CHANNEL FUNCTIONAL TEST on the Loss of Load and Power Rate of Change channels is performed prior to a reactor startup to ensure the entire channel will perform its intended function if required. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. ~~The Loss of Load pressure sensor cannot be tested during reactor operation without closing the high pressure TSV, which would result in a turbine trip or reactor trip.~~ The Power Rate of Change - High trip Function is required during startup operation and is bypassed when shut down or > 15% RTP.

The Loss of Load trip Function is not tested during reactor operation because performing this test during operation could cause a pressure perturbation in the emergency trip fluid header common to all four channels resulting in a turbine trip and reactor trip.

1 R1

SR 3.3.1.6 is modified by two Notes as identified in Table 3.3.1-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value. Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. 3 5

the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report, respectively

SR 3.3.1.7

SR 3.3.1.7 is a CHANNEL FUNCTIONAL TEST similar to SR 3.3.1.4, except SR 3.3.1.7 is applicable only to bypass Functions and is performed once within 92 days prior to each startup. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. Proper operation of bypass permissives is critical during plant startup because the bypasses must be in place to allow startup operation and must be removed at the appropriate points during power ascent to enable certain reactor trips. Consequently, the appropriate time to verify bypass removal function OPERABILITY is just prior to startup. The allowance to conduct this test within 92 days of startup is based on the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 10). Once the operating bypasses are removed, the bypasses must not fail in such a way that the associated trip Function gets inadvertently bypassed. This feature is verified by the trip Function CHANNEL FUNCTIONAL TEST, SR 3.3.1.4. Therefore, further testing of the bypass function after startup is unnecessary.

SR 3.3.1.8

SR 3.3.1.8 is the performance of a CHANNEL CALIBRATION.

CHANNEL CALIBRATION is a complete check of the instrument channel including the sensor. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive tests. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

BASES

SURVEILLANCE REQUIREMENTS (continued)

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the frequency extension analysis. The requirements for this review are outlined in Reference ~~[~~10~~]~~. 3

SR 3.3.1.8 is modified by two Notes as identified in Table 3.3.1-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value (e.g., outside the conservative side of the as-found acceptance criteria band) 5 Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition.

The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[LTSP]~~. Where a setpoint more conservative than the ~~[LTSP]~~ is used in the plant surveillance procedures ~~[NTSP]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and/or Analytical Limit is maintained. If the as-left channel setting cannot be returned to a setting within the as-left ~~tolerance~~ of the ~~[LTSP]~~, then the channel shall be declared inoperable. 5 5 3 5

The second Note also requires that ~~[LTSP]~~ and the methodologies for calculating the as-left and the as-found ~~tolerances~~ be in ~~[insert the facility FSAR reference or the name of any document incorporated into the facility FSAR by reference]~~ . the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report, respectively 5 3

~~[The Frequency is based upon the assumption of an 18 month calibration interval for the determination of the magnitude of equipment drift.~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4

The Surveillance is modified by a Note to indicate that the neutron detectors are excluded from CHANNEL CALIBRATION because they are passive devices with minimal drift and because of the difficulty of simulating a meaningful signal. Slow changes in detector sensitivity are compensated for by performing the calorimetric calibration (SR 3.3.1.2) and the linear subchannel gain check (SR 3.3.1.3).

SR 3.3.1.9

This SR ensures that the RPS RESPONSE TIMES are verified to be less than or equal to the maximum values assumed in the safety analysis. Individual component response times are not modeled in the analyses. The analyses model the overall or total elapsed time from the point at which the parameter exceeds the trip setpoint value at the sensor to the point at which the RTCBs open. ~~[Response times are conducted on an [18] month STAGGERED TEST BASIS. This results in the interval between successive surveillances of a given channel of n x 18 months, where n is the number of channels in the function. The Frequency of [18] months is based upon operating experience, which has shown that random failures of instrumentation components causing serious response time degradation, but not channel failure, are infrequent occurrences. Also, response times cannot be determined at power, since equipment operation is required.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~----------REVIEWER'S NOTE----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~ 4 3

BASES

SURVEILLANCE REQUIREMENTS (continued)

Testing may be performed in one measurement or in overlapping segments, with verification that all components are tested.

~~----------REVIEWER'S NOTE----------~~
~~Applicable portions of the following TS Bases are applicable to plants adopting CEOG Topical Report CE NPSD-1167-1, "Elimination of Pressure Sensor Response Time Testing Requirements," and the methodology contained in Attachment 1 to TSTF-569.~~
~~----------~~ 4

Response time may be verified by any series of sequential, overlapping or total channel measurements, including allocated sensor response time, such that the response time is verified. Allocations for sensor response times may be obtained from records of test results, vendor test data, or vendor engineering specifications. Topical Report CE NPSD-1167-A, "Elimination of Pressure Sensor Response Time Testing Requirements," (Ref. 11) provides the basis and methodology for using allocated sensor response times in the overall verification of the channel response time for specific sensors identified in the Topical Report. The response time may be verified for components that replace the components that were previously evaluated in Ref. 11 provided that the components have been evaluated in accordance with the NRC approved methodology as discussed in Attachment 1 to TSTF-569, "Methodology to Eliminate Pressure Sensor and Protection Channel (for Westinghouse Plants only) Response Time Testing," (Ref. 12). Response time verification for other sensor types must be demonstrated by test. The allocation of sensor response times must be verified prior to placing a new component in operation and reverified after maintenance that may adversely affect the sensor response time.

A Note is added to indicate that the neutron detectors are excluded from RPS RESPONSE TIME testing because they are passive devices with minimal drift and because of the difficulty of simulating a meaningful signal. Slow changes in detector sensitivity are compensated for by performing the daily calorimetric calibration (SR 3.3.1.2).

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.1 BASES, REACTOR PROTECTIVE SYSTEM (RPS) INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The heading for ISTS 3.3.3 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. PSL does not use the terms “as-found tolerance” and “Limiting Trip Setpoint (LTSP)” in plant specific instrument calculations or the Updated Final Safety Analysis Report. Therefore, the use of these terms in Footnotes (a) and (b) in ISTS Table 3.3.1-1 are revised in the ITS to include the plant specific terminology. To comply with the guidance provided in NRC Regulatory Issue Summary 2006-17, “NRC Staff Position on the Requirements of 10 CFR 50.36, ‘Technical Specifications,’ Regarding Limiting Safety System Settings During Periodic Testing and Calibration of Instrument Channels,” the PSL setpoint calculations have been structured to include a Nominal Trip Setpoint (NTSP), also known as the field trip setpoint, and determination of an OPERABILITY limit range, referred to in CTS as acceptance criteria band. For PSL, the Nominal Trip Setpoint (NTSP) is synonymous with the Limiting Trip Setpoint (LTSP) and the as-found acceptance criteria band (i.e., OPERABILITY limit range) is synonymous with the as-found tolerance.

6. Figure B 3.3.1-1 is removed because the figure is included in the UFSAR.

7. Editorial clarification.

8. Changes made to reflect changes made to the Specification consistent with the current licensing basis as approved in License Amendment 243 (Unit 1) and Amendment 194 (Unit 2), dated October 31, 2017 (NRC ADAMS Accession Number ML17257A015).

9. Changes made to reflect changes made to the Specification consistent with the current licensing basis with Bases of ACTIONS A and B adapted from the Bases ISTS Specification 3.3.1 (Digital), and the Bases of Specification SR 3.0.3.

Specific No Significant Hazards Considerations (NSHCs)

DETERMINATION OF NO SIGNIFICANT HAZARDS CONSIDERATIONS
ITS 3.3.1, REACTOR PROTECTIVE SYSTEM (RPS) INSTRUMENTATION

There are no specific No Significant Hazards Considerations for this Specification.

3/4.3 INSTRUMENTATION

SYSTEM (RPS) LOGIC AND TRIP INITIATION

3/4.3.1 REACTOR PROTECTIVE ~~INSTRUMENTATION~~

LIMITING CONDITION FOR OPERATION

LCO 3.3.2

3.3.1.1 ~~As a minimum, the reactor protective instrumentation channels and bypasses of Table 3.3-1~~ shall be OPERABLE.

A02

Six channels of RPS Matrix Logic, four channels of RPS Initiation Logic, four channels of reactor trip circuit breakers (RTCB)s, and four channels of Manual Trip

M01

Applicability

APPLICABILITY: ~~As shown in Table 3.3-1.~~

MODES 1 and 2,
MODES 3, 4, and 5, with any RTCBs closed and any control element assemblies capable of being withdrawn.

A03

ACTION:

As shown in Table 3.3-1.

SURVEILLANCE REQUIREMENTS

SR 3.3.2.1
SR 3.3.2.2
SR 3.3.2.3

4.3.1.1.1 Each ~~reactor protective instrumentation~~ channel shall be demonstrated OPERABLE by the performance of the ~~CHANNEL CHECK, CHANNEL CALIBRATION and~~ CHANNEL FUNCTIONAL TEST ~~operations during the modes and at the frequencies shown in Table 4.3-1~~.

A01

4.3.1.1.2 The logic for the bypasses shall be demonstrated OPERABLE during the at power CHANNEL FUNCTIONAL TEST of channels affected by bypass operation. The total bypass function shall be demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program during CHANNEL CALIBRATION testing of each channel affected by bypass operation.

4.3.1.1.3 The REACTOR TRIP SYSTEM RESPONSE TIME of each reactor trip function shall be demonstrated to be within its limit in accordance with the Surveillance Frequency Control Program. Neutron detectors are exempt from response time testing. Each test shall include at least one channel per function.

See ITS 3.3.1

Add proposed SR 3.3.2.4

** Mode 1 applicable only when Power Range Neutron Flux power ≤ 15% of RATED THERMAL POWER.

(a) Trip may be bypassed below 1% of RATED THERMAL POWER; bypass shall be automatically removed when Wide Range Logarithmic Neutron Flux power is ≥ 1% of RATED THERMAL POWER.

(b) Trip may be manually bypassed below 685 psig; bypass shall be automatically removed at or above 685 psig.

(c) Trip may be bypassed below 15% of RATED THERMAL POWER; bypass shall be automatically removed when Power Range Neutron Flux power is ≥ 15% of RATED THERMAL POWER.

(d) Trip may be bypassed below 10^{-4}% and above 15% of RATED THERMAL POWER; bypass shall be automatically removed when Wide Range Logarithmic Neutron Flux power is ≥ 10^{-4}% and Power Range Neutron Flux power ≤ 15% of RATED THERMAL POWER.

(e) Deleted.

(f) There shall be at least two decades of overlap between the Wide Range Logarithmic Neutron Flux Monitoring Channels and the Power Range Neutron Flux Monitoring Channels.

See ITS 3.3.1

ACTION STATEMENTS

One manual trip channel inoperable in MODE 1 or 2

ACTION A (Manual Trip)

ACTION 1 - ~~With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirement,~~ restore ~~the inoperable channel~~ to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program, or be in HOT STANDBY within the next 6 hours and ~~/or~~ open the protective system trip breakers.

ACTION E (Manual Trip)

ACTION 2 - With the number of OPERABLE channels one less than the Total Number of Channels, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied:

a. The inoperable channel is placed in either the bypassed or tripped condition within 1 hour. For the purposes of testing and maintenance, the inoperable channel may be bypassed for up to 48 hours from time of initial loss of OPERABILITY; however, the inoperable channel shall then be either restored to OPERABLE status or placed in the tripped condition.

See ITS 3.3.1

Add proposed ACTION A (Matrix Logic)

M01

TABLE 3.3-1 (Continued)

ACTION STATEMENTS

b. Within one hour, all functional units receiving an input from the inoperable channel are also bypassed or tripped.

c. The Minimum Channels OPERABLE requirement is met; however, one additional channel may be bypassed for up to 48 hours while performing tests and maintenance on than channel provided the other inoperable channel is placed in the tripped condition.

See ITS 3.3.1

ACTION 3 - With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirement, verify compliance with the SHUTDOWN MARGIN requirements of Specification 3.1.1.1 or 3.1.1.2, as applicable, within 1 hour and at least once per 12 hours thereafter.

See ITS 3.3.11

One channel RTCB or initiation logic inoperable in MODE 1 or 2.

ACTION B (RTCBs and Initiation Logic)

ACTION 4 - ~~With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirement, be in HOT STANDBY within 6 hours; however, one channel may be bypassed for up to 1 hour for surveillance testing per Specification 4.3.1.1.1~~.

TABLE 4.3-1 (Continued)

TABLE NOTATION

Applicability * - With reactor trip breaker closed.

~~(1) - If not performed in previous 7 days.~~

L02

(2) - Heat balance only, above 15% of RATED THERMAL POWER; adjust "Nuclear Power Calibrate" potentiometer to null "Nuclear Pwr – ΔT Pwr." During PHYSICS TESTS, these daily calibrations of nuclear power and ΔT power may be suspended provided these calibrations are performed upon reaching each major test power plateau and prior to proceeding to the next major test power plateau.

(3) - Above 15% of RATED THERMAL POWER, recalibrate the excore detectors which monitor the AXIAL SHAPE INDEX by using the incore detectors or restrict THERMAL POWER during subsequent operations to ≤ 90% of the maximum allowed THERMAL POWER level with the existing Reactor Coolant Pump combination.

(4) - Adjust "ΔT Pwr Calibrate" potentiometers to make ΔT power signals agree with calorimetric calculation.

(5) - Neutron detectors may be excluded from CHANNEL CALIBRATION.

(6) - If the as-found setpoint is either outside its predefined as-found acceptance criteria band or is not conservative with respect to the Allowable Value, then the channel shall be declared inoperable and shall be evaluated to verify that it is functioning as required before returning the channel to service.

(7) - The instrument channel setpoint shall be reset to a value that is within the as-left tolerance of the Field Trip Setpoint, otherwise that channel shall not be returned to OPERABLE status. The Field Trip Setpoint and the methodology used to determine the Field Trip Setpoint, the as-found acceptance criteria band, and the as-left acceptance criteria are specified in the UFSAR Section 7.2.

* - Only if the reactor trip breakers are in the closed position and the CEA drive system is capable of CEA withdrawal.

~~(1) - Each startup or when required with the reactor trip breakers closed and the CEA drive system capable of rod withdrawal, if not performed in the previous 7 days.~~

L02

See ITS 3.3.1

(2) - Heat balance only (CHANNEL FUNCTIONAL TEST not included), above 15% of RATED THERMAL POWER; adjust "Nuclear Power Calibrate" potentiometer to null "Nuclear Power – ΔT Power". During PHYSICS TESTS, these daily calibrations may be suspended provided these calibrations are performed upon reaching each major test power plateau and prior to proceeding to the next major test power plateau.

(3) - Above 15% of RATED THERMAL POWER, recalibrate the excore detectors which monitor the AXIAL SHAPE INDEX by using the incore detectors or restrict THERMAL POWER during subsequent operations to ≤ 90% of the maximum allowed THERMAL POWER level with the existing reactor coolant pump combination.

(4) - Neutron detectors may be excluded from CHANNEL CALIBRATION.

(5) - Adjust "ΔT Pwr Calibrate" potentiometers to make ΔT power signals agree with calorimetric calculation.

SR 3.3.2.4

(6) - In accordance with the Surveillance Frequency Control Program and following maintenance or adjustment of the reactor trip breakers, the CHANNEL FUNCTIONAL TEST shall include verification of the independent OPERABILITY of the undervoltage and shunt trips.

~~(7) - The fuse circuitry in the matrix fault protection circuitry shall be determined to be OPERABLE by testing with the installed test circuitry.~~

LA05

(8) - If the as-found channel setpoint is either outside its predefined as-found acceptance criteria band or is not conservative with respect to the Allowable Value, then the channel shall be declared inoperable and shall be evaluated to verify that it is functioning as required before returning the channel to service.

(9) - The instrument channel setpoint shall be reset to a value that is within the as-left tolerance of the Field Trip Setpoint, otherwise that channel shall not be returned to OPERABLE status. The Field Trip Setpoint and the methodology used to determine the Field Trip Setpoint, the as-found acceptance criteria band, and the as-left acceptance criteria are specified in UFSAR Section 7.2.

See ITS 3.3.1

DISCUSSION OF CHANGES
ITS 3.3.2, REACTOR PROTECTIVE SYSTEM (RPS) LOGIC AND INITIATION INSTRUMENTATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2 Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications – Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 **Unit 1 only:** CTS Table 3.3-1 Functional Unit 1 provides requirements for Manual Reactor Trip. The Total No. Of Channels and Minimum Channels Operable columns specify 2 channels. ITS LCO 3.3.2, in part, requires four channels of Manual Trip to be OPERABLE. This changes the CTS by requiring four Manual Reactor Trip channels instead of two channels.

The purpose of the required number of channels is to ensure a manual reactor trip can be initiated coincident with a single failure. As shown in UFSAR Figure 7.2-1, the Reactor Protective System manual trip function is comprised of two manual trip push buttons per Manual Trip circuit; Manual Trip #1 and #2. Two pushbuttons associated with either Manual Trip circuit are required to trip the reactor. CTS Table 3.3-1 Functional Unit 1 specifies a Manual Trip Circuit as a channel (i.e., Manual Trip #1 and #2). ISTS LCO 3.3.3 (ITS LCO 3.3.2) and the associated ACTIONS and Surveillances are formatted to address each individual manual trip push button as a channel. The PSL Unit 1 and Unit 2 manual reactor trip circuit design is consistent with the manual reactor trip circuit design discussed in the Bases of ISTS 3.3.3. The Background section of the ISTS 3.3.3 Bases states, in part, “Each set of RTCBs is operated by… a Manual Trip push button…. There are four Manual Trip push buttons, arranged in two sets of two…. Depressing both push buttons in either set will result in a reactor trip.” Therefore, changing the minimum number of required channels from 2 to 4 results is an equivalent requirement; two sets of two manual push buttons must be OPERABLE and one set of two manual push buttons are required to initiate a manual reactor trip.

This change is a presentation preference and is consistent with NUREG-1432, Rev. 5 and PSL Unit 2 CTS Table 3.3-1 Functional Unit 1 Total No. of Channels and Minimum Channels Operable columns. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 **Unit 1 only**: CTS Table 3.3-1 lists the applicability of the RPS Manual Reactor Trip (Functional Unit 1) as MODES 1, 2 and * CTS Table 3.3-1 also lists the applicability of the Reactor Protective System Logic (Functional Unit 12) and Reactor Trip Breakers (Functional Unit 13) as MODES 1 and 2*. Footnote * provides the clarification that the applicability includes “with the protective system trip breakers in the closed position and the CEA drive system capable of CEA withdrawal.” ITS 3.3.2 Applicability states MODES 1 and 2, and MODES 3, 4, and 5, with any RTCBs closed and any control element assemblies capable of

being withdrawn. This changes the CTS by specifically adding MODES 3, 4, and 5 to the specific condition of with any RTCBs closed and any control element assemblies capable of being withdrawn

The purpose of the CTS Applicability is to ensure the RPS manual trip channel and logic and initiation instrumentation is also applicable when the plant is shutdown if the RTCBs are closed and the CEAs are capable of being withdrawn to ensure a withdrawn CEA can be inserted if required. Clarifying the Applicability of MODES 3, 4, and 5 avoids any confusion of the RPS requirements when the reactor vessel head is de-tensioned or removed (i.e., MODE 6). Other Technical Specifications (e.g., LCO 3.9.1, “Boron Concentration,”) ensure adequate Shutdown Margin is provided in MODE 6. This change is consistent with NUREG-1432, Rev. 5 and the Applicability for the same RPS Functions in Unit 2 CTS Table 3.3-1. This change is solely a clarification of the existing requirement and is designated as administrative because it does not result in technical changes to the CTS.

A04 **Unit 2 only**: Unit 2 CTS Table 3.3-1 Function 11 (Reactor Protection System Logic) requires 3 channels in the Minimum Channels Operable column for MODES 1 and 2. ITS 3.3.2 requires four channels for Function 11 (RPS Initiation Logic) to be OPERABLE for MODES 1 and 2. This changes the Unit 2 CTS to require four Reactor Protective System Logic (Function 11) channels instead of three channels.

The purpose of the required number of channels is to ensure the RPS Initiation Logic trip can be initiated coincident with a single failure. As shown in UFSAR Figure 7.2-1, the Reactor Protective System RPS Initiation Logic function is comprised of two channels per trip circuit. Changing the minimum number of required channels from 3 to 4 results in an equivalent requirement; two channels per trip circuit are required to satisfy single failure criteria.

This change is consistent with NUREG-1432, Rev. 5 and PSL Unit 2 CTS Table 3.3-1 Functional Unit 11 Total No. of Channels, Minimum Channels Operable, and Channels to Trip columns. This change is designated as administrative because it does not result in technical changes to the CTS.

A05 **Unit 2 only:** CTS 3.3.1 Table 3.3-1 Footnote* states, in part. “and fuel in the reactor vessel.” ITS 3.3.2 does not include this detail related to an operational MODE. The ITS definition of a MODE states that a MODE, in part, with fuel in the reactor vessel. This changes the CTS by removing redundant information already addressed by the Technical Specification definitions.

The purpose of the statement regarding fuel in the reactor in CTS Table 3.3-1 Footnote * is to clarify that the Applicability applies with fuel in the reactor vessel. The equivalent ITS 3.3.2 Applicability clarifies the requirements are applicable in MODES 3, 4, and 5, which include fuel in the reactor vessel. The ITS definition of a MODE is defined, in part, with fuel in the reactor vessel. ITS 3.3.2 retains the requirement for the RPS Logic and Trip Initiation to be OPERABLE in MODES 3, 4, and 5 with any RTCBs closed and any control element assemblies capable of being withdrawn. This change is solely a presentation preference difference and

is designated as administrative because it does not result in technical changes to the CTS.

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.3.1.1 and Unit 2 CTS 3.3.1 do not specifically identify the RPS Matrix Logic channels as a functional unit required to satisfy RPS logic OPERABILITY. ITS 3.3.2 requires six channels of RPS Matrix Logic to be OPERABLE. This changes CTS by specifically adding six channels of RPS Matrix Logic to the channel OPERABILITY requirements and adding the associated proposed ACTION for inoperable RPS Matrix Logic channels.

The proposed change results in more specific requirements for the RPS Logic and Trip Initiation channels including the actions to be taken for inoperability. The proposed change is acceptable because the matrix logic is currently part of the RPS logic and trip initiation system but are not specifically identified within the OPERABILITY requirements. ITS 3.3.2 specifically identifies the six RPS Matrix Logic channels as an LCO requirement. The PSL Unit 1 and Unit 2 RPS matrix logic design is consistent with the RPS matrix logic design discussed in the Bases of ISTS 3.3.3. ITS 3.3.2 ACTION A requires the inoperable channels to be restored to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time Program when one Matrix Logic channel is inoperable or when three Matrix Logic channels are inoperable due to a common power source failure de-energizing three matrix power supplies. The Completion Time of 48 hours provides the operator time to take appropriate actions and still ensures that any risk involved in operating with a failed channel is acceptable. Operating experience has demonstrated that the probability of a random failure of a second Matrix Logic channel is low during any given 48 hour interval. By providing specific requirements for the six RPS Matrix Logic channels, the proposed change provides additional assurance that the RPS function is available when required. This change conforms the PSL CTS to the ISTS. This change is considered a more restrictive change because additional specific requirements have been added that are not required by the CTS.

M02 **Unit 1 only**: CTS 3.3.1.1 does not have a specific surveillance requirement that requires an additional CHANNEL FUNCTIONAL TEST that includes a separate verification of the undervoltage and shunt trips on each RTCB channel. ITS SR 3.3.2.4 requires the performance of a CHANNEL FUNCTIONAL TEST, including separate verification of the undervoltage and shunt trips on each RTCB channel in accordance with the SFCP. This changes the CTS by adding an additional surveillance requirement ITS SR 3.3.2.4.

The purpose of SR 3.3.2.4 is to individually test all four sets of undervoltage coils and all four sets of shunt trip coils. This change is acceptable because it ensures that every undervoltage coil and every shunt trip coil is capable of performing its intended function and that no single failure of an RTCB component will prevent a reactor trip. PSL controls periodic Frequencies for Surveillances in accordance with the SFCP per CTS 6.8.4.o (Unit 1) and CTS 6.8.4.q (Unit 2). Therefore, the initial Frequency in accordance with the Surveillance Frequency Control Program will be specified as 18 months consistent with ISTS 3.3.3.4 and based on the

need to perform the Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power.

The SFCP was established as described in FPL (PSL Unit 1 and Unit 2) "Application for Technical Specification Change Regarding Risk-Informed Justifications for the Relocation of Specific Surveillance Frequency Requirements to a Licensee Controlled Program" (ADAMS Accession No. ML14070A087). The NRC issued Amendment No. 223 to Renewed Facility Operating License No. DPR-67 and Amendment No. 173 to Renewed Facility Operating License No. NPF-16 for the St. Lucie Plant, Unit Nos. 1 and 2 (St. Lucie 1 and 2), respectively (ADAMS Accession No. ML15127A066).

This change is acceptable and is designated as more restrictive since the CTS does not currently require this verification for the undervoltage and shunt trips on each RTCB channel.

M03 Unit 1 CTS 3.3.1.1 does not provide specific Actions for one or two inoperable channels of Manual Trip, RTCBs, or Initiation Logic. Unit 2 CTS 3.3.1 does not provide specific Actions for two channels of Manual Trip, RTCBs, or Initiation Logic affecting the same trip leg inoperable when in MODES 3, 4, and 5. ITS 3.3.2 ACTION C requires affected RTCBs to be opened within 48 hours with one channel of Manual Trip, RTCBs, or Initiation Logic inoperable in MODE 3, 4, or 5. ITS 3.3.2 ACTION D requires the affected RTCBs to be opened immediately with two channels of Manual Trip, RTCBs, or Initiation Logic affecting the same trip leg inoperable when in any required MODE of applicability. This changes Unit 1 CTS 3.3.1.1 by adding specific ACTIONs (ITS 3.3.2 ACTION C) for one channel inoperable in MODE 3, 4, or 5 and (ITS 3.3.2 ACTION D) for two channels of Manual Trip, RTCBs, or Initiation Logic affecting the same trip leg inoperable for all applicable MODES; and, changes Unit 2 CTS 3.3.1 by adding a specific ACTION (ITS 3.3.2 ACTION D) for two channels of Manual Trip, RTCBs, or Initiation Logic channel affecting the same trip leg inoperable for MODES 3, 4, and 5, with any RTCBs closed and any control element assemblies capable of being withdrawn.

The purpose of ITS 3.3.2 ACTION C is to remove the need for the affected channel by performing its associated safety function. The purpose of ITS 3.3.2 ACTION D is to allow for a single failure within a trip leg when one or both trip function channels in the same trip leg fails in a non-trip condition. This change is acceptable because with both trip channels of a trip function in the same trip leg inoperable opening of the affected RTCBs ensures the trip capability is maintained. This change is considered a more restrictive change because additional requirements have been added to the CTS.

M04 Unit 1 CTS 3.3.1.1 and Unit 2 CTS 3.3.1 do not provide specific Actions when the Action and Completion time for more than one Initiation Logic or RTCB channel inoperable. ITS ACTION E requires the unit to be placed in MODE 3 in 6 hours and all RTCBs opened in 6 hours when the Required Action and Associated Completion Time of Condition A (manual trip channel or matrix logic channel inoperable), Condition B (RTCB or Initiation Logic channel inoperable) or

Condition D (two channels affecting the same trip leg inoperable) are not met or "one or more Functions with two or more Manual Trip, Matrix Logic, Initiation Logic, or RTCB channels inoperable for reasons other than Condition A or D." This changes the CTS by adding Action E in its entirely for the Initiation Logic and RTCB functions and adding the second Condition for the manual trip function.

The purpose of ITS ACTION E is to place the unit in a MODE where the LCO does not apply and ensuring no CEA withdrawal occurs when Required Actions and associated Completion Times are not met or when one or more Functions have two or more channels inoperable for reasons other than Condition A or D. This change is acceptable because the ACTIONS specified in ITS 3.3.2 adopt ISTS for placing the unit outside the MODE of applicability. A Completion Time of 6 hours is reasonable, based on operating experience, to reach the required MODE from full power conditions in an orderly manner and without challenging plant systems and to open RTCBs. This change is considered a more restrictive change because additional requirements have been added to the CTS.

M05 **Unit 2 only:** CTS 3.3.1 Table 3.3-1 ACTION 2b. with two Reactor Protective System Logic channels inoperable, states, "Verify that one of the inoperable channels has been bypassed and place the other inoperable channel in the tripped condition within 1 hour." ITS 3.3.2 ACTION D requires the affected RTCBs to be opened immediately with two channels of RPS Initiation Logic channel affecting the same trip leg inoperable. This changes Unit 2 CTS 3.3.1 by requiring the affected RTCBs to be opened immediately. The purpose of ITS 3.3.2 ACTION D is to allow for a single failure within a trip leg when one or both trip function channels in the same trip leg fails in a non-trip condition. This change is necessary because with both trip channels of a trip function in the same trip leg inoperable, opening of the affected RTCBs ensures the trip capability is maintained. This change is considered a more restrictive change because a more restrictive completion time is required to open the RTCBs than is required in the CTS.

M06 **Unit 2 only**: CTS 3.3.1 Table 3.3-1 ACTION 5 requires that with one channel of Manual Trip, RTCBs, or RPS Initiation Logic inoperable in MODE 3, 4, or 5 that the inoperable channel be restored within 48 hours or the reactor trip breakers must be opened within the next hour (total of 49 hours). ITS 3.3.2 ACTION C for the same condition that the affected RTCBs be opened in 48 hours. This changes the Unit 2 CTS by changing the time to open the RTCBs from 49 hours to 48 hours. This change is considered a more restrictive change because a more restrictive completion time is required to open the RTCBs than is required in the CTS.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 1 – Removing Details of System Design and System Description, Including Design Limits)* CTS Table 3.3-1 for RPS instrumentation has three columns stating various requirements for each function. These columns are labeled, "TOTAL NO. OF CHANNELS," "CHANNELS TO TRIP," and "MINIMUM CHANNELS OPERABLE." ITS 3.3.2 does not retain these columns but retains the requirements in the MINIMUM CHANNELS OPERABLE column in the LCO. This changes the CTS by moving the information of the "TOTAL NO. OF CHANNELS" and "CHANNELS TO TRIP" columns to the ITS Bases.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA02 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS 3.3.1.1 ACTION 4 and Unit 2 CTS 3.3.1 ACTION 4 states, in part. “one channel may be bypassed for up to 1 hour for surveillance testing.” The equivalent ITS 3.3.2 ACTION B requires the affected RTCBs to be opened in 1 hour. ITS 3.3.2 does not include these procedural details because the channel may continue to be bypassed under the ITS ACTION A. This changes the CTS by moving the procedural detail to the ITS Bases.

The removal of these details, related to methods of surveillance test performance, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specifications Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to methods of surveillance test performance is being removed from the Technical Specifications.

LA03 **Unit 2 only:** *(Type 2 – Removing Descriptions of System Operation)* CTS Table 3.3-1 Footnote (f) states, "Each channel shall be comprised of two trip breakers; actual trip logic shall be one-out-of-two taken twice." ITS 3.3.2 does not include these system details. This changes the CTS by moving the system detail to the ITS Bases.

The removal of these details, that are related to system operation, from the Technical Specifications is acceptable, because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement for the RTCBs to be OPERABLE and the relocated material describes aspects of the RTCB design. In addition, this change is acceptable, because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system operation is being removed from the Technical Specifications.

LA04 **Unit 2 only:** (*Type 4 – Removal of LCO, SR, or other TS Requirement to the TRM, UFSAR, ODCM, NQAP, CLRT Program, IST Program, or ISI Program*) CTS 3.3.1 Table 3.3-1 ACTION 2.a, states in part, "The channel shall be returned to OPERABLE status no later than during the next COLD SHUTDOWN." ITS 3.3.2 does not include these procedural details. This changes the CTS by moving the operational detail to procedures controlled under the PSL Quality Assurance Topical Report (QATR).

The removal of these details from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. OPERABILITY requirements following a unit shutdown are governed by the Technical Specifications MODE requirements, Technical Specification rules of usage (specifically LCO 3.0.4) and operating procedures when transitioning from Cold Shutdown (MODE 5). Also, this change is acceptable because the removed information will be adequately controlled by the requirements of 10 CFR 50, Appendix B, the PSL Quality Assurance Topical Report, and associated implementing procedures. Section XVI, "Corrective Action," of 10 CFR 50, Appendix B requires measures to be established to assure that conditions adverse to quality, such as failures, malfunctions, deficiencies, deviations, defective material and equipment, and nonconformances are promptly identified and corrected. This regulatory requirement will ensure that the inoperable RPS Initiation Logic channels are restored to OPERABLE status promptly. Changes to the QATR implementing procedures are controlled under 10 CFR 50.54(a)(3) which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA05 **Unit 2 only:** (*Type 2 – Removing Descriptions of System Operation*) CTS 3.3.1 Table 4.3-1 Note 7, states, "The fuse circuitry in the matrix fault protection | R1

circuitry shall be determined to be OPERABLE by testing with the installed test circuitry." ITS SR 3.3.2.2 requires a CHANNEL FUNCTIONAL TEST to be performed on each RPS Initiation logic channel but does not include these procedural/operational details. This changes the CTS by moving the procedural detail to the ITS Bases. | R1

The removal of these details, related to methods of surveillance test performance, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS retains the requirement to perform a CHANNEL FUNCTIONAL TEST. This change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specifications Bases Control Program in Chapter 5. This program provides for the evaluation of changes to the Bases to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to methods of surveillance test performance is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 **Unit 1 only:** *(Category 4 – Relaxation of Required Action)* CTS 3.3.1.1 Table 3.3-1 Action 4, applicable to the Reactor Protective System Logic and Reactor Trip Breaker functions, states " With the number of channels OPERABLE one less than required by the Minimum Channels OPERABLE requirement, be in HOT STANDBY within 6 hours." ITS 3.3.2 ACTION B, applicable in MODES 1 and 2, requires the affected RTCBs to be opened in 1 hour, which can allow continued plant operation. This changes the CTS by requiring the affected RTCBs to be opened rather than requiring a shutdown to HOT STANDBY (MODE 3). | R1

The purpose of ITS 3.3.2 ACTION B is to remove the need for the affected channel to automatically perform its function by manually performing the associated safety function. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the redundant systems or features. With the RTCB open, the affected Functions are in one-out-of-two logic, which meets the redundancy requirements without requiring shutdown. In this configuration, a single channel failure will not prevent a reactor trip. The Completion Time of 1 hour is adequate to open the affected RTCBs while the risk of having them closed for up to 1 hour is at an acceptable level. This change is designated as less restrictive because the unit shutdown requirement has been revised to allow for opening of the affected RTCBs. Therefore, less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L02 (*Category 7- Relaxation of Surveillance Frequency*) CTS Table 4.3-1 Functional Unit 12 (Unit 1 – Reactor Protection System Logic and Unit 2 – Reactor Trip

Breakers), including Note 1, requires the performance of a CHANNEL FUNCTIONAL TEST prior to each reactor startup if not performed in the previous 7 days. In addition, CTS Table 4.3-1 also requires the CHANNEL FUNCTIONAL TEST associated with Functional Unit 12 to be performed in accordance with the Surveillance Frequency Control Program (SFCP). ITS SR 3.3.2.2 continues to require the CHANNEL FUNCTIONAL TEST to be performed at a periodic frequency in accordance with the SFCP. However, the ITS does not require this "during startup if not performed in the previous 7 days" test. This changes the CTS by deleting the requirement to perform these startup CHANNEL FUNCTIONALTEST Surveillances.

The purpose of the CTS Table 4.3-1 Functional Unit 12 CHANNEL FUNCTIONAL TEST is to ensure the reactor trip breakers and reactor protection system logic are functioning properly. This change is acceptable because the normal periodic of the CHANNEL FUNCTIONAL TEST Surveillance Frequency in accordance with the SFCP is adequate to ensure these functions are OPERABLE. This change deletes the requirement to perform these startup Surveillances. ITS SR 3.0.4 (CTS 4.0.4) requires the normal periodic Surveillances to be performed and be current prior to entry into the applicable operational conditions. Once the applicable conditions are entered, the normal, periodic Surveillance Frequency provides adequate assurance of OPERABILITY. Therefore, the removal of this Frequency is considered acceptable. This change is designated as less restrictive because Surveillances will be performed less frequently under the ITS than under the CTS.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.2, REACTOR PROTECTION SYSTEM (RPS) LOGIC AND TRIP INITIATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The heading for ISTS 3.3.3 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2). Therefore, ISTS 3.3.2 is not included in the PSL ITS. The Reactor Protective System (RPS) Logic and Trip Initiation (ISTS 3.3.3) is renumbered as ITS 3.3.2.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.~~3~~ 2 Reactor Protective System (RPS) Logic and Trip Initiation ~~(Analog)~~ 2

BASES

BACKGROUND

The RPS initiates a reactor trip to protect against violating the core specified acceptable fuel design limits and reactor coolant pressure boundary integrity during anticipated operational occurrences (AOOs). By tripping the reactor, the RPS also assists the Engineered Safety Features (ESF) systems in mitigating accidents.

The protection and monitoring systems have been designed to ensure safe operation of the reactor. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the RPS, as well as LCOs on other reactor system parameters and equipment performance.

The LSSS, defined in this Specification as the Allowable Value, in conjunction with the LCOs, establish the threshold for protective system action to prevent exceeding acceptable limits during Design Basis Accidents.

During AOOs, which are those events expected to occur one or more times during the plant life, the acceptable limits are:

- The departure from nucleate boiling ratio shall be maintained above the Safety Limit (SL) value to prevent departure from nucleate boiling,
- Fuel centerline melting shall not occur, and
- The Reactor Coolant System pressure SL of 2750 psia shall not be exceeded.

Maintaining the parameters within the above values ensures that the offsite dose will be within the ~~10 CFR 50 (Ref. 1) and~~ 10 CFR ~~100~~ (Ref. ~~2~~) criteria during AOOs. 50.67 1 1

Accidents are events that are analyzed even though they are not expected to occur during the plant life. The acceptable limit during accidents is that the offsite dose shall be maintained within an acceptable fraction of 10 CFR ~~100~~ (Ref. ~~2~~) limits. Different accident categories allow a different fraction of these limits based on probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event. 1 50.67 1

BASES

BACKGROUND (continued)

The RPS is segmented into four interconnected modules. These modules are:

- Measurement channels,
- Bistable trip units,
- RPS Logic, and
- Reactor trip circuit breakers (RTCBs).

This LCO addresses the RPS Logic and RTCBs, including Manual Trip capability. LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation - Operating," provides a description of the role of this equipment in the RPS. This is summarized below:

RPS Logic

The RPS Logic, consisting of Matrix and Initiation Logic, employs a scheme that provides a reactor trip when bistables in any two of the four channels sense the same input parameter trip. This is called a two-out-of-four trip logic. ~~This logic and the RTCB configuration are shown in Figure B 3.3.1-1.~~ 1 5

(one out of two taken twice)

Bistable relay contact outputs from the four channels are configured into six logic matrices. Each logic matrix checks for a coincident trip in the same parameter in two bistable channels. The matrices are designated the AB, AC, AD, BC, BD, and CD matrices to reflect the bistable channels being monitored. Each logic matrix contains four normally energized matrix relays. When a coincidence is detected, consisting of a trip in the same Function in the two channels being monitored by the logic matrix, all four matrix relays de-energize.

The matrix relay contacts are arranged into trip paths, with one of the four matrix relays in each matrix opening contacts in one of the four trip paths. Each trip path provides power to one of the four normally energized RTCB control relays (K1, K2, K3, and K4). The trip paths thus each have six contacts in series, one from each matrix, and perform a logical OR function, opening the RTCBs if any one or more of the six logic matrices indicate a coincidence condition.

BASES

BACKGROUND (continued)

Each trip path is responsible for opening one set of two of the eight RTCBs. The RTCB control relays (K-relays), when de-energized, interrupt power to the breaker undervoltage trip attachments and simultaneously apply power to the shunt trip attachments on each of the two breakers. Actuation of either the undervoltage or shunt trip attachment is sufficient to open the RTCB and interrupt power from the motor generator (MG) sets to the control element drive mechanisms (CEDMs).

When a coincidence occurs in two RPS channels, all four matrix relays in the affected matrix de-energize. This in turn de-energizes all four breaker control relays, which simultaneously de-energize the undervoltage and energize the shunt trip attachments in all eight RTCBs, tripping them open.

The Initiation Logic consists of the trip path power source, matrix relays and their associated contacts, all interconnecting wiring, and solid state (auxiliary) relays through the K-relay contacts in the RTCB control circuitry.

It is possible to change the two-out-of-four RPS Logic to a two-out-of-three logic for a given input parameter in one channel at a time by trip channel bypassing select portions of the matrix logic. Trip channel bypassing a bistable effectively shorts the bistable relay contacts in the three matrices associated with that channel. Thus, the bistables will function normally, producing normal trip indication and annunciation, but a reactor trip will not occur unless two additional channels indicate a trip condition. Trip channel bypassing can be simultaneously performed on any number of parameters in any number of channels, providing each parameter is bypassed in only one channel at a time. An interlock prevents simultaneous trip channel bypassing of the same parameter in more than one channel. Trip channel bypassing is normally employed during maintenance or testing.

Reactor Trip Circuit Breakers (RTCBs)

The reactor trip switchgear~~, shown in Figure B 3.3.1-1,~~ consists of eight RTCBs, which are operated in four sets of two breakers (four channels). Power input to the reactor trip switchgear comes from two full capacity MG sets operated in parallel such that the loss of either MG set does not de-energize the CEDMs. There are two separate CEDM power supply 5

BASES

BACKGROUND (continued)

buses, each bus powering half of the CEDMs. Power is supplied from the MG sets to each bus via two redundant paths (trip legs). Trip legs 1A and 1B supply power to CEDM bus 1. Trip legs 2A and 2B supply power to CEDM bus 2. This ensures that a fault or the opening of a breaker in one trip leg (i.e., for testing purposes) will not interrupt power to the CEDM buses.

Each of the four trip legs consists of two RTCBs in series. The two RTCBs within a trip leg are actuated by separate initiation circuits.

The eight RTCBs are operated as four sets of two breakers (four channels). For example, if a breaker receives an open signal in trip leg A (for CEDM bus 1), an identical breaker in trip leg B (for CEDM bus 2) will also receive an open signal. This arrangement ensures that power is interrupted to both CEDM buses, thus preventing trip of only half of the control element assemblies (CEAs) (a half trip). Any one inoperable breaker in a channel will make the entire channel inoperable.

Each set of RTCBs is operated by either a Manual Trip push button or an RPS actuated K-relay. There are four Manual Trip push buttons, arranged in two sets of two~~, as shown in Figure B 3.3.1-1~~. Depressing both push buttons in either set will result in a reactor trip. 5

When a Manual Trip is initiated using the control room push buttons, the RPS trip paths and K-relays are bypassed, and the RTCB undervoltage and shunt trip attachments are actuated independent of the RPS.

Manual Trip circuitry includes the push button and interconnecting wiring to both RTCBs necessary to actuate both the undervoltage and shunt trip attachments, but excludes the K-relay contacts and their interconnecting wiring to the RTCBs, which are considered part of the Initiation Logic.

Functional testing of the entire RPS, from bistable input through the opening of individual sets of RTCBs, can be performed either at power or shutdown ~~and is normally performed on a quarterly basis~~. FSAR, Section ~~[~~7.2~~]~~ (Ref. ~~3~~), explains RPS testing in more detail. 1 3

in accordance with the Surveillance Frequency Control Program 2

U

APPLICABLE SAFETY ANALYSES

Reactor Protective System (RPS) Logic

The RPS Logic provides for automatic trip initiation to maintain the SLs during AOOs and assist the ESF systems in ensuring acceptable consequences during accidents. All transients and accidents that call for a reactor trip assume the RPS Logic is functioning as designed.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Reactor Trip Circuit Breakers (RTCBs)

All of the transient and accident analyses that call for a reactor trip assume that the RTCBs operate and interrupt power to the CEDMs.

Manual Trip

There are no accident analyses that take credit for the Manual Trip; however, the Manual Trip is part of the RPS circuitry. It is used by the operator to shut down the reactor whenever any parameter is rapidly trending toward its trip setpoint. A Manual Trip accomplishes the same results as any one of the automatic trip Functions.

The RPS Logic and initiation satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Reactor Protective System (RPS) Logic

Failures of individual bistable relays and their contacts are addressed in LCO 3.3.1. This Specification addresses failures of the Matrix Logic not addressed in the above, such as the failure of matrix relay power supplies or the failure of the trip channel bypass contact in the bypass condition.

instrument

Loss of a single ~~vital~~ bus will de-energize one of the two power supplies in each of three matrices. This will result in four RTCBs opening; however, the remaining four closed RTCBs will prevent a reactor trip. For the purposes of this LCO, de-energizing up to three matrix power supplies due to a single failure is to be treated as a single channel failure, providing the affected matrix relays de-energize as designed, opening the affected RTCBs. 1

Each of the four Initiation Logic channels opens one set of RTCBs if any of the six coincidence matrices de-energize their associated matrix relays. They thus perform a logical OR function. Each Initiation Logic channel has its own power supply and is independent of the others. An Initiation Logic channel includes the matrix relay through to the K-relay contacts, which open the RTCB.

It is possible for two Initiation Logic channels affecting the same trip leg to de-energize if a matrix power supply or ~~vital~~ instrument bus fails. This will result in opening the two affected sets of RTCBs. 1

BASES

LCO (continued)

If one set of RTCBs has been opened in response to a single RTCB channel, Initiation Logic channel, or Manual Trip channel failure, the affected set of RTCBs may be closed for up to 1 hour for Surveillance on the OPERABLE Initiation Logic, RTCB, and Manual Trip channels. In this case, the redundant set of RTCBs will provide protection if a trip should be required. It is unlikely that a trip will be required during the Surveillance, coincident with a failure of the remaining series RTCB channel. If a single matrix power supply or ~~vital~~ bus failure has opened two sets of RTCBs, Manual Trip and RTCB testing on the closed breakers cannot be performed without causing a trip.

instrument

1

1. Matrix Logic

   This LCO requires six channels of Matrix Logic to be OPERABLE in MODES 1 and 2, and in MODES 3, 4, and 5 when any RTCB is closed and any CEA is capable of being withdrawn.

2. Initiation Logic

   This LCO requires four channels of Initiation Logic to be OPERABLE in MODES 1 and 2, and in MODES 3, 4, and 5 when any RTCB is closed and any CEA is capable of being withdrawn.

3. Reactor Trip Circuit Breakers (RTCBs)

   The LCO requires four RTCB channels to be OPERABLE in MODES 1 and 2, as well as in MODES 3, 4, and 5 when any RTCB is closed and any CEA is capable of being withdrawn.

   Each channel consists of two breakers operated in a single set by the Initiation Logic or Manual Trip circuitry. This ensures that power is interrupted at identical locations in the trip legs for both CEDM buses, thus preventing power removal to only one CEDM bus (a half trip).

   Failure of a single breaker affects the entire channel, and both breakers in the set must be opened. Without reliable RTCBs and associated support circuitry, a reactor trip cannot occur whether initiated automatically or manually.

   Each channel of RTCBs starts at the contacts actuated by the K-relay, and the contacts actuated by the Manual Trip, for each set of breakers. The K-relay actuated contacts and the upstream circuitry are considered to be RPS Logic. Manual Trip contacts and upstream circuitry are considered to be Manual Trip circuitry.

BASES

LCO (continued)

I

~~A Note associated with the ACTIONS states that~~ If one set of RTCBs has been opened in response to a single RTCB channel, Initiation Logic channel, or Manual Trip channel failure, the affected set of RTCBs may be closed for up to 1 hour for Surveillance on the OPERABLE Initiation Logic, RTCB, and Manual Trip channels. In this case, the redundant set of RTCBs will provide protection. If a single matrix power supply or vital bus failure has opened two sets of RTCBs, Manual Trip and RTCB testing on the closed breakers cannot be performed without causing a trip. ~~This Note is not applicable to Condition A, with one Matrix Logic channel inoperable.~~ 1 1

4. Manual Trip

The LCO requires all four Manual Trip channels to be OPERABLE in MODES 1 and 2, and MODES 3, 4, and 5 when any RTCB is closed and any CEA is capable of being withdrawn.

Two independent sets of two adjacent push buttons are provided at separate locations. Each push button is considered a channel and operates two of the eight RTCBs. Depressing both push buttons in either set will cause an interruption of power to the CEDMs, allowing the CEAs to fall into the core. This design ensures that no single failure in any push button circuit can either cause or prevent a reactor trip.

APPLICABILITY

The RPS Matrix Logic, RTCBs, and Manual Trip are required to be OPERABLE in any MODE when any CEA is capable of being withdrawn from the core (i.e., RTCBs closed and power available to the CEDMs). This ensures the reactor can be tripped when necessary, but allows for maintenance and testing when the reactor trip is not needed.

In MODES 3, 4, and 5 with all the RTCBs open, the CEAs are not capable of withdrawal and these Functions do not have to be OPERABLE. However, two ~~[~~logarithmic~~]~~ ~~power~~ level channels must be OPERABLE to ensure proper indication of neutron population and to indicate a boron dilution event. This is addressed in LCO 3.3.~~13~~, "~~[~~Logarithmic~~]~~ ~~Power~~ Monitoring Channels."

neutron flux 1 3 1

Neutron Flux 11

ACTIONS

When the number of inoperable channels in a trip Function exceeds that specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 is immediately entered if applicable in the current MODE of operation.

BASES

ACTIONS (continued)

A.1

, one Manual Trip channel is inoperable, 1

Condition A applies if one Matrix Logic channel is inoperable or three Matrix Logic channels are inoperable due to a common power source failure de-energizing three matrix power supplies, in any applicable MODE. Loss of a single ~~vital~~ instrument bus will de-energize one of the two matrix power supplies in up to three matrices. This is considered a single matrix failure, providing the matrix relays associated with the failed power supplies de-energize as required. 1

Failure of the matrix relays to de-energize in all three affected matrices could, when combined with trip channel bypassing of bistable relay contacts in the other matrices, result in loss of RPS function.

The channel must be restored to OPERABLE status within 48 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The Completion Time of 48 hours provides the operator time to take appropriate actions and still ensures that any risk involved in operating with a failed channel is acceptable. Operating experience has demonstrated that the probability of a random failure of a second Matrix Logic channel is low during any given 48 hour interval. If the channel cannot be restored to OPERABLE status within 48 hours, Condition E is entered. 3

B.1

or

Condition B applies to one Initiation Logic channel, RTCB channel~~, or Manual Trip channel~~ in MODES 1 and 2, since they have the same actions. MODES 3, 4, and 5, with the RTCBs shut, are addressed in Condition C. These Required Actions require opening the affected RTCBs. This removes the need for the affected channel by performing its associated safety function. With the RTCB open, the affected Functions are in one-out-of-two logic, which meets redundancy requirements, but testing on the OPERABLE channels cannot be performed without causing a reactor trip unless the RTCBs in the inoperable channels are closed to permit testing. 1

The inoperable channel may be bypassed during the one hour period to perform testing, if necessary, provided the RTCBs are opened within the required Completion Time.

Required Action B.1 provides for opening the RTCBs associated with the inoperable channel within a Completion Time of 1 hour. This Required Action is conservative, since depressing the Manual Trip push button associated with either set of breakers in the other trip leg will cause a reactor trip. With this configuration, a single channel failure will not prevent a reactor trip. The allotted Completion Time is adequate to open the affected RTCBs while maintaining the risk of having them closed at an acceptable level. 1

BASES

ACTIONS (continued)

C.1

Condition C applies to the failure of one Initiation Logic channel, RTCB channel, or Manual Trip channel ~~affecting the same trip leg~~ in MODE 3, 4, or 5 with the RTCBs closed. The channel must be restored to OPERABLE status within 48 hours. If the inoperable channel cannot be restored to OPERABLE status within 48 hours, the affected RTCBs must be opened. ~~In some cases, this condition may effect all of the RTCBs.~~ This removes the need for the affected channel by performing its associated safety function. With the RTCBs open, the affected functions are in a one-out-of-two logic, which meets redundancy requirements. 1 1

The Completion Time of 48 hours is consistent with that of other RPS instrumentation and should be adequate to repair most failures.

Testing on the OPERABLE channels cannot be performed without causing a reactor trip unless the RTCBs in the inoperable channels are closed to permit testing.

D.1

Condition D applies to the failure of both Manual Trip or Initiation Logic channels affecting the same trip leg. Since this will open two channels of RTCBs, this Condition is also applicable to the two affected channels of RTCBs. This Condition allows for loss of a single ~~vital~~ instrument bus or matrix power supply, which will de-energize both Initiation Logic channels in the same trip leg. This will open both sets of RTCBs in the affected trip leg, satisfying the Required Action of opening the affected RTCBs. 1

Of greater concern is the failure of the initiation circuit in a nontrip condition (e.g., due to two initiation K-relay failures). With only one Initiation Logic channel failed in a nontrip condition, there is still the redundant set of RTCBs in the trip leg. With both failed in a nontrip condition, the reactor will not trip automatically when required. In either case, the affected RTCBs must be opened immediately by using the appropriate Manual Trip push buttons, since each of the four push buttons opens one set of RTCBs, independent of the initiation circuitry. Caution must be exercised, since depressing the wrong push buttons may result in a reactor trip.

BASES

ACTIONS (continued)

If two Manual Trip channels are inoperable and affecting the same trip leg, the associated RTCBs must be opened immediately to ensure Manual Trip capability is maintained. With the affected RTCBs open, any one of two Manual Trip push buttons being depressed will result in a reactor trip.

If the affected RTCB(s) cannot be opened, Condition E is entered. This would only occur if there is a failure in the Manual Trip circuitry or the RTCB(s).

E.1 and E.2

Condition E is entered if Required Actions associated with Condition A, B, or D are not met within the required Completion Time or if for one or more Functions more than one Manual Trip, Matrix Logic, Initiation Logic, or RTCB channel is inoperable for reasons other than Condition A or D.

If the RTCBs associated with the inoperable channel cannot be opened, the reactor must be shut down within 6 hours and all the RTCBs opened. A Completion Time of 6 hours is reasonable, based on operating experience, to reach the required MODE from full power conditions in an orderly manner and without challenging plant systems and to open RTCBs. All RTCBs should then be opened, placing the plant in a MODE where the LCO does not apply and ensuring no CEA withdrawal occurs.

SURVEILLANCE REQUIREMENTS

~~----------REVIEWER'S NOTE----------~~
~~In order for a plant to take credit for topical reports as the basis for justifying Frequencies, topical reports must be supported by an NRC staff Safety Evaluation Report that establishes the acceptability of each topical report for that unit (Ref. 4).~~

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~ 4

2

SR 3.3.~~3~~.2 2

A CHANNEL FUNCTIONAL TEST on each RPS Logic channel is performed to ensure the entire channel will perform its intended function when needed. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

In addition to power supply tests, the RPS CHANNEL FUNCTIONAL TEST consists of three overlapping tests as described in Reference ~~3~~. 2 1
These tests verify that the RPS is capable of performing its intended function, from bistable input through the RTCBs. The first test, the bistable test, is addressed by SR 3.3.1.4 in LCO 3.3.1.

This SR addresses the two tests associated with the RPS Logic: Matrix Logic and Trip Path.

Matrix Logic Tests

These tests are performed one matrix at a time. They verify that a coincidence in the two input channels for each Function removes power from the matrix relays. During testing, power is applied to the matrix relay test coils and prevents the matrix relay contacts from assuming their de-energized state. The Matrix Logic tests will detect any short circuits around the bistable contacts in the coincidence logic such as may be caused by faulty bistable relay or trip channel bypass contacts.

SURVEILLANCE REQUIREMENTS (continued)

Trip Path Tests

These tests are similar to the Matrix Logic tests, except that test power is withheld from one matrix relay at a time, allowing the initiation circuit to de-energize, opening the affected set of RTCBs. The RTCBs must then be closed prior to testing the other three initiation circuits, or a reactor trip may result.

~~[The Frequency of [92] days is based on the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 5).~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 4

~~]~~ 3

2

SR 3.3.~~3~~.3 2

A CHANNEL FUNCTIONAL TEST on the Manual Trip channels is performed prior to a reactor startup to ensure the entire channel will perform its intended function if required. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. The Manual Trip Function can be tested either at power or shutdown. However, the simplicity of this circuitry and the absence of drift concern makes this Frequency adequate. Additionally, operating experience has shown that these components usually pass the Surveillance when performed once within 7 days prior to each reactor startup.

BASES

SURVEILLANCE REQUIREMENTS (continued)

2

~~[~~ SR 3.3.~~3~~.4 2 3

Each RTCB is actuated by an undervoltage coil and a shunt trip coil. The system is designed so that either de-energizing the undervoltage coil or energizing the shunt trip coil will cause the circuit breaker to open. When an RTCB is opened, either during an automatic reactor trip or by using the manual push buttons in the control room, the undervoltage coil is de-energized and the shunt trip coil is energized. This makes it impossible to determine if one of the coils or associated circuitry is defective.

Therefore, a CHANNEL FUNCTIONAL TEST is performed that individually tests all four sets of undervoltage coils and all four sets of shunt trip coils. During undervoltage coil testing, the shunt trip coils shall remain de-energized, preventing their operation. Conversely, during shunt trip coil testing, the undervoltage coils shall remain energized, preventing their operation. This Surveillance ensures that every undervoltage coil and every shunt trip coil is capable of performing its intended function and that no single active failure of any RTCB component will prevent a reactor trip. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. ~~[The 18 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed at the Frequency of once every 18 months.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------~~ ~~]~~ 4 3

BASES

SURVEILLANCE REQUIREMENTS (continued)

If one set of RTCBs has been opened in response to a single RTCB channel, Initiation Logic channel, or Manual Trip channel failure, the affected set of RTCBs may be closed for up to 1 hour for Surveillance on the OPERABLE Initiation Logic, RTCB, and Manual Trip channels. In this case, the redundant set of RTCBs will provide protection if a trip should be required. It is unlikely that a trip will be required during the Surveillance, coincident with a failure of the remaining series RTCB channel. If a single matrix power supply or vital bus failure has opened two sets of RTCBs, Manual Trip and RTCB testing on the closed breakers cannot be performed without causing a trip.~~]~~ 3

B 3.3 INSTRUMENTATION ~~(Analog)~~

B 3.3.~~3~~ 2 Reactor Protective System (RPS) Logic and Trip Initiation ~~(Analog)~~ 2

BASES

BACKGROUND

The RPS initiates a reactor trip to protect against violating the core specified acceptable fuel design limits and reactor coolant pressure boundary integrity during anticipated operational occurrences (AOOs). By tripping the reactor, the RPS also assists the Engineered Safety Features (ESF) systems in mitigating accidents.

The protection and monitoring systems have been designed to ensure safe operation of the reactor. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the RPS, as well as LCOs on other reactor system parameters and equipment performance.

The LSSS, defined in this Specification as the Allowable Value, in conjunction with the LCOs, establish the threshold for protective system action to prevent exceeding acceptable limits during Design Basis Accidents.

During AOOs, which are those events expected to occur one or more times during the plant life, the acceptable limits are:

- The departure from nucleate boiling ratio shall be maintained above the Safety Limit (SL) value to prevent departure from nucleate boiling,
- Fuel centerline melting shall not occur, and
- The Reactor Coolant System pressure SL of 2750 psia shall not be exceeded.

Maintaining the parameters within the above values ensures that the offsite dose will be within the ~~10 CFR 50 (Ref. 1) and~~ 10 CFR ~~100~~ (Ref. ~~2~~) criteria during AOOs. 50.67 1 1

Accidents are events that are analyzed even though they are not expected to occur during the plant life. The acceptable limit during accidents is that the offsite dose shall be maintained within an acceptable fraction of 10 CFR ~~100~~ (Ref. ~~2~~) limits. Different accident categories allow a different fraction of these limits based on probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event. 1 50.67 1

BASES

BACKGROUND (continued)

The RPS is segmented into four interconnected modules. These modules are:

- Measurement channels,
- Bistable trip units,
- RPS Logic, and
- Reactor trip circuit breakers (RTCBs).

This LCO addresses the RPS Logic and RTCBs, including Manual Trip capability. LCO 3.3.1, "Reactor Protective System (RPS) Instrumentation - Operating," provides a description of the role of this equipment in the RPS. This is summarized below:

RPS Logic

The RPS Logic, consisting of Matrix and Initiation Logic, employs a scheme that provides a reactor trip when bistables in any two of the four channels sense the same input parameter trip. This is called a two-out-of-four trip logic. ~~This logic and the RTCB configuration are shown in Figure B 3.3.1-1.~~ 1 5

(one out of two taken twice)

Bistable relay contact outputs from the four channels are configured into six logic matrices. Each logic matrix checks for a coincident trip in the same parameter in two bistable channels. The matrices are designated the AB, AC, AD, BC, BD, and CD matrices to reflect the bistable channels being monitored. Each logic matrix contains four normally energized matrix relays. When a coincidence is detected, consisting of a trip in the same Function in the two channels being monitored by the logic matrix, all four matrix relays de-energize.

The matrix relay contacts are arranged into trip paths, with one of the four matrix relays in each matrix opening contacts in one of the four trip paths. Each trip path provides power to one of the four normally energized RTCB control relays (K1, K2, K3, and K4). The trip paths thus each have six contacts in series, one from each matrix, and perform a logical OR function, opening the RTCBs if any one or more of the six logic matrices indicate a coincidence condition.

BASES

BACKGROUND (continued)

Each trip path is responsible for opening one set of two of the eight RTCBs. The RTCB control relays (K-relays), when de-energized, interrupt power to the breaker undervoltage trip attachments and simultaneously apply power to the shunt trip attachments on each of the two breakers. Actuation of either the undervoltage or shunt trip attachment is sufficient to open the RTCB and interrupt power from the motor generator (MG) sets to the control element drive mechanisms (CEDMs).

When a coincidence occurs in two RPS channels, all four matrix relays in the affected matrix de-energize. This in turn de-energizes all four breaker control relays, which simultaneously de-energize the undervoltage and energize the shunt trip attachments in all eight RTCBs, tripping them open.

The Initiation Logic consists of the trip path power source, matrix relays and their associated contacts, all interconnecting wiring, and solid state (auxiliary) relays through the K-relay contacts in the RTCB control circuitry.

It is possible to change the two-out-of-four RPS Logic to a two-out-of-three logic for a given input parameter in one channel at a time by trip channel bypassing select portions of the matrix logic. Trip channel bypassing a bistable effectively shorts the bistable relay contacts in the three matrices associated with that channel. Thus, the bistables will function normally, producing normal trip indication and annunciation, but a reactor trip will not occur unless two additional channels indicate a trip condition. Trip channel bypassing can be simultaneously performed on any number of parameters in any number of channels, providing each parameter is bypassed in only one channel at a time. An interlock prevents simultaneous trip channel bypassing of the same parameter in more than one channel. Trip channel bypassing is normally employed during maintenance or testing.

Reactor Trip Circuit Breakers (RTCBs)

The reactor trip switchgear~~, shown in Figure B 3.3.1-1,~~ consists of eight RTCBs, which are operated in four sets of two breakers (four channels). Power input to the reactor trip switchgear comes from two full capacity MG sets operated in parallel such that the loss of either MG set does not de-energize the CEDMs. There are two separate CEDM power supply 5

BASES

BACKGROUND (continued)

buses, each bus powering half of the CEDMs. Power is supplied from the MG sets to each bus via two redundant paths (trip legs). Trip legs 1A and 1B supply power to CEDM bus 1. Trip legs 2A and 2B supply power to CEDM bus 2. This ensures that a fault or the opening of a breaker in one trip leg (i.e., for testing purposes) will not interrupt power to the CEDM buses.

Each of the four trip legs consists of two RTCBs in series. The two RTCBs within a trip leg are actuated by separate initiation circuits.

The eight RTCBs are operated as four sets of two breakers (four channels). For example, if a breaker receives an open signal in trip leg A (for CEDM bus 1), an identical breaker in trip leg B (for CEDM bus 2) will also receive an open signal. This arrangement ensures that power is interrupted to both CEDM buses, thus preventing trip of only half of the control element assemblies (CEAs) (a half trip). Any one inoperable breaker in a channel will make the entire channel inoperable.

Each set of RTCBs is operated by either a Manual Trip push button or an RPS actuated K-relay. There are four Manual Trip push buttons, arranged in two sets of two~~, as shown in Figure B 3.3.1-1~~. Depressing both push buttons in either set will result in a reactor trip. 5

When a Manual Trip is initiated using the control room push buttons, the RPS trip paths and K-relays are bypassed, and the RTCB undervoltage and shunt trip attachments are actuated independent of the RPS.

Manual Trip circuitry includes the push button and interconnecting wiring to both RTCBs necessary to actuate both the undervoltage and shunt trip attachments, but excludes the K-relay contacts and their interconnecting wiring to the RTCBs, which are considered part of the Initiation Logic.

Functional testing of the entire RPS, from bistable input through the opening of individual sets of RTCBs, can be performed either at power or shutdown ~~and is normally performed on a quarterly basis~~. FSAR, Section ~~[~~7.2~~]~~ (Ref. ~~3~~), explains RPS testing in more detail. 1 3

in accordance with the Surveillance Frequency Control Program

2

U

APPLICABLE SAFETY ANALYSES

Reactor Protective System (RPS) Logic

The RPS Logic provides for automatic trip initiation to maintain the SLs during AOOs and assist the ESF systems in ensuring acceptable consequences during accidents. All transients and accidents that call for a reactor trip assume the RPS Logic is functioning as designed.

BASES

APPLICABLE SAFETY ANALYSES (continued)

Reactor Trip Circuit Breakers (RTCBs)

All of the transient and accident analyses that call for a reactor trip assume that the RTCBs operate and interrupt power to the CEDMs.

Manual Trip

There are no accident analyses that take credit for the Manual Trip; however, the Manual Trip is part of the RPS circuitry. It is used by the operator to shut down the reactor whenever any parameter is rapidly trending toward its trip setpoint. A Manual Trip accomplishes the same results as any one of the automatic trip Functions.

The RPS Logic and initiation satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

Reactor Protective System (RPS) Logic

Failures of individual bistable relays and their contacts are addressed in LCO 3.3.1. This Specification addresses failures of the Matrix Logic not addressed in the above, such as the failure of matrix relay power supplies or the failure of the trip channel bypass contact in the bypass condition.

instrument

Loss of a single ~~vital~~ bus will de-energize one of the two power supplies in each of three matrices. This will result in four RTCBs opening; however, the remaining four closed RTCBs will prevent a reactor trip. For the purposes of this LCO, de-energizing up to three matrix power supplies due to a single failure is to be treated as a single channel failure, providing the affected matrix relays de-energize as designed, opening the affected RTCBs. 1

Each of the four Initiation Logic channels opens one set of RTCBs if any of the six coincidence matrices de-energize their associated matrix relays. They thus perform a logical OR function. Each Initiation Logic channel has its own power supply and is independent of the others. An Initiation Logic channel includes the matrix relay through to the K-relay contacts, which open the RTCB.

It is possible for two Initiation Logic channels affecting the same trip leg to de-energize if a matrix power supply or ~~vital~~ instrument bus fails. This will result in opening the two affected sets of RTCBs. 1

BASES

LCO (continued)

If one set of RTCBs has been opened in response to a single RTCB channel, Initiation Logic channel, or Manual Trip channel failure, the affected set of RTCBs may be closed for up to 1 hour for Surveillance on the OPERABLE Initiation Logic, RTCB, and Manual Trip channels. In this case, the redundant set of RTCBs will provide protection if a trip should be required. It is unlikely that a trip will be required during the Surveillance, coincident with a failure of the remaining series RTCB channel. If a single matrix power supply or ~~vital~~ bus failure has opened two sets of RTCBs, Manual Trip and RTCB testing on the closed breakers cannot be performed without causing a trip.

instrument

1

1. Matrix Logic

   This LCO requires six channels of Matrix Logic to be OPERABLE in MODES 1 and 2, and in MODES 3, 4, and 5 when any RTCB is closed and any CEA is capable of being withdrawn.

2. Initiation Logic

   This LCO requires four channels of Initiation Logic to be OPERABLE in MODES 1 and 2, and in MODES 3, 4, and 5 when any RTCB is closed and any CEA is capable of being withdrawn.

3. Reactor Trip Circuit Breakers (RTCBs)

   The LCO requires four RTCB channels to be OPERABLE in MODES 1 and 2, as well as in MODES 3, 4, and 5 when any RTCB is closed and any CEA is capable of being withdrawn.

   Each channel consists of two breakers operated in a single set by the Initiation Logic or Manual Trip circuitry. This ensures that power is interrupted at identical locations in the trip legs for both CEDM buses, thus preventing power removal to only one CEDM bus (a half trip).

   Failure of a single breaker affects the entire channel, and both breakers in the set must be opened. Without reliable RTCBs and associated support circuitry, a reactor trip cannot occur whether initiated automatically or manually.

   Each channel of RTCBs starts at the contacts actuated by the K-relay, and the contacts actuated by the Manual Trip, for each set of breakers. The K-relay actuated contacts and the upstream circuitry are considered to be RPS Logic. Manual Trip contacts and upstream circuitry are considered to be Manual Trip circuitry.

BASES

LCO (continued)

I

~~A Note associated with the ACTIONS states that~~ If one set of RTCBs has been opened in response to a single RTCB channel, Initiation Logic channel, or Manual Trip channel failure, the affected set of RTCBs may be closed for up to 1 hour for Surveillance on the OPERABLE Initiation Logic, RTCB, and Manual Trip channels. In this case, the redundant set of RTCBs will provide protection. If a single matrix power supply or vital bus failure has opened two sets of RTCBs, Manual Trip and RTCB testing on the closed breakers cannot be performed without causing a trip. ~~This Note is not applicable to Condition A, with one Matrix Logic channel inoperable.~~ 1 1

4. Manual Trip

The LCO requires all four Manual Trip channels to be OPERABLE in MODES 1 and 2, and MODES 3, 4, and 5 when any RTCB is closed and any CEA is capable of being withdrawn.

Two independent sets of two adjacent push buttons are provided at separate locations. Each push button is considered a channel and operates two of the eight RTCBs. Depressing both push buttons in either set will cause an interruption of power to the CEDMs, allowing the CEAs to fall into the core. This design ensures that no single failure in any push button circuit can either cause or prevent a reactor trip.

APPLICABILITY

The RPS Matrix Logic, RTCBs, and Manual Trip are required to be OPERABLE in any MODE when any CEA is capable of being withdrawn from the core (i.e., RTCBs closed and power available to the CEDMs). This ensures the reactor can be tripped when necessary, but allows for maintenance and testing when the reactor trip is not needed.

In MODES 3, 4, and 5 with all the RTCBs open, the CEAs are not capable of withdrawal and these Functions do not have to be OPERABLE. However, two ~~[~~logarithmic~~]~~ ~~power~~ level channels must be OPERABLE to ensure proper indication of neutron population and to indicate a boron dilution event. This is addressed in LCO 3.3.~~13~~, "~~[~~Logarithmic~~]~~ ~~Power~~ Monitoring Channels."

neutron flux 1 3 1

Neutron Flux 11

ACTIONS

When the number of inoperable channels in a trip Function exceeds that specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 is immediately entered if applicable in the current MODE of operation.

BASES

ACTIONS (continued)

A.1

, one Manual Trip channel is inoperable, 1

Condition A applies if one Matrix Logic channel is inoperable or three Matrix Logic channels are inoperable due to a common power source failure de-energizing three matrix power supplies, in any applicable MODE. Loss of a single ~~vital~~ instrument bus will de-energize one of the two matrix power supplies in up to three matrices. This is considered a single matrix failure, providing the matrix relays associated with the failed power supplies de-energize as required. 1

Failure of the matrix relays to de-energize in all three affected matrices could, when combined with trip channel bypassing of bistable relay contacts in the other matrices, result in loss of RPS function.

The channel must be restored to OPERABLE status within 48 hours ~~[~~or in accordance with the Risk Informed Completion Time Program~~]~~. The Completion Time of 48 hours provides the operator time to take appropriate actions and still ensures that any risk involved in operating with a failed channel is acceptable. Operating experience has demonstrated that the probability of a random failure of a second Matrix Logic channel is low during any given 48 hour interval. If the channel cannot be restored to OPERABLE status within 48 hours, Condition E is entered. 3

B.1

or

Condition B applies to one Initiation Logic channel, RTCB channel~~, or Manual Trip channel~~ in MODES 1 and 2, since they have the same actions. MODES 3, 4, and 5, with the RTCBs shut, are addressed in Condition C. These Required Actions require opening the affected RTCBs. This removes the need for the affected channel by performing its associated safety function. With the RTCB open, the affected Functions are in one-out-of-two logic, which meets redundancy requirements, but testing on the OPERABLE channels cannot be performed without causing a reactor trip unless the RTCBs in the inoperable channels are closed to permit testing. 1

The inoperable channel may be bypassed during the one hour period to perform testing, if necessary, provided the RTCBs are opened within the required Completion Time.

Required Action B.1 provides for opening the RTCBs associated with the inoperable channel within a Completion Time of 1 hour. This Required Action is conservative, since depressing the Manual Trip push button associated with either set of breakers in the other trip leg will cause a reactor trip. With this configuration, a single channel failure will not prevent a reactor trip. The allotted Completion Time is adequate to open the affected RTCBs while maintaining the risk of having them closed at an acceptable level.

BASES

ACTIONS (continued)

C.1

Condition C applies to the failure of one Initiation Logic channel, RTCB channel, or Manual Trip channel ~~affecting the same trip leg~~ in MODE 3, 4, or 5 with the RTCBs closed. The channel must be restored to OPERABLE status within 48 hours. If the inoperable channel cannot be restored to OPERABLE status within 48 hours, the affected RTCBs must be opened. ~~In some cases, this condition may effect all of the RTCBs.~~ This removes the need for the affected channel by performing its associated safety function. With the RTCBs open, the affected functions are in a one-out-of-two logic, which meets redundancy requirements. 1 1

The Completion Time of 48 hours is consistent with that of other RPS instrumentation and should be adequate to repair most failures.

Testing on the OPERABLE channels cannot be performed without causing a reactor trip unless the RTCBs in the inoperable channels are closed to permit testing.

D.1

Condition D applies to the failure of both Manual Trip or Initiation Logic channels affecting the same trip leg. Since this will open two channels of RTCBs, this Condition is also applicable to the two affected channels of RTCBs. This Condition allows for loss of a single ~~vital~~ instrument bus or matrix power supply, which will de-energize both Initiation Logic channels in the same trip leg. This will open both sets of RTCBs in the affected trip leg, satisfying the Required Action of opening the affected RTCBs. 1

Of greater concern is the failure of the initiation circuit in a nontrip condition (e.g., due to two initiation K-relay failures). With only one Initiation Logic channel failed in a nontrip condition, there is still the redundant set of RTCBs in the trip leg. With both failed in a nontrip condition, the reactor will not trip automatically when required. In either case, the affected RTCBs must be opened immediately by using the appropriate Manual Trip push buttons, since each of the four push buttons opens one set of RTCBs, independent of the initiation circuitry. Caution must be exercised, since depressing the wrong push buttons may result in a reactor trip.

BASES

ACTIONS (continued)

If two Manual Trip channels are inoperable and affecting the same trip leg, the associated RTCBs must be opened immediately to ensure Manual Trip capability is maintained. With the affected RTCBs open, any one of two Manual Trip push buttons being depressed will result in a reactor trip.

If the affected RTCB(s) cannot be opened, Condition E is entered. This would only occur if there is a failure in the Manual Trip circuitry or the RTCB(s).

E.1 and E.2

Condition E is entered if Required Actions associated with Condition A, B, or D are not met within the required Completion Time or if for one or more Functions more than one Manual Trip, Matrix Logic, Initiation Logic, or RTCB channel is inoperable for reasons other than Condition A or D.

If the RTCBs associated with the inoperable channel cannot be opened, the reactor must be shut down within 6 hours and all the RTCBs opened. A Completion Time of 6 hours is reasonable, based on operating experience, to reach the required MODE from full power conditions in an orderly manner and without challenging plant systems and to open RTCBs. All RTCBs should then be opened, placing the plant in a MODE where the LCO does not apply and ensuring no CEA withdrawal occurs.

SURVEILLANCE REQUIREMENTS

~~----------REVIEWER'S NOTE----------~~
~~In order for a plant to take credit for topical reports as the basis for justifying Frequencies, topical reports must be supported by an NRC staff Safety Evaluation Report that establishes the acceptability of each topical report for that unit (Ref. 4).~~
~~----------~~ 4

2
SR 3.3.~~3~~.1 2

A CHANNEL FUNCTIONAL TEST is performed on each RTCB channel. This verifies proper operation of each RTCB. The RTCB must then be closed prior to testing the other RTCBs, or a reactor trip may result~~. [The Frequency of 31 days is based on the reliability analysis presented in Topical Report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation," (Ref. 5).~~ 3

BASES

SURVEILLANCE REQUIREMENTS (continued)

OR

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

SR 3.3.~~3~~.2

A CHANNEL FUNCTIONAL TEST on each RPS Logic channel is performed to ensure the entire channel will perform its intended function when needed. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

In addition to power supply tests, the RPS CHANNEL FUNCTIONAL TEST consists of three overlapping tests as described in Reference ~~3~~. These tests verify that the RPS is capable of performing its intended function, from bistable input through the RTCBs. The first test, the bistable test, is addressed by SR 3.3.1.4 in LCO 3.3.1.

This SR addresses the two tests associated with the RPS Logic: Matrix Logic and Trip Path.

Matrix Logic Tests

These tests are performed one matrix at a time. They verify that a coincidence in the two input channels for each Function removes power from the matrix relays. During testing, power is applied to the matrix relay test coils and prevents the matrix relay contacts from assuming their de-energized state. The Matrix Logic tests will detect any short circuits around the bistable contacts in the coincidence logic such as may be caused by faulty bistable relay or trip channel bypass contacts.

The matrix logic includes fuses in all matrix interbay connections as part of the fault protection circuitry. A test circuit is provided for checking the fuses associated with the matrix fault protection circuitry.

BASES

SURVEILLANCE REQUIREMENTS (continued)

Trip Path Tests

These tests are similar to the Matrix Logic tests, except that test power is withheld from one matrix relay at a time, allowing the initiation circuit to de-energize, opening the affected set of RTCBs. The RTCBs must then be closed prior to testing the other three initiation circuits, or a reactor trip may result.

~~[The Frequency of [92] days is based on the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 5).~~

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------]~~

SR 3.3.~~3~~.3

A CHANNEL FUNCTIONAL TEST on the Manual Trip channels is performed prior to a reactor startup to ensure the entire channel will perform its intended function if required. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. The Manual Trip Function can be tested either at power or shutdown. However, the simplicity of this circuitry and the absence of drift concern makes this Frequency adequate. Additionally, operating experience has shown that these components usually pass the Surveillance when performed once within 7 days prior to each reactor startup.

BASES

SURVEILLANCE REQUIREMENTS (continued)

2

~~[~~ SR 3.3.~~3~~.4 3 2

Each RTCB is actuated by an undervoltage coil and a shunt trip coil. The system is designed so that either de-energizing the undervoltage coil or energizing the shunt trip coil will cause the circuit breaker to open. When an RTCB is opened, either during an automatic reactor trip or by using the manual push buttons in the control room, the undervoltage coil is de-energized and the shunt trip coil is energized. This makes it impossible to determine if one of the coils or associated circuitry is defective.

Therefore, a CHANNEL FUNCTIONAL TEST is performed that individually tests all four sets of undervoltage coils and all four sets of shunt trip coils. During undervoltage coil testing, the shunt trip coils shall remain de-energized, preventing their operation. Conversely, during shunt trip coil testing, the undervoltage coils shall remain energized, preventing their operation. This Surveillance ensures that every undervoltage coil and every shunt trip coil is capable of performing its intended function and that no single active failure of any RTCB component will prevent a reactor trip. A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. ~~[The 18 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed at the Frequency of once every 18 months.~~ 3

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

~~---------- REVIEWER'S NOTE ----------~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~
~~----------~~ ~~]~~ 4 3

BASES

SURVEILLANCE REQUIREMENTS (continued)

If one set of RTCBs has been opened in response to a single RTCB channel, Initiation Logic channel, or Manual Trip channel failure, the affected set of RTCBs may be closed for up to 1 hour for Surveillance on the OPERABLE Initiation Logic, RTCB, and Manual Trip channels. In this case, the redundant set of RTCBs will provide protection if a trip should be required. It is unlikely that a trip will be required during the Surveillance, coincident with a failure of the remaining series RTCB channel. If a single matrix power supply or vital bus failure has opened two sets of RTCBs, Manual Trip and RTCB testing on the closed breakers cannot be performed without causing a trip.~~]~~ 3

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.2 BASES, REACTOR PROTECTION SYSTEM (RPS) LOGIC AND TRIP INITIATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant-specific nomenclature, number, reference, system description, analysis, or licensing basis description.

2. The heading for ISTS 3.3.3 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2). Therefore, ISTS 3.3.2 is not included in the PSL ITS. The Reactor Protective System (RPS) Logic and Trip Initiation (ISTS 3.3.3) is renumbered as ITS 3.3.2.

3. The ISTS contains bracketed information and/or values that are generic to Combustion Engineering vintage plants. The brackets are removed and the proper plant information/value is inserted to reflect the current licensing basis.

4. The Reviewer's Note has been deleted. This information is for the NRC reviewer to be keyed into what is needed to meet this requirement. This Note is not meant to be retained in the final version of the plant specific submittal.

5. Figure B 3.3.1-1 was removed from the ITS 3.3.1-1 Bases because the figure is included in the UFSAR.

TABLE NOTATION

(1) Testing of Automatic Actuation Logic shall include energization/de-energization of each initiation relay (solid-state component) and verification of the OPERABILITY of each initiation relay (solid-state component).

(2) An actuation relay test shall be performed which shall include the energization/de-energization of each actuation relay and verification of the OPERABILITY of each actuation relay.

(3) A subgroup relay test shall be performed which shall include the energization/de-energization of each subgroup relay and verification of the OPERABILITY of each subgroup relay. Testing of the ESFAS subgroup relays shall be performed in accordance with the Surveillance Frequency Control Program.

See ITS 3.3.4

DISCUSSION OF CHANGES
ITS 3.3.3, ENGINEERED SAFETY FEATURES ACTUATION SYSTEM (ESFAS) INSTRUMENTATION

ADMINISTRATIVE CHANGES

A01 In the conversion of the St. Lucie Plant (PSL) Unit 1 and Unit 2, Current Technical Specifications (CTS) to the plant specific Improved Technical Specifications (ITS), certain changes (wording preferences, editorial changes, reformatting, revised numbering, etc.) are made to obtain consistency with NUREG-1432, Rev. 5.0, "Standard Technical Specifications-Combustion Engineering Plants" (ISTS).

These changes are designated as administrative changes and are acceptable because they do not result in technical changes to the CTS.

A02 CTS Table 3.3-3 Actions describe the actions to be taken when ESFAS Function instrument channels are inoperable. ITS 3.3.3 also describes Actions to be taken when ESFAS Function instrument channels are inoperable and contains a note that separate condition entry is allowed for each ESFAS Function. This changes the CTS by adding a Note stating that separate condition entry is allowed for each Function, those ESFAS Functions being the SIAS, CSAS, CIS (Unit 1) and CIAS (Unit 2), MSIS, RAS, and AFAS Functions.

The purpose of the CTS Actions is to provide the appropriate compensatory actions for inoperable ESFAS Functions. This proposed change will allow separate condition entry for each ESFAS Function. The Note clarifies that ESFAS Functions are treated as separate entities, each with separate Completion Times. In addition, the AFAS Functions are allowed separate Condition entry on a per steam generator basis since the channels associated with each steam generator will provide the associated AFAS trip based on the logic associated with the channels on a steam generator basis. This change is acceptable because it clearly states the current requirement. The CTS considers each ESFAS Function to be separate and independent from the others. This change is designated as administrative because it does not result in technical changes to the CTS.

A03 Unit 1 CTS 4.3.2.1.2 and Unit 2 CTS 4.3.2.2 require the logic for the bypasses to be demonstrated OPERABLE during the at-power CHANNEL FUNCTIONAL TEST. These Surveillance Requirements also require, “The total bypass function shall be demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program during CHANNEL CALIBRATION testing of each channel affected by bypass operation.” Unit 1 CTS 4.3.2.1.3 and Unit 2 CTS 4.3.2.3 require ENGINEERED SAFETY FEATURE (ESF) RESPONSE TIME testing for each ESFAS function and includes a statement that each test shall include at least one channel per function. ITS SR 3.3.3.3 requires a CHANNEL FUNCTIONAL TEST on each automatic bypass removal function. ITS SR 3.3.3.4 requires a CHANNEL CALIBRATION of each ESFAS instrument channel, including bypass removal functions. These ITS Surveillances do not explicitly state that the total bypass function shall be demonstrated OPERABLE during the Channel Calibration test of each channel affected by bypass operation or that the ESF RESPONSE TIME test must include at least one channel per function.

The purpose of the CTS statements in the Surveillance Requirements associated with the CHANNEL FUNCTIONAL TEST of the bypass channels and the ESF RESPONSE TIME test is to ensure required features are tested to verify the ESFAS instrument Functions are OPERABLE. However, these statements are redundant to the definition of a CHANNEL FUNCTIONAL TEST and ESF RESPONSE TIME provided in ITS Section 1.1 and therefore are not necessary.

The definition of a CHANNEL FUNCTIONAL TEST states, in part, that the test "…may be performed by means of any series of sequential, overlapping, or total channel steps, and each step must be performed within the Frequency in the Surveillance Frequency Control Program for the devices included in the step." Thus, the definition, combined with the requirement to include the bypass removal function in the CHANNEL CALIBRATION, ensures the total bypass function is demonstrated OPERABLE in accordance with the Surveillance Frequency Control Program during CHANNEL CALIBRATION testing of each channel affected by bypass operation.

The definition of the ESF RESPONSE TIME states, in part, that the test, "…shall be that time interval from FEATURE (ESF) RESPONSE when the monitored parameter exceeds its ESF actuation TIME setpoint at the channel sensor until the ESF equipment is capable of performing its safety function. This encompasses the requirement that at least once channel per Function be included in an ESF RESPONSE TIME. The required testing will continue, per the ITS SR wording and the definitions provided in Section 1.1, to include the features necessary to verify the ESFAS instrument Functions are OPERABLE.

This change is designated as administrative because it does not result in technical changes to the CTS.

A04 CTS Table 3.3-3 for ESFAS instrumentation has three columns stating various requirements for each function. These columns are labeled, "TOTAL NO. OF CHANNELS," "CHANNELS TO TRIP," and "MINIMUM CHANNELS OPERABLE." ITS Table 3.3.3-1 does not retain the "TOTAL NO. OF CHANNELS" or "CHANNELS TO TRIP" columns. DOC LA01 describes the change that moves the information of the "TOTAL NO. OF CHANNELS" and "CHANNELS TO TRIP" columns to the Bases. This changes the CTS by changing the "MINIMUM CHANNELS OPERABLE" column to "REQUIRED CHANNELS OPERABLE" and changing the number of channels to four (4) channels for those Functions with a "MINIMUM CHANNELS OPERABLE" criteria less than four (4) channels. Additionally, the revised "MINIMUM CHANNELS OPERABLE" criteria are moved to the ITS 3.3.3. LCO statement and the "MINIMUM CHANNELS OPERABLE" column is not included in ITS Table 3.3.3-1. This change is designated as administrative because it does not result in a technical change to the CTS.

A05 Unit 1 CTS Table 3.3-3, Actions 9.b, 10A.b, 14.b, and Unit 2 CTS Table 3.3-3, Actions 13, 14.b, 20.b state, in part, that all functional units receiving an input from the inoperable channel are also bypassed or tripped. The ITS instrumentation format is presented by Functions based on parameters the channels sense and systems the instrument Functions actuate. As a result,

when a functional unit impacts OPERABILITY of multiple ESFAS Functions, each Function is addressed separately and independently depending on the nature of the inoperability. ITS 3.3.3 ACTIONS are applied to each Function, as applicable, and include a Required Action to place the affected trip unit in trip or bypass within 1 hour, as appropriate. CTS 3.0.2 (ITS LCO 3.0.2) establishes that upon discovery of a failure to meet an LCO, the associated ACTIONS shall be met. Therefore, when a common instrument becomes inoperable, LCO 3.0.2 requires each Function affected by the inoperability to be declared inoperable and the associated ACTIONS shall be met. The additional clarifying statement in the CTS Actions is not necessary and is not included in the presentation of the ITS 3.3.3 ACTIONS. This change is designated as administrative because it does not result in a technical change to the CTS.

A06 Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.3.2 do not contain a default action to perform when the Table 3.3-3 Actions cannot be completed within the required time; therefore, an entry into CTS 3.0.3 would be required. ITS 3.3.3 ACTION H requires the unit to be in MODE 3 in 6 hours and MODE 4 in 12 hours when one or more Required Actions is not met within its associated Completion Time. This changes the CTS by explicitly stating shutdown ACTIONS when actions cannot be performed within the required time.

The purpose of ITS 3.3.3 ACTION I is to ensure the plant is brought to a MODE in which the LCO for the ESFAS Functions does not apply within a reasonable amount of time in a controlled manner because the Technical Specification actions cannot be completed as required. Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.3.2 are silent on these actions, deferring to CTS 3.0.3 for the actions to accomplish this. The proposed change is acceptable because the ACTIONS specified in ITS 3.3.3 adopt the ISTS structure for placing the unit outside the MODE of Applicability without changing the time specified to enter MODE 3 or MODE 4. A default Condition eliminates the need to LCO 3.0.3 when one or more Required Actions cannot be met within the associated Completion Times. This change is designated as administrative because it does not result in a technical change to the CTS.

A07 Unit 1 CTS 3.3.2.1 Table 3.3-3 Action 14, and Unit 2 CTS 3.3.2 Table 3.3-3 Action 20 provide actions when one channel of an AFAS Function is inoperable. CTS 3.3.2 Table 3.3-3 Action 13 also provides actions when one channel of an SIAS, CIAS, or MSIS Function is inoperable. These CTS Actions state in part, “The channel shall be returned to OPERABLE status no later than during the next COLD SHUTDOWN.” ITS 3.3.3 ACTIONS C and D include this action to restore the channel to OPERABLE with a Completion Time of, “Prior to entering MODE 3 following the following next MODE 5 entry.” This presentation preference is similar to the Completion Time specified in ISTS 3.3.5 (Digital), Required Action A.2. ITS 3.3.3, Conditions C and D are modified by a Note which requires the action to restore the channel to OPERABLE status within the Completion Time to be performed whenever the Condition is entered. This changes the CTS by explicitly stating that the Required Action must be performed within the Completion Time whenever the condition is entered.

This change is necessary to eliminate the conflict with the general CTS 3.0.2 (ITS LCO 3.0.2) requirement that if the LCO is met or is no longer applicable prior to expiration of the specified time interval(s), completion of the ACTIONS is not required, unless otherwise stated. The addition of the Note constitutes an "unless otherwise stated." The Note will require the action to be completed within the Completion Time even when the LCO is no longer applicable, to ensure the channel is restored to OPERABLE prior to the next reactor startup from MODE 5 conditions. This change is acceptable because it reflects the current understanding and application of the CTS Actions requiring the applicable channel to be restored to OPERABLE status whenever the LCO is not met.

This change is designated as administrative as it clarifies the current understanding of the CTS requirement while providing an "unless otherwise stated," to the requirements of CTS 3.0.2 (ITS LCO 3.0.2).

MORE RESTRICTIVE CHANGES

M01 Unit 1 CTS 3.3.2.1 Action a. and Unit 2 CTS 3.3.2 Action a. state, in part, that with an ESFAS instrumentation channel trip setpoint less conservative than the value shown in the Allowable Values column of Table 3.3-4, declare the channel inoperable. ITS Table 3.3.3-1 Footnote (a) states, "If the as-found channel setpoint is outside its predefined as-found acceptance criteria, then the channel shall be evaluated to verify that it is functioning as required before returning the channel to service." ITS 3.3.3 Bases, referring to the Allowable Values, states: "This value needs to be specified in the Technical Specifications in order to define OPERABILITY of the channels and is designated as the Allowable Value." ITS Section 3.3.3 Bases also states, "If the actual setting (as-found setpoint) of the channel is found to be conservative with respect to the Allowable Value but is beyond the as-found acceptance criteria band (e.g., conservative side of the as-found acceptance criteria band), the channel is OPERABLE, but degraded. The degraded condition will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the Nominal Trip Setpoint (NTSP) (within the allowed tolerance) and evaluating the channel response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance." This changes the CTS by requiring an evaluation of channel functionality (extent of which is expanded on in the TS Bases) prior to returning it to service in addition to the as-found value being conservative to the Allowable Value.

The purpose of this Note is to address a concern that the Technical Specification requirements for Limiting Safety System Settings (LSSS) may not be fully in compliance with the intent of 10 CFR 50.36. Specifically, the concern is that the existing Surveillance Requirements may not provide adequate assurance that instruments will actuate safety functions at the point assumed in the applicable safety analysis. 10 CFR 50.36(c)(1)(ii)(A) states, "Limiting safety system settings for nuclear reactors are settings for automatic protective devices related to those variables having significant safety functions. Where a limiting safety system setting is specified for a variable on which a safety limit has been placed, the settings must be so chosen that automatic protective action will correct the

abnormal situation before a safety limit is exceeded. If, during operation, it is determined that the automatic safety system does not function as required, the licensee shall take appropriate action, which may include shutting down the reactor." The proposed change clarifies the Technical Specification requirements to ensure that the automatic protective action will correct the abnormal situation before a safety limit is exceeded. Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition. This change is consistent with the ISTS. This change is considered a more restrictive change because additional requirements have been added to Surveillance Requirements.

M02 Unit 1 CTS 3.3.2.1 Action a. and Unit 2 CTS 3.3.2 Action a. state, in part, that with an ESFAS instrumentation channel trip setpoint less conservative than the value shown in the Allowable Values column of Table 3.3-4, declare the channel inoperable and apply the applicable ACTION statement requirement of Specification 3.3.1.1 until the channel is restored to OPERABLE status "with its trip setpoint adjusted consistent with the Trip Setpoint value." ITS Table 3.3.3-1 Footnote (b) states, "The instrument channel setpoint shall be reset to a value that is within the as-left acceptance criteria around the Nominal Trip Setpoint (NTSP) at the completion of the surveillance; otherwise, the channel shall not be returned to OPERABLE status. Setpoints more conservative than the NTSP are acceptable provided that the as-found and as-left acceptance criteria apply to the actual setpoint implemented in the Surveillance procedures to confirm channel performance. The NTSP and the methodologies used to determine the as-found and as-left acceptance criteria are specified in the Technical Requirements Manual and Section 7.2 of the Updated Final Safety Analysis Report." This changes the CTS by providing more detailed information describing what "consistent with the Trip Setpoint" means and states a specific location where the methodology for determining the double-sided NTSP instrument tolerance bands is located.

The purpose of this Note is to address a concern that the Technical Specification requirements for LSSS may not be fully in compliance with the intent of 10 CFR 50.36. Specifically, the concern is that the existing Surveillance Requirements may not provide adequate assurance that instruments will always actuate safety functions at the point assumed in the applicable safety analysis. 10 CFR 50.36(c)(1)(ii)(A) states, "Limiting safety system settings for nuclear reactors are settings for automatic protective devices related to those variables having significant safety functions. Where a limiting safety system setting is specified for a variable on which a safety limit has been placed, the settings must be so chosen that automatic protective action will correct the abnormal situation before a safety limit is exceeded. If, during operation, it is determined that the automatic safety system does not function as required, the licensee shall take appropriate action, which may include shutting down the reactor." The proposed change

clarifies the Technical Specification requirements to ensure that the automatic protective action will correct the abnormal situation before a safety limit is exceeded. This change is consistent with the ISTS and is considered a more restrictive change because additional requirements have been added to Surveillance Requirements.

RELOCATED SPECIFICATIONS

None

REMOVED DETAIL CHANGES

LA01 *(Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.2.2 Table 3.3-4, ESFAS Instrumentation Trip Values, has two columns stating trip setpoints and allowable values for each Function. Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.2.2 require the ESFAS instrumentation setpoints to be set consistent with the Trip Setpoint values shown in Table 3.3-4. However, the CTS Action is only required to be taken when the setpoint is less conservative than the Allowable Value column of Table 3.3-4. When the setpoint is less conservative than the Allowable Value, the channel is to be declared inoperable and adjusted consistent with the Trip Setpoint value. CTS Table 3.3-4 specifies both the Trip Setpoints and Allowable Values for the ESFAS Instrumentation Functional Units. ITS 3.3.3 requires the ESFAS instrumentation for each Function in Table 3.3.3-1 to be OPERABLE. ITS Table 3.3.3-1 specifies only the Allowable Values for the ESFAS Instrumentation Functions. The Allowable Values represent the OPERABILITY limit of the channels in ITS. This changes the CTS by moving the Trip Setpoints to the Technical Requirements Manual (TRM). R1 R1

The purpose of the trip setpoint requirements is to ensure required automatic safety systems are actuated to protect against violating core design limits, breaching the Reactor Coolant System pressure boundary, and to mitigate accidents. Pursuant to 10 CFR 50.36(c)(1)(ii)(A), if it is determined that an automatic protective device for a variable on which a safety limit has been placed (i.e., limiting safety system setting) does not function as required, appropriate action is taken to ensure the abnormal situation is corrected before a safety limit is exceeded, which may include shutting down the reactor. The PSL Instrument Setpoint Methodology calculates Nominal Trip Setpoints (NTSPs) using methods consistent with the guidance provided in NRC Regulatory Guide 1.105, “Setpoints For Safety-Related Instrumentation,” and ANSI/ISA Standard 67.04, "Setpoints for Nuclear Safety-Related Instrumentation." Additionally, pre-defined limits (double-sided Operability limits and as-left limits) are determined for each instrument consistent with the guidance provided in NRC Regulatory Guide 1.105 and ANSI/ISA–RP67.04, “Methodologies for the Determination of Setpoints for Nuclear Safety-Related Instrumentation.” The instrument Operability limit band in plant uncertainty calculations is synonymous with the as-found acceptance criteria band specified in ITS and is centered about the nominal equipment setting (clarified in calculations as the field trip setpoint or NTSP). The PSL

Instrument Setpoint Methodology, including the method of determining instrument uncertainties, was reviewed by the NRC during the review of Extended Power Uprate (EPU) as documented in the EPU safety evaluations for License Amendments 213 (Unit 1) and 163 (Unit 2), dated July 9, 2012 and September 24, 2012, respectively (NRC ADAMS Accession Nos. ML12181A019 and ML12235A463). The NRC staff determined that the PSL Instrument Setpoint Methodology described in the EPU license request meets the requirements of 10 CFR 50, Appendix A, General Design Criterion 13 and the regulatory guidance in RG 1.105 (EPU SE pg. 92 (Unit 1) and 95 (Unit 2)). The NRC staff also determined that the application of the clarifications of RG 1.105 in Regulatory Issue Summary 2006-17 "NRC Staff Position on the Requirements of 10 CFR 50.36, 'Technical Specifications,' Regarding Limiting Safety System Settings During Periodic Testing and Calibration of Instrument Channels," is acceptable (EPU SE pg. 94 (Unit 1) and 97 (Unit 2)). | R1

The removal of these details for meeting Technical Specification requirements from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the Allowable Values associated with the ESFAS Instrumentation, which are designated as the Operability limits for the required instrument Functions. Footnotes (a) and (b) in Table 3.3.3-1 are added ensure channel performance continues to verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology consistent with the NRC guidance specified in Regulatory Issue Summary 2006-17. Also, this change is acceptable because these types of procedural details will be adequately controlled in the TRM. Any changes to the TRM are made under 10 CFR 50.59, which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because procedural details for meeting Technical Specification requirements are being removed from the Technical Specifications.

LA02 (*Type 1 – Removing Details of System Design and System Description, Including Design Limits*) CTS Table 3.3-3 for ESFAS instrumentation has three columns stating various requirements for each function. These columns are labeled, "TOTAL NO. OF CHANNELS," "CHANNELS TO TRIP," and "MINIMUM CHANNELS OPERABLE." ITS Table 3.3.3-1 does not retain the "TOTAL NO. OF CHANNELS" or "CHANNELS TO TRIP" columns. This changes the CTS by moving the information of the "TOTAL NO. OF CHANNELS" and "CHANNELS TO TRIP" columns to the Bases. The MINIMUM CHANNELS OPERABLE" column is deleted as described in discussion of change (DOC) A04. | R1

The removal of these details, which are related to system design, from the Technical Specifications, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement for the number of required channels and the appropriate Condition to enter if a required channel becomes inoperable. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program

in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LA03 (*Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements)* CTS Table 3.3-3 Action 14.a (Unit 1) and 20.a (Unit 2) require, in part, AFAS-1 or AFAS-2 associated with the inoperable channel to be placed in the bypass position when a steam generator (SG) level AFAS channel cannot be restored to OPERABLE status within the 48 hours. These CTS actions also require both AFAS-1 and AFAS-2 associated with the inoperable channel to be placed in the bypass position when a SG differential pressure or feedwater header differential pressure AFAS channel cannot be restored to OPERABLE status within the 48 hours. ITS 3.3.3 Required Action B.2.2 requires, in part, to place the affected trip unit in bypass as an option to restoring an AFAS instrument channel to OPERABLE status within 48 hours. ITS 3.3.3 ACTION B does not include the procedural details on which trip units to place in bypass (i.e., AFAS-1 or AFAS-2) based on the inoperable AFAS function. This changes the CTS by moving the procedural detail on what AFAS channels to bypass to the Bases.

The removal of these details, which are related to details on how to perform a Technical Specification Required Action, is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement to bypass the affected trip unit when a AFAS Function instrument channel is inoperable. Also, this change is acceptable because the removed information will be adequately controlled in the ITS Bases. Changes to the Bases are controlled by the Technical Specification Bases Control Program in Chapter 5. This program provides for the evaluation of changes to ensure the Bases are properly controlled. This change is designated as a less restrictive removal of detail change because information relating to how to perform an action is being removed from the Technical Specifications.

LA04 **Unit 2 only:** (*Type 3 – Removing Procedural Details for Meeting TS Requirements or Reporting Requirements*) CTS Table 3.3-3, Actions 13, 14.b, and 20.b state, in part, that all functional units receiving an input from the inoperable channel are also bypassed or tripped. CTS Table 3.3-3, Actions 13 and 14.b provide a process instrument and Function bypass list that identifies the associated Functions that must be bypassed if the instrument becomes inoperable, and Action 20.b references the Action 13 list. ITS 3.3.3 ACTIONS for each Function include a Required Action to place the affected trip unit in trip or bypass within 1 hour. CTS LCO 3.0.2 and ITS LCO 3.0.2 establish that upon discovery of a failure to meet an LCO, the associated ACTIONS shall be met. Therefore, when an instrument channel becomes inoperable, LCO 3.0.2 requires each Function affected by the inoperability shall be declared inoperable and the associated ACTIONS shall be met. The CTS process instrument and Function bypass list is not necessary in the Specifications. This information is removed from the Technical Specifications and moved to the UFSAR.

The removal of these details, which are related to system design, from the Technical Specifications is acceptable because this type of information is not necessary to be included in the Technical Specifications to provide adequate protection of public health and safety. The ITS still retains the requirement that all functional units receiving an input from an inoperable channel are bypassed or tripped. ITS 3.3.3 ACTIONS for each Function include a Required Action to place the affected trip unit in trip or bypass within 1 hour. Also, this change is acceptable because the removed information will be adequately controlled in the UFSAR. The UFSAR is controlled under 10 CFR 50.59 which ensures changes are properly evaluated. This change is designated as a less restrictive removal of detail change because information relating to system design is being removed from the Technical Specifications.

LESS RESTRICTIVE CHANGES

L01 *(Category 2 – Relaxation of Applicability)* Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.3.2 require the MSIS Steam Generator Pressure – Low Function (Table 3.3-3 Functional Unit 4.b) to be OPERABLE in MODES 1, 2, and 3 except when bypassed as noted by Note (c). Unit 2 CTS 3.3.2 also requires the MSIS Containment Pressure – High channel to be OPERABLE in MODES 1, 2, and 3. ITS 3.3.3 also requires the same MSIS Function to be OPERABLE. However, Table 3.3.3-1, Function 4.a (MSIS Steam Generator Pressure – Low) modifies MODES 2 and 3 by Footnote (f) that states that the Main Steam Isolation Signal (MSIS) Function Steam Generator Pressure - Low signal is not required to be OPERABLE when all associated valves isolated by the MSIS Function are closed. Unit 2 Table 3.3.3-1, Functions 4.a (MSIS Steam Generator Pressure – Low) and 4.b (MSIS Containment Pressure – High) modifies MODES 2 and 3 by Footnote (f) that states that the Main Steam Isolation Signal (MSIS) Function Steam Generator Pressure - Low and Containment Pressure - High signals are not required to be OPERABLE when all associated valves isolated by the MSIS Function are closed. This changes the CTS by relaxing the MODE 2 and 3 requirements of the MSIS Steam Generator Pressure – Low instrument Function and the Unit 2 MSIS Containment Pressure - High instrument Function.

The purpose of the Applicability of the MSIS Steam Generator Pressure – Low and Unit 2 MSIS Containment Pressure - High instrument Functions is to ensure the ESFAS MSIS Functions are OPERABLE when the supported equipment (i.e., main steam isolation valves (MSIVs) and main feedwater isolation valves (MFIVs)) is required to be OPERABLE. Automatic steam line and feedwater line isolation is assumed in the mitigation of a major secondary system pipe rupture accident (e.g., main steam line break or feedwater line break). In MODES 1, 2, and 3, there is sufficient energy in the primary and secondary systems to warrant automatic ESF System response to ensure the main steam and feedwater lines can be isolated in the event of a high energy secondary system pipe rupture. The exception to MODE 2 and 3 is added to clarify that the MSIS Functions are not required to be OPERABLE when the valves actuated by the MSIS instrumentation are in a position that supports the safety analyses. When the valves isolated by the MSIS Functions are in the closed position, they are in their assumed accident position. This change is acceptable, because when the

MSIVs and MFIVs are closed, the adverse effects of a high energy secondary system pipe rupture are precluded and the requirements continue to ensure that the structures, systems, and components are maintained in the MODES and other specified conditions assumed in the safety analyses. The proposed applicability change provides the same level of protection as the current requirements for the supported equipment and is consistent with the applicability for Function 4.a in ISTS Table 3.3.4-1 (Analog) and Function 4.b in ISTS Table 3.3.5-1 (Digital). This change is designated as less restrictive because the ITS LCO requirements are applicable in fewer operating conditions than in the CTS.

L02 (*Category 4 – Relaxation of Required Action*) Unit 1 CTS Table 3.3-3 Actions 9.c and 13, which apply to the SIAS, CIS and MSIS Functions and the RAS Function, respectively, require the minimum number of channels to be OPERABLE (i.e., three of four channels) except an additional channel may be bypassed for up to 48 hours (Action 9) or 2 hours (Action 13) while performing tests and maintenance on that channel provided the other inoperable channel is placed in the trip condition. Unit 2 CTS Table 3.3-3 Action 19, which applies to the RAS Function, requires the minimum number of channels to be OPERABLE (i.e., three of four channels) except an additional channel may be bypassed for up to 2 hours while performing testing per Specification 4.3.2.1. ITS 3.3.3 ACTION F provides the same condition (i.e., two of four channels inoperable) for the SIAS, CIS (Unit 1), CIAS (Unit 2), MSIS, and RAS Functions. When one or more Functions (except CSAS or AFAS) with two ESFAS trip units or associated instrument channels are inoperable, one trip unit must be placed in bypass and the other trip unit must be placed in trip within 1 hour and one trip unit must be restored to OPERABLE status within 48 hours. This changes the CTS by allowing two ESFAS Function trip units or associated instrument channels to be inoperable for reasons other than maintenance and testing and extends the time to restore the Unit 2 RAS ESFAS Function to OPERABLE status from 2 hours to 48 hours.

The purpose of the CTS Actions is to allow an additional ESFAS channel to be inoperable for the purposes of testing. The SIAS, CIS (Unit 1), CIAS (Unit 2), MSIS, and RAS ESFAS Function channels are configured in a two-out of-four coincidence. The two-out-of-four ESFAS logic is changed to a two-out-of-three logic for a given input parameter in one channel at a time by bypassing one channel input to the logic. With one channel of protective instrumentation bypassed, the ESFAS Function is in two-out-of-three logic, but with another channel failed the ESFAS may be operating with a two-out-of-two logic. This is outside the assumptions made in the analyses and should be corrected. To correct the problem, the second channel is placed in trip. This places the ESFAS in a one-out-of-two logic. If any of the other OPERABLE channels receives a trip signal, ESFAS actuation will occur. Therefore, it is also acceptable to allow an additional channel to be inoperable for reasons other than testing provided one channel is in bypass and the other channel is in trip. This change is acceptable because the Required Actions are used to establish remedial measures that must be taken in response to the degraded conditions in order to minimize risk associated with continued operation while providing time to repair inoperable features. The Required Actions are consistent with safe operation under the specified Condition, considering the OPERABLE status of the remaining ESFAS

instrument channels, a reasonable time for repairs or replacement, and the low probability of a DBA occurring during the repair period. This change also provides appropriate remedial actions in lieu of requiring initiation of an unnecessary plant transient per ITS LCO 3.0.3 (CTS 3.0.3). The 48-hour Completion Time is based upon operating experience, which has demonstrated that a random failure of another channel occurring during the 48 hour period is a low probability event. This change is designated as less restrictive because less stringent Required Actions are being applied in the ITS than were applied in the CTS.

L03 (*Category 4 – Relaxation of Required Action*) Unit 1 CTS 3.3.2.1 and Unit 2 CTS 3.3.2 do not explicitly provide requirements associated with the bypass removal feature associated with the SIAS or MSIS ESFAS Functions. However, CTS 4.3.2.1.2 and Unit 2 CTS 4.3.2.2 require channel functional and calibration testing of the channel bypass logic, which includes the bypass removal feature. Therefore, per the requirements of CTS 4.0.1 (ITS SR 3.0.1), CTS 3.3.2.1 (Unit 1) and CTS 3.3.2 (Unit 2) encompass the ESFAS channel bypass removal feature. If an ESFAS bypass removal channel is inoperable, CTS 3.0.3 is entered since there is no Condition and Action specified in the CTS. ITS 3.3.3 also includes Surveillances for the channel bypass removal feature. In addition, ITS 3.3.3 ACTIONS G and H are added to provide remedial measures when the bypass removal capability is inoperable to an SIAS or MSIS ESFAS Function channel. ITS Required Actions G.1 and H.1 require disabling the inoperable bypass channel within 1 hour when one or two bypass removal channels is inoperable. When one bypass removal channel is inoperable, ITS 3.3.3 ACTION G alternately allows placing the affected channel in bypass or trip within 1 hour and restoring the channel to OPERABLE status within 48 hours. When two bypass removal channels are inoperable, ITS 3.3.3 ACTION H alternately allows placing one channel in trip and the other channel in bypass and restoring one channel to OPERABLE status within 48 hours. This changes the CTS by adding specific Technical Specification actions when one or two bypass removal channels are inoperable to the SIAS or MSIS ESFAS Functions.

The purpose of the proposed actions is to provide appropriate remedial actions in the event the automatic bypass removal feature is inoperable. With one or two bypass removal channels inoperable, it is permissible to continue operation with the bypass permissive removal channels failed, providing the bypass is disabled. This can be accomplished by removing the bypass with the manual bypass key switch, which disables the bypass in its respective train. Since the bypass Function must be manually enabled, the bypass permissive Function will not by itself cause an undesired bypass insertion. Alternatively, the bypass may be disabled by defeating the bypass permissive input in one or two of the four channels to the two-out-of-four bypass removal logic, placing the bypass removal feature in one-out-of-three logic. Thus, any of the remaining channels is capable of removing the bypass feature when the bypass enable conditions are no longer valid. The Completion Times are consistent with the completion times for one or two inoperable SIAS or MSIS ESFAS Function channels. This change is also consistent with the ISTS.

This change is considered acceptable because the proposed remedial actions will ensure the related ESFAS Functions can continue to perform their related safety function when required by the plant design basis and safety analysis by requiring the bypass removal channel to be disabled or take action consistent with the current actions for an inoperable ESFAS channel. This change also provides appropriate remedial actions in lieu of requiring initiation of an unnecessary plant transient per ITS LCO 3.0.3 (CTS 3.0.3). This change is designated as less restrictive because the ITS ACTIONS provide remedial actions that are less restrictive than the CTS Action requiring a plant shutdown.

JUSTIFICATION FOR DEVIATIONS
ITS 3.3.3, ENGINEERED SAFETY FEATURES ACTUATION SYSTEM (ESFAS) INSTRUMENTATION

1. Changes are made (additions, deletions, and/or changes) to the ISTS that reflect the plant specific nomenclature, number, reference, system description, analysis, licensing basis, or licensing basis description.

2. The ISTS contains bracketed information and/or values that are generic to all Combustion Engineering vintage plants. The brackets are removed, and the proper plant specific information/value is provided. This is acceptable since the information/value is changed to reflect the current licensing basis.

3. The heading for ISTS 3.3.4 includes the parenthetical expression (Analog). This identifying information is not included in the PSL ITS. This information is provided in the NUREG-1432, Rev. 5.0 to assist in identifying the appropriate Specifications to be used as a model for a plant-specific ITS conversion but serves no purpose in a plant-specific implementation. In addition, PSL design does not include the Reactor Protective System (RPS) Instrumentation – Shutdown (ISTS 3.3.2). Therefore, ISTS 3.3.2 is not included in the PSL ITS. The successive Specifications are renumbered as necessary.

4. PSL does not use the terms “as-found tolerance” and “Limiting Trip Setpoint (LTSP)” in plant specific instrument calculations or the Updated Final Safety Analysis Report. Therefore, the use of these terms in Footnotes (a) and (b) in ISTS Table 3.3.1-1 are revised in the ITS to include the plant specific terminology. To comply with the guidance provided in NRC Regulatory Issue Summary 2006-17, “NRC Staff Position on the Requirements of 10 CFR 50.36, ‘Technical Specifications,’ Regarding Limiting Safety System Settings During Periodic Testing and Calibration of Instrument Channels,” the PSL setpoint calculations have been structured to include a Nominal Trip Setpoint (NTSP), also known as the field trip setpoint, and determination of an OPERABILITY limit range, referred to in CTS as acceptance criteria band. For PSL, the Nominal Trip Setpoint (NTSP) is synonymous with the Limiting Trip Setpoint (LTSP) and the as-found acceptance criteria band (i.e., OPERABILITY limit range) is synonymous with the as-found tolerance.

5. Condition B is added to ITS 3.3.3 (ISTS 3.3.4) to provide specific actions for one inoperable Containment Sump Recirculation Actuation Signal (RAS) trip unit or associated instrument. In addition, Condition C is also added to provide specific actions for one or more inoperable Auxiliary Feedwater Actuation Signal (AFAS) trip unit or associated instrument. A Note is added to proposed ITS 3.3.3 Condition C (Insert 1 to ISTS 3.3.4) stating that Required Action C.2.2.2 shall be completed when Condition C is entered. This Note constitutes an “unless otherwise stated” exception to LCO 3.0.2 to require the action to be completed within the associated Completion Time even when the LCO is no longer applicable. The added Note is similar to other Notes in the ISTS (e.g., Note to Condition A of ISTS 3.2.3 and the Note to Conditions A and C of ISTS 3.4.3.). These additional ITS ACTIONS are consistent with the PSL current licensing basis and consider the differing actions related to RAS, AFAS, and the remaining ESFAS functions based on whether instruments must be restored in 48 hours, may be optionally restored in accordance with the Risk Informed Completion Time Program, or channel restoration is extended to prior to entering MODE 3 following the next MODE 5 entry. Subsequent Conditions and Required Actions have been renumerated, as applicable, and Condition exceptions revised to reflect the additional ITS ACTIONS.

6. **Unit 2 only:** ISTS 3.3.4, Required Action B.2.2 is deleted and the Completion Time of Required Action B.2.1 (ITS 3.3.3, Required Action D.2) is modified in the Unit 2 ITS consistent with the PSL current licensing basis to allow the channel to be in trip or bypass until the next plant startup following entry into MODE 5 and similar to ISTS 3.3.5 (Digital), Required Action A.2. The Unit 2 ESFAS design includes independence of the four protection channels to ensure no single failure (e.g., circuit fault) can adversely affect more than one channel. As discussed in Section 7.2.4 of NUREG-0843, "Safety Evaluation Report – St. Lucie Unit 2," the NRC concluded that the ESFAS design enhancements were sufficient to ensure the independence of the four protection channels. Thus, the Unit 2 Technical Specifications allow a failed channel to be placed in long term trip or bypass condition provided the channel is restored no later than the next cold shutdown following the channel malfunction. A Note is added to ITS 3.3.3 Condition D (ISTS 3.3.4, Condition B) stating that Required Action D.2 shall be completed when Condition D is entered. This Note constitutes an "unless otherwise stated" exception to LCO 3.0.2 to require the action to be completed within the associated Completion Time even when the LCO is no longer applicable. The added Note is similar to other Notes in the ISTS (e.g., Note to Condition A of ISTS 3.2.3 and the Note to Conditions A and C of ISTS 3.4.3.).

Improved Standard Technical Specifications (ISTS) Bases Markup and Justification for Deviations (JFDs)

B 3.3 INSTRUMENTATION ~~(Analog)~~ 3

B 3.3.~~4~~ Engineered Safety Features Actuation System (ESFAS) Instrumentation ~~(Analog)~~ 3

3

BASES

BACKGROUND

The ESFAS initiates necessary safety systems, based upon the values of selected unit parameters, to protect against violating core design limits and the Reactor Coolant System (RCS) pressure boundary and to mitigate accidents. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the ESFAS, as well as LCOs on other reactor system parameters and equipment performance.

Technical Specifications are required by 10 CFR 50.36 to include LSSSs for variables that have significant safety functions. LSSS are defined by the regulation as "Where a LSSS is specified for a variable on which a safety limit has been placed, the setting must be chosen so that automatic protective actions will correct the abnormal situation before a Safety Limit (SL) is exceeded." The Analytical Limit is the limit of the process variable at which a safety action is initiated, as established by the safety analysis, to ensure that a SL is not exceeded. Any automatic protection action that occurs on reaching the Analytical Limit therefore ensures that the SL is not exceeded. However, in practice, the actual settings for automatic protection channels must be chosen to be more conservative than the Analytical Limit to account for instrument loop uncertainties related to the setting at which the automatic protective action would actually occur.

~~REVIEWER'S NOTE~~

~~The term "Limiting Trip Setpoint" [LTSP] is generic terminology for the calculated trip setting (setpoint) value calculated by means of the plant specific setpoint methodology documented in a document controlled under 10 CFR 50.59. The term [LTSP] indicates that no additional margin has been added between the Analytical Limit and the calculated trip setting.~~ 4

~~"Nominal Trip Setpoint [NTSP]" is the suggested terminology for the actual setpoint implemented in the plant surveillance procedures where margin has been added to the calculated [LTSP]. The as-found and as-left tolerances will apply to the [NTSP] implemented in the Surveillance procedures to confirm channel performance.~~ 4

BASES

BACKGROUND (continued)

~~Licensees are to insert the name of the document(s) controlled under 10 CFR 50.59 that contain the methodology for calculating the as-left and as-found tolerances, in Note b of Table 3.3.4-1 for the phrase "[insert the name of a document controlled under 10 CFR 50.59 such as the Technical Requirements Manual or any document incorporated into the facility FSAR]" throughout these Bases.~~

~~Where the [LTSP] is not included in Table 3.3.4-1, the plant specific location for the [LTSP] or [NTSP] much be cited in Note b of Table 3.3.4-1. The brackets indicate plant specific terms may apply, as required and approved by the NRC.~~

The ~~[Limiting~~ Trip Setpoint (~~LTSP)]~~ specified in ~~Table 3.3.4-1~~ is a predetermined setting for a protection channel chosen to ensure automatic actuation prior to the process variable reaching the Analytical Limit and thus ensuring that the SL would not be exceeded. As such, the ~~[LTSP]~~ accounts for uncertainties in setting the channel (e.g., calibration), uncertainties in how the channel might actually perform (e.g., repeatability), changes in the point of action of the channel over time (e.g., drift during surveillance intervals), and any other factors which may influence its actual performance (e.g., harsh accident environments). In this manner, the ~~[LTSP]~~ ensures that SLs are not exceeded. As such, the ~~[LTSP]~~ meets the definition of an LSSS (Ref. ~~1~~).

Technical Specifications contain values related to the OPERABILITY of equipment required for safe operation of the facility. OPERABLE is defined in Technical Specifications as "...being capable of performing its safety function(s)." Relying solely on the ~~[LTSP]~~ to define OPERABILITY in Technical Specifications would be an overly restrictive requirement if it were applied as an OPERABILITY limit for the "as-found" value of a protection channel setting during a Surveillance. This would result in Technical Specification compliance problems, as well as reports and corrective actions required by the rule which are not necessary to ensure safety. For example, an automatic protection channel with a setting that has been found to be different from the ~~[LTSP]~~ due to some drift of the setting may still be OPERABLE because drift is to be expected. This expected drift would have been specifically accounted for in the setpoint methodology for calculating the ~~[LTSP]~~ and thus the automatic protective action would still have ensured that the SL would not be exceeded with the "as-found" setting of the protection channel. Therefore, the channel would still be OPERABLE because it would have performed its safety function and the only corrective action required would be to reset the channel within the established as-left ~~tolerance~~ around the ~~[LTSP]~~ to account for further drift during the next surveillance interval. Note that,

BASES

BACKGROUND (continued)

although the channel is OPERABLE under these circumstances, the trip setpoint must be left adjusted to a value within the as-left ~~tolerance~~, in accordance with uncertainty assumptions stated in the referenced setpoint methodology (as-left criteria), and confirmed to be operating within the statistical allowances of the uncertainty terms assigned (as-found criteria).

However, there is also some point beyond which the channel may not be able to perform its function due to, for example, greater than expected drift. This value needs to be specified in the Technical Specifications in order to define OPERABILITY of the channels and is designated as the Allowable Value.

If the actual setting (as-found setpoint) of the channel is found to be conservative with respect to the Allowable Value but is beyond the as-found ~~tolerance~~ band, the channel is OPERABLE, but degraded. The degraded condition will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the ~~[Normal Trip Setpoint (~~NTSP~~)]~~ (within the allowed ~~tolerance~~), and evaluating the channel response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation.

During anticipated operational occurrences (AOOs), which are those events expected to occur one or more times during the plant life, the acceptable limits are:

- The departure from nucleate boiling ratio (DNBR) shall be maintained above the SL value to prevent departure from nucleate boiling,
- Fuel centerline melting shall not occur, and
- The Reactor Coolant System (RCS) pressure SL of ~~[~~2750~~]~~ psia shall not be exceeded.

Maintaining the parameters within the above values ensures that the offsite dose will be within the 10 CFR 50 (Ref. ~~2~~) and 10 CFR ~~100~~ (Ref. ~~3~~) criteria during AOOs.

Accidents are events that are analyzed even though they are not expected to occur during the plant life. The acceptable limit during accidents is that the offsite dose shall be maintained within an acceptable fraction of 10 CFR ~~100~~ (Ref. ~~3~~) limits. Different accident categories allow

BASES

BACKGROUND (continued)

a different fraction of these limits based on probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event.

The ESFAS contains devices and circuitry that generate the following signals when the monitored variables reach levels that are indicative of conditions requiring protective action:

1. Safety Injection Actuation Signal (SIAS),
2. Containment Spray Actuation Signal (CSAS),
3. Containment Isolation Signal (CI~~A~~S),
4. Main Steam Isolation Signal (MSIS),
5. Recirculation Actuation Signal (RAS), and
6. Auxiliary Feedwater Actuation Signal (AFAS).

Equipment actuated by each of the above signals is identified in the FSAR (Ref. ~~4~~).

Each of the above ESFAS actuation systems is segmented into four sensor subsystems and two actuation subsystems. Each sensor subsystem includes measurement channels and bistables. ~~The actuation subsystems include two logic subsystems for sequentially loading the diesel generators.~~

Each of the four sensor subsystem channels monitors redundant and independent process measurement channels. Each sensor is monitored by at least one bistable. The bistable associated with each ESFAS Function will trip when the monitored variable exceeds the ~~[LTSP]~~. When tripped, the sensor subsystems provide outputs to the two actuation subsystems.

The two independent actuation subsystems compare the four sensor subsystem outputs. If a trip occurs in the same parameter in two or more sensor subsystem channels, the two-out-of-four logic in each actuation subsystem will initiate one train of ESFAS. Each train can provide protection to the public in the case of a Design Basis Event. Actuation Logic is addressed in LCO 3.3.~~5~~, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual ~~Trip~~."

Each of the four sensor subsystems is mounted in a separate cabinet, excluding the sensors and field wiring.

BASES

BACKGROUND (continued)

The role of the sensor subsystem (measurement channels and bistables) is discussed below; actuation subsystems are discussed in LCO 3.3.~~5~~ 4. 1

Measurement Channels

Measurement channels, consisting of field transmitters or process sensors and associated instrumentation, provide a measurable electronic signal based upon the physical characteristics of the parameter being measured.

Four identical measurement channels with electrical and physical separation are provided for each parameter used in the generation of trip signals. These are designated Channels A through D. Measurement channels provide input to ESFAS bistables within the same ESFAS channel. ~~In addition, some measurement channels may also be used as inputs to Reactor Protective System (RPS) bistables, and most provide indication in the control room.~~ Measurement channels used as an input to ~~the RPS or~~ ESFAS are not used for control Functions. 1

When a channel monitoring a parameter indicates an unsafe condition, the bistable monitoring the parameter in that channel will trip. Tripping two or more channels of bistables monitoring the same parameter will de-energize both channels of Actuation Logic of the associated Engineered Safety Features (ESF) equipment.

Three of the four measurement and bistable channels are necessary to meet the redundancy and testability of GDC 21 in Appendix A to 10 CFR 50 (Ref. 2). The fourth channel provides additional flexibility by allowing one channel to be removed from service (trip channel bypass) for maintenance or testing while still maintaining a minimum two-out-of-three logic. The single failure criterion is met during this condition. 1

~~In order to take full advantage of the four channel design, adequate channel to channel independence must be demonstrated, and approved by the NRC staff. Plants not currently licensed to credit four channel independence that may desire this capability must have approval of the NRC staff documented by an NRC Safety Evaluation Report (Ref. 5). Adequate channel to channel independence includes physical and electrical independence of each channel from the others. Furthermore, each channel must be energized from separate inverters and station batteries. Plants not demonstrating four channel independence may operate in a two-out-of three logic configuration for 48 hours.~~ 1

Since no single failure will either cause or prevent a protective system actuation and no protective channel feeds a control channel, this arrangement meets the requirements of IEEE Standard ~~79~~279-1971 (Ref. 6). 1 3

BASES

BACKGROUND (continued)

Bistable Trip Units

Bistable trip units receive an analog input from the measurement channels, compare the analog input to trip setpoints, and provide contact output to the Actuation Logic. They also provide local trip indication and remote annunciation.

There are four channels of bistables, designated A through D, for each ESF Function, one for each measurement channel. ~~In cases where two ESF Functions share the same input and trip setpoint (e.g., containment pressure input to CSAS, CIAS, and SIAS and a Pressurizer Pressure - Low input to the RPS and SIAS), the same bistable may be used to satisfy both Functions.~~

The trip setpoints and Allowable Values used in the bistables are based on the analytical limits stated in Reference 7. The selection of these trip setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, instrument drift, and severe environment effects, for those ESFAS channels that must function in harsh environments as defined by 10 CFR 50.49 (Ref. 8), Allowable Values specified in Table 3.3.~~4~~-1, in the accompanying LCO, are conservatively adjusted with respect to the analytical limits. A detailed description of the method used to calculate the trip setpoints, including their explicit uncertainties, is provided in ~~the "Plant Protection System Selection of Trip Setpoint Values"~~ (Ref. 9). The actual trip setpoint entered into the bistable is normally still more conservative than that specified by the Allowable Value to account for changes in random measurement errors detectable by a CHANNEL FUNCTIONAL TEST. One example of such a change in measurement error is drift during the interval between surveillances.

The ~~[LTSP]~~ is the value at which the bistable is set and is the expected value to be achieved during calibration. The ~~[LTSP]~~ value is the LSSS and ensures the safety analysis limits are met for the surveillance interval selected when a channel is adjusted based on stated channel uncertainties.

~~[LTSPs]~~, in conjunction with the use of as-found and as-left ~~tolerances~~, consistent with the requirements of the Allowable Value will ensure that Safety Limits of Chapter 2.0, "SAFETY LIMITS (SLs)," are not violated during AOOs and that the consequences of Design Basis Accidents (DBAs) will be acceptable, providing the plant is operated from within the LCOs at the onset of the AOO or DBA and the equipment functions as designed.

BASES

BACKGROUND (continued)

Note that in the accompanying LCO 3.3.~~4~~, the Allowable Values of the Table 3.3.~~4~~-1 are the least conservative value of the as-found setpoint that a channel can have during a periodic CHANNEL CALIBRATION or CHANNEL FUNCTIONAL TEST.

ESFAS Logic

It is possible to change the two-out-of-four ESFAS logic to a two-out-of-three logic for a given input parameter in one channel at a time by ~~disabling~~ bypassing one channel input to the logic. Thus, the bistables will function normally, producing normal trip indication and annunciation~~, but ESFAS actuation will not occur since the bypassed channel is effectively removed from the coincidence logic. Trip channel bypassing can be simultaneously performed on any number of parameters in any number of channels, providing each parameter is bypassed in only one channel at a time. At some plants an interlock prevents simultaneous trip channel bypassing of the same parameter in more than one channel.~~ Trip channel bypassing is normally employed during maintenance or testing.

ESFAS Logic is addressed in LCO 3.3.~~5~~.

APPLICABLE SAFETY ANALYSES

Each of the analyzed accidents can be detected by one or more ESFAS Functions. One of the ESFAS Functions is the primary actuation signal for that accident. An ESFAS Function may be the primary actuation signal for more than one type of accident. An ESFAS Function may also be a secondary, or backup, actuation signal for one or more other accidents. Functions such as Manual Initiation, not specifically credited in the accident analysis, serve as backups to Functions and are part of the NRC approved licensing basis for the plant.

~~Permissive and interlock setpoints allow the blocking of trips during plant startups, and restoration of trips when the permissive conditions are not satisfied, but they are not explicitly modeled in the Safety Analyses. These permissives and interlocks ensure that the starting conditions are consistent with the safety analysis, before preventive or mitigating actions occur. Because these permissives or interlocks are only one of multiple conservative starting assumptions for the accident analysis, they are generally considered as nominal values without regard to measurement accuracy.~~

ESFAS protective Functions are as follows:

APPLICABLE SAFETY ANALYSES (continued)

1. Safety Injection Actuation Signal

The SIAS ensures acceptable consequences during loss of coolant accident (LOCA) events, including steam generator tube rupture, and main steam line breaks (MSLBs) or feedwater line breaks (FWLBs) (inside containment). To provide the required protection, either a high containment pressure or a low pressurizer pressure signal will initiate SIAS. SIAS initiates the Emergency Core Cooling Systems (ECCS), control room isolation, and several other Functions, such as starting the emergency diesel generators.

2. Containment Spray Actuation Signal

The CSAS initiates containment spray, preventing containment overpressurization during a LOCA or MSLB. ~~At some plants,~~ both a high- high containment pressure signal and an SIAS have to actuate to provide the required protection. This configuration reduces the likelihood of inadvertent containment spray. 1

3. Containment Isolation Signal 1

The CIS actuates the Containment Isolation System, ensuring acceptable consequences during LOCAs and MSLBs or FWLBs (inside containment). To provide protection, a high containment pressure signal will initiate CIS at the same setpoint at which an SIAS is generated. A high containment radiation signal will also initiate CIS. 1

4. Main Steam Isolation Signal

The MSIS ensures acceptable consequences during an MSLB or FWLB by isolating both steam generators if either generator indicates a low steam generator pressure. The MSIS, concurrent with or following a reactor trip, minimizes the rate of heat extraction and subsequent cooldown of the RCS during these events. 1

5. Recirculation Actuation Signal

At the end of the injection phase of a LOCA, the refueling water tank (RWT) will be nearly empty. Continued cooling must be provided by the ECCS to remove decay heat. The source of water for the ECCS pumps is automatically switched to the containment recirculation sump. Switchover from RWT to the containment sump must occur before the RWT empties to prevent damage to the ECCS pumps and

APPLICABLE SAFETY ANALYSES (continued)

a loss of core cooling capability. For similar reasons, switchover must not occur before there is sufficient water in the containment sump to support pump suction. Furthermore, early switchover must not occur to ensure sufficient borated water is injected from the RWT to ensure the reactor remains shut down in the recirculation mode. An RWT Level - Low signal initiates the RAS.

6. Auxiliary Feedwater Actuation Signal

An AFAS initiates feedwater flow to ~~both~~ steam generator~~s~~ if a low level is indicated in ~~either~~ steam generator, unless the generator is ~~ruptured~~. 1

the affected

faulted

the affected

The AFAS maintains a steam generator heat sink during the following events:

- MSLB,
- FWLB,
- Inadvertent opening of a steam generator atmospheric dump valve, and
- Loss of feedwater.

A low steam generator water level signal will initiate auxiliary feed to the affected steam generator.

, or feedwater header (FW) differential pressure (FW-A > FW-B) or (FW-B > FW-A), 1

Secondary steam generator (SG) differential pressure (SG-A > SG-B) or (SG-B > SG-A) inhibits auxiliary feed to a generator identified as being ~~ruptured~~. This input to the AFAS logic prevents loss of the intact generator while preventing feeding a ~~ruptured~~ generator during MSLBs and FWLBs. This prevents containment overpressurization during these events. 1

faulted

faulted

The ESFAS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires all channel components necessary to provide an ESFAS actuation to be OPERABLE. Failure of any required portion of the instrument channel renders the affected channel(s) inoperable and reduces the reliability of the affected Functions. The specific criteria for determining channel OPERABILITY differ slightly between Functions. These criteria are discussed on a Function by Function basis below.

BASES

LCO (continued)

Actions allow maintenance (trip channel) bypass of individual channels~~, but the bypass activates interlocks that prevent operation with a second channel in the same Function bypassed~~. Plants are restricted to 48 hours in a trip channel bypass condition before either restoring the Function to four channel operation (two-out-of-four logic) or placing the channel in trip (one-out-of-three logic). ~~At plants where adequate channel to channel independence has been demonstrated, specific exceptions may be approved by the NRC staff to permit one of the two-out-of-four channels to be bypassed for an extended period of time.~~

Allowable Values for ESFAS Instrumentation (Analog) Functions are specified in Table 3.3.~~4~~-1. ~~[LTSPs]~~ and the methodologies for calculation of the as-left and as-found ~~tolerances~~ are described in ~~[insert the name of a document controlled under 10 CFR 50.59 such as~~ the Technical Requirements Manual~~or any document incorporated into the facility FSAR]~~. The ~~[LTSPs]~~ are selected to ensure that the actual setpoints remain conservative with respect to the as-found ~~tolerance~~ band between successive CHANNEL CALIBRATIONS. After each calibration the trip setpoint shall be left within the as-left band around the ~~[LTSP]~~.

The Bases for the LCO on ESFAS Functions are:

1. Safety Injection Actuation Signal

   a. Containment Pressure - High

      This LCO requires four channels of SIAS Containment Pressure - High to be OPERABLE in MODES 1, 2, and 3.

      The Allowable Value for this trip is set high enough to allow for small pressure increases in containment expected during normal operation (i.e., plant heatup) and is not indicative of an offnormal condition. The setting is low enough to initiate the ESF Functions when an offnormal condition is indicated. This allows the ESF systems to perform as expected in the accident analyses to mitigate the consequences of the analyzed accidents.

   b. Pressurizer Pressure - Low

      This LCO requires four channels of SIAS Pressurizer Pressure - Low to be OPERABLE in MODES 1, 2, and 3.

LCO (continued)

The Allowable Value for this trip is set low enough to prevent actuating the SIAS during normal plant operation and pressurizer pressure transients. The setting is high enough that with a LOCA or MSLB it will actuate to perform as expected, mitigating the consequences of the accidents.

The Pressurizer Pressure - Low trip may be blocked when pressurizer pressure is reduced during controlled plant shutdowns. This block is permitted below ~~1800~~ 1725 psia, and block permissive responses are annunciated in the control room. This allows for a controlled depressurization of the RCS, while maintaining administrative control of ESF protection. From a blocked condition, the block will be automatically removed as pressurizer pressure increases above ~~1800~~ 1725 psia, as sensed by two of the four sensor subsystems~~, in accordance with the bypass philosophy of removing bypasses when the enabling conditions are no longer satisfied~~.

This LCO requires four channels of the bypass permissive removal for SIAS Pressurizer Pressure - Low to be OPERABLE in MODES 1, 2, and 3.

The bypass permissive channels consist of four sensor subsystems and two actuation subsystems. This LCO applies to failures in the four sensor subsystems, including sensors, bistables, and associated equipment. Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in LCO 3.3.~~5~~ 4.

This LCO applies to the bypass removal feature only. If the bypass enable Function is failed so as to prevent entering a bypass condition, operation may continue.

The block permissive is set low enough so as not to be enabled during normal plant operation, but high enough to allow blocking prior to reaching the trip setpoint.

2. Containment Spray Actuation Signal

CSAS is initiated either manually or automatically. ~~At many plants,~~ it is also necessary to have an automatic or manual SIAS for complete actuation. ~~The SIAS opens the containment spray valves, whereas the CSAS actuates other required components.~~ The SIAS requirement should always be satisfied on a legitimate CSAS, since

BASES

LCO (continued)

lower than the Containment Pressure – High-High signal

The parameters used for CSAS (Containment Pressure High-High and SIAS) give direct indication of a LOCA. The time to actuate CSAS depends on the break size. The Containment Pressure High-High set point is the controlling parameter since for all break sizes it takes longer to reach this set point than the SIAS set point.

the Containment Pressure - High signal setpoint used in the SIAS is ~~the same~~ setpoint used in the CSAS. ~~At many plants, the transmitters used to initiate CSAS are independent of those used in the SIAS to prevent inadvertent containment spray due to failures in two sensor channels.~~ 1

a. Containment Pressure - High -High 1

This LCO requires four channels of CSAS Containment Pressure - High to be OPERABLE in MODES 1, 2, and 3. -High 1

The Allowable Value is set high enough to allow for small pressure increases in containment expected during normal operation (i.e., plant heatup) and is not indicative of an offnormal condition. The setting is low enough to initiate the ESF Functions when an offnormal condition is indicated. This allows the ESF systems to perform as expected in the accident analyses to mitigate the consequences of the analyzed accidents.

~~The Containment Pressure - High setpoint is the same in the SIAS (Function 1), CSAS (Function 2), and CIAS (Function 3). However, different sensors and logic are used in each of these Functions.~~ 1

3. Containment Isolation ~~Actuation~~ Signal 1

a. Containment Pressure - High

This LCO requires four channels of CI~~A~~S Containment Pressure - High to be OPERABLE in MODES 1, 2, and 3. 1

The Allowable Value is set high enough to allow for small pressure increases in containment expected during normal operation (i.e., plant heatup) and is not indicative of an offnormal condition. The setting is low enough to initiate the ESF Functions when an offnormal condition is indicated. This allows the ESF systems to perform as expected in the accident analyses to mitigate the consequences of the analyzed accidents.

The Containment Pressure - High setpoint is the same in the SIAS (Function 1)~~, CSAS (Function 2),~~ and CI~~A~~S (Function 3). However, different ~~sensors and~~ logic ~~are~~ is used in each of these Functions. 1

LCO (continued)

b. Containment Radiation - High

This LCO requires four channels of CI~~A~~S Containment Radiation - High to be OPERABLE in MODES 1, 2, and 3. 1

The Allowable Value is high enough to avoid unnecessary actuation, but adequate to provide diverse actuation of the CI~~A~~S in the event of a LOCA. 1

4. Main Steam Isolation Signal

The MSIS is required to be OPERABLE in MODES 1, 2, and 3 except when all associated valves are closed and de-activated.

a. Steam Generator Pressure - Low

This LCO requires four channels of MSIS Steam Generator Pressure - Low for each steam generator to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value is set below the full load operating value for steam pressure so as not to interfere with normal plant operation. However, the setting is high enough to provide the required protection for excessive steam demand. An excessive steam demand causes the RCS to cool down, resulting in a positive reactivity addition to the core. An MSIS is required to prevent the excessive cooldown.

This Function may be manually blocked when steam generator pressure is reduced during controlled plant cooldowns. The block is permitted below ~~785~~ psia, and block permissive responses are annunciated in the control room. This allows a controlled depressurization of the secondary system, while maintaining administrative control of ESF protection. From a blocked condition, the block will be removed automatically as steam generator pressure increases above ~~785~~ psia, as sensed by two of the four sensor subsystems~~, in accordance with the bypass philosophy of removing bypasses when the enabling conditions are no longer satisfied~~.

685 685 1 1 1

This LCO requires four channels per steam generator of the bypass removal for MSIS Steam Generator Pressure - Low to be OPERABLE in MODES 1, 2, and 3.

1 3 1

LCO (continued)

The bypass removal channels consist of four sensor subsystems and two actuation subsystems. This LCO applies to failures in the four sensor subsystems, including sensors, bistables, and associated equipment. Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in LCO 3.3.~~5~~.4 3

This LCO applies to the bypass removal feature only. If the bypass enable Function is failed so as to prevent entering a bypass condition, operation may continue.

The block permissive is set low enough so as not to be enabled during normal plant operation, but high enough to allow blocking prior to reaching the trip setpoint.

5. Recirculation Actuation Signal

a. Refueling Water Tank Level - Low

This LCO requires four channels of RWT Level - Low to be OPERABLE in MODES 1, 2, and 3.

The upper limit on the Allowable Value for this trip is set low enough to ensure RAS does not initiate before sufficient water is transferred to the containment sump. Premature recirculation could impair the reactivity control Function of safety injection by limiting the amount of boron injection. Premature recirculation could also damage or disable the recirculation system if recirculation begins before the sump has enough water to prevent air ~~containment~~ entrainment in the suction. The lower limit on the RWT Level - Low trip Allowable Value is high enough to transfer suction to the containment sump prior to emptying the RWT. 1

6. Auxiliary Feedwater Actuation Signal

The AFAS logic actuates auxiliary feedwater (AFW) to a steam generator on low level in that generator unless it has been identified as being ~~ruptured~~ faulted.

A low level in ~~either~~ the faulted steam generator, as sensed by each steam a two-out-of-four coincidence of four wide range sensors for ~~any~~ generator, will generate an AFAS start signal, which starts ~~both~~ the affected trains of AFW 1 1

BASES

LCO (continued)

pumps and feeds ~~both~~ steam generator~~s~~. The AFAS also monitors the secondary differential pressure in both steam generators and initiates an AFAS block signal to a ~~ruptured~~ generator, if the pressure in ~~that generator is lower than that in the other generator~~ by the differential pressure setpoint.

a. Steam Generator A/B Level - Low

This LCO requires four channels for each steam generator of Steam Generator Level - Low to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value ensures adequate time exists to initiate AFW while the steam generators can function as a heat sink.

b. Steam Generator Pressure Difference - High (SG-A > SG-B) or (SG-B > SG-A)

This LCO requires four channels per steam generator of Steam Generator Pressure Difference - High to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value for this trip is high enough to allow for small pressure differences and normal instrumentation errors between the steam generator channels during normal operation without an actuation. The setting is low enough to detect and inhibit feeding of a ~~ruptured~~ steam generator in the event of an MSLB or FWLB, while permitting the feeding of the intact steam generator.

INSERT 1

The ESFAS channels satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

APPLICABILITY All ESFAS Functions are required to be OPERABLE in MODES 1, 2, and 3. In MODES 1, 2, and 3 there is sufficient energy in the primary and secondary systems to warrant automatic ESF System responses to:

- Close the main steam isolation valves to preclude a positive reactivity addition,
- Actuate AFW to preclude the loss of the steam generators as a heat sink (in the event the normal feedwater system is not available),
- Actuate ESF systems to prevent or limit the release of fission product radioactivity to the environment by isolating containment and limiting the containment pressure from exceeding the containment design pressure during a design basis LOCA or MSLB, and

1

INSERT 1

b. Feedwater Header Pressure Difference - High
(FW-A > FW-B) or (FW-B > FW-A)

This LCO requires four channels per feedwater subsystem of Feedwater Header Pressure Difference - High to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value for this trip is high enough to allow for small pressure differences and normal instrumentation errors between the feedwater header channels during normal operation without an actuation. The setting is low enough to detect and inhibit feeding of a faulted steam generator in the event of an MSLB or FWLB, while permitting the feeding of the intact steam generator.

BASES

APPLICABILITY (continued)

- Actuate ESF systems to ensure sufficient borated inventory to permit adequate core cooling and reactivity control during a design basis LOCA or MSLB accident.

In MODES 4, 5, and 6, automatic actuation of ESFAS Functions is not required because adequate time is available for plant operators to evaluate plant conditions and respond by manually operating the ESF components, if required, as addressed by LCO 3.3.~~5~~. In LCO 3.3.~~5~~, manual capability is required for Functions other than AFAS in MODE 4, even though automatic actuation is not required. Because of the large number of components actuated on each ESFAS, actuation is simplified by the use of the Manual ~~Trip~~ push buttons. Manual ~~Trip~~ of AFAS is not required in MODE 4 because AFW or shutdown cooling will already be in operation in this MODE.

Actuation

Actuation

The ESFAS Actuation Logic must be OPERABLE in the same MODES as the automatic and Manual ~~Trip~~. In MODE 4, only the portion of the ESFAS logic responsible for the required Manual ~~Trip~~ must be OPERABLE.

Actuation

Actuation

In MODES 5 and 6, ESFAS initiated systems are either reconfigured or disabled for shutdown cooling operation. Accidents in these MODES are slow to develop and would be mitigated by manual operation of individual components.

ACTIONS

The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the plant specific setpoint analysis.

Typically, the drift is small and results in a delay of actuation rather than a total loss of function. Determination of setpoint drift is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the process instrument is set up for adjustment to bring it to within specification. If the actual trip setpoint is nonconservative with respect to the Allowable Value in Table 3.3.~~4~~-1, the channel is inoperable and the appropriate Condition(s) are entered.

In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value in Table 3.3.~~4~~-1, or the channel is not functioning as required, or the sensor, instrument loop, signal processing electronics, or ESFAS bistable is found inoperable, then all affected Functions provided by that channel must be declared inoperable and the plant must enter the Condition statement for the particular protection Function affected.

BASES

ACTIONS (continued)

When the number of inoperable channels in a trip Function exceeds those specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered if applicable in the current MODE of operation.

A Note has been added to clarify the application of the Completion Time rules. The Conditions of this Specification may be entered independently for each Function in Table 3.3.~~4~~-1. Completion Times for the inoperable channel of a Function will be tracked separately.

INSERT A

~~[A.1~~

INSERT B

INSERT C

~~Condition A applies to one CSAS Containment Pressure - High channel inoperable. CSAS logic is identical to that of the other ESFAS Functions; however, the inadvertent actuation of a CSAS is undesirable, since it may damage equipment inside containment. For this reason, placing the inoperable channel in trip is not an option as it is in Conditions B and C.]~~

~~[For those plants in which the SIAS is required for a complete CSAS actuation, Condition B for one ESFAS channel inoperable and Condition C for two ESFAS channels inoperable may be preferable to Condition A.~~

~~If one CSAS channel is inoperable, operation is allowed to continue, providing the inoperable channel is placed in bypass within 1 hour. The Completion Time of 1 hour allotted to bypass the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.]~~

~~B~~.1, ~~B~~.2.1, and ~~B~~.2.2

Condition ~~B~~ applies to the failure of a single channel of one or more input parameters in the following ESFAS Functions:

1. Safety Injection Actuation Signal
   Containment Pressure - High
   Pressurizer Pressure – Low

2. Containment Spray Actuation Signal
   Containment Pressure - High-High

3. Containment Isolation Actuation Signal
   Containment Pressure - High
   Containment Radiation - High

1

INSERT A

A.1, A.2.1, and A.2.2

Condition A applies to the failure of a single channel of one or more input parameters in the Containment Spray Actuation Signal (CSAS) ESFAS Function.

CSAS coincidence logic is normally two-out-of-four. If one CSAS channel is inoperable, startup or power operation is allowed to continue as long as action is taken to restore the design level of redundancy.

If one CSAS channel is inoperable, startup or power operation is allowed to continue, providing the inoperable channel is placed in bypass or trip within 1 hour (Required Action A.1). With one channel in bypass, no additional random failure of a single channel could spuriously cause an actuation and a valid trip signal can still cause an actuation. With one channel in trip, an additional random failure of a single channel could spuriously cause an actuation. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to bypass or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.

One failed channel is restored to OPERABLE status or is placed in trip within 48 hours (Required Action A.2.1 or A.2.2). Required Action A.2.1 restores the full capability of the function. Required Action A.2.2 places the function in a one-out-of-three configuration. In this configuration, common cause failure of the dependent channel cannot prevent ESFAS actuation. The 48 hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the 48 hour period is a low probability event.

1

INSERT B

B.1 and B.2

Condition B applies to the failure of a single channel of one or more input parameters in the Containment Sump Recirculation Actuation Signal (RAS) ESFAS Function.

ESFAS coincidence logic is normally two-out-of-four. If one ESFAS channel is inoperable, startup or power operation is allowed to continue as long as action is taken to restore the design level of redundancy.

If one ESFAS channel is inoperable, startup or power operation is allowed to continue, providing the inoperable channel is placed in bypass or trip within 1 hour (Required Action B.1). With one channel in bypass, no additional random failure of a single channel could spuriously cause an actuation and a valid trip signal can still cause an actuation. With one channel in trip, an additional random failure of a single channel could spuriously cause an actuation. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to bypass or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.

The failed channel is restored to OPERABLE status within 48 hours (Required Action B.2). Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program (Required Action B.2). The 48 hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the 48 hour period is a low probability event.

1

INSERT C

C.1, C.2.1, C.2.2.1, C.2.2.2

Condition C applies to the failure of a single channel of one or more input parameters in the Auxiliary Feedwater Actuation Signal (AFAS) ESFAS Function.

AFAS coincidence logic is normally two-out-of-four. If one AFAS channel is inoperable, startup or power operation is allowed to continue as long as action is taken to restore the design level of redundancy.

If one AFAS channel is inoperable, startup or power operation is allowed to continue, providing the inoperable channel is placed in bypass or trip within 1 hour (Required Action C.1). With one channel in bypass, no additional random failure of a single channel could spuriously cause an actuation and a valid trip signal can still cause an actuation. With one channel in trip, an additional random failure of a single channel could spuriously cause an actuation. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to bypass or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.

One failed channel is restored to OPERABLE status or is placed in bypass within 48 hours (Required Action C.2.1 or C.2.2.1). Required Action C.2.1 restores the full capability of the function. Required Action C.2.2.1 places the function in a two-out-of-three configuration. In this configuration, common cause failure of the dependent channel cannot prevent AFAS actuation. The 48 hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the 48 hour period is a low probability event. R1

Additionally, the failed channel must be restored to OPERABLE status prior to entering MODE 3 following the next MODE 5 entry. The Completion Time of Required Action C.2.2.2 is based on adequate channel to channel independence, which allows a two-out-of-three channel operation since no single failure will cause or prevent a reactor trip. However, it is expected that the inoperable channel will be restored to OPERABLE status at the first reasonable opportunity. The determination of the first reasonable opportunity should include consideration of the impact on plant risk (from delaying restoration of the channel as well as any plant configuration changes required or shutting the plant down to repair the channel) and impact on any analysis assumptions, in addition to unit conditions, planning, availability of personnel, and the time required to repair the channel. This risk impact should be managed through the program in place to implement 10 CFR 50.65(a)(4) and NRC Regulatory Guide 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants."

Condition C is modified by a Note requiring Required Action C.2.2.2 to be completed whenever the Condition is entered even when the LCO is no longer applicable to ensure the channel is restored to OPERABLE prior to the next reactor startup from MODE 5 conditions.

BASES

ACTIONS (continued)

4. Main Steam Isolation Signal
   Steam Generator Pressure - Low

5. ~~Recirculation Actuation Signal~~
   ~~Refueling Water Tank Level - Low~~

6. ~~Auxiliary Feedwater Actuation Signal~~
   ~~Steam Generator Level - Low~~
   ~~Steam Generator Pressure Difference - High~~

ESFAS coincidence logic is normally two-out-of-four. If one ESFAS channel is inoperable, startup or power operation is allowed to continue as long as action is taken to restore the design level of redundancy.

If one ESFAS channel is inoperable, startup or power operation is allowed to continue, providing the inoperable channel is placed in bypass or trip within 1 hour (Required Action ~~B~~.1). With one channel in bypass, no additional random failure of a single channel could spuriously ~~trip the reactor~~ and a valid trip signal can still ~~trip the reactor~~. With one channel in trip, an additional random failure of a single channel could spuriously ~~trip the reactor~~. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to bypass or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.

One failed channel is restored to OPERABLE status or is placed in trip within ~~[~~48~~]~~ hours ~~[or in accordance with the Risk Informed Completion Time Program]~~ (Required Action ~~B~~.2.1 or ~~B~~.2.2). Required Action ~~B~~.2.1 restores the full capability of the function. Required Action ~~B~~.2.2 places the function in a one-out-of-three configuration. In this configuration, common cause failure of the dependent channel cannot prevent ESFAS actuation. The ~~[~~48~~]~~ hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the ~~[~~48~~]~~ hour period is a low probability event. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~

INSERT E

~~C~~.1 and ~~C~~.2

Condition ~~C~~ applies to the failure of two channels in any of the following ESFAS functions:

1

INSERT E

E.1 and E.2

Condition E applies to failure of two or more channels in the Auxiliary Feedwater Actuation Signal (AFAS) ESFAS Function or two channel in the Containment Spray Actuation System (CSAS) ESAFS Function.

With two inoperable channels, one channel should be placed in bypass, and the other channel should be placed in trip within the 1 hour Completion Time. With one channel of protective instrumentation bypassed, the ESFAS Function is in two-out-of-three logic, but with another channel failed the ESFAS may be operating with a two-out-of-two logic. This is outside the assumptions made in the analyses and should be corrected. To correct the problem, the second channel is placed in trip. This places the ESFAS in a one-out-of-two logic. If any of the other OPERABLE channels receives a trip signal, ESFAS actuation will occur.

One of the failed channels should be restored to OPERABLE status within 48 hours. The 48 hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the 48 hour period is a low probability event. After one channel is restored to OPERABLE status, the provisions of Condition C still apply to the remaining inoperable channel. Therefore, the channel that is still inoperable after completion of Required Action E.2 must be placed in bypass if more than 48 hours has elapsed since the initial channel failure. Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.

BASES

ACTIONS (continued)

1. Safety Injection Actuation Signal
   Containment Pressure - High
   Pressurizer Pressure - Low

3. Containment Isolation ~~Actuation~~ Signal
   Containment Pressure - High
   Containment Radiation - High

4. Main Steam Isolation Signal
   Steam Generator Pressure - Low

5. Recirculation Actuation Signal
   Refueling Water Tank Level - Low

~~6. Auxiliary Feedwater Actuation Signal~~
~~Steam Generator Level - Low~~
~~Steam Generator Pressure Difference - High~~

With two inoperable channels, one channel should be placed in bypass, and the other channel should be placed in trip within the 1 hour Completion Time. With one channel of protective instrumentation bypassed, the ESFAS Function is in two-out-of-three logic, but with another channel failed the ESFAS may be operating with a two-out-of-two logic. This is outside the assumptions made in the analyses and should be corrected. To correct the problem, the second channel is placed in trip. This places the ESFAS in a one-out-of-two logic. If any of the other OPERABLE channels receives a trip signal, ESFAS actuation will occur.

One of the failed channels should be restored to OPERABLE status within ~~[~~48~~]~~ hours, for reasons similar to those stated under Condition ~~B~~. After one channel is restored to OPERABLE status, the provisions of Condition ~~B~~ still apply to the remaining inoperable channel. Therefore, the channel that is still inoperable after completion of Required Action ~~C~~.2 must be placed in trip if more than ~~[~~48~~]~~ hours has elapsed since the initial channel failure.

except for Function 5 - RAS

Function 1 - SIAS, Function 3 – CIS, Function 4 – MSIS

After one Function 5 – RAS channel is restored to OPERABLE status, the provisions of Condition B still apply to the remaining inoperable channel. The RAS channel that is still inoperable after completion of Required Action F.2 must be restored to OPERABLE status within 48 hours or in accordance with the Risk Informed Completion Time since the initial channel failure.

~~D~~.1, ~~D~~.2.1, ~~D~~.2.2.1, and ~~D~~.2.2.2

Condition ~~D~~ applies to the failure of one bypass removal channel.

The bypass removal channels consist of four sensor subsystems and two actuation subsystems. Condition ~~D~~ applies to failures in one of the four sensor subsystems, including sensors, bistables, and associated

BASES

ACTIONS (continued)

equipment. Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in LCO 3.3.~~5~~.

In Condition ~~D~~, it is permissible to continue operation with one bypass permissive removal channel failed, providing the bypass is disabled (Required Action ~~D~~.1). This can be accomplished by removing the bypass with the manual bypass key switch, which disables the bypass in its respective ~~both~~ train~~s~~. Since the bypass Function must be manually enabled, the bypass permissive Function will not by itself cause an undesired bypass insertion.

Alternatively, the bypass may be disabled by defeating the bypass permissive input in one of the four channels to the two-out-of-four bypass removal logic, placing the bypass removal feature in one-out-of-three logic. Thus, any of the remaining three channels is capable of removing the bypass feature when the bypass enable conditions are no longer valid.

If the bypass removal feature in the inoperable channel cannot be defeated, actions to address the inoperability of the affected automatic trip channel must be taken. Required Action ~~D~~.2.1, Required Action ~~D~~.2.2.1, and Required Action ~~D~~.2.2.2 are equivalent to the Required Actions for a single automatic trip channel failure (Condition ~~B~~). The Completion Times have the same bases as discussed for Condition ~~B~~. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~

~~E~~.1, ~~E~~.2.1, and ~~E~~.2.2

Condition ~~E~~ applies to two inoperable bypass removal channels. The bypass removal channels consist of four sensor subsystems and two actuation subsystems. This Condition applies to failures in two of the four sensor subsystems. With two of the four sensor subsystems failed in a nonconservative direction (enabling the bypass Function), the bypass removal feature is in two-out-of-two logic. Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in LCO 3.3.~~5~~.

In Condition ~~E~~, it is permissible to continue operation with two bypass permissive channels failed, providing the bypasses are disabled in a similar manner as discussed for Condition ~~D~~.

BASES

ACTIONS (continued)

If the failed bypasses cannot be disabled, actions to address the inoperability of the affected automatic trip channels must be taken. Required Action ~~E~~.2.1 and Required Action ~~E~~.2.2 are equivalent to the Required Actions for a two automatic trip channel failure (Condition ~~C~~). Also similar to Condition ~~C~~, after one set of inoperable channels is restored, the provisions of Condition ~~D~~ still apply to the remaining inoperable channel, with the Completion Time measured from the point of the initial bypass channel failure. The Completion Times have the same bases as discussed for Condition ~~C~~. ~~[Alternatively, a Completion Time can be determined in accordance with the Risk Informed Completion Time Program.]~~

~~F~~.1 and ~~F~~.2

If the Required Actions and associated Completion Times of Condition A, B, C, D, ~~or~~ E are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 within ~~[~~12~~]~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

The SRs for any particular ESFAS Function are found in the SRs column of Table 3.3.~~4~~-1 for that Function. Most functions are subject to CHANNEL CHECK, CHANNEL FUNCTIONAL TEST, CHANNEL CALIBRATION, and response time testing.

~~REVIEWER'S NOTE~~

~~In order for a unit to take credit for topical reports as the basis for justifying Frequencies, topical reports should be supported by an NRC staff Safety Evaluation Report that establishes the acceptability of each topical report for that unit.~~

~~REVIEWER'S NOTE~~

~~Notes a and b are applied to the setpoint verification Surveillances for each ESFAS Instrumentation (Analog) Function in Table 3.3.4-1 unless one or more of the following exclusions apply:~~

~~1. Manual actuation circuits, automatic actuation logic circuits or instrument functions that derive input from contacts which have no associated sensor or adjustable device, e.g., limit switches, breaker position switches, manual actuation switches, float switches, proximity~~

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~detectors, etc. are excluded. In addition, those permissives and interlocks that derive input from a sensor or adjustable device that is tested as part of another TS function are excluded.~~

~~2. Settings associated with safety relief valves are excluded. The performance of these components is already controlled (i.e., trended with as-left and as-found limits) under the ASME Code for Operation and Maintenance of Nuclear Power Plants testing program.~~ 4

~~3. Functions and Surveillance Requirements which test only digital components are normally excluded. There is no expected change in result between SR performances for these components. Where separate as-left and as-found tolerance is established for digital component SRs, the requirements would apply.~~

3

SR 3.3.~~4~~.1 3

Performance of the CHANNEL CHECK ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the plant staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit. If the channels are within the criteria, it is an indication that the channels are OPERABLE. If the channels are normally off scale during times when Surveillance is required, the CHANNEL CHECK will only verify that they are off scale in the same direction. Offscale low current loop channels are verified to be reading at the bottom of the range and not failed downscale.

~~[The Frequency of about once every shift is based on operating experience that demonstrates channel failure is rare. Since the probability of two random failures in redundant channels in any 12 hour period is extremely low, the CHANNEL CHECK minimizes the chance of loss of protective function due to failure of redundant channels. The~~ 2

~~REVIEWER'S NOTE~~
~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~ 2
~~]~~

A CHANNEL FUNCTIONAL TEST on each ESFAS instrument channel is performed to ensure the entire channel will perform its intended function when needed.

A successful test of the required contact(s) of a channel relay may be performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions. 1

The CHANNEL FUNCTIONAL TEST tests the individual sensor subsystems using an analog test input to each bistable.

BASES

SURVEILLANCE REQUIREMENTS (continued)

A test signal is superimposed on the input in one channel at a time to verify that the bistable trips within the specified ~~tolerance~~ around the setpoint. Any setpoint adjustment shall be consistent with the assumptions of the plant specific setpoint analysis.

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the surveillance interval extension analysis. ~~The requirements for this review are outlined in Reference [10].~~

SR 3.3.~~4~~.2 is modified by two Notes as identified in Table 3.3.~~4~~-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value. Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition. The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[~~LTSP~~]~~. Where a setpoint more conservative than the ~~[~~LTSP~~]~~ is used in the plant surveillance procedures ~~[~~NTSP~~]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and/or Analytical Limit is maintained. If the as-left channel setting cannot be returned to a setting within the as-left ~~tolerance~~ of the ~~[~~LTSP~~]~~, then the channel shall be declared inoperable.

The second Note also requires that ~~[~~LTSP~~]~~ and the methodologies for calculating the as-left and the as-found ~~tolerances~~ be in ~~[insert the facility FSAR reference or the name of any document incorporated into the facility FSAR by reference]~~.

SR 3.3.~~4~~.3

SR 3.3.~~4~~.3 is a CHANNEL FUNCTIONAL TEST similar to SR 3.3.~~4~~.2, except 3.3.~~4~~.3 is ~~performed within 92 days prior to startup and is~~ only applicable to bypass Functions. These include the Pressurizer Pressure - Low bypass and the MSIS Steam Generator Pressure - Low bypass. A successful test of the required contact(s) of a channel relay may be

BASES

SURVEILLANCE REQUIREMENTS (continued)

performed by the verification of the change of state of a single contact of the relay. This clarifies what is an acceptable CHANNEL FUNCTIONAL TEST of a relay. This is acceptable because all of the other required contacts of the relay are verified by other Technical Specifications and non-Technical Specifications tests at least once per refueling interval with applicable extensions.

~~The CHANNEL FUNCTIONAL TEST for proper operation of the bypass removal Functions is critical during plant heatups because the bypasses may be in place prior to entering MODE 3 but must be removed at the appropriate points during plant startup to enable the ESFAS Function. Consequently, just prior to startup is the appropriate time to verify bypass removal Function OPERABILITY. Once the bypasses are removed, the bypasses must not fail in such a way that the associated ESFAS Function is inappropriately bypassed. This feature is verified by the appropriate ESFAS Function CHANNEL FUNCTIONAL TEST.~~ 1

~~The allowance to conduct this Surveillance within 92 days of startup is based upon the reliability analysis presented in topical report CEN-327, "RPS/ESFAS Extended Test Interval Evaluation" (Ref. 11).~~ 1

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program. 1

3

SR 3.3.~~4~~.4 3

CHANNEL CALIBRATION is a complete check of the instrument channel, including the sensor. The Surveillance verifies that the channel responds to a measured parameter within the necessary range and accuracy. CHANNEL CALIBRATION leaves the channel adjusted to account for instrument drift between successive calibrations to ensure that the channel remains operational between successive surveillances. CHANNEL CALIBRATIONS must be performed consistent with the plant specific setpoint analysis.

The as-found and as-left values must also be recorded and reviewed for consistency with the assumptions of the extension analysis. ~~The requirements for this review are outlined in Reference [10].~~ 1

~~[The Frequency is based upon the assumption of an [18] month calibration interval for the determination of the magnitude of equipment drift in the setpoint analysis.~~ 2

~~OR~~

The Surveillance Frequency is controlled under the Surveillance Frequency Control Program.

Move to end of this SR 3.3.3.4 description

BASES

SURVEILLANCE REQUIREMENTS (continued)

~~REVIEWER'S NOTE~~

~~Plants controlling Surveillance Frequencies under a Surveillance Frequency Control Program should utilize the appropriate Frequency description, given above, and the appropriate choice of Frequency in the Surveillance Requirement.~~

~~]~~

SR 3.3.4.4 is modified by two Notes as identified in Table 3.3.4-1. The first Note requires evaluation of channel performance for the condition where the as-found setting for the channel setpoint is outside its as-found ~~tolerance~~ but conservative with respect to the Allowable Value. Evaluation of channel performance will verify that the channel will continue to behave in accordance with safety analysis assumptions and the channel performance assumptions in the setpoint methodology. The purpose of the assessment is to ensure confidence in the channel performance prior to returning the channel to service. For channels determined to be OPERABLE but degraded, after returning the channel to service the performance of these channels will be evaluated under the plant Corrective Action Program. Entry into the Corrective Action Program will ensure required review and documentation of the condition. The second Note requires that the as-left setting for the channel be returned to within the as-left ~~tolerance~~ of the ~~[~~LTSP~~]~~. Where a setpoint more conservative than the ~~[~~LTSP~~]~~ is used in the plant surveillance procedures ~~[~~NTSP~~]~~, the as-left and as-found ~~tolerances~~, as applicable, will be applied to the surveillance procedure setpoint. This will ensure that sufficient margin to the Safety Limit and~~/or~~ Analytical Limit is maintained. If the as-left channel setting cannot be returned to a setting within the as-left ~~tolerance~~ of the ~~[~~LTSP~~]~~, then the channel shall be declared inoperable.

The second Note also requires that ~~[~~LTSP~~]~~ and the methodologies for calculating the as-left and the as-found ~~tolerances~~ be in ~~[insert the facility FSAR reference or the name of any document incorporated into the facility FSAR by reference]~~.

SR 3.3.4.5

This Surveillance ensures that the train actuation response times are the maximum values assumed in the safety analyses. Individual component response times are not modeled in the analyses. The analysis models the overall or total elapsed time, from the point at which the parameter exceeds the trip setpoint value at the sensor to the point at which the equipment in both trains reaches the required functional state (e.g.,

SURVEILLANCE REQUIREMENTS (continued)

pumps at rated discharge pressure, valves in full open or closed position). Response time testing acceptance criteria are included in Reference 5. The test may be performed in one measurement or in overlapping segments, with verification that all components are measured.

~~---------- REVIEWER'S NOTE ----------~~
~~Applicable portions of the following TS Bases are applicable to plants adopting CEOG Topical Report CE NPSD-1167-1, "Elimination of Pressure Sensor Response Time Testing Requirements," and the methodology contained in Attachment 1 to TSTF-569.~~
~~----------~~ 2

Response time may be verified by any series of sequential, overlapping or total channel measurements, including allocated sensor response time, such that the response time is verified. Allocations for sensor response times may be obtained from records of test results, vendor test data, or vendor engineering specifications. ~~Topical Report CE NPSD-1167-A, "Elimination of Pressure Sensor Response Time Testing Requirements," (Ref. 12) provides the basis and methodology for using allocated sensor response times in the overall verification of the channel response time for specific sensors identified in the Topical Report. The response time may be verified for components that replace the components that were previously evaluated in Ref. 12 provided that the components have been evaluated in accordance with the NRC approved methodology as discussed in Attachment 1 to TSTF-569, "Methodology to Eliminate Pressure Sensor and Protection Channel (for Westinghouse Plants only) Response Time Testing," (Ref. 13). Response time verification for other sensor types must be demonstrated by test. The allocation of sensor response times must be verified prior to placing a new component in operation and reverified after maintenance that may adversely affect the sensor response time.~~ 1

~~[ESF RESPONSE TIME tests are conducted on a STAGGERED TEST BASIS of once every [18] months. This results in the interval between successive tests of a given channel of n x 18 months, where n is the number of channels in the Function. Surveillance of the final actuation devices, which make up the bulk of the response time, is included in the testing of each channel. Therefore, staggered testing results in response time verification of these devices every [18] months. The [18] month STAGGERED TEST BASIS Frequency is based upon plant operating experience, which shows that random failures of instrumentation components causing serious response time degradation, but not channel failure, are infrequent occurrences.~~ 2

BASES

BACKGROUND

The ESFAS initiates necessary safety systems, based upon the values of selected unit parameters, to protect against violating core design limits and the Reactor Coolant System (RCS) pressure boundary and to mitigate accidents. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the ESFAS, as well as LCOs on other reactor system parameters and equipment performance.

Technical Specifications are required by 10 CFR 50.36 to include LSSSs for variables that have significant safety functions. LSSS are defined by the regulation as "Where a LSSS is specified for a variable on which a safety limit has been placed, the setting must be chosen so that automatic protective actions will correct the abnormal situation before a Safety Limit (SL) is exceeded." The Analytical Limit is the limit of the process variable at which a safety action is initiated, as established by the safety analysis, to ensure that a SL is not exceeded. Any automatic protection action that occurs on reaching the Analytical Limit therefore ensures that the SL is not exceeded. However, in practice, the actual settings for automatic protection channels must be chosen to be more conservative than the Analytical Limit to account for instrument loop uncertainties related to the setting at which the automatic protective action would actually occur.

~~REVIEWER'S NOTE~~

~~The term "Limiting Trip Setpoint" [LTSP] is generic terminology for the calculated trip setting (setpoint) value calculated by means of the plant specific setpoint methodology documented in a document controlled under 10 CFR 50.59. The term [LTSP] indicates that no additional margin has been added between the Analytical Limit and the calculated trip setting.~~

~~"Nominal Trip Setpoint [NTSP]" is the suggested terminology for the actual setpoint implemented in the plant surveillance procedures where margin has been added to the calculated [LTSP]. The as-found and as-left tolerances will apply to the [NTSP] implemented in the Surveillance procedures to confirm channel performance.~~

BASES

BACKGROUND (continued)

~~Licensees are to insert the name of the document(s) controlled under 10 CFR 50.59 that contain the methodology for calculating the as-left and as-found tolerances, in Note b of Table 3.3.4-1 for the phrase "[insert the name of a document controlled under 10 CFR 50.59 such as the Technical Requirements Manual or any document incorporated into the facility FSAR]" throughout these Bases.~~

~~Where the [LTSP] is not included in Table 3.3.4-1, the plant specific location for the [LTSP] or [NTSP] much be cited in Note b of Table 3.3.4-1. The brackets indicate plant specific terms may apply, as required and approved by the NRC.~~

The ~~[Limiting~~ Trip Setpoint (~~LTSP)]~~ specified in ~~Table 3.3.4-1~~ is a predetermined setting for a protection channel chosen to ensure automatic actuation prior to the process variable reaching the Analytical Limit and thus ensuring that the SL would not be exceeded. As such, the ~~[LTSP]~~ accounts for uncertainties in setting the channel (e.g., calibration), uncertainties in how the channel might actually perform (e.g., repeatability), changes in the point of action of the channel over time (e.g., drift during surveillance intervals), and any other factors which may influence its actual performance (e.g., harsh accident environments). In this manner, the ~~[LTSP]~~ ensures that SLs are not exceeded. As such, the ~~[LTSP]~~ meets the definition of an LSSS (Ref. ~~1~~).

Technical Specifications contain values related to the OPERABILITY of equipment required for safe operation of the facility. OPERABLE is defined in Technical Specifications as "...being capable of performing its safety function(s)." Relying solely on the ~~[LTSP]~~ to define OPERABILITY in Technical Specifications would be an overly restrictive requirement if it were applied as an OPERABILITY limit for the "as-found" value of a protection channel setting during a Surveillance. This would result in Technical Specification compliance problems, as well as reports and corrective actions required by the rule which are not necessary to ensure safety. For example, an automatic protection channel with a setting that has been found to be different from the ~~[LTSP]~~ due to some drift of the setting may still be OPERABLE because drift is to be expected. This expected drift would have been specifically accounted for in the setpoint methodology for calculating the ~~[LTSP]~~ and thus the automatic protective action would still have ensured that the SL would not be exceeded with the "as-found" setting of the protection channel. Therefore, the channel would still be OPERABLE because it would have performed its safety function and the only corrective action required would be to reset the channel within the established as-left ~~tolerance~~ around the ~~[LTSP]~~ to account for further drift during the next surveillance interval. Note that,

BASES

BACKGROUND (continued)

although the channel is OPERABLE under these circumstances, the trip setpoint must be left adjusted to a value within the as-left ~~tolerance~~, in accordance with uncertainty assumptions stated in the referenced setpoint methodology (as-left criteria), and confirmed to be operating within the statistical allowances of the uncertainty terms assigned (as-found criteria).

However, there is also some point beyond which the channel may not be able to perform its function due to, for example, greater than expected drift. This value needs to be specified in the Technical Specifications in order to define OPERABILITY of the channels and is designated as the Allowable Value.

If the actual setting (as-found setpoint) of the channel is found to be conservative with respect to the Allowable Value but is beyond the as-found ~~tolerance~~ band, the channel is OPERABLE, but degraded. The degraded condition will be further evaluated during performance of the SR. This evaluation will consist of resetting the channel setpoint to the ~~[Normal Trip Setpoint (~~NTSP~~)]~~ (within the allowed ~~tolerance~~), and evaluating the channel response. If the channel is functioning as required and is expected to pass the next surveillance, then the channel is OPERABLE and can be restored to service at the completion of the surveillance. After the surveillance is completed, the channel as-found condition will be entered into the Corrective Action Program for further evaluation.

During anticipated operational occurrences (AOOs), which are those events expected to occur one or more times during the plant life, the acceptable limits are:

- The departure from nucleate boiling ratio (DNBR) shall be maintained above the SL value to prevent departure from nucleate boiling,
- Fuel centerline melting shall not occur, and
- The Reactor Coolant System (RCS) pressure SL of ~~[~~2750~~]~~ psia shall not be exceeded.

Maintaining the parameters within the above values ensures that the offsite dose will be within the 10 CFR 50 (Ref. ~~2~~) and 10 CFR ~~100~~ (Ref. ~~3~~) criteria during AOOs.

Accidents are events that are analyzed even though they are not expected to occur during the plant life. The acceptable limit during accidents is that the offsite dose shall be maintained within an acceptable fraction of 10 CFR ~~100~~ (Ref. ~~3~~) limits. Different accident categories allow

BASES

BACKGROUND (continued)

a different fraction of these limits based on probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event.

The ESFAS contains devices and circuitry that generate the following signals when the monitored variables reach levels that are indicative of conditions requiring protective action:

1. Safety Injection Actuation Signal (SIAS),
2. Containment Spray Actuation Signal (CSAS),
3. Containment Isolation Actuation Signal (CIAS),
4. Main Steam Isolation Signal (MSIS),
5. Recirculation Actuation Signal (RAS), and
6. Auxiliary Feedwater Actuation Signal (AFAS).

Equipment actuated by each of the above signals is identified in the FSAR (Ref. ~~4~~ 5). U 1

Each of the above ESFAS actuation systems is segmented into four sensor subsystems and two actuation subsystems. Each sensor subsystem includes measurement channels and bistables. ~~The actuation subsystems include two logic subsystems for sequentially loading the diesel generators.~~ 1

Each of the four sensor subsystem channels monitors redundant and independent process measurement channels. Each sensor is monitored by at least one bistable. The bistable associated with each ESFAS Function will trip when the monitored variable exceeds the ~~[LTSP]~~. When tripped, the sensor subsystems provide outputs to the two actuation subsystems. 2 NTSP

The two independent actuation subsystems compare the four sensor subsystem outputs. If a trip occurs in the same parameter in two or more sensor subsystem channels, the two-out-of-four logic in each actuation subsystem will initiate one train of ESFAS. Each train can provide protection to the public in the case of a Design Basis Event. Actuation Logic is addressed in LCO 3.3.~~5~~, "Engineered Safety Features Actuation System (ESFAS) Logic and Manual ~~Trip~~." 3 4 Actuation

Each of the four sensor subsystems is mounted in a separate cabinet, excluding the sensors and field wiring.

BASES

BACKGROUND (continued)

The role of the sensor subsystem (measurement channels and bistables) is discussed below; actuation subsystems are discussed in LCO 3.3.~~5~~ 4. 1

Measurement Channels

Measurement channels, consisting of field transmitters or process sensors and associated instrumentation, provide a measurable electronic signal based upon the physical characteristics of the parameter being measured.

Four identical measurement channels with electrical and physical separation are provided for each parameter used in the generation of trip signals. These are designated Channels A through D. Measurement channels provide input to ESFAS bistables within the same ESFAS channel. ~~In addition, some measurement channels may also be used as inputs to Reactor Protective System (RPS) bistables, and most provide indication in the control room.~~ Measurement channels used as an input to ~~the RPS or~~ ESFAS are not used for control Functions. 1

When a channel monitoring a parameter indicates an unsafe condition, the bistable monitoring the parameter in that channel will trip. Tripping two or more channels of bistables monitoring the same parameter will de-energize both channels of Actuation Logic of the associated Engineered Safety Features (ESF) equipment.

Three of the four measurement and bistable channels are necessary to meet the redundancy and testability of GDC 21 in Appendix A to 10 CFR 50 (Ref. 2). The fourth channel provides additional flexibility by allowing one channel to be removed from service (trip channel bypass) for maintenance or testing while still maintaining a minimum two-out-of-three logic. The single failure criterion is met during this condition. 1

~~In order to take full advantage of the four channel design, adequate channel to channel independence must be demonstrated, and approved by the NRC staff. Plants not currently licensed to credit four channel independence that may desire this capability must have approval of the NRC staff documented by an NRC Safety Evaluation Report (Ref. 5). Adequate channel to channel independence includes physical and electrical independence of each channel from the others. Furthermore, each channel must be energized from separate inverters and station batteries. Plants not demonstrating four channel independence may operate in a two-out-of three logic configuration for 48 hours.~~ 1

Since no single failure will either cause or prevent a protective system actuation and no protective channel feeds a control channel, this arrangement meets the requirements of IEEE Standard ~~79~~279-1971 (Ref. 6). 1 3 1

BASES

BACKGROUND (continued)

Bistable Trip Units

Bistable trip units receive an analog input from the measurement channels, compare the analog input to trip setpoints, and provide contact output to the Actuation Logic. They also provide local trip indication and remote annunciation.

There are four channels of bistables, designated A through D, for each ESF Function, one for each measurement channel. ~~In cases where two ESF Functions share the same input and trip setpoint (e.g., containment pressure input to CSAS, CIAS, and SIAS and a Pressurizer Pressure - Low input to the RPS and SIAS), the same bistable may be used to satisfy both Functions.~~ 1 R1

SIAS and MSIS Functions share the containment pressure measurement channel inputs and trip setpoints. The bistables are shared to satisfy both Functions.

The trip setpoints and Allowable Values used in the bistables are based on the analytical limits stated in Reference 7. The selection of these trip setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, instrument drift, and severe environment effects, for those ESFAS channels that must function in harsh environments as defined by 10 CFR 50.49 (Ref. 8), Allowable Values specified in Table 3.3.~~4~~-1, in the accompanying LCO, are conservatively adjusted with respect to the analytical limits. A detailed description of the method used to calculate the trip setpoints, including their explicit uncertainties, is provided in ~~the "Plant Protection System Selection of Trip Setpoint Values"~~ (Ref. 9). The actual trip setpoint entered into the bistable is normally still more conservative than that specified by the Allowable Value to account for changes in random measurement errors detectable by a CHANNEL FUNCTIONAL TEST. One example of such a change in measurement error is drift during the interval between surveillances. 3 3 1

IC-3.17, “FPL Setpoint Standard”

NTSP NTSP

The ~~[~~LTSP~~]~~ is the value at which the bistable is set and is the expected value to be achieved during calibration. The ~~[~~LTSP~~]~~ value is the LSSS and ensures the safety analysis limits are met for the surveillance interval selected when a channel is adjusted based on stated channel uncertainties. 2

acceptance criteria bands

NTSP ~~[~~LTSPs~~]~~, in conjunction with the use of as-found and as-left ~~tolerances~~, consistent with the requirements of the Allowable Value will ensure that Safety Limits of Chapter 2.0, "SAFETY LIMITS (SLs)," are not violated during AOOs and that the consequences of Design Basis Accidents (DBAs) will be acceptable, providing the plant is operated from within the LCOs at the onset of the AOO or DBA and the equipment functions as designed. 2 1

BASES

BACKGROUND (continued)

Note that in the accompanying LCO 3.3.~~4~~, the Allowable Values of the Table 3.3.~~4~~-1 are the least conservative value of the as-found setpoint that a channel can have during a periodic CHANNEL CALIBRATION or CHANNEL FUNCTIONAL TEST.

ESFAS Logic

It is possible to change the two-out-of-four ESFAS logic to a two-out-of-three logic for a given input parameter in one channel at a time by ~~disabling~~ bypassing one channel input to the logic. Thus, the bistables will function normally, producing normal trip indication and annunciation~~, but ESFAS actuation will not occur since the bypassed channel is effectively removed from the coincidence logic. Trip channel bypassing can be simultaneously performed on any number of parameters in any number of channels, providing each parameter is bypassed in only one channel at a time. At some plants an interlock prevents simultaneous trip channel bypassing of the same parameter in more than one channel.~~ Trip channel bypassing is normally employed during maintenance or testing.

ESFAS Logic is addressed in LCO 3.3.~~5~~.

APPLICABLE SAFETY ANALYSES

Each of the analyzed accidents can be detected by one or more ESFAS Functions. One of the ESFAS Functions is the primary actuation signal for that accident. An ESFAS Function may be the primary actuation signal for more than one type of accident. An ESFAS Function may also be a secondary, or backup, actuation signal for one or more other accidents. Functions such as Manual Initiation, not specifically credited in the accident analysis, serve as backups to Functions and are part of the NRC approved licensing basis for the plant.

~~Permissive and interlock setpoints allow the blocking of trips during plant startups, and restoration of trips when the permissive conditions are not satisfied, but they are not explicitly modeled in the Safety Analyses. These permissives and interlocks ensure that the starting conditions are consistent with the safety analysis, before preventive or mitigating actions occur. Because these permissives or interlocks are only one of multiple conservative starting assumptions for the accident analysis, they are generally considered as nominal values without regard to measurement accuracy.~~

ESFAS protective Functions are as follows:

BASES

APPLICABLE SAFETY ANALYSES (continued)

1. Safety Injection Actuation Signal

The SIAS ensures acceptable consequences during loss of coolant accident (LOCA) events, including steam generator tube rupture, and main steam line breaks (MSLBs) or feedwater line breaks (FWLBs) (inside containment). To provide the required protection, either a high containment pressure or a low pressurizer pressure signal will initiate SIAS. SIAS initiates the Emergency Core Cooling Systems (ECCS), control room isolation, and several other Functions, such as starting the emergency diesel generators.

2. Containment Spray Actuation Signal

The CSAS initiates containment spray, preventing containment overpressurization during a LOCA or MSLB. ~~At some plants,~~ both a high- high containment pressure signal and an SIAS have to actuate to provide the required protection. This configuration reduces the likelihood of inadvertent containment spray. 1

3. Containment Isolation Actuation Signal 1

The CI~~A~~S actuates the Containment Isolation System, ensuring acceptable consequences during LOCAs and MSLBs or FWLBs (inside containment). To provide protection, a high containment pressure signal will initiate CIAS at the same setpoint at which an SIAS is generated. A high containment radiation signal will also initiate CIAS. 1

4. Main Steam Isolation Signal

The MSIS ensures acceptable consequences during an MSLB or FWLB by isolating both steam generators if either generator indicates a low steam generator pressure. The MSIS, concurrent with or following a reactor trip, minimizes the rate of heat extraction and subsequent cooldown of the RCS during these events. A high containment pressure signal will also initiate MSIS. 1

5. Recirculation Actuation Signal

At the end of the injection phase of a LOCA, the refueling water tank (RWT) will be nearly empty. Continued cooling must be provided by the ECCS to remove decay heat. The source of water for the ECCS pumps is automatically switched to the containment recirculation sump. Switchover from RWT to the containment sump must occur before the RWT empties to prevent damage to the ECCS pumps and

APPLICABLE SAFETY ANALYSES (continued)

a loss of core cooling capability. For similar reasons, switchover must not occur before there is sufficient water in the containment sump to support pump suction. Furthermore, early switchover must not occur to ensure sufficient borated water is injected from the RWT to ensure the reactor remains shut down in the recirculation mode. An RWT Level - Low signal initiates the RAS.

6. Auxiliary Feedwater Actuation Signal

the affected

An AFAS initiates feedwater flow to ~~both~~ steam generator~~s~~ if a low level is indicated in ~~either~~ steam generator, unless the generator is ~~ruptured~~. 1

faulted

the affected

The AFAS maintains a steam generator heat sink during the following events:

- MSLB,
- FWLB,
- Inadvertent opening of a steam generator atmospheric dump valve, and
- Loss of feedwater.

A low steam generator water level signal will initiate auxiliary feed to the affected steam generator.

, or feedwater header (FW) differential pressure (FW-A > FW-B) or (FW-B > FW-A), 1

Secondary steam generator (SG) differential pressure (SG-A > SG-B) or (SG-B > SG-A) inhibits auxiliary feed to a generator identified as being ~~ruptured~~. This input to the AFAS logic prevents loss of the intact generator while preventing feeding a ~~ruptured~~ generator during MSLBs and FWLBs. This prevents containment overpressurization during these events. 1

faulted

faulted

The ESFAS satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requires all channel components necessary to provide an ESFAS actuation to be OPERABLE. Failure of any required portion of the instrument channel renders the affected channel(s) inoperable and reduces the reliability of the affected Functions. The specific criteria for determining channel OPERABILITY differ slightly between Functions. These criteria are discussed on a Function by Function basis below.

BASES

LCO (continued)

Actions allow maintenance (trip channel) bypass of individual channels~~, but the bypass activates interlocks that prevent operation with a second channel in the same Function bypassed~~. Plants are restricted to 48 hours in a trip channel bypass condition before either restoring the Function to four channel operation (two-out-of-four logic) or placing the channel in trip (one-out-of-three logic). ~~At plants where adequate channel to channel independence has been demonstrated, specific exceptions may be approved by the NRC staff to permit one of the two-out-of-four channels to be bypassed for an extended period of time.~~

Allowable Values for ESFAS Instrumentation (Analog) Functions are specified in Table 3.3.~~4~~-1. ~~[LTSPs]~~ and the methodologies for calculation of the as-left and as-found ~~tolerances~~ are described in ~~[insert the name of a document controlled under 10 CFR 50.59 such as~~ the Technical Requirements Manual~~or any document incorporated into the facility FSAR]~~. The ~~[LTSPs]~~ are selected to ensure that the actual setpoints remain conservative with respect to the as-found ~~tolerance~~ band between successive CHANNEL CALIBRATIONS. After each calibration the trip setpoint shall be left within the as-left band around the ~~[LTSP]~~.

The Bases for the LCO on ESFAS Functions are:

1. Safety Injection Actuation Signal

   a. Containment Pressure - High

      This LCO requires four channels of SIAS Containment Pressure - High to be OPERABLE in MODES 1, 2, and 3.

      The Allowable Value for this trip is set high enough to allow for small pressure increases in containment expected during normal operation (i.e., plant heatup) and is not indicative of an offnormal condition. The setting is low enough to initiate the ESF Functions when an offnormal condition is indicated. This allows the ESF systems to perform as expected in the accident analyses to mitigate the consequences of the analyzed accidents.

   b. Pressurizer Pressure - Low

      This LCO requires four channels of SIAS Pressurizer Pressure - Low to be OPERABLE in MODES 1, 2, and 3.

LCO (continued)

The Allowable Value for this trip is set low enough to prevent actuating the SIAS during normal plant operation and pressurizer pressure transients. The setting is high enough that with a LOCA or MSLB it will actuate to perform as expected, mitigating the consequences of the accidents.

The Pressurizer Pressure - Low trip may be blocked when pressurizer pressure is reduced during controlled plant shutdowns. This block is permitted below ~~1800~~ 1836 psia, and block permissive responses are annunciated in the control room. This allows for a controlled depressurization of the RCS, while maintaining administrative control of ESF protection. From a blocked condition, the block will be automatically removed as pressurizer pressure increases above ~~1800~~ 1836 psia, as sensed by two of the four sensor subsystems~~, in accordance with the bypass philosophy of removing bypasses when the enabling conditions are no longer satisfied~~. 1

This LCO requires four channels of the bypass permissive removal for SIAS Pressurizer Pressure - Low to be OPERABLE in MODES 1, 2, and 3.

The bypass permissive channels consist of four sensor subsystems and two actuation subsystems. This LCO applies to failures in the four sensor subsystems, including sensors, bistables, and associated equipment. Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in LCO 3.3.~~5~~ 4. 3

This LCO applies to the bypass removal feature only. If the bypass enable Function is failed so as to prevent entering a bypass condition, operation may continue.

The block permissive is set low enough so as not to be enabled during normal plant operation, but high enough to allow blocking prior to reaching the trip setpoint.

2. Containment Spray Actuation Signal

CSAS is initiated either manually or automatically. ~~At many plants,~~ it is also necessary to have an automatic or manual SIAS for complete actuation. ~~The SIAS opens the containment spray valves, whereas the CSAS actuates other required components.~~ The SIAS requirement should always be satisfied on a legitimate CSAS, since 1 1

BASES

LCO (continued)

lower than the Containment Pressure – High-High signal

The parameters used for CSAS (Containment Pressure High-High and SIAS) give direct indication of a LOCA. The time to actuate CSAS depends on the break size. The Containment Pressure High-High set point is the controlling parameter since for all break sizes it takes longer to reach this set point than the SIAS set point.

the Containment Pressure - High signal setpoint used in the SIAS is ~~the same~~ setpoint used in the CSAS. ~~At many plants, the transmitters used to initiate CSAS are independent of those used in the SIAS to prevent inadvertent containment spray due to failures in two sensor channels.~~ 1

a. Containment Pressure - High -High 1

This LCO requires four channels of CSAS Containment Pressure - High to be OPERABLE in MODES 1, 2, and 3. -High 1

The Allowable Value is set high enough to allow for small pressure increases in containment expected during normal operation (i.e., plant heatup) and is not indicative of an offnormal condition. The setting is low enough to initiate the ESF Functions when an offnormal condition is indicated. This allows the ESF systems to perform as expected in the accident analyses to mitigate the consequences of the analyzed accidents.

~~The Containment Pressure - High setpoint is the same in the SIAS (Function 1), CSAS (Function 2), and CIAS (Function 3). However, different sensors and logic are used in each of these Functions.~~ 1

3. Containment Isolation Actuation Signal 1

a. Containment Pressure - High

This LCO requires four channels of CIAS Containment Pressure - High to be OPERABLE in MODES 1, 2, and 3. 1

The Allowable Value is set high enough to allow for small pressure increases in containment expected during normal operation (i.e., plant heatup) and is not indicative of an offnormal condition. The setting is low enough to initiate the ESF Functions when an offnormal condition is indicated. This allows the ESF systems to perform as expected in the accident analyses to mitigate the consequences of the analyzed accidents.

The Containment Pressure - High setpoint is the same in the SIAS (Function 1)~~, CSAS (Function 2),~~ and CIAS (Function 3). However, different ~~sensors and~~ logic ~~are~~ is used in each of these Functions. 1

LCO (continued)

b. Containment Radiation - High

This LCO requires four channels of CIAS Containment Radiation - High to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value is high enough to avoid unnecessary actuation, but adequate to provide diverse actuation of the CIAS in the event of a LOCA. R1

4. Main Steam Isolation Signal

The MSIS is required to be OPERABLE in MODES 1, 2, and 3 except when all associated valves are closed and de-activated.

a. Steam Generator Pressure - Low

This LCO requires four channels of MSIS Steam Generator Pressure - Low for each steam generator to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value is set below the full load operating value for steam pressure so as not to interfere with normal plant operation. However, the setting is high enough to provide the required protection for excessive steam demand. An excessive steam demand causes the RCS to cool down, resulting in a positive reactivity addition to the core. An MSIS is required to prevent the excessive cooldown.

This Function may be manually blocked when steam generator pressure is reduced during controlled plant cooldowns. The block is permitted below ~~785~~ psia, and block permissive responses are annunciated in the control room. This allows a controlled depressurization of the secondary system, while maintaining administrative control of ESF protection. From a blocked condition, the block will be removed automatically as steam generator pressure increases above ~~785~~ psia, as sensed by two of the four sensor subsystems~~, in accordance with the bypass philosophy of removing bypasses when the enabling conditions are no longer satisfied~~.

700 700 1 1 1

This LCO requires four channels per steam generator of the bypass removal for MSIS Steam Generator Pressure - Low to be OPERABLE in MODES 1, 2, and 3.

LCO (continued)

The bypass removal channels consist of four sensor subsystems and two actuation subsystems. This LCO applies to failures in the four sensor subsystems, including sensors, bistables, and associated equipment. Failures in the actuation subsystems, including the manual bypass key switches, are considered Actuation Logic failures and are addressed in LCO 3.3.~~5~~. 4 3

This LCO applies to the bypass removal feature only. If the bypass enable Function is failed so as to prevent entering a bypass condition, operation may continue.

The block permissive is set low enough so as not to be enabled during normal plant operation, but high enough to allow blocking prior to reaching the trip setpoint.

INSERT 1A 1

5. Recirculation Actuation Signal

a. Refueling Water Tank Level - Low

This LCO requires four channels of RWT Level - Low to be OPERABLE in MODES 1, 2, and 3.

The upper limit on the Allowable Value for this trip is set low enough to ensure RAS does not initiate before sufficient water is transferred to the containment sump. Premature recirculation could impair the reactivity control Function of safety injection by limiting the amount of boron injection. Premature recirculation could also damage or disable the recirculation system if recirculation begins before the sump has enough water to prevent air ~~containment~~ entrainment in the suction. The lower limit on the RWT Level - Low trip Allowable Value is high enough to transfer suction to the containment sump prior to emptying the RWT. 1

6. Auxiliary Feedwater Actuation Signal

The AFAS logic actuates auxiliary feedwater (AFW) to a steam generator on low level in that generator unless it has been identified as being ~~ruptured~~ faulted.

A low level in ~~either~~ the faulted steam generator, as sensed by each steam generator, a two-out-of-four coincidence of four wide range sensors for ~~any~~ generator, will generate an AFAS start signal, which starts ~~both~~ the affected trains of AFW 1 1

1

INSERT 1A

b. Containment Pressure - High

This LCO requires four channels of MSIS Containment Pressure - High to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value is set high enough to allow for small pressure increases in containment expected during normal operation (i.e., plant heatup) and is not indicative of an offnormal condition. The setting is low enough to initiate the ESF Functions when an offnormal condition is indicated. This allows the ESF systems to perform as expected in the accident analyses to mitigate the consequences of the analyzed accidents.

BASES

LCO (continued)

the affected

, and the feedwater header differential pressure in both feedwater headers,

pumps and feeds ~~both~~ steam generator~~s~~. The AFAS also monitors the secondary differential pressure in both steam generators and initiates an AFAS block signal to a ~~ruptured~~ generator, if the pressure in ~~that generator is lower than that in the other generator~~ by the differential pressure setpoint.

one steam generator is lower than the other steam generator, or the pressure in one feedwater header is lower than the other feedwater header,

faulted

a. Steam Generator A/B Level - Low

This LCO requires four channels for each steam generator of Steam Generator Level - Low to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value ensures adequate time exists to initiate AFW while the steam generators can function as a heat sink.

b. Steam Generator Pressure Difference - High (SG-A > SG-B) or (SG-B > SG-A)

This LCO requires four channels per steam generator of Steam Generator Pressure Difference - High to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value for this trip is high enough to allow for small pressure differences and normal instrumentation errors between the steam generator channels during normal operation without an actuation. The setting is low enough to detect and inhibit feeding of a ~~ruptured~~ steam generator in the event of an MSLB or FWLB, while permitting the feeding of the intact steam generator.

faulted

INSERT 1

The ESFAS channels satisfy Criterion 3 of 10 CFR 50.36(c)(2)(ii).

APPLICABILITY All ESFAS Functions are required to be OPERABLE in MODES 1, 2, and 3. In MODES 1, 2, and 3 there is sufficient energy in the primary and secondary systems to warrant automatic ESF System responses to:

- Close the main steam isolation valves to preclude a positive reactivity addition,
- Actuate AFW to preclude the loss of the steam generators as a heat sink (in the event the normal feedwater system is not available),
- Actuate ESF systems to prevent or limit the release of fission product radioactivity to the environment by isolating containment and limiting the containment pressure from exceeding the containment design pressure during a design basis LOCA or MSLB, and

1

INSERT 1

b. Feedwater Header Pressure Difference - High
(FW-A > FW-B) or (FW-B > FW-A)

This LCO requires four channels per feedwater subsystem of Feedwater Header Pressure Difference - High to be OPERABLE in MODES 1, 2, and 3.

The Allowable Value for this trip is high enough to allow for small pressure differences and normal instrumentation errors between the feedwater header channels during normal operation without an actuation. The setting is low enough to detect and inhibit feeding of a faulted steam generator in the event of an MSLB or FWLB, while permitting the feeding of the intact steam generator.

BASES

APPLICABILITY (continued)

- Actuate ESF systems to ensure sufficient borated inventory to permit adequate core cooling and reactivity control during a design basis LOCA or MSLB accident.

In MODES 4, 5, and 6, automatic actuation of ESFAS Functions is not required because adequate time is available for plant operators to evaluate plant conditions and respond by manually operating the ESF components, if required, as addressed by LCO 3.3.~~5~~. In LCO 3.3.~~5~~, manual capability is required for Functions other than AFAS in MODE 4, even though automatic actuation is not required. Because of the large number of components actuated on each ESFAS, actuation is simplified by the use of the Manual ~~Trip~~ push buttons. Manual ~~Trip~~ of AFAS is not required in MODE 4 because AFW or shutdown cooling will already be in operation in this MODE.

The ESFAS Actuation Logic must be OPERABLE in the same MODES as the automatic and Manual ~~Trip~~. In MODE 4, only the portion of the ESFAS logic responsible for the required Manual ~~Trip~~ must be OPERABLE.

In MODES 5 and 6, ESFAS initiated systems are either reconfigured or disabled for shutdown cooling operation. Accidents in these MODES are slow to develop and would be mitigated by manual operation of individual components.

ACTIONS

The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the plant specific setpoint analysis.

Typically, the drift is small and results in a delay of actuation rather than a total loss of function. Determination of setpoint drift is generally made during the performance of a CHANNEL FUNCTIONAL TEST when the process instrument is set up for adjustment to bring it to within specification. If the actual trip setpoint is nonconservative with respect to the Allowable Value in Table 3.3.~~4~~-1, the channel is inoperable and the appropriate Condition(s) are entered.

In the event a channel's trip setpoint is found nonconservative with respect to the Allowable Value in Table 3.3.~~4~~-1, or the channel is not functioning as required, or the sensor, instrument loop, signal processing electronics, or ESFAS bistable is found inoperable, then all affected Functions provided by that channel must be declared inoperable and the plant must enter the Condition statement for the particular protection Function affected.

BASES

ACTIONS (continued)

When the number of inoperable channels in a trip Function exceeds those specified in any related Condition associated with the same trip Function, then the plant is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered if applicable in the current MODE of operation.

A Note has been added to clarify the application of the Completion Time rules. The Conditions of this Specification may be entered independently for each Function in Table 3.3.~~4~~-1. Completion Times for the inoperable channel of a Function will be tracked separately.

INSERT A

~~[A.1~~

INSERT B

~~Condition A applies to one CSAS Containment Pressure - High channel inoperable. CSAS logic is identical to that of the other ESFAS Functions; however, the inadvertent actuation of a CSAS is undesirable, since it may damage equipment inside containment. For this reason, placing the inoperable channel in trip is not an option as it is in Conditions B and C.]~~

INSERT C

~~[For those plants in which the SIAS is required for a complete CSAS actuation, Condition B for one ESFAS channel inoperable and Condition C for two ESFAS channels inoperable may be preferable to Condition A.~~

~~If one CSAS channel is inoperable, operation is allowed to continue, providing the inoperable channel is placed in bypass within 1 hour. The Completion Time of 1 hour allotted to bypass the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.]~~

~~B~~.1, ~~B~~.2.1, and ~~B~~.2.2

Condition ~~B~~ applies to the failure of a single channel of one or more input parameters in the following ESFAS Functions:

1. Safety Injection Actuation Signal
   Containment Pressure - High
   Pressurizer Pressure – Low
2. Containment Spray Actuation Signal
   Containment Pressure - High-High
3. Containment Isolation Actuation Signal
   Containment Pressure - High
   Containment Radiation - High

1

INSERT A

A.1, A.2.1, and A.2.2

Condition A applies to the failure of a single channel of one or more input parameters in the Containment Spray Actuation Signal (CSAS) ESFAS Function. R1

CSAS coincidence logic is normally two-out-of-four. If one CSAS channel is inoperable, startup or power operation is allowed to continue as long as action is taken to restore the design level of redundancy.

If one CSAS channel is inoperable, startup or power operation is allowed to continue, providing the inoperable channel is placed in bypass or trip within 1 hour (Required Action A.1). With one channel in bypass, no additional random failure of a single channel could spuriously cause an actuation and a valid trip signal can still cause an actuation. With one channel in trip, an additional random failure of a single channel could spuriously cause an actuation. Therefore, it is preferable to place an inoperable channel in bypass rather than trip.

The Completion Time of 1 hour allotted to bypass or trip the channel is sufficient to allow the operator to take all appropriate actions for the failed channel and still ensures that the risk involved in operating with the failed channel is acceptable.

One failed channel is restored to OPERABLE status or is placed in trip within 48 hours (Required Action A.2.1 or A.2.2). Required Action A.2.1 restores the full capability of the function. Required Action A.2.2 places the function in a one-out-of-three configuration. In this configuration, common cause failure of the dependent channel cannot prevent ESFAS actuation. The 48 hour Completion Time is based upon operating experience, which has demonstrated that a random failure of a second channel occurring during the 48 hour period is a low probability event.

1

INSERT B

B.1 and B.2

Condition B applies to the failure of a single channel of one or more input parameters in the Containment Sump Recirculation Actuation Signal (RAS) ESFAS Function.

ESFAS coincidence logic is normally two-out-of-four. If one ESFAS channel is inoperable, startup or power operation is allowed to continue as long as action is taken to restore the design level of redundancy.
